Knot1, Knot2, Knot3, etc	Knot vectors (0.0 to 1.0) of this trimming vector. There must be NPTUtrim+NORUtrim entries. (Real)

Remarks:

1. Named continuation entries are ignored for a deformable curve or surface (BEHAV=DEFO), except for "HEAT".
2. The grid CGID is the reference grid for the rigid body motion. Loads and enforced motion must be defined in the global coordinate system of CGID.
3. All continuation lines may be omitted if not required.
4. WARNING: For rigid contact, the right hand rule determines the interior side of the rigid surface. A deformable surface which contacts a rigid surface must be on the exterior side of the rigid surface (i.e., in the direction opposite to the right hand rule). If a rigid surface is described backwards, contact will not occur because the deformable body is already inside the rigid body at the start of the analysis. For 3D patches, if all need to be reversed, the parameter PARAM,MARCREVR,1 may be entered to automatically reverse all 3D patches.
5. For BEZIER surfaces, enter np1\*np2 points in the order shown below:

Mesh	Normal Order	Reversed Order
2x2	1,2,3,4	2,1,4,3
3x2	1,2,3,4,5,6	3,2,1,6,5,4
3x3	1,2,3,4,5,6,7,8,9	3,2,1,6,5,4,9,8,7

6. For NURBS, enter NPTU grid points G1, G2, G3, etc. (set NPTU to a positive value equal to the number of grid points or enter X1, Y1, Z1, X2, Y2, Z2, etc. coordinates for abs(NPTU) points and set NPTU to a negative value.
7. When IDSPL is greater than 1, these nodes are entered in pairs. For a quad surface (for example, CQUAD4 or edge of a CHEXA) usually 4 sets of nodal pairs are needed to describe the surface. For example, a CQUAD4 with grid numbering 1,2,4,3 would need pairs of nodes, 1,2 2,4 4,3 3,1. The nodal pairs may be entered in any order. See Marc Volume C SPLINE (SOL 400 chapter 9) option documentation for more details.
8. For hard contact, with HGLUE=1 (see BCTABLE for the meaning of HGLUE):
  - a. The temperature of the contacting grid is tied to the temperatures of the contacted element face or the temperature of the rigid geometry when it has a scalar point associated with it.

- b. The temperature of the contacting grid is set to the rigid geometry temperature when it has no scalar point associated with it.

**Note:** “Glued” thermal contact can result in overshoot of the temperatures at the interface, in particular, if two bodies that have non-uniform initial temperatures are placed in contact. The overshoot effect may be damped somewhat if one uses a near contact distance with some convective heat transfer.

9. For hard contact, with HGLUE=0:

The convective heat flow per unit area over the two interfaces is given by:

$$q = CHEAT \cdot (T_A - T_B)$$

where  $T_A$  is the contacting grid temperature and  $T_B$  is the face temperature in the contact point in case of a meshed body or the  $T_{BODY}$  temperature in case of a rigid geometry. It is recommended to enter the CHEAT value on the BCTABLE Bulk Data input, since it generally applies to body pairs and is not a property of a single body.

10. For near contact:

$$\begin{aligned} q = & HCV \cdot (T_A - T_B) + \\ & HNC \cdot (T_A - T_B)^{BNC} + \\ & HNL \cdot (T_A^{BNL} - T_B^{BNL}) + \\ & \sigma \cdot EMISS \cdot (T_A^A - T_B^A) + \\ & \left[ CHEAT \cdot \left( 1 - \frac{dist}{DQNEAR} \right) + HBL \cdot \frac{dist}{DQNEAR} \right] \cdot (T_A \cdot T_B) \end{aligned}$$

where the last term is only activated when  $HBL \neq 0$ ,  $T_A$  is the contacting grid temperature and  $T_B$  is the face temperature in the contact point in case of a meshed body or the  $T_{BODY}$  temperature in case of a rigid geometry. It is recommended to enter the near contact heat transfer coefficients and the corresponding exponents on the BCTABLE Bulk Data input, since they generally apply to body pairs and are not properties of a single body.

11. For no contact:

$$\begin{aligned}
 q = & CFILM \cdot (T_A - T_{SINK}) + \\
 & HNCE \cdot (T_A - T_{SINK})^{BNCE} + \\
 & HNLE \cdot (T_A^{BNLE} - T_{SINK}^{BNLE}) + \\
 & \sigma \cdot EMISS \cdot (T_A^4 - T_{SINK}^4)
 \end{aligned}$$

12. The heat transfer coefficients and associated exponents can all be temperature dependent, when they are entered as an integer value. This integer value is the table ID of a TABLEM1, TABLEM2 or TABL3D entry (formulas are not supported on TABL3D).
13. The  $T_{SINK}$  and  $T_{BODY}$  temperatures can be time dependent when they are entered as a positive integer value. This integer value is the table ID of a TABLED1, TABLED2 or TABL3D entry (formulas are not supported on TABL3D).
14. Table IDs of tables used on the BCBODY and the BCTABLE entry must be unique.
15. TBODY entries only apply to rigid bodies (i.e., RIGID as the BEHAV value). TSINK entries only apply to deformable bodies (meshed regions with DEFORM or HEAT as the BEHAV value).

**BCBODY****Flexible or Rigid Contact Body in 2D and 3D in SOL 600**

Defines a flexible or rigid contact body in 2D or 3D used in SOL 600 only.

**Important Notes for SOL 600:**

1. The 2nd line is required if any of the subsequent lines are to be entered (if this line is blank, enter a “+” in column 1 or Nastran will ignore the entire line).
2. PARAM,MRCONVER,11 is required if CTYPE, APPROV, or GROW headers are entered.
3. PARAM,MRCONTAB,11 is required if any of the variables are described by tables.

Use only as many forms (i.e., HEAT, PATCH3D, BEZIER, POLY, CYLIND, SPHERE, NURBS2, or NURBS) as necessary to describe the body (if rigid). Deformable bodies are described using as many standard elements as necessary and are specified by the BSID field with BEHAV=DEFORM (only the first line should be entered for deformable bodies). Unless shrink fit its being analyzed, deformable bodies should not be inside other deformable bodies when the thickness of each body is taken into account.

The “RIGID” header may be used with any of the other rigid entries but only once per body. Also, only one of the character entries after RIGID (HEAT, PATCH3D, NURBS, etc.) should be entered for any particular body. See Remark 4. for an important note regarding how to define the outward direction of rigid bodies (which must point towards a flexible body for contact to occur).

**Format:**

Examples (of Deformable and Rigid Contact):

Example 1 -- Typical deformable body

BCBODY	1		DEFOR M	101	0	.05			
--------	---	--	------------	-----	---	-----	--	--	--

## Example 2 -- Simple 4-node rigid patch (see Remark 5 for rigid bodies)

BCBODY	2		RIGID		0				
	PATCH3D	1							
		1	101	102	103	104			

Example 3-- Same as Example 2 except that a user subroutine named motion.f will be employed to specify the rigid body motion.

BCBODY	2		RIGID		0				
	ADVANCE			M					
	PATCH3D	1							
		1	101	102	103	104			

Describer	Meaning
BID (4,1)	Contact body identification number referenced by BCTABLE, BCHANGE, or BCMOVE. (Integer > 0; Required)
DIM	Dimension of body. (Character; Default = 3D) DIM=2D planar body in x-y plane of the basic coordinate system, composed of 2D elements or curves. DIM=3D any 3D body composed of rigid surfaces, shell elements or solid elements.
BEHAV (4,8)	Behavior of curve or surface (Character; Default = DEFORM) DEFORM body is deformable, RIGID body is rigid, SYMM body is a symmetry body, ACOUS indicates an acoustic body, WORK indicates body is a workpiece, HEAT indicates body is a heat-rigid body. <i>See Remark 3. for Rigid Bodies.</i>
BSID	Identification number of a BSURE, BCBOX, BCPROP or BCMATL entry if BEHAV=DEFORM. (Integer > 0)
ISTYP (4,3)	Check of contact conditions. (Integer $\geq$ 0; Default = 0) ISTYP is not supported in segment-to-segment contact. For a deformable body: =0 symmetric penetration, double sided contact. =1 unsymmetric penetration, single sided contact. (Integer > 0) =2 double-sided contact with automatic optimization of contact constraint equations (this option is known as “optimized contact”). Notes: single-sided contact (ISTYP=1) with the contact bodies arranged properly using the contact table frequently runs much faster than ISTYP=2. For a rigid body: =0 no symmetry condition on rigid body. =1 rigid body is a symmetry plane.

Describer	Meaning
FRIC (6,7)	Friction coefficient. (Real $\geq 0$ or integer; Default = 0) If the value is an integer it represents the ID of a TABL3Di.
IDSPL (4,5)	Set IDSPL=1 to activate the SPLINE (analytical contact) option for a deformable body and for a rigid contact surface. Set it to zero or leave blank to not have analytical contact. (Integer; Default = 0) <u>SOL 600 Options:</u> =0 or blank, SPLINE option is turned off. =1, The body is smoothed out with splines (2D) or Coons surfaces (3D). If SANGLE is not entered, the default 60.0 degrees is used. IDSPL=1 triggers the Marc SPLINE option with the 3rd field of the 3rd datablock set to 1. If analytical contact changes between increment zero and any subcase, the SANGLE Bulk Data entry is required (see the following SANGLE). SANGLE is placed in the 4th field of the 3rd Mac SPLINE datablock and a value of 1 is placed in the 3rd field of the 3rd datablock. >1, Identification number of a BLSEG entry that lists nodes on edges of the body which are excluded from the SPLINE option. (See Remark 10.) This option may be used for deformable or rigid contact surfaces. See PARAM,MSPLINC0 to enforce C0 continuity.
CONTROL (4,6)	Indicates the type of control for the body. Integer: = -1 for position control, = 0 for velocity control. = positive number for “load control” (the positive number is the grid number which has translational forces or SDCP’s are applied. The position of this grid is at the center of rotation given in the CGID field. For velocity controlled surfaces, the velocity of the body must be specified by the VELRBi fields. For displacement controlled surfaces the final displacement can be specified using SPCD at the grid ID specified by CONTROL. CONTROL > 0 is not available for enforced motion using SPCD’s for 2D contact using SOL 600.
NLOAD (4,7)	Enter a positive number if “load controlled” and rotations are allowed (Integer). The positive number is the grid number where the moments or rotations are applied. The position of this grid is at the center of rotation given in the CGID field. The rotations are specified using SPCD at grid ID NLOAD and can be specified using dof’s 1-3 (for rotation about x, y, z respectively), or starting with the MSC Nastran 2007 release by dof’s 4-6 (for rotation about x, y, z respectively). For versions prior to MSC Nastran 2007 only dof’s 1-3 could be used.
ANGVEL (6,1)	Angular velocity or angular position about local axis through center of rotation. (Real or Integer; Default = 0.0) If the value is an integer it represents the ID of a TABL3Di.
DCOS1 (6,4)	3D - First component direction cosine of local axis if ANGVEL is nonzero. (Real)  2D - First coordinate of initial position of rotation of rigid body.

Describer	Meaning
DCOS2 (6,5)	3D - Second component direction cosine of local axis if ANGVEL is nonzero. (Real)  2D - Second coordinate of initial position of rotation of rigid body
DCOS3 (6,6)	3D - Third component direction cosine of local axis if ANGVEL is nonzero. (Real)  2D - Not used.
VELRB1 (5,4)	2D & 3D - Velocity or final position (depending on the value of CONTROL) of rigid body in 1st direction. (Real or Integer; Default = 0.0) If the value is an integer it represents the ID of a TABL3Di.
VELRB2 (5,5)	2D & 3D - Velocity or final position (depending on the value of CONTROL) of rigid body in 2nd direction. (Real or Integer; Default = 0.0) If the value is an integer it represents the ID of a TABL3Di.
VELRB3 (5,6)	3D - Velocity or final position (depending on the value of CONTROL) of rigid body in 3rd direction. (Real or Integer; Default = 0.0) If the value is an integer it represents the ID of a TABL3Di.  2D - Not used.
ADVANCE	The entries for this continuation line are for advanced options starting with MSC Nastran 2007.
SANGLE	Threshold for automatic discontinuity detection in degrees. (Real, Default = 60.0) SANGLE values on the BCBODY entry can be overridden using the SANGLE Bulk Data entry. This allows SANGLE to change for different subcases. It also allows analytical contact for this body to be "on" or "off" for different subcases (see the SANGLE Bulk Data entry). [Marc Spline option (3,4)]
COPTB	Flag to indicate how body surfaces may contact. See Remark 9. on the BCTABLE entry. (Integer; Default = 0)

Describer	Meaning
USER	<p>A series of character flags to indicate which (if any) user subroutines are required for this contact body. Enter as many characters as necessary to specify the user subroutines desired, for example to use MOTION and UFIRC enter MF. (Character; Default = blank meaning no user subroutines are required) (SOL 600 Only)</p> <p>M = The MOTION user subroutine is required to describe complex motion of a rigid contact body.</p> <p>F = The UFRIC or UFRICBBC user subroutine is required to describe complex friction behavior of the contact body.</p> <p>C = Film coefficient and sink temperature user subroutine UHTCON is required (coupled structural/heat analysis only)</p> <p>P = 4-Node patch user subroutine DIGEOM is required (the coordinates of the patch are entered in the user subroutine rather than on the BCBODY entry).</p> <p>S = The SEPSTR or SEPFOR user subroutine is required depending on whether stress-based or force-based friction has been specified using BCPARA IBSEP.</p>
“CTYPE”	<p>The entries of this continuation line define whether the original node-to-segment or segment-to-segment contact algorithm is used. Also the selection of general or small sliding contact and associated values when segment-to-segment contact is selected are entered here. These options may be placed on BCPARA instead of BCBODY (which is the recommended option. BCBODY entries override BCPARA entries). For MSC Nastran 2012, these items should be considered beta-test capabilities.</p>
ISMAIL [3,1]	<p>Enter 0 for general contact or 1 for small sliding, small displacement contact. See Remarks 15 and 16. (Integer; Default = 0)</p>
ICTYPE [3,2]	<p>Enter 0 for node-to-segment contact or 1 for segment-to-segment contact. See Remarks 15 and 16. (Integer; Default = 0)</p>
IAUG [3,3]	<p>This entry applies only if segment-to-segment contact is selected. See Remarks 15 and 16. (Integer; Default = 0)</p> <p>0 = No augmentation</p> <p>1 = Augmentation is based on a constant Lagrange multiplier field for linear elements and on a bilinear Lagrange multiplier field for quadratic elements.</p> <p>2 = Augmentation is based on a constant Lagrange multiplier field.</p> <p>3 = Augmentation is based on a bilinear Lagrange multiplier field.</p>

Describer	Meaning
PENALT [5,1]	Augmented Lagrange penalty factor, used by segment-to-segment contact only. The default is derived from the contact tolerance distance and the stiffness of the deformable contact bodies or average stiffness if two deformable bodies are in contact. See Remark 18. (Real; Default = leave blank)
AUGDIST [5,2]	Penetration distance beyond which an augmentation will be applied, used by segment-to-segment contact only. this default is 1% of the contact tolerance distance. See Remark 18. (Real; Default = leave blank)
“RIGID”	The entries of this continuation line are for the rigid body description. See Remark 3.
CGID (5,i) i=1,2,3 (4,6)	Grid point identification number defining the initial position of the center of rotation for the rigid body or the point where a concentrated force or moment is applied.
NENT (4,2)	Number of geometric entities to describe this rigid surface. A rigid surface can be described by multiple sets of patches, nurbs, etc. For example, if it takes 3 sets of PATCH3D entries to describe a rigid surface, then set NENT=3. (Integer > 0; Default = 1)
Rigid Body Name (4,9)	Name associated with the rigid body. (Default is blank, 24-characters maximum)
“APPROV”	The entries for this continuation line are used for rigid contact body approach velocity and angular velocity. (For SOL 600, APPVEL may be used instead of APPROV if desired.)
A	Angular velocity about local axis through center of rotation. The local axis is defined by DCOS1, DCOS2, DCOS3. (Real; Default = 0.0)
Ni	Not used by SOL 600. The direction cosines for approach velocity in SOL 600 are DCOS1, DCOS2, DCOS3 on the second BCBODY line. (Real; Default = 0.0; Ni values entered on this line are ignored for SOL 600)
Vi	V1, V2 and V3 define the three components of approach velocity. For 2D contact only two should be entered as defined by Rx or Ry (see each 2D rigid contact body description for the meaning of Rx and Ry). (Real; Default = 0.0)
“RTEMP”	The entries of this continuation line describe rigid contact surface temperature variations.
G(Temp)	Grid point identification number defining the location of the temperature. (Integer; no Default)
Tempr	Temperature at the start of the run. (Real; no Default)
T(Temp)	Identification number of a TABL3Di describing the variation of the rigid body temperature during the analysis. (Integer; Default = 0 which means a constant value Ttempr is used during the entire analysis)

Describer	Meaning
<b>“SINK”</b>	The entries of this continuation line describe sink temperatures and their variation for flexible or heat transfer bodies.
G(sink)	Grid point identification number of defining the location of the sink temperature. (Integer; no Default)
Tsink	Sink temperature at the start of the run. (Real; no Default)
T(Tsink)	Identification number of a TABL3Di describing the variation of the sink temperature during the analysis. (Integer; Default = 0 which means a constant value Tsink is used during the entire analysis)
<b>“GROW”</b>	The entries for this continuation line are for rigid body growth - This line is rarely used. If entered PARAM,MRCONVER,11 must be used. If tables are used for growth, they should either be TABLED1 (growth vs time) or TABL3Di (growth vs one or more variables) and PARAM,MRCONTAB,11 must be entered.
GF1 (7,5)	Growth factor of rigid body in first coordinate direction. (Real; Default = 1.0)
GF2 (7,6)	Growth factor of rigid body in second coordinate direction. (Real; Default = 1.0)
GF3 (7,7)	Growth factor of rigid body in third coordinate direction. (Real; Default = 1.0)
TAB-GF1 (8,5)	Table for growth factor of rigid body in first coordinate direction. (Integer or blank; Default is blank which means no table and growth factor varies from 0.0 to 1.0 over the subcase being analyzed.)
TAB-GF2 (8,6)	Table for growth factor of rigid body in second coordinate direction. (Integer or blank; Default is blank which means no table and growth factor varies from 0.0 to 1.0 over the subcase being analyzed.)
TAB-GF3 (8,7)	Table for growth factor of rigid body in third coordinate direction. (Integer or blank; Default is blank which means no table and growth factor varies from 0.0 to 1.0 over the subcase being analyzed.)
<b>“HEAT”</b>	The entries of this continuation line(s) are for contact in heat transfer. Do not enter these line(s) for structural analyses.
CFILM (9,1)/(10,1)	Heat transfer coefficient (film) to environment. (Real or Integer; Default = 0.0 for a heat transfer problem, omit for a structural problem) If Real, the value entered is the film coefficient. If Integer, the value entered is the ID of a TABLEM1 entry specifying the heat transfer coefficient vs temperature. This is usually called HCVE in the Marc documentation.

Describer	Meaning
TSINK (9,2)/(10,2)	Environment sink temperature. (Real or Integer; Default = 0.0 for a heat transfer problem, omit for a structural problem). If Real, the value entered is the sink temperature. If Integer, the value entered is the ID of a TABLEM1 entry specifying temperature vs time. At present, this variable should not be a function of temperature.
CHEAT (9,3)/(10,3)	Contact heat transfer coefficient. (Real or Integer; Default = 1.0 for a heat transfer problem, omit for a structural problem). If Real, the value entered is the contact heat transfer coefficient. If Integer, the value entered is the ID of a TABLEM1 entry specifying the contact heat transfer coefficient vs temperature.
TBODY (9,4)/(10,4)	Body temperature. (Real or Integer; Default = 0.0 for a heat transfer problem, omit for a structural problem). If Real, the value entered is the body temperature. If Integer, the value entered is the ID of a TABLEM1 entry specifying the body temperature vs time. At present, this variable should not be a function of temperature.
HCV (9,5)/(10,5)	Convection coefficient for near field behavior (Real or Integer; Default = 1.0 for a heat transfer problem, omit for a structural problem). If Real the value entered is the near field convection coefficient. If Integer, the value entered is the ID of a TABLEM1 entry specifying the near field convection coefficient vs temperature.
HNC (9,6)/(10,6)	Natural convection coefficient for near field behavior (Real or Integer; Default = 1.0 for a heat transfer problem, omit for a structural problem). If Real, the value entered is the near field natural convection coefficient. If Integer, the value entered is the ID of a TABLEM1 entry specifying the near field natural convection coefficient vs temperature.
ITYPE [4,8]	An option entry for heat transfer only (Integer; no Default) 1 - Heat sink 4 - Heat conduction body
BNC (9,7)/(10,7)	Exponent associated with the natural convection coefficient for near field behavior (Real or Integer; Default = 0.0 for a heat transfer problem, omit for a structural problem). If Real, the value entered is the exponent associated with the near field natural convection coefficient. If Integer, the value entered is the ID of a TABLEM1 entry specifying the exponent associated with the near field natural convection coefficient vs temperature. At present, this variable should not be a function of temperature.
EMISS (9,8)/(10,8)	Emissivity for radiation to the environment or near thermal radiation (Real or Integer; Default = 0.0 for a heat transfer problem, omit for a structural problem). If real, the value entered is the emissivity. If Integer, the value entered is the ID of a TABLEM1 entry specifying the emissivity vs temperature.

Describer	Meaning
HBL (11,1)[12,1]	Separation distance dependent thermal convection coefficient (Real or Integer; Default = 0.0 for a heat transfer problem, omit for a structural problem). If Real, the value entered is a convection coefficient. If Integer, the value entered is the ID of a TABLEM1 entry specifying the convection coefficient vs temperature.
<b>“PATCH3D”</b>	Entries for this continuation line describe a rigid body made up of as many 4-node patches as desired. (Triangular patches are not available.)
IDP	ID of the patch (Integer number 1 through highest value).
G1, G2, G3, G4	Grid numbers for each of the 4 nodes of the patch (see Note 5).
<b>“BEZIER”</b>	Entries for this continuation line describe a rigid body made up of Bezier Surfaces.
NP1	Number of points in 1st direction. (Integer > 0)
NP2	Number of points in 2nd direction. (Integer > 0)
NSUB1	Number of subdivisions in 1st direction. (Integer > 0)
NSUB2	Number of subdivisions in 2nd direction. (Integer > 0)
G1, G2, G3, etc	Grid numbers of each point (must be in order). There must be NP1*NP2 grid points defined. Enter NP1 points for NP2=1, then NP2 points for NP2=2, etc. (Integer)
<b>“POLY”</b>	Entries for this continuation line describe a rigid body made up of Poly Surfaces.
NP1	Number of points in the 1st direction. (Integer > 0)
NP2	Number of points in the 2nd direction. (Integer > 0)
G1, G2, G3, etc	Grid numbers of each point (must be in order). There must be NP1*NP2 grid points defined. Enter NP1 points for NP2=1, then NP2 points for NP2=2, etc. (Integer)
<b>“CYLIND”</b>	Entries for this continuation line describe a cylindrical rigid body.
NSUB	Number of subdivisions. (Integer > 0)
Gtop	Grid point ID of a grid in the center of the top of the cylinder. (Integer > 0)
Rtop	Radius of the top of the cylinder. (Real > 0.0)
Gbottom	Grid point ID of a grid in the center of the bottom of the cylinder. (Integer > 0)
Rbottom	Radius of the bottom of the cylinder. (Real > 0.0)
<b>“SPHERE”</b>	Entries for this continuation line describe a spherical rigid body.
NSUB	Number of subdivisions. (Integer > 0)
Gcenter	Grid point ID of a grid in the center of the sphere. (Integer > 0)
Radius	Radius of the sphere. (Real > 0.0)
<b>“LINE”</b>	Entries for this continuation line describe a 2D rigid body made up of as many line segments as desired.

Describer	Meaning
NPTS	Number of points in the line segment.
Ix	Grid direction (1, 2, or 3) of the G1, G2, ... list to be used as the first coordinate in Marc's 2D line description. See Remark 12. (Integer; Default = 1).
Iy	Grid direction (1, 2, or 3) of the G1, G2, ... list to be used as the second coordinate in Marc's 2D line description. See Remark 12. (Integer; Default = 2).
Rx	Direction (1, 2, or 3) used as the first VELRBi in Marc's 2D contact description. (Integer; Default = 1)
Ry	Direction (1, 2, or 3) used as the second VELRBi in Marc's 2D contact description. (Integer; Default = 2)
G1, G2, G3, G4	Grid numbers for each of the NPTS points on the line segment.
"ARC"	Entries for this continuation line describe a 2D rigid body made up of as many segments as desired describing an arc.
NPTS	Number of points in the arc. NPTS must be 4 for an ARC.
MethArc	Method to generate arc (Integer 0 to 4) (see Marc volume C Contact description (SOL 400 chapter 9) Figures 3-3 and 3-4).
Ix	Grid direction (1, 2, or 3) of the G1, G2, ... list to be used as the first coordinate in Marc's 2D line description. See Remark 12. (Integer; Default = 1).
Iy	Grid direction (1, 2, or 3) of the G1, G2, ... list to be used as the second coordinate in Marc's 2D line description. See Remark 12. (Integer; Default = 2).
Rx	Direction (1, 2, or 3) used as the first VELRBi in Marc's 2D contact description. (Integer; Default = 1)
Ry	Direction (1, 2, or 3) used as the second VELRBi in Marc's 2D contact description. (Integer; Default = 2)
G1, G2, G3, G4	Grid numbers for each of the 4 points as described by method.
"SPLINE"	Entries for this continuation line describe a 2D rigid body made up of as many spline segments as desired.
NPTS	Number of points for the spline.
Ix	Grid direction (1, 2, or 3) of the G1, G2, ... list to be used as the first coordinate in Marc's 2D line description. See Remark 12. (Integer; Default = 1).
Iy	Grid direction (1, 2, or 3) of the G1, G2, ... list to be used as the second coordinate in Marc's 2D line description. See Remark 12. (Integer; Default = 2).
Rx	Direction (1, 2, or 3) used as the first VELRBi in Marc's 2D contact description. (Integer; Default = 1)
Ry	Direction (1, 2, or 3) used as the second VELRBi in Marc's 2D contact description. (Integer; Default = 2)
G1, G2, G3, G4	Grid numbers for each of the NPTS points on the spline.

Describer	Meaning
“NURBS2D”	Entries for this continuation line describe a 2D rigid body made up of nurmbs.
NPTU	Number of control points. If the control points are entered as coordinates rather than grid IDs NPTU may be set to a negative value whose absolute value is the number of xyz coordinates, but that is not required. (Integer; no Default)
NORU	Order
NSUB	Number of subdivisions
Rx	Direction (1, 2, or 3) used as the first VELRBi in Marc’s 2D contact description. (Integer; Default = 1)
Ry	Direction (1, 2, or 3) used as the second VELRBi in Marc’s 2D contact description. (Integer; Default = 2)
G1, G2, G3, G4	Grid numbers for each of the NPTU control points
X1, Y1, X2, Y2, etc.	Alternate method to define control points without using GRID points. There must be $\text{abs}(\text{NPTU}) \cdot \text{NPTV}$ (x,y,z) entries.
Homo1, Homo2, Homo3, etc.	Homogeneous coordinates (0.0 to 1.0) (Real). There must be NPTU entries.
Knot1, Knot2, Knot3, etc.	Knot vectors (0.0 to 1.0) (Real). There must be (NPTU+NORU) entries.
“NURBS2”	Entries for this continuation line describe a rigid body made up of nurbs.
IDN	ID of a matching GMNURB entry. The GMNURB is an entry that contains the same information as at shown for the NURBS option. (Integer > 0)
“NURBS”	Entries for this continuation line describe a rigid body made up of nurbs.
NPTU	Number of control points. If the control points are entered as coordinates rather than grid IDs NPTU may be set to a negative value whose absolute value is the number of xyz coordinates, but that is not required. (Integer; no Default)
NPTV	Number of control points in V direction. (Integer > 0; Required)
NORU	Order along U direction. (Integer > 0; Required)
NORV	Order along V direction (Integer > 0; Required)
NSUBU	Number of subdivisions in U direction (Integer > 0; Required)
NSUBV	Number of subdivisions in V direction (Integer > 0; Required)
NTRIM	Number of trimming curves (Integer $\geq$ 0 or blank)
G1, G2, G3, etc.	Grid point IDs defining control points (Integer > 0). There must be $\text{NPTU} \cdot \text{NPTV}$ entries.
X1, Y1, Z1, X2, Y2, Z2, etc.	Alternate method to define control points without using GRID points. There must be $\text{abs}(\text{NPTU}) \cdot \text{NPTV}$ (x,y,z) entries.

Describer	Meaning
Homo1, Homo2, Homo3, etc	Homogeneous coordinates (0.0 to 1.0). There must be NPTU*NPTV entries. (Real)
Knot1, Knot2, Knot3, etc	Knot vectors (0.0 to 1.0). There must be (NPTU+NORU)+(NPTV+NORV) entries. (Real)
IDtrim	ID of trimming vector. There must NTRIM of these entries and those entries that follow. (Integer > 0)
NPUTtrim	Number of control points for this trimming vector. (Integer > 0)
NORUtrim	Order for this trimming vector. (Integer > 0)
NSUBtrim	Number of subdivisions for this trimming vector. (Integer > 0)
Xisoparam	First coordinate of point in isoparametric space. (Real)
Ysoparam	Second coordinate of point in isoparametric space. (Real)
Homo1, Homo2, Homo3, etc	Homogeneous coordinates (0.0 to 1.0) of this trimming vector. There must be NPTUtrim entries. (Real)
Knot1, Knot2, Knot3, etc	Knot vectors (0.0 to 1.0) of this trimming vector. There must be NPTUtrim+NORUtrim entries. (Real)

#### Remarks:

1. Named continuation entries are ignored for a deformable curve or surface (BEHAV=DEFO), except for "HEAT".
2. The grid CGID is the reference grid for the rigid body motion. Loads and enforced motion must be defined in the global coordinate system of CGID.
3. WARNING: For rigid contact, the right hand rule determines the interior side of the rigid surface. A deformable surface which contacts a rigid surface must be on the exterior side of the rigid surface (i.e., in the direction opposite to the right hand rule). If a rigid surface is described backwards, contact will not occur because the deformable body is already inside the rigid body at the start of the analysis. For 3D patches, if all need to be reversed, the parameter PARAM,MARCREVR,1 may be entered to automatically reverse all 3D patches.
4. (i,j) refers to data block i and field j of Marc's CONTACT model definition entry. IDSPL covers the SPLINE history definition in Marc. For structural analysis (i,j) refers to contact without tables. For heat transfer (i,j) refers to contact with tables.
5. For BEZIER surfaces, enter np1\*np2 points in the order shown:

Mesh	Normal Order	Reversed Order
2x2	1,2,3,4	2,1,4,3
3x2	1,2,3,4,5,6	3,2,1,6,5,4
3x3	1,2,3,4,5,6,7,8,9	3,2,1,6,5,4,9,8,7

6. For NURBS, enter NPTU grid points G1, G2, G3, etc. (set NPTU to a positive value equal to the number of grid points or enter X1, Y1, Z1, X2, Y2, Z2, etc. coordinates for abs(NPTU) points and set NPTU to a negative value.
7. The heat transfer options are available for SOL 600 starting with MSC Nastran 2005 r2 and must use Marc 2005 or later.
8. For heat transfer items described using a TABLEM1 ID, the smallest value in the table will be entered into Marc's 9th contact (with tables) datablock. The table ID will be translated directly to Marc's 10th contact (with tables) datablock.
9. All flexible surfaces must have smaller BID values then the rigid surfaces so that in the Marc file all flexible surfaces are defined prior to all rigid surfaces. This is a Marc limitation.
10. When IDSPL is greater than 1, these nodes are entered in pairs. For a quad surface (for example, CQUAD4 or edge of a CHEXA) usually 4 sets of nodal pairs are needed to describe the surface. For example, a CQUAD4 with grid numbering 1,2,4,3 would need pairs of nodes, 1,2 2,4 4,3 3,1. The nodal pairs may be entered in any order. See Marc Volume C SPLINE (SOL 400 chapter 9) option documentation for more details.
11. With NURBS2D, the coordinates x1, x2, y1, y2 etc. or those given by G1, G2, etc. will be reversed (Y becomes X and X becomes Y) if any CQUADX, CTRIAX or CTRIAX6 entries are found in the bulk data. It is up to the user to ensure that the rigid contact surface is orientated in the correct direction after this reversal. If the user does not want the reversal to happen, enter PARAM,MARCREVX,-1 in the bulk data.
12. Ix and Iy for LINE, ARC, SPLINE and NURBS2D must be the same for all entries in the model. An example would be if CTRIAX6 is defined in the Z-X plane, set Ix = 3 and Iy = 1 for all 2D rigid surfaces in the model. For CTRIAX and CQUADX, normally Ix=2 and Iy=1.
13. Rx and Ry for LINE, ARC, SPLINE and NURBS2D must be the same for all entries in the model. An example would be if CTRIAX6 is defined in the Z-X plane, set Rx = 3 and Ry = 1 for all 2D rigid surfaces in the model. For CTRIAX and CQUADX, normally Rx=2 and Ry=1.
14. For SOL 600, tables using integers for ANGVEL, VELRB1, VELRB2 and/or VELRB3 require PARAM,MRCONVER,11 and PARAM,MARCTOTT,1 to be set. the TABLE3D's used must define the entire motion/velocity desired.
15. If any CTYPE entries are used, PARAM,MRCONVER,11 and PARAM,MRCONVER,11 are required.

16. ISMALL, ITYPE, IAUG should be the same for all BCTABLE entries. The first entry “CTYPE” entry will be used for all bodies. PENALT and AUGDIST may vary from body to body.
17. 2D and 3D rigid bodies may not be mixed in the same input file.
18. The entries on the CTYPE header may optionally be specified on the BCPARA entry.

Correlation between BCBODY “CTYPE” entries and equivalent BCPARA entries:

BCPARA	BCPARA	CTYPE value(s)
METHOD	NODESURF	ictype=0, ismall=0
METHOD	NODSMALL*	ictype=0, ismall=1
METHOD	SEGSMALL	ictype=1, ismall=1
METHOD	SEGMENT*	ictype=1, ismall=1
METHOD	SEGLARGE*	ictype=1, ismall=0
AUTMENT	Integer Value	IAUG=Integer Value
PENALT	Real Value	PENALT=Real Value
AUGDIST	Real Value	AUTDIST=Real Value
* Not available in SOL 600.		

19. Most continuation lines may be omitted if not required except that the second line is required if the third or subsequent lines are to be entered.

## BCBODY1 Flexible or Rigid Contact Body in 2D and 3D (New Form)

Defines a flexible or rigid contact body in 2D or 3D used in SOLs 101, 400, and 700 only.

If the body is rigid, this entry may refer to BCRIGID entry by the BCRGID field to describe the body. See Remark 1. for an important note regarding how to define the outward direction of rigid bodies (which must point towards a flexible body for contact to occur).

Deformable bodies are described using as many standard elements as necessary and are specified by the BSID field with BEHAV=DEFORM. Unless shrink fit or interference fit is being analyzed, deformable bodies should not be inside other deformable bodies when the thickness of each body is taken into account.

Format: (SOLs 101 and 400 only)

1	2	3	4	5	6	7	8	9	10
BCBODY1	BID	BPID	DIM	BEHAV	BSID	BCRGID	BCGOUT		

Format: (SOL 700 only)

1	2	3	4	5	6	7	8	9	10
BCBODY1	BID				BSID				

Examples of Deformable and Rigid Contact:

Example 1 -- Typical deformable body

BCBODY1	94	3001		DEFORM	103				
---------	----	------	--	--------	-----	--	--	--	--

Example 2 -- Simple rigid patch (see Remark 1. for rigid bodies)

BCBODY1	6	3001		RIGID	206	115			
---------	---	------	--	-------	-----	-----	--	--	--

Describer	Meaning
BID	Unique contact body identification number referenced by BCONECT, BCHANGE, or BCMOVE. (Integer > 0; Required)
BPID	Parameter identification number of a BCBDPRP entry. (Integer > 0 or blank) Ignored in SOL 700. See Remark 2.
DIM	Dimension of body. (Character; Default= 3D) Ignored in SOL 700. DIM=2D: planar body in x-y plane of the basic coordinate system, composed of 2D elements or curves. DIM=3D: any 3D body composed of rigid surfaces, shell elements or solid elements.
BEHAV	Behavior of curve or surface (Character; Default = DEFORM) Ignored in SOL 700. DEFORM body is deformable; RIGID body is rigid (See Remark 1.); SYMM body is a symmetry rigid body; HEAT indicates body is a heat-rigid body (See Remark 3..).

BSID	For SOLs 101 and 400: Identification number of a BSURF or BCPROP entry if BEHAV=DEFORM or HEAT, or identification number of a BCRGSRF, BCPATCH, BCBZIER, BCNURB2, or BCNURBS entry if BEHAV=RIGID or SYMM (See Remark 4.).
	For SOL 700: Identification number (RBID) of a BSURF, BCBOX, BCPROP, BCMATL, BCSEG, BCGRID or BCELIPS entry. (Integer > 0).
BCRGID	For SOLs 101 and 400: Identification number of a BCRIGID entry if BEHAV=RIGID or SYMM. Ignored in SOL 700. (Integer > 0)
BCGOUT	Reference point in basic coordinate system to calculate the global resultant contact force/moment (integer)
	-1      Origin
	0        Estimated centroid of deformable body (default)

#### Remarks:

1. **WARNING:** For rigid contact, the right hand rule determines the interior side of the rigid surface. A deformable surface which contacts a rigid surface must be on the exterior side of the rigid surface (i.e., in the direction opposite to the right hand rule). If a rigid surface is described backwards, contact will not occur because the deformable body is already inside the rigid body at the start of the analysis. For 3D patches, if all need to be reversed, the parameter PARAM,MARCREVR,1 may be entered to automatically reverse all 3D patches
2. If BPID field is blank, then default values are set for the parameters defined in BCBDPRP entry.
3. For pure thermal analysis, BEHAV=DEFORM and BEHAV=HEAT are identical. However, in coupled thermal-mechanical analysis, BEHAV=DEFORM specifies a deformable in mechanical analysis part, while BEHAV=HEAT defines a rigid meshed body in mechanical analysis part.
4. If BCRGSRF entry does not exist, BCBODY1 entry can refer to one of the identification number of BCPATCH, BCBZIER, BCNURB2, or BCNURBS entry directly (RBID).

## BCBOX

## 3D Contact Region

Defines a 3D contact region - all elements within the region define a contact body in SOL 600 and 700.

Format (Form 1):

1	2	3	4	5	6	7	8	9	10
BCBOX	ID		HOW						
	N1	N2	N3	N4	N5	N6	N7	N8	

Form 2:

BCBOX	ID	COORD	HOW						
			X1	Y1	Z1	X2	Y2	Z2	
			X3	Y3	Z3	X4	Y4	Z4	
			X5	Y5	Z5	X6	Y6	Z6	
			X7	Y7	Z7	X8	Y8	Z8	

Example (for Form 1):

BCBOX	101		0						
	1001	1002	1003	1004	1005	1006	1007	1008	

Describer	Meaning	
-----------	---------	--

**ID** Identification of a deformable surface corresponding to a BSID value on the BCBODY entry if the Case Control BCONTACT=BCBOX is specified. All elements corresponding to the designated box may potentially come into contact. See Remark 1. (Integer > 0)

**COORD** Enter COORD in field 3 if x,y,z coordinates of the box are to be specified rather than grid IDs. (Character)

**HOW** A flag indicating whether an element is in the defined box or not. (Integer; Default = 0)

0 If only one grid point of an element is in the box, the entire element is considered to be in the box.

1 All grid points comprising the element must be within the box, otherwise the element is considered outside of the box.

**N1-N8** Enter 8 Grid IDs defining a box (hexa-like region) if the third field is blank. (Integer; Required if COORD is blank)

**Xi, Yi, Zi** Enter eight x,y,z values in the basic coordinate system if the third field is COORD. See Remark 6. (Real; Required if "COORD" is entered in field 3 of line 1)

**Remarks:**

1. ID must be unique with respect to all other BSURF, BCBOX, BCPROP, and BCMATL entries.
2. The deformable surface may alternately be defined using BSURF, BCPROP, or BCMATL entries.
3. Only one kind of entry (BSURF, BCBOX, BCPROP, or BCMATL) may be used to define a particular deformable surface.
4. All elements corresponding to the IDs entered will be used to define the deformable surface.
5. The model is searched to determine whether each element lies within the specified box region as specified by the HOW criteria option.
6. For SOL 700, the BCBOX allows a general box and edges do not need to be aligned with the coordinates axis. The eight grid points define the box identical to the CHEXA grid point numbering.
7. BCBOX is not supported in SOLs 101 and 400.

**BCBZIER**

Defines a Rigid Contact Body Made up of Bezier Surfaces in SOLs 101 and 400

Defines a rigid contact body made up of Bezier surfaces used in SOLs 101 and 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCBZIER	RBID	NP1	NP2	NSUB1	NSUB2				
	G1	G2	G3	G4	-etc.-				

Example:

BCBZIER	98	3	3	25	15				
	21	11	1	84	74	64	147	137	
	127								

Descriptor    Meaning

RBID            Unique identification number referenced by a BCRGSRF or BCBODY1 entry. (Integer > 0) See Remark 1.

NP1            Number of points in 1st direction. (Integer > 0)

NP2            Number of points in 2nd direction. (Integer > 0)

NSUB1        Number of subdivisions in 1st direction. (Integer > 0)

NSUB2        Number of subdivisions in 2nd direction. (Integer > 0)

G1, G2, G3, etc.    Grid numbers of each point (must be in order). There must be NP1\*NP2 grid points defined. Enter NP1 points for NP2=1, then NP1 points for NP2=2, etc. (Integer > 0)

Remarks:

1. If BCRGSRF entry does not exist, BCBZIER entry will be referenced by the **BCBODY1** entry directly.
2. For BEZIER surfaces, enter np1\*np2 points in the order shown below

Mesh	Normal Order	Reversed Order
2x2	1,2,3,4	2,1,4,3
3x2	1,2,3,4,5,6	3,2,1,6,5,4
3x3	1,2,3,4,5,6,7,8,9	3,2,1,6,5,4,9,8,7

## BCELIPS

### Contact Ellipsoid List- SOL 700

Defines a list of ellipsoid names (character strings) for use of contact analysis. Used in SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCELIPS	CID	NAME1	NAME2	NAME3	NAME4	NAMEi	etc		

Example:

BCELIPS	1	HUB	RIM	HEAD	CHEST				
---------	---	-----	-----	------	-------	--	--	--	--

Field	Content
CID	Unique identification number of ellipsoid names which can be used for contact. (Integer > 0; required)
NAME	Name of an ellipsoid. (Character; required)

Remarks:

Use as many continuations as required to define the complete list of names. A blank field terminates the list..

## BCGRID (SOL 700 only)

## Contact Node Region

Grids to be included in contact analyses in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCGRID	CID	GID1	GID2	GID3	GID4	GID5	GID6	GID7	
	GID8	GID9	GID10	GID11	GID12	GID13	-etc.-		

Example:

BCGRID	100	12	14	17	121	234	235	270	
	309	1001	THRU	2000	BY	2			

Describer	Meaning
ID	Unique identification number of a “cloud” of grid points which can be used for contact or RCONN, BJOIN or WALL. (Integer > 0; Required)
GID1, GID2,...	Gridpoint ID. THRU indicates a range to be used. BY is the increment to be used within this range. (Integer > 0; Required)

Remarks:

1. ID must be unique with respect to all other BSURF, BCBOX, BCPROP, BCMATL, or BCSEG entries.
2. BCGRID may only be used for SECNDRY body definitions on the BCTABLE entry.
3. As many continuation lines as necessary may be used to define all GRID points used in the definition.

## BCGRID

## Contact region by a list of grid points.

Define a contact region by a grid point list, for SOLs 101, 103, 105, 107, 108, 109, 110, 111, 112, 200 and 400.

Format:

1	2	3	4	5	6	7	8	9	10
BCGRID	BID	BPID	DIM						
	GID1	GID2	GID3	"THRU"	GID4	"BY"	GID5	GID6	
	GID7								

Example:

BCGRID	2	3	3D						
	12	21	THRU	101	3	6			

Describer	Meaning
BID	Unique contact face identification number referenced by BCONECT (Integer > 0; Required). See remark 1.
BPID	Parameter identification number of a BCBDPRP entry. (Integer > 0 or blank)
DIM	Dimension of the contact entry. (Character; Default= "3D"), "3D" or "2D".
GIDi	Grid point ids. (Integer > 0)

Remarks:

1. BID must be unique among all BCSURF, BCBODY1 and BCGRID entries.
2. BCGRID entries are able to coexist with BCBODY1 entries. A BCGRID entry can be used with a BCSURF or a BCBODY1 entry to construct a contact pair. The BCGRID entry must be a secondary, the BCSURF or BCBODY must be a primary.
3. This entry only works in node to segment method.
4. The identification of BCGRID cannot be specified in the continuations of a BCONECT entry.
5. If a BCRIGID is referenced by a BCONECT, COPTS and COPTM in the BCONPRG referenced by the BCONECT will be ignored.

## BCHANGE

## Changes Definitions of Contact Bodies

Changes definitions of contact bodies used in SOL 101 and SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
BCHANGE	ID	TYPE			IDBOD1	N1	N2	INC	
	IDBOD2	N1	N2	INC	IDBOD3	etc.			

Example:

BCHANGE	201	NODE			1	1001	1010	1	
	2	2001	2021	2					

Describer	Meaning	
ID	Identification number referenced by a BCONTACT or BCHANGE Case Control command within a SUBCASE or STEP. See Remark 1. (Integer $\geq 0$ ; Required)	
Type	Type of modification (Character; Required)	
	NODE	Defines nodes of a contact body which may come into contact.
	EXCLUDE	Excludes 2 node segments in 2D or 4 node patches in 3D.
IDBODi	Identification number of a contact body, BCBODY or BCBODY1 entry. (Integer $> 0$ )	
N1	Starting grid ID. More than one N1-N2-INC range may be entered for each body, see Remark 7. (Integer $> 0$ ; Default = 1)	
N2	Ending grid ID.	
INC	Grid ID increment.	

Remarks:

1. To place an entry in the loadcase 0, set ID=0, which does not need any corresponding Case Control command BCONTACT=0 or BCHANGE=0, and it is always executed automatically. To place an entry in any physical loadcase (SUBCASE or STEP), the ID must be selected by the Case Control command BCONTACT=ID or BCHANGE=ID. Note that if BCHANGE Case Control command exists, it always dominates the selection of BCHANGE Bulk Data entries.
2. The BCHANGE entry does not apply to rigid bodies. Multiple BCHANGE entries are allowed. A body may be entered more than once with different grid IDs.
3. BCHANGE is useful only for saving computer time and is not recommended for general usage.
4. Warning -- For the NODE option, if some nodes in a body are inadvertently omitted, they may penetrate other bodies.
5. BCHANGE with the NODE option is not supported in Segment-to-segment contact.

6. NODE and EXCLUDE may not be used simultaneously in the same BCHANGE entry.
7. If TYPE=NODE, the form of N1-N2-INC range has the following rules:
  - a. The format of INC is either blank or integer ( $\geq 0$ ).
  - b. N1-N2-0 or N1-N2-blank represents 2 nodes (N1,N2) where  $0 < N1$  and  $0 < N2$ ,
  - c. N1-N2-INC,  $INC > 0$ , represent a range input but  $0 < N1 < N2$ .
8. If TYPE=EXCLUDE, the form of N1-N2-INC range has the following rules:
  - a. For node segment, N1-N2-INC is used. If  $0 < N1 < N2$  and  $INC > 0$ , the range is applied. If INC-blank or 0, it is 2 nodes (N1,N2) input that can be in any order.
  - b. For 4 nodes patch, (N1,N2,N3,N4), 2 sets of range, which have to input in sequence, are required.  
(IDBOD1,-N1,N2,INC1) and (IDBOD2,N3,N4,INC2) where  $IDBOD1 = IDBOD2$ ,  $N_i > 0$ , INC1 and INC2 are ignored.

The following example is for a 4-node patch (100,110,300,200)

1	2	3	4	5	6	7	8	9	10
BCHANGE	1	EXCLUDE			1	-100	110		
	1	300	200						

- c. For 3 nodes patch, (N1,N2,N3), 2 sets of range, which have to input in sequence, are required (IDBOD1,-N1,N2,INC1) and (IDBOD2,N3,N3,INC2) where  $IDBOD1 = IDBOD2$ ,  $N_i > 0$ , INC1 and INC2 are ignored.

The following example is for a 3-noded patch (132,97,95)

1	2	3	4	5	6	7	8	9	10
BCHANGE	1	EXCLUDE			1	-132	97		
	1	95	95						

## BCHANGE

## Changes Definitions of Contact Bodies in SOL 600

Changes definitions of contact bodies used in SOL 600.

Format:

1	2	3	4	5	6	7	8	9	10
BCHANGE	ID	TYPE	NBOD		IDBOD1	N1	N2	INC	
	IDBOD2	N1	N2	INC	IDBOD3	etc.			

Example:

BCHANGE	201	NODE	2		1	1001	1010	1	
	2	2001	2021	2					

Descriptor	Meaning
ID	Identification number referenced by a SUBCASE Case Control command. See Remark 2. (Integer $\geq 0$ ; Required)
Type	Type of modification (Character; Required) NODE Defines nodes of a contact body which may come into contact. EXCLUDE Excludes 2 node segments in 2D or 4 node patches in 3D.
NBOD	Number of bodies to be modified -- must match number of bodies actually entered. More than one N1-N2-INC range may be entered for each body, see Remark 7. See N1 below. (Integer $> 0$ ; Default = 1)
IDBODi	Identification number of a contact body, BCBODY entry. (Integer $> 0$ )
N1	Starting grid ID.
N2	Ending grid ID.
INC	Grid ID increment.

Remarks:

- To place an entry in Marc's phase 0, set ID=0. To activate the entry for the first SUBCASE, SET ID=1, for the 2nd, set ID=2.
- The BCHANGE entry does not apply to rigid bodies. Multiple BCHANGE entries are allowed. A body may be entered more than once with different grid IDs.
- The BCHANGE entry covers Marc's history definitions CONTACT NODE and EXCLUDE.
- BCHANGE is useful only for saving computer time and is not recommended for general usage.
- Warning -- For the NODE option, if some nodes in a body are inadvertently omitted, they may penetrate other bodies.

6. If more than one N1-N2-INC range is required for a body, enter N1 as a negative value for all ranges except for the last range for which N1 is entered as a positive value.
7. If more than one N1-N2-INC range is required, all ranges with IBOD1 must come first, followed by all with IBOD2, etc.
8. The EXCLUDE option is obsolete. The reasons why it was added in the past have been alleviated by better improved contact algorithms. If the EXCLUDE option is entered for 3D shapes two N1-N2-INC ranges are normally required to define all 4 nodes of a patch. If the patch is triangular, the last two nodes must be repeated. The following are examples of how data are entered for one element using the exclude option. The first example is for a 4-node patch (nodes 100, 110, 200, 300) and the second is for a 3-node patch (nodes 132, 97, 95, 95).

BCHANGE	1	EXCLUDE	1		1	-100	110	10	
	1	200	300	100					

BCHANGE	1	EXCLUDE	1		1	-132	132	0	
	1	-97	97	0	1	-95	95	0	
	1	95	95	0					

## BCMATL

## 3D Contact Region by Element Materials

Defines a 3D contact region by element material. All elements with the specified materials define a contact body used in SOL 600 and SOL 700.

Format:

1	2	3	4	5	6	7	8	9	10
BCMATL	ID	IM1	IM2	IM3	IM4	IM5	IM6	IM7	
	IM8	IM9	etc.						

Example:

BCMATL	1001	101	201	301					
--------	------	-----	-----	-----	--	--	--	--	--

Describer	Meaning
ID	Identification of a deformable surface corresponding to a BSID value on the BCBODY entry if the Case Control command, BCONTACT=BCMATL is specified. All elements corresponding to the material IDs specified may potentially come into contact. See Remark 1. (Integer > 0)
IMi	Material ID. A minimum of one entry is required. (Integer)

Remarks:

1. ID must be unique with respect to all other BSURF, BCBOX, BCPROP, and BCMATL entries.
2. The deformable surface may alternately be defined using BSURF, BCBOX, or BCPROP entries.
3. Only one kind of entry (BSURF, BCBOX, BCPROP, or BCMATL) may be used to define a particular deformable surface.
4. All elements corresponding to the IDs entered will be used to define the deformable surface.
5. As many continuation lines as necessary may be used to define all material IDs associated with a particular deformable body.
6. BCMATL may not be used to define contact regions made up of composite elements.

**BCMOVE****Movement of Bodies in Contact**

Defines movement of bodies in contact used in SOL 101 and SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
BCMOVE	ID	MTYPE							
	IDRBOD1	IDRBOD2	IDRBOD3	etc.					

Examples:

BCMOVE	33	RELEASE							
	1	3	5	7					
BCMOVE	1	approach							

Describer	Meaning
ID	Identification number referenced by a BCONTACT or BCMOVE Case Control command within a SUBCASE or STEP. See Remark 1. (Integer $\geq 0$ ; Required)
MTYPE	Movement type. (Character; Default = APPROACH)
	APPROACH      All rigid bodies are moved so that they all make contact with deformable bodies.
	RELEASE        The contact condition is released for selected bodies.
	SYNCHRON      All rigid bodies are moved until the first rigid body makes contact with a deformable body.
IDRBODi	Identification numbers of contact bodies to be released, for option RELEASE only. Points to BCBODY or BCBODY1 Bulk Data entries.

Remarks:

1. To place an entry in the loadcase 0, set ID=0, which does not need any corresponding Case Control command BCONTACT=0 or BCMOVE=0, and it is always executed automatically. To place an entry in any physical loadcase (SUBCASE or STEP), the ID must be selected by the Case Control command BCONTACT=ID or BCMOVE=ID. Note that if BCMOVE Case Control command exists, it always dominates the selection of BCMOVE Bulk Data entries. ID must be unique (only one BCMOVE per SUBCASE).
2. For MTYPE=APPROACH and MTYPE=SYNCHRON leave all following fields blank.
3. The APPROACH and SYNCHRON options apply to rigid contact surfaces only.
4. You may release a deformable body from contact with either a deformable or rigid body.

## BCMOVE

### Movement of Bodies in Contact in SOL 600

Defines movement of bodies in contact to be used in SOL 600.

Format:

1	2	3	4	5	6	7	8	9	10
BCMOVE	ID	MTYPE	IREL						
	IDRBOD1	IDRBOD2	IDRBOD3	etc.					

Examples:

BCMOVE	33	RELEASE	20						
	1	3	5	7					
BCMOVE	1	approach							

Describer	Meaning
ID	Identification number referenced by a SUBCASE or STEP Case Control command. See Remark 1. (Integer $\geq 0$ ; Required)
MTYPE	Movement type. (Character; Default = APPROACH) APPROACH      All rigid bodies are moved so that they all make contact with deformable bodies. RELEASE        The contact condition is released for selected bodies. SYNCHRON      All rigid bodies are moved until the first rigid body makes contact with a deformable body.
IREL	Flag to indicate how contact forces are removed, for option RELEASE only. (Integer) = 0              Contact forces are immediately removed. (Default) > 0              Contact forces are reduced to zero over the number of increments specified in this load period. See NLPARM and TSTEP1 for the number of increments.
IDRBODi	Identification numbers of rigid bodies to be released, for option RELEASE only. Points to BCBODY Bulk Data entries.

Remarks:

1. To place an entry in Marc's phase 0, set ID=0. To activate the entry for the 1st SUBCASE, SET ID=1, for the 2nd, set ID=2. ID must be unique (only one BCMOVE per SUBCASE).
2. This entry matches Marc's history definitions RELEASE, APPROACH, and SYNCHRONIZED. Note that Marc's history definition MOTION CHANGE is done in MSC Nastran by describing the enforced motion for the grid which is defined to be the center of rotation of the rigid body, see CGID of the BCBODY entry.

3. For MTYPE=APPROACH and MTYPE=SYNCHRON leave all following fields blank.
4. The APPROACH and SYNCHRON options apply to rigid contact surfaces only.
5. You may release a deformable body from contact with either a deformable or rigid body.

**BCNURB2**

Defines a 2D Rigid Contact Body Made up of NURBS in SOLs 101 and 400

Defines a 2D rigid contact body made up of NURBS used in SOLs 101 and 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCNURB2	RBID	NPTU	NORU	NSUB					
	“GRID” or “COORD”	G1 or X1	G2 or Y1	G3 or X2	G4 or Y2	-etc.-			
	“HOMO”	Homo1	Homo2	Homo3	Homo4	-etc.-			
	“KNOT”	Knot1	Knot2	Knot3	Knot4	Knot5	-etc.-		

Examples:

BCNURB2	102	4	1	1					
	GRID	237	101	104	235				
	HOMO	0.0	0.5	0.5	1.0				
	KNOT	0.0	0.2	0.4	0.8	1.0			

BCNURB2	3001	-5	3	50					
	COORD	-.1	.14	-.1	.04	-1.4-16	.04		
		.1	.04	.1	.14				
	HOMO	1.	.707107	1.	.707107	1.			
	KNOT	0.0	0.0	0.0	0.5	0.5	1.0	1.0	
		1.0							

Describer

Meaning

RBID

Unique identification number referenced by a BCRGSRF or BCBODY1 entry. (Integer &gt; 0) See Remark 1.

NPTU

Number of control points. If the control points are entered as coordinates rather than grid IDs NPTU must be set to a negative value whose absolute value is the number of xy coordinates. (Integer; no Default)

NORU

Order along U direction. (Integer &gt; 0)

NSUB

Number of subdivisions. (Integer &gt; 0)

“GRID”

Indicate the start of the list of grid numbers. See Remark 2.

G1, G2, G3, G4,  
etc.

Grid numbers for each of the NPTU control points. (Integer &gt; 0)

“COORD”

Indicate the start of the list of xy coordinates. See Remark 2.

X1, Y1, X2, Y2, etc.	Alternate method to define control points without using GRID points. There must be abs(NPTU) set of (x,y) entries. (Real)
“HOMO”	Indicate the start of the list of homogeneous coordinates.
Homo1, Homo2, Homo3, etc.	Homogeneous coordinates. (Real; 0.0 to 1.0) There must be NPTU entries.
“KNOT”	Indicate the start of the list of knot vectors.
Knot1, Knot2, Knot3, etc.	Knot vectors. (Real; 0.0 to 1.0) There must be (NPTU+NORU) entries.

#### Remarks:

1. If BCRGSRF entry does not exist, BCNURB2 entry will be referenced by the [BCBODY1](#) entry directly.
2. The list of grid IDs (“GRID”) and the list of xy coordinates (“COORD”) cannot coexist.

## BCNURBS Defines a Rigid Contact Body Made up of NURBS in SOLs 101 and 400

Defines a rigid contact body made up of NURBS used in SOLs 101 and 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCNURBS	RBID	NPTU	NPTV	NORU	NORV	NSUBU	NSUBV		
	“GRID”	G1	G2	G3	G4	G5	G6		
	or	or	or	or	or	or	or	-etc.-	
	“COORD”	X1	Y1	Z1	X2	Y2	Z2		
	“HOMO”	Homo1	Homo2	Homo3	Homo4	Homo5	Homo6	Homo7	
		Homo8	Homo9	-etc.-					
	“KNOT”	Knot1	Knot2	Knot3	Knot4	Knot5	Knot6	Knot7	
		Knot8	Knot9	-etc.-					
	“TRIM”	IDtrim1	IDtrim2	IDtrim3	-etc.-				

Examples:

BCNURBS	48	2	1	2	1	50	50		
	GRID	3005	102						
	HOMO	1.	.3333						
	KNOT	0.0	0.0	0.5	0.5	1.	1.		

BCNURBS	63	-2	2	2	2	50	50		
	COORD	.3	-.6	0.	.3	-.1	0.		
	HOMO	1.	1.	1.	1.				
	KNOT	0.0	0.0	1.	1.	0.	0.		
		1.	1.						
	TRIM	511	2002	87	704				

Describer	Meaning
RBID	Unique identification number referenced by a BCRGSRF or BCBODY1 entry. (Integer > 0) See Remark 1.
NPTU	Number of control points in U direction. If the control points are entered as coordinates rather than grid IDs, NPTU must be set to a negative value whose absolute value is the number of xyz coordinates. See Remark 2. (Integer > 0; Required)
NPTV	Number of control points in V directions. (Integer > 0; Required)
NORU	Order along U direction. (Integer > 0; Required)

NORV	Order along V direction. (Integer > 0; Required)
NSUBU	Number of subdivisions in U direction. (Integer > 0; Required)
NSUBV	Number of subdivisions in V direction. (Integer > 0; Required)
“GRID”	Indicate the start of the list of grid numbers. See Remark 3.
G1, G2, G3, etc.	Grid point IDs defining control points. (Integer > 0) There must be $NPTU \cdot NPTV$ entries.
“COORD”	Indicate the start of the list of xyz coordinates. See Remark 3.
X1, Y1, Z1, X2, Y2, Z2, etc.	Alternate method to define control points without using GRID points. There must be $abs(NPTU) \cdot NPTV$ sets of (x,y,z) entries.
“HOMO”	Indicate the start of the list of homogeneous coordinates.
Homo1, Homo2, Homo3, etc.	Homogeneous coordinates (0.0 to 1.0). There must be $abs(NPTU) \cdot NPTV$ entries. (Real)
“KNOT”	Indicate the start of the list of knot vectors.
Knot1, Knot2, Knot3, etc.	Knot vectors (0.0 to 1.0). There must be $(abs(NPTU) + NORU) + (NPTV + NORV)$ entries. (Real)
“TRIM”	Indicate the start of the list of trimming vector IDs.
IDtrimi	Trimming vector identification number of a BCTRIM entry. (Integer > 0)
Homot1, Homot2, Homot3, etc.	Homogeneous coordinates (0.0 to 1.0) of this trimming vector. There must be $NPTU_{trim}$ entries. (Real)
Knott1, Knott2, Knott3, etc.	Knot vectors (0.0 to 1.0) of this trimming vector. There must be $NPTU_{trim} + NORU_{trim}$ entries. (Real)

#### Remarks:

1. If BCRGSRF entry does not exist, BCNURBS entry will be referenced by the BCBODY1 entry directly.
2. Enter NPTU grid points G1, G2, G3, etc. (set NPTU to a positive value equal to the number of grid points) or enter X1, Y1, Z1, X2, Y2, Z2, etc. coordinates for  $abs(NPTU)$  points and set NPTU to a negative value.
3. The list of grid IDs (“GRID”) and the list of xyz coordinates (“COORD”) cannot coexist.

## BCONECT Defines a Contact Pair

Defines a contact pair used in SOLs 101, 103, 105, 107, 108, 109, 110, 111, 112, 200, 400 and 700. Only SOL 101, 400 and 700 can support all contact types: touching contact, glued, step glue and permanent glue (see [Chapter 7: Contact Types](#) of *Nastran SOL 400 Getting Started Guide*). Note that SOL 700 calls it “tie” contact to glue (also step glue or permanent glue). SOL 103-112 and standard 200 (without calling SOL 400) can only support permanent glue. When SOL 200 calls SOL 400 (or say SOL 400 optimization), it can support all contact types.

Format:

1	2	3	4	5	6	7	8	9	10
BCONECT	ID	BCGPID	BCPPID	IDSCND	IDPRIM				
	“SECNDRY”	IDSEC1	IDSEC2	IDSEC3	IDSEC4	IDSEC5	IDSEC6	IDSEC7	
		IDSEC8	IDSEC9	-etc.-					
	“PRIMARY”	IDPRIM1	IDPRIM2	IDPRIM3	IDPRIM4	IDPRIM5	IDPRIM6	IDPRIM7	
		IDPRIM8	IDPRIM9	-etc.-					

Examples:

BCONECT	57	306		2	1002				
BCONECT	9		108						
	SECNDRY	30	26						
	PRIMARY	294	135	528					

Describer	Meaning
ID	Unique identification number referenced by a BCTABL1 entry (Integer ≥ 0). See Remark <a href="#">1</a> .
BCGPID	Parameter identification number of a BCONPRG entry (Integer ≥ 0 or blank). See Remark <a href="#">2</a> .
BCPPID	Parameter identification number of a BCONPRP entry (Integer ≥ 0 or blank). See Remark <a href="#">2</a> .
IDSCND	Identification number of BCBODY1, BCSURF and BCGRID entry defining the touching body (Integer ≥ 0 or blank). See Remarks <a href="#">3</a> . and <a href="#">4</a> .
IDPRIM	Identification number of BCBODY1 and BCSURF entry defining the touched body (Integer ≥ 0 or blank). See Remarks <a href="#">5</a> . and <a href="#">6</a> .
“SECNDRY”	Indicates the start of the list of the touching bodies. See Remark <a href="#">4</a> .

IDSECI	Identification number of BCBODY1 entry defining the touching bodies (Integer $\geq 0$ or blank).  For SOL 700, leaving IDSEC1 blank will result in contact for all elements in the model. In this case, you are allowed to use ADAPT=YES.
“PRIMARY”	Indicates the start of the list of bodies touched by touching bodies. See Remark 6.
IDPRIMI	Identification number of BCBODY1 entry defining touched bodies (Integer $\geq 0$ or blank).

#### Remarks:

1. BCONNECT can be selected by the Case Control command BCONTACT=ID to define surface contact if BCTABL1 entry does not exist. See Remarks 2. and 3. of BCTABL1 entry.
2. If BCGPID or BCPPID field is blank, then default values are set for the parameters of touching bodies.
3. A short input to define a single touching body exists if the user provides IDSCND. On the other hand, if the user leaves IDSCND blank, then “SECNDRY” descriptor is required and IDSEC1 must be specified. Exceptions are for SOL 700 self-contact, which may use a secondary IDSEC1 of zero and no “PRIMARY” entry.
4. “SECNDRY” and IDSECI fields will be ignored if IDSCND exists. If IDSCND field is blank, then “SECNDRY” and IDSECI must be specified. In this case, each IDSECI will be processed separately.
5. A short input to define a single touched body exists if the user provides IDPRIM. On the other hand, if the user leaves IDPRIM blank, then “PRIMARY” descriptor is required and IDPRIM1 must be specified.
6. “PRIMARY” and IDPRIMI fields will be ignored if IDPRIM exists. If IDPRIM field is blank, then “PRIMARY” and IDPRIMI must be specified.
7. The concept of Secondary and Primary relation is important to the node-to-segment contact but not relevant for segment-to-segment contact. In segment-to-segment contact, they are mainly used to define the contact pair(s).
8. If all the BCONPRG that are referenced by a BCONNECT (which is referenced by BCTABL1) have a value of IGLUE  $> 0$ , and this BCONNECT is referenced in the 1st Loadcase SOL 101 to 112 and SOL 200 or the 1st Step (SOL 400) then the connections are considered to be permanent and do not change (unless a BCPARA is used to deactivate the permanent glue).

## BCONP Contact Parameters

Defines the parameters for a contact region and its properties for slideline contact in SOL 106 or SOL 129. SOL 400 is the preferred method for contact analysis, see BCBODY1, BCONNECT, BCONPRG, BCONPRP, BCPARA and BCTABL1.

Format:

1	2	3	4	5	6	7	8	9	10
BCONP	ID	SECNDRY	PRIMARY		SFAC	FRICID	PTYPE	CID	

Example:

BCONP	95	10	15		1.0	33	1		
-------	----	----	----	--	-----	----	---	--	--

Descriptor	Meaning
ID	Contact region identification number. See Remark 1. (Integer > 0)
SECNDRY	Secondary region identification number. See Remark 2. (Integer > 0)
PRIMARY	Primary region identification number. See Remark 3. (Integer > 0)
SFAC	Stiffness scaling factor. SFAC is used to scale the penalty values automatically calculated by the program. See Remark 4. (Real > 0.0; Default = 1.0)
FRICID	Contact friction identification number. See Remark 5. (Integer > 0 or blank)
PTYPE	Penetration type. See Remark 6. (Integer 1 or 2; Default = 1) 1            Unsymmetrical (secondary penetration only--Default) 2            Symmetrical
CID	Coordinate system identification number to define the slideline plane vector and the slideline plane of contact. See Remark 7. (Integer > 0; Default = 0, which means the basic coordinate system)

Remarks:

1. ID field must be unique with respect to all other BCONP identification numbers.
2. The referenced SECNDRY is the identification number in the BLSEG Bulk Data entry. This is the secondary line. The width of each secondary segment must also be defined to get proper contact stresses. See the Bulk Data entry, [BWIDTH](#) for the details of specifying widths.
3. The referenced PRIMARY is the identification number in the BLSEG Bulk Data entry. This is the primary line. For symmetrical penetration, the width of each primary segment must also be defined. See the Bulk Data entry, [BWIDTH](#) for the details of specifying widths.

4. SFAC may be used to scale the penalty values automatically calculated by the program. The program calculates the penalty value as a function of the diagonal stiffness matrix coefficients that are in the contact region. In addition to SFAC, penalty values calculated by the program may be further scaled by the ADPCON parameter (see description of ADPCON parameter for more details). The penalty value is then equal to  $k \cdot \text{SFAC} \cdot |\text{ADPCON}|$ , where  $k$  is a function of the local stiffness. It should be noted that the value in SFAC applies to only one contact region, whereas the ADPCON parameter applies to all the contact regions in the model.
5. The referenced FRICID is the identification number of the BFRIC Bulk Data entry. The BFRLC defines the frictional properties for the contact region.
6. In an unsymmetrical contact algorithm only secondary nodes are checked for penetration into primary segments. This may result in primary nodes penetrating the secondary line. However, the error depends only on the mesh discretization. In symmetric penetration both secondary and primary nodes are checked for penetration. Thus, no distinction is made between secondary and primary. Symmetric penetration may be up to thirty percent more expensive than the unsymmetric penetration.
7. In Figure 9-2, the unit vector in the Z-axis of the coordinate system defines the slideline plane vector. The slideline plane vector is normal to the slideline plane. Relative motions outside the slideline plane are ignored, and therefore must be small compared to a typical primary segment. For a primary segment the direction from primary node 1 to primary node 2 gives the tangential direction ( $t$ ). The normal direction for a primary segment is obtained by the cross product of the slideline plane vector with the unit tangent vector (i.e.,  $n = z \times t$ ). The definition of the coordinate system should be such that the normal direction must point toward the secondary region. For symmetric, penetration, the normals of primary segments and secondary segments must face each other. This is generally accomplished by traversing from primary line to secondary line in a counterclockwise or clockwise fashion depending on whether the slideline plane vector forms a right-hand or left-hand coordinate system with the slideline plane.

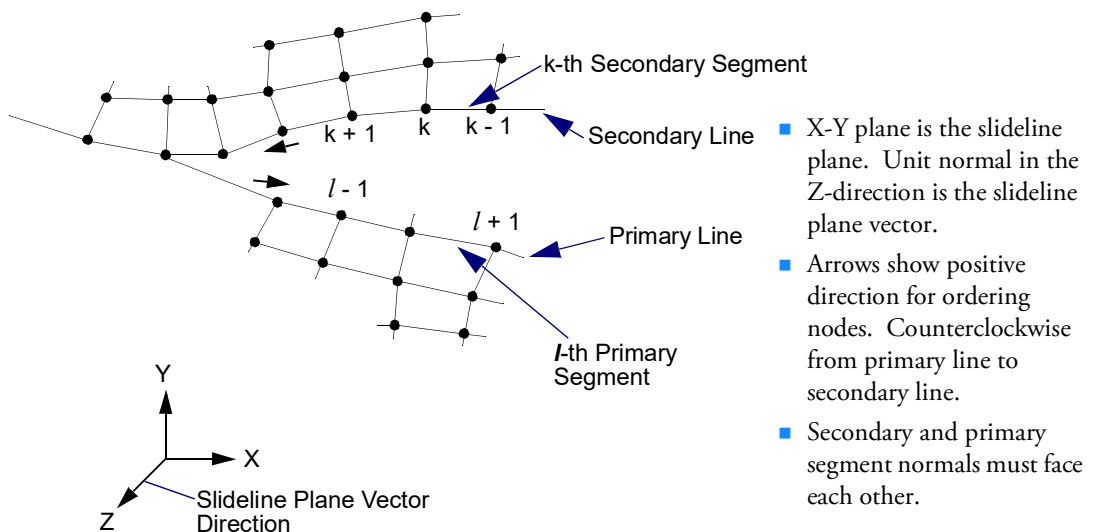

Figure 9-2 A Typical Finite Element Slideline Contact Region

## BCONPRG      Geometric Contact Parameters of Touching Bodies

Defines geometric contact parameters used to determine if contact occurs between bodies. For segment-to-segment contact it also defines additional numerical parameters used to apply the constraints. The parameters defined here are referenced by the BCONNECT entry. This entry is used in conjunction with the BCONPRP entry.

Geometric Contact Parameters of Touching Bodies in SOLs 101 and 400 for General Contact or in SOLs 101, 103, 105, 107 - 112, 200 and 400 for the Permanently Glued or Tied Contact.

Format:

1	2	3	4	5	6	7	8	9	10
BCONPRG	BCGPID		PARAM1	VAL1	PARAM2	VAL2	PARAM3	VAL3	
	PARAM4	VAL4	PARAM5	VAL5	-etc.-				

Example:

BCONPRG	90		ICOORD	1	IGLUE	1			
---------	----	--	--------	---	-------	---	--	--	--

Describer	Meaning
BCGPID	Identification number for geometric contact parameters (Integer > 0).
PARAMi	Name of a parameter. Allowable names are given in <a href="#">Table 9-4</a> (Character).
VALi	Value of a parameter. See <a href="#">Table 9-4</a> (Real or Integer).

Table 9-4 Geometric Contact Parameters of Touching Bodies in SOLs 101, 103, 105, 107-112, 200 and 400

Name	Description, Type and Value (Default is 0 for integer, 0.0 for Real Unless Otherwise Indicated)
AUGDIST	Penetration distance beyond which an augmentation will be applied; used by the segment-to-segment contact algorithm only. (Real $\geq 0.0$ , see Remark 6. for default)
BIAS	Contact tolerance bias factor. If this field is left blank, the default is the BIAS of the BCPARA entry. A nonblank entry will override the BIAS entered on the BCPARA entry. Note 0.0 is not default, and will override the BIAS on BCPARA. SYSTEM(758)=1 will set 0.0 same as blank. (0.0 $\leq$ Real $\leq$ 1.0)
CINTERF	The definition varies depending on OPINTRF. (Real; Default = 0.0) When OPINTRF is set to 0 (default), Interference closure amount, normal to the contact surface. For CINTERF > 0.0, overlap between bodies. For CINTERF < 0.0, gap between bodies. When OPINTRF is set to 1, interference closure magnitude. To clear penetration, set a negative value. When OPINTRF is set to 2, magnitude of translation vector defining in VXINTRF, VYINTRF and VZINTRF. When OPINTRF is set to 3, not used. When OPINTRF is set to 4, not used.
COPTS, COPTM	Flag to indicate how secondary and primary surfaces may contact. See Remark 2. (Integer; Default = 1011). COPTS and COPTM are ignored if secondary or primary in BCONECT is a BCGRID entry but honored if it is a BCSURF entry.
ERROR	Distance below which a node is considered touching a body. Default = blank, automatic calculation. See BCPARA Bulk Data entry for more details. (Real)
HARDS	Hard-soft ratio. This entry is only used if double-sided contact with automatic constraint optimization is used, i.e. ISTYP=2 on the BCBDPRP entry. The hard-soft ratio can be used by the program if there is a significant difference in the average stiffness of the contact bodies (expressed by the trace of the initial stress-strain law). If the ratio of the stiffnesses is larger than the hard-soft ratio, the nodes of the softest body are the preferred secondary nodes. (Real; Default = 2.0) This parameter is ignored for the permanently glued contact.
FGCFLG	Flag to activate Cohesive (Flexible) Glued Contact: (See Remark 12.) 0 – no Cohesive (Flexible) Glued Contact 1 – activate Cohesive (Flexible) Glued Contact
FGCNST	Equivalent normal contact stiffness of connector for Cohesive (Flexible) Glued Contact
FGCTST	Equivalent tangential contact stiffness of connector for Cohesive (Flexible) Glued Contact
FGCNSTR	ID of table for define contact normal stress versus relative displacement for Cohesive (Flexible) Glued Contact. Only TABL3D allowable.
FGCTSTR	ID of table for define contact tangential stress versus relative displacement for Cohesive (Flexible) Glued Contact. Only TABL3D allowable.

FGCNSTI	ID of table for define contact normal stiffness versus relative displacement or temperature for Cohesive (Flexible) Glued Contact. Only TABL3D allowable.
FGCTSTI	ID of table for define contact tangential stiffness versus relative displacement or temperature for Cohesive (Flexible) Glued Contact. Only TABL3D allowable.
FGRCEN	Reference Grid at which resultant contact force of secondary body to primary body is evaluated. See Remark 12.
FGRCN1	Reference Grid at which resultant contact force of primary body to secondary body is evaluated.  Default of FGRCN1 is FGRCEN
ICOORD	Enter 1 to modify the coordinates of a node in contact with a deformable body so that stress-free initial contact can be obtained. Enter 2 to extend the tangential error tolerance at sharp corners of deformable bodies to delay sliding off a contacted segment. Enter 3 to have both 1 and 2 active. (Integer; Default = 0)
IGLUE	Flag to activate glue options (Integer $\geq 0$ ). Default is 0, no glue option. See JGLUE option for controlling a glue contact type in details. This field must be specified for the permanently glued contact. See Remarks 4. and 5. A negative value of IGLUE indicates that this method of glue will be used for the entire Step in SOL 400. See Remark 9.
1 or -1	Activates the glue option. In the glue option, all degrees-of- freedom of the contact nodes are tied in case of deformable-deformable contact once the node comes in contact. The relative tangential motion of a contact node is zero in case of deformable-rigid contact. The node will be projected onto the contact body. For the permanently glued contact, this option is recommended when there is no gap or overlap between contact surfaces or initial stress free contact is specified.
2 or -2	Activates a special glue option to insure that there is no relative tangential and normal displacement when a node comes into contact. An existing initial gap or overlap between the node and the contacted body will not be removed, as the node will not be projected onto the contacted body. To maintain an initial gap, ERROR should be set to a value slightly larger than the physical gap.
3 or -3	Insures full moment carrying glue when shells contact. The node will be projected onto the contacted body. For the permanently glued contact, this option is recommended when moments are important and there is no gap or overlap between contact surfaces or initial stress free contact is specified.
4 or -4	Insures full moment carrying glue when shells contact. The node will not be projected onto the contact body and an existing initial gap or overlap between the node and the contacted body will not be removed, as the node will not be projected onto the contacted body.

ISEARCH	<p>Option for contact searching order, from Secondary to Primary or from Primary to Secondary, for deformable contact bodies. ISEARCH is not necessary in segment-to-segment contact. (Integer; Default = 0)</p> <p>0 (Double orders search) the search order is from lower BCBODY1 ID's to higher ones first. Then it searches the opposite order. See Remark 3.</p> <p>1 (Single order search) the searching order is from Secondary to Primary.</p> <p>2 (Single order search) let the program decide which search order. See Remark 3.</p> <p>Note that ISTYP in BCB DPRP or BCBODY is supported with ISEARCH=0 only.</p>
JGLUE	<p>This option is only relevant if the glue option is invoked (JGLUE &gt; 0). Enter 0 if a node should not separate (default). Enter 1 to invoke the standard separation behavior based on the maximum residual force (related to FNTOL parameter of BCPARA or BCONPRP entry). Enter 2 to activate breaking glue (related to BGM, BGN, BGSN and BGST parameters of BCONPRP entry). (Integer; Default = 0) This parameter is ignored for the permanently glued contact or step glued contact, see Remark 9.</p>
PENALT	<p>Augmented Lagrange penalty factor; used by the segment-to-segment contact algorithm only. (Real <math>\geq 0.0</math>; see Remark 7. for default)</p>
SLIDE	<p>Delayed slide off distance. This entry should not be made unless ICOORD <math>\geq 2</math> (see above). When using the delayed slide off option, a node sliding on a segment will slide off this segment only if it passes the node (2-D) or edge (3-D) at a sharp corner over a distance larger than the delayed slide off distance. By default, the delayed slide off distance is related to the dimensions of the contacted segment by a 20 percent increase of its isoparametric domain. (Real; Default=0.0)</p>
STKSLP	<p>Maximum allowable slip distance for sticking, beyond it there is no sticking, only sliding exists, used by the segment-to-segment contact algorithm only. (Real <math>\geq 0.0</math>; Default = 0.0) See Remark 8.</p>
TPENALT	<p>Augmented Lagrange penalty factor for sticking part of friction, used by the segment-to-segment contact algorithm only. (Real &gt; 0.0) The default is PENALT/1000, where PENALT parameter is the Augmented Lagrange penalty factor for normal contact.</p>
OPINTRF	<p>The method for interference fit. (Integer<math>\geq 0</math>; Default=0) See Remark 10.</p> <p>0 small interference fit (solved in one increment)</p> <p>1 interference fit varying with time; resolved in the normal direction</p> <p>2 interference fit varying with time in a user specified direction</p> <p>3 interference fit varying with time using scale factor</p> <p>4 automatic interference fit varying with time and node location</p>

TBINTRF	TABLED1 id used by interference fit. (Integer>0; Required only when OPINTRF > 0) When OPINTRF=1, TABLED1 id giving variation of interference closure with respect to time When OPINTRF=2, TABLED1 id giving variation of magnitude of translation vector with respect to time When OPINTRF=3, TABLED1 id giving variation of magnitude of scale factor with respect to time When OPINTRF=4, TABLED1 id giving variation of magnitude of penetration vector projected node position on the primary segment with respect to time
CBINTRF	Contact body selection for interference fit. Only required when OPINTRF=2, 3 or 4. (Integer=0 or 1; Default=0) 0 is secondary body, 1 is primary body When OPINTRF=2, secondary or primary body for which translation vector to be used When OPINTRF=3, secondary or primary body for which scale factors to be used. When OPINTRF=4, secondary or primary body of which penetrations to be determined.
CDINTRF	Coordinate system ID of VXINTRF, VYINTRF and VZINTRF for interference fit. Only required when OPINTRF=2, 3. (Integer≥0; Default=0) When OPINTRF=2, Coordinate system for direction cosines for the translation vector. When OPINTRF=3, Coordinate system for scale factor vector.
VXINTRF	X component of vector for interference fit. Only required when OPINTRF=2, 3. (Real; default=0.0) When OPINTRF=2, Direction cosines for the translation vector. When OPINTRF=3, scale factor vector
VYINTRF	Y component of vector for interference fit. Only required when OPINTRF=2, 3. (Real; default=0.0) When OPINTRF=2, Direction cosines for the translation vector. When OPINTRF=3, scale factor vector.
VZINTRF	Z component of vector for interference fit. Only required when OPINTRF=2, 3. (Real; default=0.0) When OPINTRF=2, Direction cosines for the translation vector. When OPINTRF=3, scale factor vector.
PTINTRF	Penetration search tolerance for interference fit. Only required when OPINTRF=4. (Real≥0.0; default=error tolerance*100)
XCINTRF	X component of center of scaling. Only required when OPINTRF=3. (Real; default=0.0) Center is described in global coordinate (Coord0).
YCINTRF	Y component of center of scaling. Only required when OPINTRF=3. (Real; default=0.0) Center is described in global coordinate (Coord0).
ZCINTRF	Z component of center of scaling. Only required when OPINTRF=3. (Real; default=0.0) Center is described in global coordinate (Coord0).
OPINGP	Initial gap or overlap option. See Remark 1. (Integer ≥0; default=0) 0 not used 1 initial gap or overlap

TOLINGP	Search tolerance of initial overlap. (Real $\geq 0.0$ ; default= average edge length of all contact segments, required only when OPINGP =1)
TOLING1	Search tolerance of initial gap. (Real $\geq 0.0$ ; default=average edge length of all contact segments, required only when OPINGP =1) See Remark 14.
CDINGP	Contact body to be adjusted. (Integer $\geq 0$ ; default=0, required only when OPINGP =1) 0 secondary body 1 primary body
MGINGP	Gap or overlap magnitude. (Real ; default=0.0, required only when OPINGP =1) > 0 gap =0 Preserve initial clearance distance. See Remark 11. < 0 overlap
SFNPNTL	Scale factor of augmented Lagrange penalty factor along contact normal direction; used by segment-to-segment contact method only. (Real>0.0;Default=1.0) SFNPNTL*PENALT is used in analysis. If this field is left default, value of SFNPNTL entered in BCPARA will be used. A nonblank value entered in SFNPNTL will override the value of SFNPNTL in BCPARA.
SFTPNTL	Scale factor of augmented Lagrange penalty factor along contact tangential direction; used by segment-to-segment contact method only. (Real>0.0;Default=1.0) SFTPNTL*TPENALT is used in analysis. If this field is left default, value of SFTPNTL entered in BCPARA will be used. A nonblank value entered in SFTPNTL will override the value of SFTPNTL in BCPARA.
TCNTCTL	Flag to define the touching contact status in linear perturbation and ignoring the touching Contact status determined by the contact analysis in NLSTATIC analysis at the load point assigned by NLIC. (Integer; Default = 0). Value of TCNTCTL defined in BCONPRG will override one defined in BCPARA. 0 - Skip this option, keep the original contact status obtained in NLSTATIC 1 - Assuming sliding status of touching contact for contact and frictional stiffness matrix calculation. 2 - Assuming sticking status of touching contact for contact and frictional stiffness matrix calculation. 3 - Assuming glued contact status for touching contact for contact stiffness matrix calculation.

Remarks:

1. The multipoint constraint equations (MPC equations) internally created from general contact or glued contact can be printed out in standard Nastran punch file by using Case Control command, NLOPRM MPCPCH.
2. COPTS and COPTM are packed numbers designating how the surfaces may contact using the formula

$$COPT_x = A + 10 * B + 1000 * C$$

where the following codes apply:

A: the outside of the solid elements in the body.

- = 1: the outside will be in the contact description (Default).

B: (flexible bodies): the outside of the shell elements in the body.

- = 1: both top and bottom faces will be in the contact description, thickness offset will be included (Default).
- = 2: only bottom faces will be in the contact description, thickness offset will be included.
- = 3: only bottom faces will be in the contact description, shell thickness will be ignored.
- = 4: only top faces will be in the contact description, thickness offset will be included.
- = 5: only top faces will be in the contact description, shell thickness will be ignored.
- = 6: both top and bottom faces will be in the contact description, shell thickness will be ignored.

Note: The choice B = 6 for both bodies in a contact combination is only meaningful for glued contact. If in such cases separation is allowed, separated nodes will not come into contact anymore, unless a new CONTACT TABLE is defined to reset the value of B.

Note: for segment-to-segment contact only use B=1 or B-6.

Note: For thermal contact with 2D shell elements, i.e. uniform temperature gradient across thickness, do not use B=2 or B=3.

B: (rigid bodies): the rigid surface.

- = 1: the rigid surface should be in the contact description (Default).

C: (flexible bodies): the edges of the body.

- = 1: only the beam/bar edges are included in the contact description (Default).
- = 10: only the free and hard shell edges are included in the contact description.
- = 11: both the beam/bar edges and the free and hard shell edges are included in the contact description.

Note that C has no effect if beam-to-beam contact is not switched on. (BEAMB ≠ 1 on BCPARA).

Note that C has no effect if segment-to-segment contact is used.

3. When ISEARCH=0 (and ISTYP=0 in default on BCB DPRP), the search order is from lower BCBODOY1 ID to higher one to create the first set of contact constraints and then add the constraints in the search order from higher BCBODY1 ID to lower one as long as they are not in conflict with the first set.

When ISEARCH=2, the program looks into the smallest element edge at the outer boundary (and the smallest thickness in case of shell elements) of each BCBODY1. Then, the search order of the two deformable contact bodies is determined by the following rule when ID1 < ID2.

CL1= Min(1/20 of the smallest edge, 1/4 of the smallest thickness) of BCBODY1 ID1

CL2= Min(1/20 of the smallest edge, 1/4 of the smallest thickness) of BCBODY1 ID2

The search order is from lower BCBODY1 ID1 to higher BCBODY1 ID2 if  $CL1 \leq 1.05 * CL2$ . Otherwise, if  $CL1 > 1.05 * CL2$  the search order is from BCBODY1 ID2 to BCBODY1 ID1.

4. For the permanently glued contact, IGLUE = ±2 or ±4 is favorable to pass the GROUND CHECK. The initial stress free contact is also available to preserve the six rigid body modes with IGLUE = ±1 or ±3.

5. A permanently glued contact for small rotation cannot be used to glue a deformable body to a rigid one. If it is a SOL 101 or SOL 400 job, the permanently glued contact for large deformation and rotation (IGLUE < 0) or general contact (IGLUE > 0) with glued option must be performed.
6. By default, the threshold value of this penetration distance is 0.05 times the default contact characteristic distance.

$$\text{AUGDIST} = 0.05 L$$

7. The penalty factor used in the augmented Lagrange method is by default derived from the contact characteristic distance and the stiffness of the deformable contact bodies involved (note that the dimension of the penalty factor is force per cubic length).

$$\text{PENALT} = \frac{0.5(S_i + S_j)}{L}$$

The body stiffness ( $S_i$  and  $S_j$ ), are either defined by the average trace of the initial stress-strain law of the elements defining the two contact bodies or by the average bulk modulus for (nearly) incompressible rubber materials, whichever of the two is the largest.

For continuum elements, the characteristic length ( $L$ ) is given by one half of the average length of all the edges being part of the contact boundary. For shell elements, the characteristic length is given by half of the average thickness of all the shell elements being part of a contact body. When there is contact between a solid and a shell element, then the characteristic length is defined by the shell element.

In case of contact with a rigid body, since there is no body stiffness associated with a rigid body, the default value is related to the deformation body only and is given by

$$\text{PENALT} = \frac{1000S_i}{L}$$

8. If STKSLP is set to 0.0 (Default), the sticking stiffness  $K1$  is equal to the maximum friction force ( $\mu \cdot F_{\text{normal}}$ , where  $\mu$  is the friction coefficient) divided by the maximum sticking displacement. Otherwise,  $K1$  is equal to the maximum friction force divided by the value of STKSLP.
9. A negative value of IGLUE enforces the gluing of the pair of bodies in the BCONNECT that reference this BCONPRG is based upon the geometric conditions at the beginning of the step and will not change over this step. IGLUE will be changed to negative automatically if SYSTEM(758)=2 when Permanently Glued setting is found with large rotation/deformation effect turned on.
10. For interference fit contact, the following options are available.  
CINTERF, OPINTRF, TBINTRF, CBINTRF, CDINTRF, VXINTRF, VYINTRF, VZINTRF, PTINTRF, XCINTRF, YCINTRF and ZCINTRF
11. For setting the initial gap or overlap, the following options are available. OPINGP, TOLINGP, CDINGP and MGINGP.

When OPINGP is 1 in means that there it will try to preserve a distance between the two bodies often called the clearance distance.

When MGINGP is zero, the clearance is not changed from the distance between the original coordinate positions of the nodes. This is call the distance  $D0$

When  $MINGP$  is  $> 0$  it means the distance between the bodies can shrink (i.e. the bodies can get closer together), but when the distance reaches  $D0 - MINGP$ . The clearance condition is satisfied and this clearance distance ( $D0 - MINGP$ ) is preserved.

When  $MINGP$  is  $< 0$  it means that it considers the bodies to be overlapping, so it first tries to separate them by a distance =  $|MINGP|$ ; then it imposes the clearance condition such that the clearance distance is  $D0 + |MINGP|$

12. Please note that
  - Cohesive Contact is supported for only for segment-to-segment contact.
  - All limitations of segment-to-segment contact is applicable for cohesive contact feature also.
  - Breaking Glue feature is not supported with Cohesive contact.
  - $FGCNST/FGCNSTI/FGCNSTR$  are mutually exclusive;  $FGCTST/FGCTSTR/FGCRSTI$  are mutually exclusive.
  - $FGRCEN/FGRCN1$  applies to all contact pairs, not limited to cohesive contact ( $FGFLG=1$ ) pairs .
13. When the initial stress-free( $ICOORD=1$ ), Node-to-Segment updates model geometry to close the gap, nodes are projected onto the contact body; but Segment-to-Segment treats initial stress-free as pre-stress in the equation without geometry update, no node projection is considered.
14.  $TOLINGP$  and  $TOLING1$  follows the rules below.
  - a. When both of  $TOLINGP$  and  $TOLING1$  are not defined, the default value of average edge length of all contact segments will be used for both.
  - b. When  $TOLINGP$  is only defined,  $TOLINGP$  value will be used for both of  $TOLINGP$  and  $TOLING1$ .
  - c. When  $TOLING1$  is only defined,  $TOLING1$  value will be used for  $TOLING1$  only, and the default value of average edge length of all contact segments will be used for  $TOLINGP$ .
  - d. When both of  $TOLINGP$  and  $TOLING1$  are defined, each values are used for each case

## BCONPRG-700

## Geometric Contact Parameters of Touching Bodies in SOL 700

Defines geometric contact parameters of touching bodies used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10	11
BCONPRP	PID		PARAM1	VAL1	PARAM2	VAL2	PARAM3	VAL3		
	PARAM4	VAL4	PARAM5	VAL5	-etc.-					

Example:

BCONPRP	90		IGLUE	1						
---------	----	--	-------	---	--	--	--	--	--	--

Describer      Meaning

PID              Parameter identification number (Integer > 0).

PARAMi        Name of a parameter. Allowable names are given in [Table 9-5](#) (Character).

VALi            Value of a parameter. See [Table 9-5](#) (Real or Integer).

Table 9-5 Geometric Contact Parameters of Touching Bodies in SOL 700

Name	Description, Type and Value (Default is 0 for integer, 0.0 for Real Unless Otherwise Indicated)
IGLUE	<p>Flag to activate glue option (Integer = 0 or 1). Default is 0, no glue option. JGLUE option controls a glue contact type in details. Without assigning IGLUE and JGLUE options, tied contact methods (METHOD=TIEDxxx) can assign glue contact types as well.</p> <p>0. No glue contact.</p> <p>1. Activates the glue option. In the glue option, all degrees-of- freedom of the contact nodes are tied in case of deformable-deformable contact once the node comes in contact. The relative tangential motion of a contact node is zero in case of deformable-rigid contact. The node will be projected onto the contact body.</p>
JGLUE	<p>This option is only relevant if the glue option is invoked (IGLUE &gt; 0). See METHOD=TIEDxxx. (Integer ≥ 0; Default = 0) The following options are available:</p> <p>0 Secondary nodes in contact and which come into contact will permanently stick. Tangential motion is inhibited. This option is only available with METHOD=SS1WAY or SS2WAY and AUTO=YES.</p>
METHOD	<p>Character, Influences the contact type used. See Remark 18. (Character, Default = FULL)</p> <p>Options are:</p> <p>FULL: Regular Contact</p> <p>AIRBAG: Single Surface Contact</p> <p>SS1WAY: Surface To Surface One Way</p> <p>SS2WAY: Surface To Surface Two Way</p> <p>RB1WAY: Rigid Body One Way To Rigid Body</p> <p>RB2WAY: Rigid Body Two Way To Rigid Body</p> <p>RNRB: Rigid Nodes To Rigid Body</p> <p>TIEDNS: Tied Nodes to Surface</p> <p>TIEDNSO: Tied Nodes to Surface with Offset</p> <p>RELLIPS: Tied contact between grid points or rigid materials to ATB dummies. See Remark 4.</p> <p>BELT: Suited for modeling contact between a belt element and a rigid structure. Primary secondary contact only. The contact logic doesn't apply a contact force, but applies an enforced displacement and velocity that keeps the secondary nodes exactly on top of the primary face. The secondary node does not slide relative to the primary face when the friction coefficient (FS) is set to 1E20</p>

	<p>BELT1: Identical to BELT algorithm, except that the secondary nodes are initially repositioned on top of the closest primary face. All secondary nodes initially penetrated or within a distance of INITMON from a primary face, are repositioned.</p> <p>DRAWBEAD: Suited for modeling a drawbead. STYPE Must be GRID. The list of secondary nodes must be ordered along the drawbead line. MTYPE Must be SURF. The restraining force per unit drawbead length is specified in the field DRWBEADF. It is V2 version contact.</p> <p>DRAWBDV4: Suited for modeling a drawbead. STYPE Must be GRID. The list of secondary nodes must be ordered along the drawbead line. MTYPE Must be SURF. The restraining force per unit drawbead length is specified in the field DRWBEADF. It is V4 version contact.</p>
ADAPT	<p>Character, influences the contact type used. (Character, Default = NO)</p> <p>Options are NO or YES.</p> <p>When ADAPT=YES, the BCBODY1 entries IDPRIMi must be defined as:</p> <p style="padding-left: 40px;">behav=DEFORM</p> <p style="padding-left: 40px;">bsid references a BCPROP</p>
THICK	Shell thickness scale factor. (Real > 0.0; Default = same as the value in DYPARAM,CONTACT,THICK)
THICKOF	Artificial contact thickness offset. (Real > 0.0; Default = 0.0)
PENV	Overwrites the default maximum penetration distance factor. (Real > 0.0;Default = 1.E20)
MAXPAR	Maximum parametric coordinate in segment. (Real > 0.0; Default = 1.025), search (values 1.025 and 1.20 recommended). Larger values can increase cost. If zero, the default is set to 1.025. This factor allows an increase in the size of the segments. May be useful at sharp corners.
SOFT	<p>Soft constraint option: (Integer ≥ 0; Default = 1)</p> <p style="padding-left: 40px;">1 Soft constraint formulation (same as original Dytran method).</p> <p>In the soft constraint option, the interface stiffness is based on the nodal mass and the global time step size. This method is more suited for contact between two materials where the elastic moduli vary greatly.</p>
IGNORE	<p>Ignore initial penetrations. (Integer, Default = 1)</p> <p style="padding-left: 40px;">0 Take default from PARAM,DYCONIGNORE*,&lt;value&gt; (Default)</p> <p style="padding-left: 40px;">1 Allow initial penetrations to exist by tracking it</p> <p style="padding-left: 40px;">2 Move nodes to eliminate initial penetrations</p>

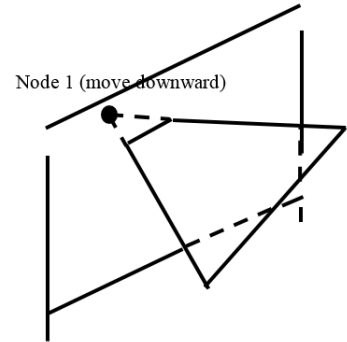

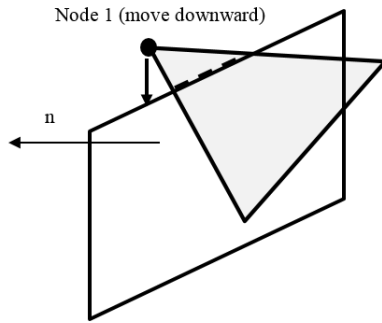

AUTO	<p>Activation of automatic contact (Character, Default = Yes.)</p> <p>Options are:</p> <p style="padding-left: 40px;">YES Automatic Contacts Activated</p> <p style="padding-left: 40px;">NO Non-Automatic Contact Activated. This option is not recommended when Distributed Memory Parallel is activated.</p>
SIDE	<p>Defines which side will be the monitoring side of a primary face. The opposite side of the primary face will be the penetration side. See Remark 1. (Characters; default=BOTH)</p> <p>BOTH: The side from which a secondary node approaches the primary face will become the monitoring side.</p> <p>TOP: The monitoring side will always be on the side of the primary face that its normal is pointing at.</p> <p>BOTTOM: The monitoring side is always on the opposite side of the primary face that its normal is pointing at.</p>
WEIGHT	<p>The contact force is multiplied by a mass-weighting factor. The following options are available. See Remark 25. (Character; default=BOTH)</p> <p>BOTH: <math>M\_scale = (M\_secondary \cdot M\_primary) / (M\_secondary + M\_primary)</math></p> <p>SECNDRY: <math>M\_scale = M\_secondary</math></p> <p>PRIMARY: <math>M\_scale = M\_primary</math></p> <p>NONE: <math>M\_scale = 1.0</math></p>
MONDIS	<p>Defines the fixed part of the monitoring distance. When the normal distance of a secondary node to a primary face becomes smaller than the monitoring distance the secondary node will tag itself to the primary face. The side from which the secondary node is moving towards the primary face becomes the monitoring region. (Character; default=FACTOR)</p> <p>FACTOR: The monitoring distance is equal to a factor times a characteristic length of the primary faces. The factor is specified in MONDISV.</p> <p>DISTANCE: The monitoring distance is specified in MONDISV.</p>
MONDISV	<p>Value of the monitoring distance or value of the FACTOR to calculate the monitoring distance. (Real; default=2.0)</p>
INITMON	<p>Fixed part of the monitoring distance used during the initialization. If not specified, the value of MONDIS is used. (Real &gt; 0.0; default=MONDIS)</p>

Remarks:

1. When METHOD=RELLIPS is used, BCGRID or BCMATL are only available for SECNDRY body and BCELIPS is only available for PRIMARY body. When BCMATL is used, the MATRIG id or RBE2 id are only acceptable. When Euler solver is deactivated, no output will be generated for the Eulerian elements.
2. The options TOP/BOTTOM are useful in the following cases:
  - a. When a secondary node initially is located on the primary face (see the picture below), the contact situation is uniquely defined, only if the TOP or BOTTOM side of the primary surface is defined:  
SIDE=TOP case:

- b. When hooking of secondary nodes on the wrong side of a primary face might occur. This often is the case when the primary face is at the edge of a shell element structure:  
SIDE=BOTTOM case: penetration of node 1 (SIDE=BOTH: no penetration of node 1)

3. Recommended usage of WEIGHT:

SECNDRY	PRIMARY	WEIGHT
Deformable	Deformable	BOTH
Deformable	Rigid	SECNDRY
Rigid	Deformable	PRIMARY
Rigid	Rigid	NONE

Default setting when BCELIPS is used in SECNDRY or PRIMARY:

SECNDRY	PRIMARY	WEIGHT
Non-BCELIPS	Non-BCELIPS	NONE
	BCELIPS	

- When METHOD=RELLIPS is used, BCGRID or BCMATL are only available for SECNDRY body and BCELIPS is only available for PRIMARY body. When BCMATL is used, the MATRIG id or RBE2 id are only acceptable.

## BCONPRP Physical Contact Parameters of Touching Bodies in SOLs 101 and 400

Defines physical contact parameters of touching bodies used in SOLs 101 and 400 only. The parameters defined here are referenced by the BCONNECT entry. This entry is used in conjunction with the BCONPRG entry.

Format:

1	2	3	4	5	6	7	8	9	10
BCONPRP	PID		PARAM1	VAL1	PARAM2	VAL2	PARAM3	VAL3	
	PARAM4	VAL4	PARAM5	VAL5	-etc.-				

Example:

BCONPRP	90		FRIC	0.3					
---------	----	--	------	-----	--	--	--	--	--

Descriptor      Meaning

PID              Parameter identification number (Integer > 0).

PARAMi        Name of a parameter. Allowable names are given in [Table 9-6](#) (Character).

VALi            Value of a parameter. See [Table 9-6](#) (Real or Integer).

Table 9-6 Physical Contact Parameters of Touching Bodies in SOLs 101 and 400

Name	Description, Type and Value (Default is 0 for integer, 0.0 for Real Unless Otherwise Indicated)
BGM	Exponent for the tangential stress term in deciding if a glue-contact will break. See Remark 1. (Real; Default = 2.0)
BGN	Exponent for the normal stress term in deciding if a glue-contact will break. See Remark 1. (Real; Default = 2.0)
BGSN	Maximum normal stress for breaking glue. See Remark 1. (Real; Default = 0.0)
BGST	Maximum tangential stress for breaking glue. See Remark 1. (Real; Default = 0.0)
BNC	Exponent associated with the natural convection coefficient for near field behavior. If Real, the value entered is the exponent associated with near field natural convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the exponent associated with the near field natural convection coefficient vs. temperature or a TABL3D entry specifying the exponent associated with the near field natural convection coefficient vs. temperature and possibly other variables. Ignored in a pure structural analysis. See Remark 5. (Real or Integer; Default = 1.0.)
BNL	Exponent associated with the nonlinear convective heat flow for near field behavior. If Real, the value entered is the exponent associated with the near field nonlinear convection coefficient. If Integer, the value entered is the ID of a TABLEM1 OR TABLEM2 entry specifying the exponent associated with the near field nonlinear convection coefficient vs temperature or a TABL3D entry specifying the exponent associated with the near field nonlinear convection coefficient vs temperature and possibly other variables. Ignored in a pure structural analysis. See Remark 5. (Real or Integer; Default = 1.0)
DQNEAR	Distance below which near thermal contact behavior occurs. Used in heat transfer analysis only. See Remark 2. (Real; Default = 0.0; which means near contact does not occur)
EMISS	Emissivity for radiation to the environment or near thermal radiation. If Real, the value entered is the emissivity. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the emissivity vs. temperature or a TABL3D entry specifying the emissivity vs. temperature and possibly other variables. Ignored in a pure structural analysis. See Remark 5. (Real or Integer; Default = 0.0)
FNTOL	Separation force, stress, or fraction above which a node separates from a body. FNTOL is closely related to IBSEP. Its default value is dependent on the IBSEP value. (Real)
FRIC	Friction coefficient. If the value is an integer, it represents the ID of a TABLEM1, TABLEM2 or TABL3D, i.e., a temperature-dependent or multi-dimensional table. (Real $\geq$ 0.0 or Integer $>$ 0; Default = 0.0)
FRLIM	Friction stress limit. This entry is only used for friction type 6 (Coulomb friction using the bilinear model). If the shear stress due to friction reaches this limit value, then the applied friction stress will be reduced so that the maximum friction stress is given by $\min(\mu\sigma_n, \sigma_{\text{limit}})$ , with $\mu$ the friction coefficient and $\sigma_n$ the contact normal stress. (Real; Default = 1.0E20)

HBL	Separation distance dependent thermal convection coefficient. If Real, the value entered is the convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the convection coefficient vs. temperature or a TABL3D entry specifying the convection coefficient vs. temperature and possibly other variables. Ignored in a pure structural analysis. See Remark 5. (Real or Integer; Default = 0.0)
HCT	Contact heat transfer coefficient. If Real, the value entered is the contact heat transfer coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the contact heat transfer coefficient vs. temperature or a TABL3D entry specifying the contact heat transfer coefficient vs. temperature and possibly other variables. Ignored in a pure structural analysis. See Remark 5. (Real or Integer; Default = 0.0; In a thermal/mechanical coupled analysis a default value of 1.0E6 is used when the mechanical glue option is activated, i.e., when IGLUE > 0.)
HCV	Convection coefficient for near field behavior. If Real, the value entered is the near field convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the near field convection coefficient vs. temperature or a TABL3D entry specifying the near field convection coefficient vs. temperature and possibly other variables. Ignored in a pure structural analysis. See Remark 5. (Real or Integer; Default = 0.0)
HGLUE	Flag to activate the thermal glue option. When left blank or set to zero, thermal contact conditions will be treated by convective heat transfer between the bodies. When set to 1, the temperature fields of the bodies are tied as soon as they come in contact and there will be no convective heat transfer over the body interfaces. Ignored in a pure structural analysis. See Remarks 3. , 4. and 5. ( $0 \leq \text{Integer} \leq 1$ ; Default = 0)
HNC	Natural convection coefficient for near field behavior. If Real, the value entered is the near field natural convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the near field natural convection coefficient vs. temperature or a TABL3D entry specifying the near field natural convection coefficient vs. temperature and possibly other variables. Ignored in a pure structural analysis. See Remark 5. (Real or Integer; Default = 0.0).
HNL	Heat transfer coefficient for nonlinear convective heat flow for near field behavior. If Real, the value entered is the near field nonlinear convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the near field nonlinear convection coefficient vs. temperature or a TABL3D entry specifying the near field nonlinear convection coefficient vs. temperature and possibly other variables. Ignored in a pure structural analysis. See Remark 5. (Real or Integer; Default = 0.0)

#### Remarks:

1. Breaking Glue provides glued contact to all GRID's at their very 1st contact. This kind of glued-contact will break if

$$(\sigma_n/\text{BGSN})^{**}\text{bgn} + (\sigma_t/\text{BGST})^{**}\text{bgm} > 1.0$$

When a contact node breaks due to the above criterion, standard contact is activated if it comes into contact again. If  $BGSN = 0.0$  the first term is ignored. Similarly, the second term is ignored if  $BGST = 0.0$ . For SOL 400, parameters  $BGSN$ ,  $BGST$ ,  $BGM$  and  $BGN$  are only required if  $JGLUE = 2$ . If both  $BGSN$  and  $BGST$  are equal to 0.0,  $JGLUE$  will be set to 0 internally. If Step Glue is used, then Breaking Glue is inactive in this step. If Permanent Glue is active, then Breaking Glue is inactive.

2. For near contact the following convective heat flow law describes the heat exchange per unit area between the body areas (“near” contact is when bodies are not touching each other – but are close enough for convection and radiation.):

$$q = HCV \cdot (T_A - T_B) +$$

$$HNC \cdot (T_A - T_B)^{BNC} +$$

$$HNL \cdot (T_A^{BNL} - T_B^{BNL}) +$$

$$\sigma \cdot EMISS \cdot (T_A^4 - T_B^4) +$$

$$\left[ HCT \cdot \left( 1 - \frac{dist}{DQNEAR} \right) + HBL \cdot \frac{dist}{DQNEAR} \right] \cdot (T_A - T_B)$$

where the last term is only activated when  $HBL \neq 0$ ,  $T_A$  is the contacting grid temperature and  $T_B$  is the face temperature in the contact point in case of a meshed body or the  $T_{BODY}$  temperature in case of a rigid geometry.

3. For hard contact (i.e., two bodies are actually touching each other – heat transfer mode between the bodies is conduction), with  $HGLUE=1$ :
  - a. The temperature of the contacting grid is tied to the temperatures of the contacted element face or the temperature of the rigid geometry when it has a scalar point associated with it.
  - b. The temperature of the contacting grid is set to the rigid geometry temperature when it has no scalar point associated with it.

**Note:** “Glued” thermal contact can result in overshoot of the temperatures i.e. Gibbs Phenomenon or the temperature oscillations at the interface, in particular, if two bodies that have non-uniform initial temperatures are placed in contact. The overshoot effect may be damped somewhat if one uses a near contact distance with some convective heat transfer.

4. For hard contact, with  $HGLUE=0$ :

The convective heat flow per unit area over the two interfaces is given by:

$$q = HCT \cdot (T_A - T_B)$$

where  $T_A$  is the contacting grid temperature and  $T_B$  is the face temperature in the contact point in case of a meshed body or the  $T_{BODY}$  temperature in case of a rigid geometry.

5. The heat transfer coefficients and associated exponents can all be temperature dependent, when they are entered as an integer value. This integer value is the table ID of a TABLEM1, TABLEM2 or TABL3D entry (formulas are not supported on TABL3D). Table IDs of tables used on the BCBDPRP entry and the BCONPRP entry must be unique.
6. Parameters BGM, BGN, BGSN, BGST and DQNEAR are not supported in segment to segment contact analysis.

**BCONPRP-700****Physical Contact Parameters of Touching Bodies in SOL 700**

Defines physical contact parameters of touching bodies used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCONPRP	PID		PARAM1	VAL1	PARAM2	VAL2	PARAM3	VAL3	
	PARAM4	VAL4	PARAM5	VAL5	-etc.-				

Example:

BCONPRP	90		FRIC	0.3					
---------	----	--	------	-----	--	--	--	--	--

Describer      Meaning

PID              Parameter identification number (Integer > 0).

PARAMi        Name of a parameter. Allowable names are given in [Table 9-7](#) (Character).

VALi            Value of a parameter. See [Table 9-7](#) (Real or Integer).

**Table 9-7      Physical Contact Parameters of Touching Bodies in SOL 700**

Name	Description, Type and Value (Default is 0 for integer, 0.0 for Real Unless Otherwise Indicated)
FRIC	Static friction coefficient. When it is set to -1.0, different static friction coefficients on properties can be assigned using BCPROP1. (Real $\geq$ -1.0; Default=0.0 for SOL700)
FK	Kinetic coefficient of friction. (Real > 0.0; Default = 0.0)
EXP	Exponential decay coefficient. (Real > 0.0; Default = 0.0)
FACT	Scale factor for the contact forces. (Real > 0.0; Default = 0.1)

TSTART	Time at which the contact is activated. (Real > 0.0; Default = 0.0)
TEND	Time at which the contact is deactivated. (Real > 0.0; Default = 1.e20)
IADJ	<p>Adjacent material treatment option for solid elements. (Integer <math>\geq 0</math>; Default =1)</p> <p>0 Solid element faces are included only for free boundaries.</p> <p>1 Solid element faces are included if they are on the boundary of the material subset. This option also allows the erosion within a body and the subsequent treatment of contact.</p>
DAMPING	<p>Specifies if a high frequency damping is active or not. The damping force is based on the relative velocity of a secondary node with respect to a primary face. The damping is preferably turned on in all cases, except for RIGID-RIGID contact. In RIGID-RIGID contact it can result in a substantial loss of energy. VERSION V4 only. (Character; Default=YES).</p> <p>YES damping is activated</p> <p>NO damping is not activated.</p>

## BCONUDS

## Contact Body User Defined Service

Allows the user to provide contact routines for use with enhanced SOL 400 contact analysis.

Format:

1	2	3	4	5	6	7	8	9	10
BCONUDS	BID	BTYPE	GROUP	UNAME					
	“INT”	IDATA1	IDATA2	IDATA3	IDATA4	IDATA5	IDATA6	IDATA7	
		IDATA8	IDATA9	...	...	IDATA <sub>n</sub>			
	“REAL”	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	
		RDATA8	RDATA9	...	...	RDATA <sub>n</sub>			
	“CHAR”	CDATA1	CDATA2	...	...	CDATA <sub>n</sub>			

Example:

*In FMS Section of MSC Nastran input stream:*

```
CONNECT SERVICE CONTACT 'SCA.MDSolver.Util.Ums'
```

*In Bulk Data:*

BCONUDS	17	BCBODY	CONTACT	UFRIC					
BCONUDS	17	BCBODY	CONTACT	SEPFOR					
	REAL	.00134	1.467+4	.03					
BCONUDS	17	BCBODY	CONTACT	MOTION					
	REAL	.00134	1.467+4	.03					
	INT	8	3						

Descriptor	Meaning
BID	Contact body identification number defined by BCBODY or BCBODY1. (Integer > 0; Required)
BTYPE	The name of the contact entry. BCBODY/BCBODY1 (Character; no Default)
GROUP	The group name used for the FMS Section CONNECT SERVICE statement. (Character; no Default)
UNAME	User subroutine name associated with the entry. See Remark 6. and 7. (Character)
“INT”	Keyword indicating that the following data is integer. (Character)
IDATA <sub>i</sub>	Additional user supplied Integer data not already existing on the specified contact property entry. (Integer, no Default)
“REAL”	Keyword indicating that the following data is real. (Character)

Describer	Meaning
RDATAi	Additional user supplied Real data not already existing on the specified contact property entry. (Real; no Defaults)
“CHAR”	Keyword indicating that the following data is Character. (Character)
CDATAi	Additional user supplied Character data not already existing on the specified contact property entry. (Character; no Default)

**Remarks:**

1. This entry triggers the call to a user contact subroutine for advanced nonlinear materials. The GROUP must match the GROUP field of the CONNECT SERVICE FMS statement.
2. On the FMS CONNECT statement, only the CONNECT SERVICE can be used with this entry.
3. The BID must match an existing BID.
4. A CDATAi entry cannot be the Character “REAL”, “INT”, or “CHAR”.
5. Certain user subroutines may require integer or real data input as specified in the User Defined Services manual.
6. UNAME must be truncated to 8 characters in the bulk data field
7. The following user subroutines are currently available for user convenience. See the User Defined Services manual for details.

Type	Uname	Purpose
BCBODY	motion	Define velocity of rigid surfaces
BCBODY	ufric	Define friction coefficients
BCBODY	sepfor	Define separation forces
BCBODY	sepstr	Define separations stresses
BCBODY	ubsqueal	Define friction coefficient and effective stiffness in brake squeal analysis

## BCONUDS

## Contact Body User Subroutines in SOL 600

Allows the user to provide contact routines for use with SOL 600 contact analysis.

## Format:

1	2	3	4	5	6	7	8	9	10
BCONUDS	BID	BTYPE		UNAME					
	“INT”	IDATA1	IDATA2	IDATA3	IDATA4	IDATA5	IDATA6	IDATA7	
		IDATA8	IDATA9	...	...	IDATA <sub>n</sub>			
	“REAL”	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	
		RDATA8	RDATA9	...	...	RDATA <sub>n</sub>			

## Example:

BCONUDS	17	BCBODY		RTN1					
BCONUDS	17	BCBODY		RTN2					
	REAL	.00134	1.467+4	.03					
BCONUDS	17	BCBODY		RTN3					
	REAL	.00134	1.467+4	.03					
	INT	8	3						

Describer	Meaning
BID	Contact body identification number defined by BCBODY. (Integer > 0; Required)
BTYPE	The name of the contact entry. BCBODY (Character; no Default)
UNAME	The Marc user subroutine name. See Remarks 2. and 5. (Character; Required)
“INT”	Keyword indicating that the following data is integer. (Character)
IDATA <sub>i</sub>	Additional user supplied Integer data not already existing on the specified MAT entry. See Remark 6. (Integer; no Default)
“REAL”	Keyword indicating that the following data is real. (Character)
RDATA <sub>i</sub>	Additional user supplied Real data. See Remark 6. (Real; no Defaults)

## Remarks:

1. The BID must match an existing BID.
2. Certain user subroutines may require integer or real data input as specified in the UserSubroutine interface document.
3. The following user subroutines are currently available for user convenience. See the User Subroutine interface document for details.

UNAME	Purpose
MOTION	Define velocity of rigid surfaces
UFRIC	Define friction coefficients
DIGEOM	Define rigid surfaces
SEPFOR	Define separation forces
SEPFORBBC	Define separation forces for beam-beam contact
SEPSTR	Define separations stresses
UFRICBBC	Define the friction coefficients for beam-to-beam contact with node-to-segment contact.  This user subroutine is not used for segment-to-segment contact; use UFRIC instead.
UHTNRC	Define thermal near contact film coefficients
UMDCOE	Define variable mass and diffusion coefficients and sink pressures on a free surface
UMDCON	Define variable mass diffusion coefficients on surfaces in contact with other surfaces
UMDNRC	Define mass diffusion coefficients of surfaces in contact with other surfaces
UNDRST	Define normal stresses for elements in contact

4. The BCONUDS entry may be used instead of the USRSUB6 entry. Both entries should not be used in the same run. EVAL will be stored as a character\*16 name in common block /userch/
5. UNAME identifies the user subroutine name to be called.
6. IDATA and RDATA are not normally required. They are available should additional arguments beyond those described in Marc Vol D be required. Normally only the first line is entered.

**BCPARA****Contact Parameters -SOLs 101 and 400**

Defines contact parameters used in SOL 101 and SOL 400. This entry is not available in SOL 700.

Format:

1	2	3	4	5	6	7	8	9	10
BCPARA	ID	Param1	Value1	Param2	Value2	Param3	Value3		
	Param4	Value4	Param5	Value5	etc.				

Example:

BCPARA		ERROR	0.1	BIAS	0.5				
--------	--	-------	-----	------	-----	--	--	--	--

Describer	Meaning
ID	Subcase to which the defined parameters belong. If ID is zero, the parameters belong to all subcases. (Integer $\geq 0$ ; no Default)
Param(i)	Name of a parameter. Allowable names are given in <a href="#">Table 9-7</a> . (Character)
Value(i)	Value of the parameter. See <a href="#">Table 9-7</a> . (Real or Integer)

Table 9-8 Contact Parameters -SOLs 101 and 400

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)
ERROR	Distance below which a node is considered touching a body. (Real; Default = blank). Automatically calculated if left blank. If left blank, the code calculates ERROR as the smallest value resulting from: Either dividing the smallest nonzero element dimension (plates or solids) in the contact body by 20. Or dividing the thinnest shell thickness in the contact body by 4. This value is then used for all contact pairs.
BIAS	Contact tolerance bias factor. ( $0.0 \leq \text{Real} \leq 1.0.$ ); Default = 0.9 for IGLUE=0, if field left blank. Default = 0.0 for IGLUE <>0. Note that when IGLUE<>0, BIAS can only be given by the BCTABLE or BCONPRG. Default = 0.0 for BEHAVE=SYMM on BCBODY, if field left blank or 0.0.
FGCFLG	Flag to activate Cohesive (Flexible) Glued Contact: (See Remark 12.)
0	No Cohesive (Flexible) Glued Contact
1	Activate Cohesive (Flexible) Glued Contact
FGCNST	Equivalent normal contact stiffness of connector for Cohesive (Flexible) Glued Contact
FGCTST	Equivalent tangential contact stiffness of connector for Cohesive (Flexible) Glued Contact
FGCNSTR	ID of table for define contact normal stress versus relative displacement for Cohesive (Flexible) Glued Contact. Only TABL3D allowable.
FGCTSTR	ID of table for define contact tangential stress versus relative displacement for Cohesive (Flexible) Glued Contact. Only TABL3D allowable.
FGCNSTI	ID of table for define contact normal stiffness versus relative displacement or temperature for Cohesive (Flexible) Glued Contact. Only TABL3D allowable.
FGCTSTI	ID of table for define contact tangential stiffness versus relative displacement or temperature for Cohesive (Flexible) Glued Contact. Only TABL3D allowable.
FGRCEN	Reference Grid at which resultant contact force of secondary body to primary body is evaluated. See Remark 12.
FGCRCN1	Reference Grid at which resultant contact force of primary body to secondary body is evaluated.  Default of FGCRCN1 is FGRCEN
FNTOL	Separation force (or stress if separation is controlled by stress as determined by IBSEP) above which a node separates from a body. Automatically calculated if left blank. (Real; Default = blank). See Remark 10.

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)	
MAXSEP	Maximum number of separations allowed in each increment. After MAXSEP separations have occurred, if the standard convergence tolerance conditions are achieved, the step will converge. (Integer > 0; Default = 9999)	
ICSEP	Flag to control separation. Not used for segment-to-segment contact. (Integer ≥ 0; Default = 0)	
	0	The node separates and an iteration occurs if the force on the node is greater than the separation force.
	1	If a node which was in contact at the end of the previous increment has a force greater than the separation force, the node does NOT separate in this increment, but separates at the beginning of the next increment.
	2	If a new node comes into contact during this increment, it is not allowed to separate during this increment, prevents chattering.
	3	Both 1 and 2 are in effect.
IBSEP	Flag for separation based on stresses or forces. (Integer ≥ 0; Default = 0)	
	0	Separation based on forces.
	1	Separation based on absolute stresses (force/area)
	2	Separation based on absolute stress (extrapolating integration point stresses)
	3	Relative nodal stress (force/area)
	4	Separation based on relative stress (extrapolating integration point stresses)
	Segment to segment contact ignores IBSEP and will use 2 internally. See Remarks 6. and 8.	
RVCNST	For the bilinear friction model, RVCNST is the slip threshold. (Real ≥ 0.0; Default = 0.0).	
	Default=0.0 means that the actual value is automatically calculated.	
FTYPE	Friction type. See Remark 5. (Integer)	
	0	No friction. (Default)
	6	Bilinear Coulomb friction.
	7	Bilinear Shear friction.
BEAMB	Beam-Beam contact flag. See Remark 7. (Integer 0 or 1)	
	0	No beam-beam contact. (Default for SOLs 101/400)
	1	Activate beam-beam contact options. (Default for SOL 700)

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)
NLGLUE (SOLs 101 and 400 only)	If all secondary's for the BCTABLE or BCONPRG corresponding to the first loadcase (first subcase and first step) contain IGLUE >0, permanent glued contact with small rotation condition will be used for all SECNDRY entries in all subcases and all steps unless BCPARA,0,NLGLUE,1 is specified. If IGLUE < 0 exists, permanent glued contact for large deformation and large rotation is activated. (Integer; Default = 0)
NODSEP	Skip separation check in contact for any grid already touched and separated.  NODSEP  times within the current increment. (Integer; Default = 5)
	> 0      Keep grid contact status
	< 0      Separate grid from contact
METHOD	Flag to select Contact methods. (Character)
	NODESURF      Node to segment contact. (Default)
	SEGTOSEG      Segment to segment contact.
AUGMENT	Augmentation method used in a segment-to-segment contact analysis. (Integer)
	0      No augmentation (Default)
	1      Augmentation based on a constant Lagrange multiplier field for linear elements and on a (bi)linear Lagrange multiplier field for quadratic elements
	2      Augmentation based on a constant Lagrange multiplier field
	3      Augmentation based on a (bi)linear Lagrange multiplier field
PENALT	Augmented Lagrange penalty factor; used by the segment-to-segment contact algorithm only. (Real > 0.0; see BCTABLE or BCONPRG entries for default)
AUGDIST	Penetration distance beyond which an augmentation will be applied; used by the segment-to-segment contact algorithm only. (Real > 0; see BCTABLE entry for default)
SLDLMT	Maximum allowed sliding distance, beyond it the contact segments are redefined, for segment to segment contact analysis with large deformation. (Real ≥ 0.0; Default = 0.0) See remark 9.
SEGSYM	Specify symmetric or non-symmetric friction matrix in segment to segment contact analysis. (Integer 0 = symmetric matrix or 1 = non-symmetric matrix; Default = 0)
ERRBAS	Error computation option. (Integer 0 = compute error globally or 1 = calculate error based on each pair of secondary-primary; Default = 0)
DDULMT	Maximum value of DDU in a Newton-Raphson cycle. (Real ≥ 0.0; Default = 0.0, no limitation)
TAUGMNT	Augmentation for the sticking part of friction in a segment-to-segment contact analysis. (Integer 0 = no augmentation or 1 = use augmentation; Default = 0)

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)
TPENALT	Augmented Lagrange penalty factor for sticking part of friction, used by the segment-to-segment contact algorithm only. (Real > 0.0) The default is PENALT/1000, where PENALT parameter is the Augmented Lagrange penalty factor for normal contact.
STKSLP	Maximum allowable slip distance for sticking, beyond it there is no sticking, only sliding exists, used by the segment-to-segment contact algorithm only. (Real ≥ 0.0; Default = 0.0) See Remark 11.
THKOFF	Ignore thickness from the tolerance used by ISEARCH=2 in node-to-surface contact or from the characteristic length (for PENALT and AUGDIST) in segment-to-segment contact. (Integer 0 = do not ignore thickness or 1 = remove thickness; Default = 0)
LINCNT	Flag for Linear Contact (under infinitesimal assumption, small sliding with small deformation and rotation). Supports both node-to-segment and segment-to-segment method. See Remark 14.. 0 - (Default) general contact 1 - activate Linear Contact, the contact force is distributed based upon undeformed geometry. -1 - force Linear Contact with large displacement (not recommended).
SFNPNT	Scale factor of augmented Lagrange penalty factor along contact normal direction; used by segment-to-segment contact method only. (Real>0.0;Default=1.0) SFNPNT*PENALT is used in analysis. A nonblank value of SFNPNT entered in BCONPRG will override it.
SFTPNT	Scale factor of augmented Lagrange penalty factor along contact tangential direction; used by segment-to-segment contact method only. (Real>0.0;Default=1.0) SFTPNT*TPENALT is used in analysis. A nonblank value of SFTPNT entered in BCONPRG will override it.
SEGANGL	Minimum angle between segment normal vectors allowing the segments to come into contact; used by segment-to-segment contact only. (Real>90.0 <180.0; Default=120.0).
TCNTCTL	Flag to define the touching contact status in linear perturbation and ignoring the touching Contact status determined by the contact analysis in NLSTATIC analysis at the load point assigned by NLIC. (Integer; Default = 0) Value of TCNTCTL defined in BCONPRG will override one defined in BCPARA. 0 - Skip this option, keep the original contact status obtained in NLSTATIC. 1 - Assuming sliding status of touching contact for contact and frictional stiffness matrix calculation. 2 - Assuming sticking status of touching contact for contact and frictional stiffness matrix calculation. 3 - Assuming glued contact status for touching contact for contact stiffness matrix calculation.

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)
VERSION	Defaults version control in Segment-to-Segment method, see remark 15.
	1           Version 1
	2 (default)   Version 2 (lower default penalty, recommended)
BACKCTL	Backward compatible bit-wise control in contact analysis, see remark 16. 1 <sup>st</sup> to 7 <sup>th</sup> bit segment-to-segment only
	-1           Activate all of following items (back to 2020 SP1)
	0           None of following items will be activated
	1           Body order independent
	2           Evaluation of contact matrix/force on segment coordinates (old logic)
	4           Segment sequence renumbering (old method)
	8           No reset iteration count after separation (old logic)
	16          Creating new polygon under sliding condition (old logic)
	32          Scaled incremental displacement update in small rotation (old method)
	64          Ramping down penalty when angle of segment normals between 180 degree and SEGANGL
	128         Old algorithm of nodal projection in contact  2021.3 release onwards, the default uses the enhanced contact projection algorithm, which helps in consistent contact detection at corners and for warped surface.
GLUEOUT	Contact force and stress output preference in glued contact.
	0           Normal and tangential components are separated (segment-to-segment only)
	1 (default)   Normal and tangential components are combined
SEPACC	Flag to control the accelerated separation check in node-to-segment contact for SOL 400. See remark 17. (Integer ≥ 0; Default = 0).
	0           Accelerated separation check turned off
	1           Accelerated separation check turned on
DYNPRFA	Dynamic contact projection factor (0.0 ≤ Real ≤ 1.0; Default= 0.0)
	A value of 0.0 may show some penetration.
	Values greater than 0 reduce penetration and can introduce transient vibration. It is strongly recommended to use the default values in NLTRAN to avoid the chattering in contact analysis.

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)	
OSPLNFRQ	Output frequency of smooth spline representation of deformable contact body when BOUTPUT output requested. (Integer $\geq -1$ ; Default=-1).	
	-1	Initial output only
	0	No output
	n	Every n <sup>th</sup> output increment along with initial output.  Note that OSPLNFRQ is based on the number of output load increments, but not calculated load increments. It is determined by "NO" in fixed time stepping or "NOUT" in adaptive time stepping on NLSTEP.

#### Remarks:

1. The ID of BCPARA should be left blank or a value of zero. Blank is treated as zero.
2. Only one BCPARA entry should be made. Multiple BCPARA entries with ID=0 cause a Fatal Error.
3. All SOLs only support ID=0, this entry is applied to all the subcases, except the corresponding ones are assigned in BCTABLE or BCONPRG.
4. Refer to the Case Control command [BCONTACT \(Case\)](#), to see the lists of parameters in BCPARA that are not supported by SOLs 101 and 400.
5. In SOLs 101/400, FTYPE only supports options 0, 6, and 7. Friction with segment-to-segment contact is a pre-release capability in the 2012 release. In the 2012.2 version and later, it is fully supported.
6. Shell elements (CQUAD4 CQUAD8 CTRIA3 CTRIA6) in 3D Contact only supports IBSEP = 0, 1 and 3. If IBSEP = 2 or 4 in this case, it will automatically be set to 1 or 3, respectively. In SOLs 101/400, LINQUAD is not supported and it is set to -1 in order that the mid-side nodes are considered in Contact. Quadratic shell elements consider mid-side nodes only in 2D Contact.
  - a. If IBSEP is set to 1, then for bodies consisting of mid-side node elements, IBSEP will automatically be set to 2. This allows for using IBSEP=1 for elements without mid-side nodes and IBSEP=2 for elements with mid-side nodes in one analysis.
  - b. If IBSEP is set to 3, then for bodies consisting of mid-side nodes elements, IBSEP will automatically be set to 4. This allows for using IBSEP=3 for elements without mid-side nodes and IBSEP=4 for elements with mid-side nodes in one analysis.

This rule is always applied to the solid elements with mid-side nodes. However, the mid-side nodes of CQUAD8 and CTRIA6 shell elements are ignored in node-to-segment 3D contact with separation because there is no normal stress in shell elements, and the contact normal forces for these elements do not give a good estimation of the nodal contact stress. Hence it is not recommended to use CQUAD8 and CTRIA6 shell elements in a node-to-segment contact analysis with separation.

7. For SOLs 101/400 if BEAMB=1, Bulk Data entry BCBMRAD must be entered. Those entries are not required in the beam contact of segment-to-segment contact.

8. Parameters MAXSEP, ICSEP, IBSEP, RVCNST and BEAMB are not supported in segment to segment contact analysis.
9. The default of SLDLMT parameter is 5 times the default error tolerance. See the description of ERROR parameter for the definition of default error tolerance.
10. IBSEP and FNTOL are related to each other. The Default value of FNTOL is dependent on IBSEP value.
  - a. IBSEP=0 : Separation is based on forces. A contact node will separate if the contact pulling force exceeds FNTOL. If FNTOL is zero it will be taken as the absolute value of the largest component in the residual force vector.
  - b. IBSEP=1 : Separation is based on nominal contact stresses (force/area). A contact node will separate if the nominal contact pulling stress exceeds FNTOL. If FNTOL is zero, it will be 0.1 times of the maximum nominal contact pushing stress of any node of any contact body.
  - c. IBSEP=2 : Separation is based on nodal stress (extrapolating integration point stresses). A contact node will separate if the nodal pulling stress exceeds FNTOL. If FNTOL is zero it will be 0.1 times of the maximum nodal pushing stress of any node of any contact body
  - d. IBSEP=3 : Separation is based on relative nominal contact stress (force/area). A contact node will separate if the nominal contact pulling stress exceeds FNTOL times of maximum nominal contact pushing stress of any node of any contact body. If FNTOL is zero, it will be taken as 0.1
  - e. IBSEP=4 : Separation is based on relative nodal stress (extrapolating integration point stresses). A contact node will separate if the nodal pulling stress exceeds FNTOL times of maximum nodal pushing stress of any node of any contact body. If FNTOL is zero, it will be taken as 0.1
11. If STKSLP is set to 0.0 (Default), the sticking stiffness  $K_1$  is equal to the maximum friction force ( $\mu \cdot F_{NORMAL}$ , where  $\mu$  is the friction coefficient) divided by the maximum sticking displacement. Otherwise,  $K_1$  is equal to the maximum friction force divided by the value of STKSLP.
12. The parameters of cohesive contact defined in BCPARA will be applied to all the contact pairs unless:
  - The contact pair has its own definition for cohesive contact in BCONPRG; or
  - Its IGLUE=0, i.e., general touching contact.
  - FGRCEN/FGRCN1 applies to all contact pairs, not limited to cohesive contact (FGCFLG=1) pairs.

Cohesive contact is only applied to glued contact, but not touching contact.

13. If Modules are present then this entry may only be specified in the main Bulk Data section.
14. LINCNT does not support RIGID contact body with velocity control.
15. Version 1 is equivalent to system cell 701=0; Version 2 is equivalent to system cell 701=1  
Version 2 is improved default values for contact problems involving geometrically and physically nonlinear behavior:
  - a. Augmented Lagrange penalty factor. For bodies with the same body stiffness, this factor is chosen to be lower than the default value. For a body combination with different values of the body stiffness, the smallest of the two is used.

- b. Penetration distance beyond which an augmentation is applied. This distance is chosen to be larger than the default value, thus avoiding too many iterations due to augmentation. It is recommended to use an augmentation procedure for contact.
  - c. Augmented Lagrange penalty factor for sticking contact. This factor is chosen to be dependent on the normal pressure.
16. Following features are defaults of segment-to-segment method since 2021.0
  - Body order dependent
  - Evaluate contact matrix/force based upon true updated segment coordinates
  - New segment sequence renumbering
  - Reset iteration count after separation (Version 2 only)
  - New logic in creating new polygons under sliding condition
  - Scaled incremental displacement update in large rotation
  - Ramping down penalty when angle of segment normals below SEGANGL (minimum segment angle, default 120 degree)
17. SEPACC=0: Nodes are checked for separation only after satisfying all specified convergence criteria.  
SEPACC=1: Nodes are checked for separation as soon as the maximum residual force in the model drops to less than 10% of the maximum reaction force in the model.
  - a. SEPACC is only applicable to node-to-segment method, not supported in segment-to-segment method.
  - b. Accelerated separation check could reduce iteration when EPSP less than 0.1
  - c. Accelerated separation check may increase total separation count, hence default MAXSEP is preferred when SEPACC=1.
  - d. Accelerated separation check algorithm is only available in NLSTEP scheme, not supported in NLPARM.

## BCPARA

## Contact Parameters in SOL 600

Defines contact parameters used in SOL 600.

Format:

1	2	3	4	5	6	7	8	9	10
BCPARA	ID	Param1	Value1	Param2	Value2	Param3	Value3		
	Param4	Value4	Param5	Value5	etc				

Example:

BCPARA		NBODIES	4	BIAS	0.5				
--------	--	---------	---	------	-----	--	--	--	--

Describer	Meaning
ID	ID is not used and should be set to zero. Only one BCPARA should be entered and it applies to all subcases. (Integer)
Param(i)	Name of a parameter. Allowable names are given in <a href="#">Table 9-7</a> . (Character)
Value(i)	Value of the parameter. See the <a href="#">Table 9-7</a> . (Real or Integer)

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)
NBODIES (2,1)	Number of contact bodies defined in the analysis. (Integer $\geq 0$ or blank)
MAXENT (2,2)	Maximum number of entities created for any contact body. (Integer $> 0$ or blank; default is max element number or 1.5 times the number of nodes whichever is smaller)
MAXNOD (2,3)	Maximum number of nodes that lie on the periphery of any deformable contact body. (Integer $> 0$ or blank; default is the number of nodes)
ERROR (3,2)	Distance below which a node is considered touching a body. Automatically calculated if left blank. If left blank, the code calculates ERROR as the smallest nonzero element dimension divided by 20 or the shell thickness divided by 4. (Real; Default = blank)
BIAS (3,6)	Contact tolerance bias factor. (Real, $0 \leq \text{BIAS} \leq 1$ , Default = 0.9 if field left blank or not entered in the file. To obtain a near zero value, enter 1.0E-16)
ISPLIT (2,7)	Flag for increment splitting procedure. (Integer $\geq 0$ ; Default = 3 for statics and 0 for dynamics)
	0 Uses increment splitting procedures for the fixed time step procedures.

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)	
	1	Suppresses splitting for the fixed time step procedures. Any penetration that occurred in the previous increment is adjusted for equilibrium at the start of the next increment. This method may require smaller time steps than the other methods
	2	Suppresses splitting for adaptive time step procedures. Any penetration that occurred in the previous increment is adjusted for equilibrium at the start of the next increment. This method may require smaller time steps than the other methods.
	3	Uses contact procedure which does not require increment splitting (3 is not available for dynamics). If a run does not converge due to an excessive number of “iterative penetration checking” messages, ISPLIT=2 may help, however the time steps may need to be set to smaller values.
FNTOL (3,5)	Separation force (or stress if separation is controlled by stress as determined by IBSEP) above which a node separates from a body. Automatically calculated if left blank. (Real; Default = blank)	
MAXSEP (2,6)	Maximum number of separations allowed in each increment. After MAXSEP separations have occurred, if the standard convergence tolerance conditions are achieved, the step will converge. (Integer > 0; Default = 9999)	
ICHECK (2,8)	Flag for interference kinematic check and bounding box check. (Integer > 0)	
	1	Activates interference kinematic check.
	2	Suppress bounding box checking.
	3	No reset of NCYCLE to zero.
	4	Check for separation only when solution has converged, for analytical surfaces only.
ICSEP (2,9)	Flag to control separation. (Integer $\geq$ 0; Default = 0)	
	0	The node separates and an iteration occurs if the force on the node is greater than the separation force.
	1	If a node which was in contact at the end of the previous increment has a force greater than the separation force, the node does NOT separate in this increment, but separates at the beginning of the next increment.
	2	If a new node comes into contact during this increment, it is not allowed to separate during this increment, prevents chattering.
	3	Both 1 and 2 are in effect.
IBSEP (2,12)	Flag for separation based on stresses or forces. (Integer $\geq$ 0; Default = 0)	
	0	Separation based on forces.

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)	
	1	Separation based on absolute stresses (force/area).
	2	Separation based on absolute stress (extrapolating integration point stresses).
	3	Relative nodal stress (force/area).
	4	Separation based on relative stress (extrapolating integration point stresses).
	Only option 2 and 4 can be used with mid-side node elements where the mid-side nodes contact (LINQUAD=-1).	
ISHELL (2,10)	Parameter governing normal direction and thickness contribution of shells. (Integer $\geq 0$ ; Default = 0)	
	0	Check node contact with top and bottom surface.
	1	Nodes only come into contact with bottom layer.
	2	Nodes only come into contact with bottom layer and shell thickness is ignored.
	-1	Nodes only come into contact with top layer.
	-2	Nodes only come into contact with top layer and shell thickness is ignored.
IPRINT (2,11)	Flag to reduce print out of surface definition. (Integer $\geq 0$ ; Default = 0)	
	0	Full print out.
	1	Reduced print out.
RVCNST (3,1)	Relative sliding velocity between bodies below which sticking is simulated. If FTYPE=5, then the value of RVCNST is the stick-slip transition region.	
FTYPE (2,4)	Friction type. (Integer)	
	0	No friction. (Default)
	1	Shear friction.
	2	Coulomb Friction.
	3	Shear friction for rolling.
	4	Coulomb friction for rolling.
	5	Stick-slip Coulomb friction.
	6	Bilinear Coulomb friction. (Default if friction is present and FTYPE is not entered.)
	7	Bilinear Shear friction.
FKIND (2,5)	Friction kind. (Integer 0 or 1)	

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)	
	0	Friction based on nodal stress.
	1	Default if friction is present and FKIND is not entered. Friction based on nodal force.
BEAMB (2,13)	Beam-Beam contact flag. (Integer 0 or 1)	
	0	No beam-beam contact. (Default)
	1	Activate beam-beam contact options.
FSSMULT (3,7)	Stick-slip friction coefficient multiplier. Applicable only to stick-slip friction. (The friction coefficient is multiplied by this value for the sticking condition.) (Real $\geq 0$ ; Required; Default = 1.05)	
FSSTOL (3,8)	Stick-slip friction force tolerance. Applicable only to stick-slip friction. (Real; Default = 0.05)	
LINQUAD (2,14)	Higher order element contact flag (Integer; Default = 1).	
	1	The outer boundary of a contact body is described by the corner nodes only and mid-side nodes can't come into contact.
	-1	The outer boundary is described by a quadratic field and both corner and mid-side nodes are considered in contact. If this flag is set to -1 and IBSEP is blank, IBSEP will be re-set to 2. This option is only available with Marc 2003 and subsequent releases.
INITCON (2,16)	If INITCON is set, tying relations (MPC's) for surfaces initially in contact will be saved. This option maybe used to model dissimilar meshes. See CONTINUE=101+ on the SOL 600 entry to use these items in the same MSC Nastran execution. The following options are available:	
	1	MPC's in Marc format are saved for initial contact (if any) in file jid.marc.t01.
	3	MPC's for each increment are saved in Marc format in file jid.marc.conmpc_xxxx where xxxx is the increment number.
	4	MPC's for each increment are saved in Nastran MPC format in file jidd.marc.conmpc_xxxx where xxxx is the increment number.
	When initcon=1, the job will stop at the end of increment zero. When initcon=3 initcon=4, the job will run to completion and the information in jid.marc.conmpc_0000 for increment zero will usually not be useful, but the information for increments one and above will contain the proper contact tying relations or mpc's.	
NVSURF	Rigid contact surface ID (BCBODY ID) for which the next 4 approach velocity values apply. Leave this entry and the next 4 out if not applicable. This entry and the next 4 may be repeated as many times as necessary to define all rigid contact surfaces with approach velocity values. (Integer; Default = 0)	

Name	Description, Type and Value (Default is 0 for Integer, 0.0 for Real Unless Otherwise Indicated)	
VELAPP1 (6,1)	Approach velocity in direction 1 of rigid contact surface - used only in increment zero. Requires PARAM,MRCONVER,11 (Real; Default = 0.0)	
VELAPP2 (6,2)	Approach velocity in direction 2 of rigid contact surface - used only in increment zero. Requires PARAM,MRCONVER,11 (Real; Default = 0.0)	
VELAPP3 (6,3)	Approach velocity in direction 3 of rigid contact surface - used only in increment zero. Requires PARAM,MRCONVER,11 (Real; Default = 0.0)	
VELAPAN (6,3)	Approach angular velocity about local axis through center of rotation of rigid contact surface - used only in increment zero. Requires PARAM,MRCONVER,1 (Real; Default = 0.0)	
NODSEP	If NODSEP is positive, ignore separation of any node that has touched and separated NODSEP times (corresponds to feature, 31xx where xx=nodsep). If NODSEP is negative, NODSEP is the number of separations of a particular node allowed. If more separations of that node actually occur, the node is assumed to be separated (corresponds to feature, -31xx where xx=nodsep). (Integer between 0 and 99; Default if not entered is 2, corresponds to feature,3102)	
METHOD	Flag to select Contact Methods (Character)	
	NODES URF	Regular 3D contact (Default: node to surface contact)
	SEGSMA LL	Segment to segment contact with small sliding
AUGMENT	Augmentation method used in a segment to segment contact analysis. (Integer)	
	0	No augmentation (Default)
	1	Augmentation based on a constant Lagrange multiplier field for linear elements and on a bilinear Lagrange multiplier field for quadratic elements.
	2	Augmentation based on a constant Lagrange multiplier field.
	3	Augmentation based on a bilinear Lagrange multiplier field.
PENALT	Augmented Lagrange penalty factor used by the segment to segment contact algorithm only. (Real > 0; set BCBODY for Default)	
AUGDIST	Penetration distance beyond which an augmentation will be applied. Used by the segment to segment contact algorithm only. (Real > 0.0; set BCBODY for Default)	

Remarks:

1. (i,j) refers to data block i and field j of the CONTACT model definition option in Marc.
2. Field 2 of the primary line should be left blank or a value of zero should be entered.
3. Only one BCPARA entry should be made. If multiple entries are made, the last will be used.

4. For FTYPE, SOLs 400 and 600 differ as follows. For SOL 400, if friction is entered but FTYPE is blank, friction is ignored. For SOL 600, if friction is entered but FTYPE is blank COULOMB friction is used. (FTYPE is reset internally to 2). In addition SOL 400 can only use friction types 0, 6 and 7.

**BCPATCH** Defines a Rigid Contact Body Made up of Quadrilateral Patches in SOLs 101 and 400

Defines a rigid contact body made up of quadrilateral patches used in SOLs 101 and 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCPATCH	RBID								
	IDP	G1	G2	G3	G4				
	IDP	G1	G2	G3	G4				
	-etc.-								

Example:

BCPATCH	12								
	1	101	102	103	104				

Describer	Meaning
RBID	Unique identification number referenced by a BCRGSRF or BCBODY1 entry (Integer > 0). See Remark 1.
IDP	ID of the patch (Integer number 1 through highest value).
G1, G2, G3, G4	Grid numbers for each of the 4 nodes of the patch.

Remarks:

1. If BCRGSRF entry does not exist, BCPATCH entry will be referenced by the BCBODY1 entry directly.

## BCPFLG Defines a beam section segment flag

Defines a beam section branch and segment for segment to segment beam contact used in SOL 101 and 400 for general contact or in SOLs 101, 103, 105, 107 - 112, 200 and 400 for the permanently glued Contact.

Format:

1	2	3	4	5	6	7	8	9	10
BCPFLG	PID	IBRNCH1	IOUTIN 1	IBRNCH2	IOUTIN2	IBRNCHi	IOUTINi		

Example:

BCPFLG	2	1	2	3	13				
--------	---	---	---	---	----	--	--	--	--

Describer	Meaning
PID	Beam property/section identification number of PBEAML/PBARL. (Integer > 0; Required)
IBRNCHi	Branch selection flag for segment generation. Only required for thin wall sections. See Remark 1, 2, 3 and 4. (Integer; default=0).  0 select all branches for thin wall sections
IOUTINi	Beam segment location. See Remark 4, 5, 6 and 7. (Integer; default=0; up to three unique integers may be placed in the field with no embedded blanks.)  0 - all segments 1 - location 1 of thin wall section or only outer of solid or tube sections 2 - location 2 of thin wall section or only inner of tube section 3 - location 3 of thin wall section (thickness direction of branch) 4 - segment not including thickness

Remarks:

- If the card is not defined but the beam property is included in segment to segment contact, all segments will be generated and used. This card is only useful when a user needs to define the specific beam segments for segment to segment contact. It will help the performance of calculation because only selected segments will be considered in the contact calculation.
- IBRNCHi fields are only required for thin wall beam sections. Solid beam sections such as rectangular, rod, etc or tube sections require only IOUTIN1.
- Each branch of thin wall beam section has four segments.
- Segment locations of thin wall beam sections are listed below. TYPE is defined by PBEAML/PBARL. The number circled is the branch number of each shape and the number without circle is the segment number which is used in IOUTINi. Segment 1 and 2 of each branch are the segments in the branch direction and segment 3's are the segment in the thickness direction of the branch.

TYPE="Z"

TYPE="CHAN2"

TYPE="T2"

TYPE="HAT"

TYPE="HAT1"

TYPE="DBOX"

5. If there is not thickness, one segment will be generated in the branch.
6. "3" cannot be used alone and "4" must be used only with "1" or "2". IOUTIN<sub>i</sub> must be one of "0", "1", "2", "12", "13", "14", "23", "24" and "123".
7. "14" and "24" generate the identical segment since the thickness is ignored but segment normal direction will be different.

## BCPROP

## 3D Contact Region by Element Properties

Defines a 3D contact region by element properties. All elements with the specified properties define a contact body.

Format:

1	2	3	4	5	6	7	8	9	10
BCPROP	ID	IP1	IP2	IP3	IP4	IP5	IP6	IP7	
	IP8	IP9	etc.						

Example:

BCPROP	1	101	201	301					
--------	---	-----	-----	-----	--	--	--	--	--

Alternate Format:

BCPROP	ID	IP1	THRU	IP2	IP3	IP4	IP5	IP6	
	IP7	IP8	IP9	etc.					

Alternate Example:

BCPROP	1	101	THRU	102	105	THRU	109	110	
--------	---	-----	------	-----	-----	------	-----	-----	--

Describer	Meaning
ID	Identification number of a deformable surface corresponding to a BSID value on the BCBODY entry. All elements corresponding to the property IDs specified that may potentially come into contact. Do not specify mixed property types (use all shell, all solid or all beam properties only). See Remark 1. (Integer > 0)
IPi	Property ID. A minimum of one entry is required. (Integer; no Default)

Remarks:

1. ID must be unique with respect to all other BSURF, BCBOX, BCPROP, and BCMATL entries.
2. The deformable surface may alternately be defined using BSURF, BCBOX, or BCMATL entries.
3. Only one kind of entry (BSURF, BCBOX, BCPROP, or BCMATL) may be used to define a particular deformable surface.
4. All elements corresponding to the IDs entered will be used to define the deformable surface.
5. As many continuation lines as necessary may be used to define all property IDs associated with a particular deformable body.
6. The alternate format is triggered if field 4 contains THRU. The THRU keyword may appear in fields 4 thru 8.
7. BCBOX and BCMATL are not available for SOL 101 or SOL 400

## BCPROP

## 3D Contact Region by Element Properties in SOL 600

Defines a 3D contact region by element properties. All elements with the specified properties define a contact body used in SOL 600.

Format:

1	2	3	4	5	6	7	8	9	10
BCPROP	ID	IP1	IP2	IP3	IP4	IP5	IP6	IP7	
	IP8	IP9	etc.						

Example:

BCPROP	1	101	201	301					
--------	---	-----	-----	-----	--	--	--	--	--

Alternate Format:

BCPROP	ID	IP1	THRU	IP2					
--------	----	-----	------	-----	--	--	--	--	--

Example for Alternate Format:

BCPROP	25	101	THRU	102					
--------	----	-----	------	-----	--	--	--	--	--

Describer	Meaning
ID	Identification number of a deformable surface corresponding to a BSID value on the BCBODY entry or if the Case Control BCONTACT = BCPROP is specified. All elements corresponding to the property IDs specified that may potentially come into contact. Do not specify mixed property types (use all shell, all solid or all beam properties only). See Remark 1. (Integer > 0)
IPi	Property ID. A minimum of one entry is required. (Integer; no Default)

Remarks:

1. ID must be unique with respect to all other BSURF, BCBOX, BCPROP, and BCMATL entries.
2. The deformable surface may alternately be defined using BSURF, BCBOX, or BCMATL entries.
3. Only one kind of entry (BSURF, BCBOX, BCPROP, or BCMATL) may be used to define a particular deformable surface.
4. All elements corresponding to the IDs entered will be used to define the deformable surface.
5. As many continuation lines as necessary may be used to define all property IDs associated with a particular deformable body.
6. The alternate format is triggered if field 4 contains THRU.

**BCRIGID**

Defines a Rigid Contact Body in SOLs 101 and 400

Defines a rigid contact body used in SOLs 101 and 400 only.

Format: (SOLs 101 and 400 only)

1	2	3	4	5	6	7	8	9	10
BCRIGID	BCRIGID	CGID	CONTROL						
	NLOAD	ANGVEL	DCOS1	DCOS2	DCOS3	VELRB1	VELRB2	VELRB3	
	“APPROV”	A	N1	N2	N3	V1	V2	V3	
	“GROW”	GF1	GF2	GF3	TAB-GF1	TAB-GF2	TAB-GF3		

Example:

BCRIGID	1001	1	1						
	0	0.	0.	0.	1.	1.	1.	1.	

**Describer**      **Meaning**

**BCRIGID**      Unique identification number referenced by a BCBODY1 entry. (Integer > 0)

**CGID**      Grid point identification number defining the initial position of the reference point of the rigid body or the point where a concentrated force or moment is applied. (Integer > 0) See Remark 1.

**CONTROL**      Indicates the type of control for the body.  
Integer:  
= -1 for position control. The coordinates of the final position of GRID Point defined in CGID is given in VELRB<sub>i</sub> in the following line.  
  
= 0 for velocity control. (default)  
= positive number for “load control”. The positive number is the grid number defined in CGID at which translational forces or SPCD are applied. (Note: The rotation in this case is defined by NLOAD in the following line.)

**NLOAD**      Enter a positive number if “load controlled” and rotations are allowed. (Integer) The positive number is the grid number where the moments or rotations are applied. The rotations are specified using SPCD at grid ID NLOAD and can be specified using dof's 1-3 (for translation along x, y, z respectively), or by dof's 4-6 (for rotation about x, y, z respectively). Note: This rotation takes the position of the grid point defined in CGID field as the center of rotation.

**ANGVEL**      Angular velocity or angular position about local axis through center of rotation. If the value is an integer it represents the ID of a TABLED1, TABLED2 or TABL3D, i.e., a time-dependent or multi-dimensional table; however, no log scales, only linear scales. (Real or Integer; Default = 0.0)

DCOSi	Components of direction cosine of local axis if ANGVEL is nonzero. If the value is an integer, it represents the ID of a TABLED1, TABLED2 or TABL3D, i.e., a time-dependent or multi-dimensional table; however, no log scales, only linear scales. (Real or Integer; Default=0.0) In 2D contact only DCOS3 is used and the Default is 1.0.
VELRBi	Tranlational velocity or final position (depending on the value of CONTROL) of rigid body at the grid point defined in CGID filed. For velocity control only, if the value is an integer, it represents the ID of TABLED1, TABLED2 or TABL3D, i.e., a time-dependent or multi-dimensional table; however, no log scales, only linear scales. Only VELRB1 and VELRB2 are used in 2D contact. (Real or Integer; Default = 0.0)
“APPROV”	The entries of this continuation line are for approaching velocity to establish initial contact.
A	Angular velocity about local axis through center of rotation. (Real, Default = 0.0)
Ni	Components of direction cosines of local axis of the angular velocity. The N1, N2, N3 define the axis through the point defined in the CGID field. Only N1 and N2 are used in 2D contact. (Real, Default = 0.0)
Vi	V1, V2 and V3 define the three components of the approaching velocity. Only V1 and V2 are used in 2D contact. (Real; Default = 0.0)
“GROW”	The entries of this continuation line are for rigid body growth. If tables are used for growth, they should either be TABLED1, TABLED2 (growth vs time) or TABL3D (growth vs one or more variables).
GFi	Components of growth factor of rigid body in the coordinate system of the CGID field. (Real, Default = 1.0)
TAB-GFi	Table IDs for growth factor of rigid body in the coordinate system of the CGID field. (Integer > 0 or blank, Default is blank)

#### Remarks:

1. The grid CGID is the reference grid for the rigid body motion. Loads and enforced motion must be defined in the global coordinate system of CGID. If CGID is not specified, basic coordinate will be used.
2. All continuation lines may be omitted if not required.

**BCRGSRF** Rigid Contact Surface List in SOLs 101 and 400

Defines a list of rigid contact surfaces used in SOLs 101 and 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCRGSRF	BSID	RBID1	RBID2	RBID3	RBID4	RBID5	RBID6	RBID7	
	RBID8	-etc.-							

Example:

BCRGSRF	1008	35	2						
---------	------	----	---	--	--	--	--	--	--

**Describer**    **Meaning**

BSID            Unique identification number referenced by a BCBODY1 entry. (Integer > 0) See Remark 1.

RBIDi          Identification number of BCPATCH, BCBZIER, BCNURB2 or BCNURBS entry. (Integer > 0)

Remarks:

1. If BCRGSRF entry does not exist, BCBODY1 entry can refer to one of the identification number of BCPATCH, BCBZIER, BCNURB2 or BCNURBS entry directly.

## BCSCAP

Defines a cap and number of segments

Defines whether a cap is added to a beam section and/or defines the number of segments used to model rod and tube sections for segment to segment beam contact in SOL 101 and 400 for general contact or in SOLs 101, 103, 105, 107 - 112, 200 and 400 for the permanently glued contact

Format:

1	2	3	4	5	6	7	8	9	10
BCSCAP	EID	IESCAP	NSEG						

Example:

1	2	3	4	5	6	7	8	9	10
BCSCAP	2	1	20						

Describer	Meaning
EID	Beam element identification number. (Integer > 0; Required)
IESCAP	End and side cap flag (Integer ≥ 0; default=0).  0 no end or side cap 1 end cap only 2 side cap only 3 averaged side cap only 4 end cap and side cap 5 end cap and averaged side cap
NSEG	Number of segments for circular sections TYPE=ROD, TUBE or TUBE2 beam sections defined on PBARL or PBEAML. See remarks 2. (Integer ≥ 3; default=32)

Remarks:

1. If the card is not defined but the beam is included in segment to segment contact, all caps will be ignored. This card is only useful when a user needs to define the cap of beams for segment to segment contact.

2. The segments for circular cross sections will be generated as the figure below.

## BCSEG

## Contact Segment Defined Using Grids

Grids which are part of an element to be used in contact analyses in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
BCSEG	ID	IBODY	G1	G2	G3	G4			

Example:

1	2	3	4	5	6	7	8	9	10
BCSEG	100	1005	11	12	13	14			

Describer	Meaning
ID	Unique identification number for this BCSEG entry. (Integer > 0; Required)
IBODY	Identification number of a surface that is called out on the 5 <sup>th</sup> field of a BCBODY entry. (Integer > 0; Required)
G1,G2,G3,G4	GRID point identification numbers of an element on this surface. For quad plates and quad surfaces of solids, enter four grid id's. For triangular plates or triangular faces of solids, leave G4 blank. (Integer > 0; Required)

Remarks:

1. This entry is used as shown in the example below:  
 BCBODY, 201,,,1005  
 BCSEG,1,1005,11,12,13,14  
 BCSEG,2,1005,21,22,23,24  
 BCSEG,3,1005,31,32,33,34  
 (In the above 11-14, 21-24 and 31-34 are GRID ID's)

## BCSURF

## Contact entry by element faces

Define a contact region by element faces for SOLs 101, 103, 105, 107, 108, 109, 110, 111, 112, 200 and 400. This has three forms based the FORM (the 6th) field. "FACE" (default) is to define contact face by element face IDs, "GRID" is to define the same by grid point ids, and "RIGID" is to define a rigid face.

### Format 1: FORM="FACE" (default)

1	2	3	4	5	6	7	8	9	10
BCSURF	BID	BPID	DIM		FORM	INCTHK	EDGCNT		
	ESID1	FACEID1	IDTYPE1		ESID2	FACEID2	IDTYPE2		
	ESID3	FACEID3	IDTYPE3		...				
	...								

### Format 2: FORM="GRID"

1	2	3	4	5	6	7	8	9	10
BCSURF	BID	BPID	DIM		"GRID"	INCTHK	EDGCNT		
	EID1	G11	G12	G13	EID2	G21	G22	G23	
	EID3	G31	G32	G33	...				
	...								

### Format 3: FORM="RIGID"

1	2	3	4	5	6	7	8	9	10
BCSURF	BID	BPID	DIM		"RIGID"				
	BSID	BCRGID							

Example:

#### FACE form (default)

BCSURF	2	3	3D			NO			
	12	S2			4	S4	SET		

#### GRID form

BCSURF	3	3	3D		GRID	YES			
	11	1	3	6	16	31	14	15	

#### RIGID form

BCSURF	4		3D		RIGID				
	101	201							

Describer	Meaning
BID	Unique contact face identification number referenced by BCONECT (Integer > 0; Required). See remark 1.
BPID	Parameter identification number of a BCBDPRP entry. (Integer > 0 or blank).
DIM	Dimension of body. (Character; Default= "3D"), "3D" or "2D".
FORM	Select a type of the entry. (Character; Default = "FACE"). FACE define the contact surface by element face IDs GRID define the contact surface by grid points on an element face RIGID define the contact surface by rigid surface
INCTHK	Option to include shell thickness offset. (Character; Default = "YES"), "YES" or "NO".
EDGCNT	Option for edge contact. (Integer, default=1), below three values can be specified. 1: only the beam/bar edges are included in the contact description (Default). 10: only the free and hard shell edges are included in the contact description. 11: both the beam/bar edges and the free and hard shell edges are included in the contact description.
ESIDi	Element id or set id. (Integer, no default). If IDTYPEi is "SET", it is a set id defined by a SET3, and the SET3 must be element type. If IDTYPEi is "ELEM" (default), it is an element id.
FACEIDi	Element face ID. (Character, blank can be used to express BOTH for shell elements and the whole bodies of beam or bar elements). See remarks 6., 7., 8. and 9.
IDTYPEi	Type of ESIDi. (Character, "ELEM"). ELEM ESIDi is an element id. SET ESIDi is a SET3 id.
EIDi	Element id. (Integer > 0)
GIDij	Three corner grid point ids of the element face. (Integer, no default). All the three fields of for an EIDi are blanks or zeros mean BOTH for shell elements and the whole bodies of bar or beam elements. See remark 2.
BSID	Identification number of a BCRGSRF, BCPATCH,BCBZIER, BCNURB2, or BCNURBS. (Integer > 0).
BCRGID	Identification number of a BCRIGID entry. (Integer > 0).

#### Remarks:

1. BID must be unique among all BCSURF, BCBODY1 and BCGRID entries.
2. BCSURF entries are able to coexist with BCBODY1 entries. A BCSURF can be used with a BCGRID, another BCSURF or a BCBODY1 entry to construct a contact pair.

3. BCSURF cannot be specified in the continuations of a BCONECT.
4. If a BCSURF is referenced by a BCONECT, COPTS and COPTM in the BCONPRG referenced by the BCONECT will be used, and FACEIDs and INCTHK fields of BCSURF are ignored.
5. For GRID form, three corner grid point IDs are required to specify a 3D element face, two corner grid point ids are required to specify a 2D element edge. For shell faces, the sequence of G1,G2,G3 of the element definition means TOP(top) and the reverse order means BTM(bottom), blanks or zeros means BOTH(both).
6. FACEIDi varies depending on element type and DIM. Refer to remark 9 for the list of FACEIDs.
7. For shell elements, TOP, BTM and BOTH are to define the contact face on top, bottom and both sides of the element. A blank is the same as BOTH. It is possible to have TOP and BTM in the same BCSURF entry but not allowed to combine BTM with BOTH or TOP with BOTH.
8. For beam elements, ENDA and ENDB express beam or bar enda and endb points respectively. A blank means the whole beam or bar body.
9. List of face ID.

**BCTABLE**

Defines a Contact Table for General Contact

Defines a contact table used in SOL 101, 400 and 700. SOL 200 (without calling SOL 400) can only support permanent glue. When SOL 200 calls SOL 400 (or say SOL 400 optimization), it can support all contact types. The BCTABL1 option is the preferred method to define a contact table.

Format: (SOLs 101 and 400 only)

1	2	3	4	5	6	7	8	9	10
BCTABLE	ID	IDSCND	IDPRIM	NGROUP	COPTS	COPTM			
	"SECNDRY"	IDSEC1	ERROR	FNTOL	FRIC	CINTERF	IGLUE		
		ISEARCH	ICOORD	JGLUE		DQNEAR			
		"FBSH"	FRLIM	BIAS	SLIDE	HARDS	COPTS1	COPTM1	
		"BKGL"	BGSN	BGST	BGM	BGN			
		"SEGS"	PENALT	AUGDIST	TPENALT	STKSLP			
		"HHHB"	HCT	HCV	HNC	BNC	EMISS	HBL	
			HNL	BNL	HGLUE				
	"PRIMARY"	IDPRIM1	IDPRIM2	IDPRIM3	IDPRIM4	IDPRIM5	IDPRIM6	IDPRIM7	
		IDPRIM8	IDPRIM9	...					

Format: (SOL 700 only)

1	2	3	4	5	6	7	8	9	10
BCTABLE	ID	IDSCND	IDPRIM	NGROUP					
	"SECNDRY"	IDSEC1			FRIC		IGLUE		
				JGLUE					
		FK	EXP	METHOD	ADAPT	THICK	THICKOF	PENV	
		FACT	TSTART	TEND	MAXPAR

	"PRIMARY"	IDPRIM1	IDPRIM2	IDPRIM3	IDPRIM4	IDPRIM5	IDPRIM6	IDPRIM7	
		IDPRIM8	IDPRIM9	...					

**Examples:**

BCTABLE	2			3					
	SECNDRY	10			0.2				
	PRIMARY	20	30						
	SECNDRY	20			0.3				
	PRIMARY	10							
	SECNDRY	30			0.2				
	PRIMARY	10							

BCTABLE	0	1	2	0					

Describer	Meaning
ID	Identification number referenced by a BCONTACT Case Control command. See Remark 5. (Integer; Required)
IDSCND	Identification number of a BCBODY entry defining the touching body. (Integer > 0 or blank)
IDPRIM	Identification number of a BCBODY Bulk Data entry defining the touched body. (Integer > 0 or blank)
NGROUP	Flag to indicate that the continuation entries "SECNDRY" and "PRIMARY" are entered or not. Zero means no continuation entries are entered. Any positive integer means one or more sets of secondary/primary entries are entered. (Integer; Default = 1).
COPTS, COPTM, COPTS1, COPTM1	Flag to indicate how secondary and primary surfaces may contact. See Remark 9. (Integer; Default = 0) COPTS and COPTM apply to all secondary and primary surfaces on this BCTABLE. To set individual secondary/primary combination differently, use COPTS1 and/or COPTM1. Ignored by SOL 700.
"SECNDRY"	Indicates that this line defines the touching body and its parameters.
IDSEC1	Identification number of a BCBODY Bulk Data entry defining the touching body. (Integer > 0) For SOL 700, leaving IDSEC1 blank will result in contact for all elements in the model. In this case, you are allowed to use ADAPT=YES.

Describer	Meaning
ERROR	Distance below which a node is considered touching a body. Default = blank automatic calculation. See the Bulk Data entry <a href="#">BCPARA</a> for more details. Ignored by SOL 700. (Real)
FNTOL	Separation force, stress, or fraction above which a node separates from a body. FNTOL is closely related to IBSEP. It's default value is dependent on the IBSEP value. See remark <a href="#">10</a> . Ignored by SOL 700. (Real)
FRIC	Friction coefficient. If the value is an integer, it represents the ID of a TABLEM1, TABLEM2 or TABL3D, i.e., a temperature-dependent or multidimensional table. SOL700 does not support the table definition. (Real > 0.0 or Integer > 0; Default = 0.0 for SOL400, Real >0.0; Default=0.0 for SOL700)
CINTERF	Interference closure amount, normal to the contact surface. Default = 0. For CINTERF > 0, overlap between bodies. For CINTERF < 0., gap between bodies. Ignored by SOL 700. (Real)
IGLUE	Flag to activate glue option (Integer ≠ 0). Default is 0, no glue option. For SOL 700, IGLUE=1 is only acceptable. JGLUE option controls a glue contact type in details. Without assigning IGLUE and JGLUE options, general contact methods (METHOD=TIEDxxx) can assign glue contact types as well. (See Remarks <a href="#">8</a> through <a href="#">16</a> .)
	±1 Activates the glue option. In the glue option, all degrees-of-freedom of the contact nodes are tied in case of deformable-deformable contact once the node comes in contact. The relative tangential motion of a contact node is zero in case of deformable-rigid contact. The node will be projected onto the contact body.
	±2 Activates a special glue option to insure that there is no relative tangential and normal displacement when a node comes into contact. An existing initial gap or overlap between the node and the contacted body will not be removed, as the node will not be projected onto the contacted body. To maintain an initial gap, ERROR should be set to a value slightly larger than the physical gap.
	±3 Insures full moment carrying glue when shells contact. The node will be projected onto the contacted body.
	±4 Insures full moment carrying glue when shells contact. The node will not be projected onto the contact body and an existing initial gap or overlap between the node and the contacted body will not be removed, as the node will not be projected onto the contacted body.
ISEARCH	Option for contact searching order, from Secondary to Primary or from Primary to Secondary, for deformable contact bodies. Ignored by SOL 700. ISEARCH is not necessary in segment-to-segment contact. (Integer; Default = 0)

Describer	Meaning
	<p>0 (Double orders search) ) the search order is from lower BCBODOY ID's to higher ones first. Then it searches the opposite order. See Remark 19.</p> <p>1 (Single order search) the searching order is from Secondary to Primary</p> <p>2 (Single order search) let the program decide which search order. See Remark 19.</p> <p>Note that ISTYP in BCBDRP or BCBODY is supported with ISEARCH=0 only.</p>
ICOORD	<p>Enter 1 to modify the coordinates of a node in contact with a deformable body so that stress-free initial contact can be obtained. Enter 2 to extend the tangential error tolerance at sharp corners of deformable bodies to delay sliding off a contacted segment. Enter 3 to have both 1 and 2 active. Ignored by SOL 700. (Integer; Default = 0)</p>
JGLUE	<p>This option is only relevant if the general glue option is invoked (JGLUE &gt; 0 and =1). Enter 0 if a node should not separate (default). Enter 1 to invoke the standard separation behavior based on the maximum residual force. For SOLs 101 and 400, enter 2 to activate breaking glue. (Integer; Default = 0)</p> <p>For SOL 700 the following options are available:</p> <p>0 Secondary nodes in contact and which come into contact will permanently stick. Tangential motion is inhibited. This option is only available with METHOD=SS1WAY or SS2WAY and AUTO=YES.</p>
DQNEAR	<p>Distance below which near thermal contact behavior occurs. Used in heat transfer analysis only. Ignored by SOL 700. (Real; Default = 0; which means near contact does not occur)</p>
"FBSH"	<p>Enter character string FBSH if the line with items FRLIM, BIAS, SLIDE, HARDS is required to change the defaults of any of these values. (SOLs 101 and 400)</p>
FRLIM	<p>Friction stress limit. This entry is only used for friction type 6 (Coulomb friction using the bilinear model). If the shear stress due to friction reaches this limit value, then the applied friction force will be reduced so that the maximum friction stress is given by <math>\min(\mu\sigma_n, \sigma_{limit})</math>, with <math>\mu</math> the friction coefficient and <math>\sigma_n</math> the contact normal stress. (Real; Default = 1.0E20)</p>
BIAS	<p>Contact tolerance bias factor. If this field is left blank, the default is the BIAS of the BCPARA entry. A nonblank entry will override the BIAS entered on the BCPARA entry. Note 0.0 is not default, and will override the BIAS on BCPARA. SYSTEM(758)=1 will set 0.0 same as blank. (0.0&lt;=Real&lt;=1.0)</p>

Describer	Meaning
SLIDE	Delayed slide off distance ratio. This entry should not be made unless ICOORD $\geq$ 2 (see above). When using the delayed slide off option, a node sliding on a segment will slide off this segment only if it passes the node (2-D) or edge (3-D) at a sharp corner over a distance larger than the delayed slide off distance. By default, the delayed slide off distance is related to the dimensions of the contacted segment by a 20 percent increase of its isoparametric domain. (Real; Default = 0.2)
HARDS	Hard-soft ratio. This entry is only used if double-sided contact with automatic constraint optimization is used, (ISTYP=2 on the BCBODY entry). The hard-soft ratio can be used by the program if there is a significant difference in the (average) stiffness of the contact bodies (expressed by the trace of the initial stress-strain law). If the ratio of the stiffnesses is larger then the hard-soft ratio, the nodes of the softest body are the preferred secondary nodes. (Real; Default = 2.0)
“BKGL”	Enter the character string BKGL if the line with items BGST, BGSN, BGM, BGN is required. (SOLs 101 and 400)
BGSN	Maximum normal stress for breaking glue. See Remark 10. (Real; Default = 0.0)
BGST	Maximum tangential stress for breaking glue. See Remark 10. (Real; Default = 0.0)
BGM	Exponent for the tangential stress term in deciding if a glue-contact will break. See Remark 10. (Real; Default = 2.0)
BGN	Exponent for the normal stress term in deciding if a glue-contact will break. See Remark 10. (Real; Default = 2.0)
“SEGS”	Enter the character string SEGS if the line with items PENALT and AUGDIST, TPENALT and STKSPL is required for the segment-to-segment contact.
PENALT	Augmented Lagrange penalty factor; used by the segment-to-segment contact algorithm only. (Real $\geq$ 0.0; see Remark 16. for default)
AUGDIST	Penetration distance beyond which an augmentation will be applied; used by the segment-to-segment contact algorithm only. (Real $\geq$ 0, see Remark 17. for default)
“HHHB”	Enter the character string HHHB if the line with items HCT, HCV, HNC, ..., up to HGLUE is required in a pure thermal analysis or in a coupled thermal/structural analysis. In a pure structural analysis they are ignored.
HCT	Contact heat transfer coefficient. If Real, the value entered is the contact heat transfer coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the contact heat transfer coefficient vs temperature or a TABL3D entry specifying the contact heat transfer coefficient vs temperature and possibly other variables. (Real or Integer; Default = 0.0; In a thermal/mechanical coupled analysis a default value of 1.0E6 is used when the mechanical glue option is activated, i.w., when IGLUE > 0.)

Describer	Meaning
HCV	Convection coefficient for near field behavior. If Real, the value entered is the near field convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the near field convection coefficient vs temperature or a TABL3D entry specifying the near field convection coefficient vs temperature and possibly other variables. (Real or Integer; Default = 0.0).
HNC	Natural convection coefficient for near field behavior. If Real, the value entered is the near field natural convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the near field natural convection coefficient vs temperature or a TABL3D entry specifying the near field natural convection coefficient vs temperature and possibly other variables. (Real or Integer; Default = 0.0).
BNC	Exponent associated with the natural convection coefficient for near field behavior. If Real, the value entered is the exponent associated with near field natural convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the exponent associated with the near field natural convection coefficient vs temperature or a TABL3D entry specifying the exponent associated with the near field natural convection coefficient vs temperature and possibly other variables. (Real or Integer; Default = 1.0.)
EMISS	Emissivity for radiation to the environment or near thermal radiation. If Real, the value entered is the emissivity. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the emissivity vs temperature or a TABL3D entry specifying the emissivity vs temperature and possibly other variables. (Real or Integer; Default = 0.0)
HBL	Separation distance dependent thermal convection coefficient. If Real, the value entered is the convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the convection coefficient vs temperature or a TABL3D entry specifying the convection coefficient vs temperature and possibly other variables. (Real or Integer; Default = 0.0).
HNL	Heat transfer coefficient for nonlinear convective heat flow for near field behavior.. If Real, the value entered is the near field nonlinear convection coefficient. If Integer, the value entered is the ID of a TABLEM1 or TABLEM2 entry specifying the near field nonlinear convection coefficient vs temperature or a TABL3D entry specifying the near field nonlinear convection coefficient vs temperature and possibly other variables. (Real or Integer; Default = 0.0)
BNL	Exponent associated with the nonlinear convective heat flow for near field behavior. If Real, the value entered is the exponent associated with the near field nonlinear convection coefficient. If Integer, the value entered is the ID of a TABLEM1 OR TABLEM2 entry specifying the exponent associated with the near field nonlinear convection coefficient vs temperature or a TABL3D entry specifying the exponent associated with the near field nonlinear convection coefficient vs temperature and possibly other variables. (Real or Integer; Default = 1.0)

Describer	Meaning
HGLUE	Flag to activate the thermal glue option. When left blank or set to zero, thermal contact conditions will be treated by convective heat transfer between the bodies. When set to 1, the temperature fields of the bodies are tied as soon as they come in contact and there will be no convective heat transfer over the body interfaces. ( $0 \leq \text{Integer} \leq 1$ ; Default = 0)
FK (SOL 700 only)	Kinetic coefficient of friction. (Real $\geq 0.0$ ; Default = 0.0)
EXP (SOL 700 only)	Exponential decay coefficient. (Real $\geq 0.0$ ; Default = 0.0)
METHOD (SOL 700 only)	Character, Influences the contact type used. See Remark 19. Options are: FULL: Regular Contact (Default) AIRBAG: Single Surface Contact SS1WAY: Surface To Surface One Way SS2WAY: Surface To Surface Two Way RB1WAY: Rigid Body One Way To Rigid Body RB2WAY: Rigid Body Two Way To Rigid Body RNRB: Rigid Nodes To Rigid Body TIEDNS: Tied Nodes to Surface TIEDNSO: Tied Nodes to Surface with Offset RELIPS: Tied contact between grid points or rigid materials to ATB dummies. See Remark 23. BELT: Suited for modeling contact between a belt element and a rigid structure. Primary secondary contact only. The contact logic doesn't apply a contact force, but applies an enforced displacement and velocity that keeps the secondary nodes exactly on top of the primary face. The secondary node does not slide relative to the primary face when the friction coefficient (FS) is set to 1E20. BELT1: Identical to BELT algorithm, except that the secondary nodes are initially repositioned on top of the closest primary face. All secondary nodes initially penetrated or within a distance of INITMON from a primary face, are repositioned. DRAWBEAD: Suited for modeling a drawbead. STYPE Must be GRID. The list of secondary nodes must be ordered along the drawbead line. MTYPE Must be SURE. The restraining force per unit drawbead length is specified in the field DRWBEADF. It is V2 version contact. DRAWBDV4: Suited for modeling a drawbead. STYPE Must be GRID. The list of secondary nodes must be ordered along the drawbead line. MTYPE Must be SURE. The restraining force per unit drawbead length is specified in the field DRWBEADF. It is V4 version contact.

Describer	Meaning
ADAPT (SOL 700 only)	Character, influences the contact type used. Options are NO or YES. Default = NO When ADAPT=YES, the BCBODY entries IDPRIMi must be defined as: behav=DEFORM bsid references a BCPROP
THICK (SOL 700 only)	Shell thickness scale factor. (Real $\geq$ 0.0; Default = same as the value in DYPARAM,CONTACT,THICK)
THICKOF (SOL 700 only)	Artificial contact thickness offset. (Real $\geq$ 0.0; Default = 0.0)
PENV (SOL 700 only)	Overwrites the default maximum penetration distance factor. (Real $\geq$ 0.0; Default = 1.E20)
FACT (SOL 700 only)	Scale factor for the contact forces. (Real $\geq$ 0.0; Default = 0.1)
TSTART (SOL 700 only)	Time at which the contact is activated. (Real $\geq$ 0.0; Default = 0.0)
TEND (SOL 700 only)	Time at which the contact is deactivated. (Real $\geq$ 0.0; Default = 1.e20)
MAXPAR (SOL 700 only)	Maximum parametric coordinate in segment. (Real $\geq$ 0.0; Default = 1.025), search (values 1.025 and 1.20 recommended). Larger values can increase cost. If zero, the default is set to 1.025. This factor allows an increase in the size of the segments. May be useful at sharp corners.
IADJ (SOL 700 only)	Adjacent material treatment option for solid elements. (Integer $\geq$ 0; Default = 1)  0            Solid element faces are included only for free boundaries. 1            Solid element faces are included if they are on the boundary of the material subset. This option also allows the erosion within a body and the subsequent treatment of contact.
IGNORE (SOL 700 only)	Ignore initial penetrations. (Integer $\geq$ 1)  1            Allow initial penetrations to exist by tracking it 2            Move nodes to eliminate initial penetrations
AUTO (SOL 700 only)	(Character) Options are: YES        Automatic Contacts Activated (Default) NO         Non-Automatic Contact Activated. This option is not recommended when Distributed Memory Parallel is activated.

Describer	Meaning
SIDE (SOL 700 only)	<p>Defines which side will be the monitoring side of a primary face. The opposite side of the primary face will be the penetration side. See Remark 24. (Character; default=BOTH)</p> <p>BOTH: The side from which a secondary node approaches the primary face will become the monitoring side.</p> <p>TOP: The monitoring side will always be on the side of the primary face that its normal is pointing at.</p> <p>BOTTOM: The monitoring side is always on the opposite side of the primary face that its normal is pointing at.</p>
WEIGHT (SOL 700 only)	<p>The contact force is multiplied by a mass-weighting factor. The following options are available. See Remark 25. (Character; default=BOTH)</p> <p>BOTH: <math display="block">M_{scale} = \frac{M_{secndry}M_{primary}}{M_{secndry} + M_{primary}}</math></p> <p>SECNDRY: <math>M_{scale} = M_{secndry}</math></p> <p>PRIMARY: <math>M_{scale} = M_{primary}</math></p> <p>NONE: <math>M_{scale} = 1.0</math></p>
MONDIS (SOL 700 only)	<p>Defines the fixed part of the monitoring distance. When the normal distance of a secondary node to a primary face becomes smaller than the monitoring distance the secondary node will tag itself to the primary face. The side from which the secondary node is moving towards the primary face becomes the monitoring region. (Character; default=FACTOR)</p> <p>FACTOR: The monitoring distance is equal to a factor times a characteristic length of the primary faces. The factor is specified in MONDISV.</p> <p>DISTANCE: The monitoring distance is specified in MONDISV.</p>
MONDISV (SOL 700 only)	<p>Value of the monitoring distance or value of the FACTOR to calculate the monitoring distance. (Real; default=2.0)</p>
INITMON (SOL 700 only)	<p>Fixed part of the monitoring distance used during the initialization. If not specified, the value of MONDIS is used. (Real &gt; 0.0; default=MONDIS)</p>
DAMPING (SOL 700 only)	<p>Specifies if a high frequency damping is active or not. The damping force is based on the relative velocity of a secondary node with respect to a primary face. The damping is preferably turned on in all cases, except for RIGID-RIGID contact. In RIGID-RIGID contact it can result in a substantial loss of energy. VERSION V4 only. (Character; Default=YES)</p> <p>YES damping is activated</p> <p>N damping is not activated</p>

Describer	Meaning
“PRIMARY”	Indicates the start of the list of bodies touched by touching body IDSEC1.
IDPRIMi	Identification numbers of BCBODY Bulk Data entries defining touched bodies. (Integer > 0)

#### Remarks:

1. BCTABLE defines surface contact.
2. If BCTABLE is not given, the default for contact analysis is assumed if BCONTACT=ALLBODY in Case Control Section, and, every body detects the possibility of contact relative to all other bodies and itself if it is a deformable body. If BCTABLE is given, the default for every body is overwritten. The touching body does not contact itself unless requested. When the touched body is deformable, double-sided contact is applied by default. BCTABLE is useful for deactivating or activating bodies to reduce computational effort and to change contact conditions between subcases.
3. A short input to define two contact bodies exits if the user provides IDSCND and IDPRIM. Then it is assumed that there are only two contact bodies, NGROUP is ignored and continuation entries are not allowed. Default values are set for the parameters on the continuation entry.
4. If the user leaves IDSCND and IDPRIM blank, then NGROUP is normally required and continuation entries are usually expected for NGROUP SECNDRY/PRIMARY combinations. Exceptions are for SOL 700 self-contact may be designated using a secondary IDSEC1 of zero and no PRIMARY entry.
5. For SOLs 101 and 400, the BCTABLE with ID=0 will be used in loadcase 0 automatically that does not need a corresponding Case Control command BCONTACT=0. The loadcase 0 is purely elastic and it can also be used to (1) move rigid contact bodies so that they just touch flexible contact bodies, and/or (2) remove any prestressed condition by adjusting the coordinates of the active nodes, which are the Grid Points on the surface of all deformable BCBODY's. BCTABLE, 0 is not used to define the contact relationship for any loadcases. ONLY BCTABLE, n(n>0), will dominate the contact analysis for each loadcase. To place an entry in any physical loadcase (SUBCASE or STEP), the ID must be selected by the Case Control command BCONTACT=ID. When BCONTACT=ALLBODY, there is no ID of BCTABLE specified; therefore, the default values of all entries of BCTABLE are assumed.
6. The line starting with “HHHB” is used for heat transfer or thermal contact analyses only. Also, see Remark 17.
7. It is not necessary to enter all continuation lines between SECNDRY and PRIMARY. For example, if an entry is required on the 4<sup>th</sup> SECNDRY line, the first 3 must be entered with some being blank and those after the 4<sup>th</sup> may be omitted. All continuation lines prior to the last needed must be entered.

8. Many secondary/primaries may be entered up to the number specified in Remark 5. A new secondary entry may not begin until the primaries from the previous entry are finished (as shown in the example). The number of primary surfaces for any given secondary surface is limited by the number specified in Remark 5., however most GUI's produce one secondary surface and one primary surface per secondary/primaries pairs.
9. COPTS, COPTM, COPTS1 and COPTM1 are packed numbers designating how the surfaces may contact using the formula

$$COP_{xxx}=A+10*B+1000*C$$

where the following codes apply:

A: the outside of the solid elements in the body

- = 1: the outside will be in the contact description (Default)

B (flexible bodies): the outside of the shell elements in the body

- = 1: both top and bottom faces will be in the contact description, thickness offset will be included (Default)
- = 2: only bottom faces will be in the contact description, thickness offset will be included
- = 3: only bottom faces will be in the contact description, shell thickness will be ignored
- = 4: only top faces will be in the contact description, thickness offset will be included
- = 5: only top faces will be in the contact description, shell thickness will be ignored
- = 6: both top and bottom faces will be in the contact description, shell thickness will be ignored

Note: The choice B = 6 for both bodies in a contact combination is only meaningful for glued contact. If in such cases separation is allowed, separated nodes will not come into contact anymore, unless a new CONTACT TABLE is defined to reset the value of B.

B (rigid bodies): the rigid surface

- = 1: the rigid surface should be in the contact description (Default)

C (flexible bodies): the edges of the body

- = 1: only the beam/bar edges are included in the contact description (Default)
- = 10: only the free and hard shell edges are included in the contact description
- = 11: both the beam/bar edges and the free and hard shell edges are included in the contact description

Note that C has no effect if beam-to-beam contact is **not** switched on (BEAMB ≠ 1 on BCPARA).

Note that C has no effect if segment-to-segment contact is used.

10. Breaking Glue provides glued contact to all GRID's at their very 1st contact. This kind of glued-contact will break if

$$(\sigma_n/BGSN)**bgn + (\sigma_t/BGST)**bgm > 1.0$$

When a contact node breaks due to the above criterion, standard contact is activated if it comes into contact again. If BGSN = 0.0 the first term is ignored. If BGST is zero, the second term is ignored.

11. For hard contact, with HGLUE=1:
  - a. The temperature of the contacting grid is tied to the temperatures of the contacted element face or the temperature of the rigid geometry when it has a scalar point associated with it.
  - b. The temperature of the contacting grid is set to the rigid geometry temperature when it has no scalar point associated with it.

**Note:** “Glued” thermal contact can result in overshoot of the temperatures at the interface, in particular, if two bodies that have non-uniform initial temperatures are placed in contact. The overshoot effect may be damped somewhat if one uses a near contact distance with some convective heat transfer.

12. For hard contact, with HGLUE=0:

The convective heat flow per unit area over the two interfaces is given by:

$$q = HCT \cdot (T_A - T_B)$$

where  $T_A$  is the contacting grid temperature and  $T_B$  is the face temperature in the contact point in case of a meshed body or the  $T_{BODY}$  temperature in case of a rigid geometry.

13. For near contact:

$$\begin{aligned} q = & HCV \cdot (T_A - T_B) + \\ & HNC \cdot (T_A - T_B)^{BNC} + \\ & HNL \cdot (T_A^{BNL} - T_B^{BNL}) + \\ & \sigma \cdot EMISS \cdot (T_A^A - T_B^A) + \\ & \left[ HCT \cdot \left( 1 - \frac{dist}{DQNEAR} \right) + HBL \cdot \frac{dist}{DQNEAR} \right] \cdot (T_A \cdot T_B) \end{aligned}$$

where the last term is only activated when  $HBL \neq 0$ ,  $T_A$  is the contacting grid temperature and  $T_B$  is the face temperature in the contact point in case of a meshed body or the  $T_{BODY}$  temperature in case of a rigid geometry.

14. The heat transfer coefficients and associated exponents can all be temperature dependent, when they are entered as an integer value. This integer value is the table ID of a TABLEM1, TABLEM2 or TABL3D entry (formulas are not supported on TABL3D).
15. Table IDs of tables used on the BCTABLE and the BCBODY entry must be unique.
16. The penalty factor used in the augmented Lagrange method is by default derived from the contact characteristic distance and the stiffness of the deformable contact bodies involved (note that the dimension of the penalty factor is force per cubic length).

$$\text{PENALT} = \frac{0.5(S_i + S_j)}{\bar{L}}$$

The body stiffness ( $S_i$  and  $S_j$ ), are either defined by the average trace of the initial stress-strain law of the elements defining the two contact bodies or by the average bulk modulus for (nearly) incompressible rubber materials, whichever of the two is the largest.

For continuum elements, the characteristic length ( $\bar{L}$ ) is given by one half of the average length of all the edges being part of the contact boundary. For shell elements, the characteristic length is given by half of the average thickness of all the shell elements being part of a contact body. When there is contact between a solid and a shell element, then the characteristic length is defined by the shell element.

In case of contact with a rigid body, since there is no body stiffness associated with a rigid body, the default value is related to the deformation body only and given by:

$$\text{PENALT} = \frac{1000S_i}{\bar{L}}$$

17. By default, the threshold value of this penetration distance is 0.05 times the default contact characteristic distance.

$$\text{AUGDIST} = 0.05\bar{L}$$

18. The multipoint constraint equations (MPC equations) internally created from body contact can be printed out in standard Nastran punch file by using Case Control command, NLOPRM MPCPCH. This capability is good for all solutions except SOL 700.
19. When ISEARCH=0 (and ISTYP=0 in default on BCBODY), the search order is from lower BCBODOY ID to higher one to create the first set of contact constraints and then add the constraints in the search order from higher BCBODY ID to lower one as long as they are not in conflict with the first set.

When ISEARCH=2, the program looks into the smallest element edge at the outer boundary (and the smallest thickness in case of shell elements) of each BCBODY. Then, the search order of the two deformable contact bodies is determined by the following rule when ID1 < ID2

CL1= Min(1/20 of the smallest edge, 1/4 of the smallest thickness) of BCBODY ID1

CL2= Min(1/20 of the smallest edge, 1/4 of the smallest thickness) of BCBODY ID2

CL1 and CL2 refers to characteristic length of BCBODY ID1 and ID2.

The search order is from lower BCBODY ID1 to higher BCBODY ID2 if  $CL1 \leq 1.05 * CL2$ .

Otherwise, if  $CL1 > 1.05 * CL2$  the search order is from BCBODY ID2 to BCBODY ID1.

20. Fields ISEARCH, DQNEAR and "BKGL" are not supported in segment to segment contact analysis.

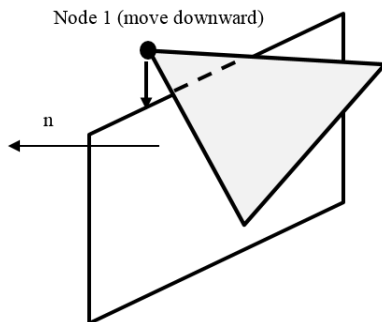

21. If STKSLP is set to 0.0 (Default), the sticking stiffness  $K1$  is equal to the maximum friction force ( $\mu \cdot F_{NORMAL}$ , where  $\mu$  is the friction coefficient) divided by the maximum sticking displacement. Otherwise,  $K1$  is equal to the maximum friction force divided by the value of STKSLP.
22. When the initial stress-free (ICoord=1), Node-to-Seg updates model geometry to close the gap, nodes are projected onto the contact body; but Seg-to-Seg treats initial stress-free as pre-stress in the equation without geometry update, no node projection is considered.
23. When METHOD=RELLIPS is used, BCGRID or BCMATL are only available for SECNDRY body and BCELIPS is only available for PRIMARY body. When BCMATL is used, the MATRIG id or RBE2 id are only acceptable.
24. The options TOP/BOTTOM are useful in the following cases:
  - a. When a secondary node initially is located on the primary face (see the picture below), the contact situation is uniquely defined, only if the TOP or BOTTOM side of the primary surface is defined:
 

SIDE=TOP case:

- b. When hooking of secondary nodes on the wrong side of a primary face might occur. This often is the case when the primary face is at the edge of a shell element structure:
 

SIDE=BOTTOM case: penetration of node 1 (SIDE=BOTH: no penetration of node 1)

25. Recommended usage of WEIGHT:

SECNDRY	PRIMARY	WEIGHT
Deformable	Deformable	BOTH
Deformable	Rigid	SECNDRY
Rigid	Deformable	PRIMARY
Rigid	Rigid	NONE

Default setting when BCELIPS is used in SECNDRY or PRIMARY:

SECNDRY	PRIMARY	WEIGHT
Non-BCELIPS	BCELIPS	SECNDRY
BCELIPS	Non-BCELIPS	NONE
	BCELIPS	

## BCTABLE - Glued Option

Defines a Contact Table for Permanently Glued Contact

Defines a glued contact used in SOLs 101, 103, 105, 107, 108, 109, 110, 111, 112, 200 and SOL 400 for the permanently-glued or general contact.

Format: (SOLs 101, 103, 105, 107, 108, 109, 110, 111, 112, 200 and 400 only)

1	2	3	4	5	6	7	8	9	10
BCTABLE	ID			NGROUP	COPTS	COPTM			
	“SECNDRY”	IDSEC1	ERROR			CINTERF	IGLUE		
		ISEARCH	ICOORD						
		“FBSH”		BIAS	SLIDE		COPTS1	COPTM1	
	“PRIMARY”	IDPRIM1	IDPRIM2	IDPRIM3	IDPRIM4	IDPRIM5	IDPRIM6	IDPRIM7	
		IDPRIM8	IDPRIM9	...					

Examples:

BCTABLE	101			2	61	61			
	SECNDRY	20	0.002		0.2		1		
		1							
		FBSH		0.01			60	60	
	PRIMARY	31	32	33					
	SECNDRY	40					1		
	PRIMARY	51	52	53	54				

Describer	Meaning
ID	Identification number of a BCTABLE entry to be selected by BCONTACT Case Control command. See Remark 5. for the general contact. Case Control, BCONTACT=ALLBODY, cannot be used for the permanently glued contact. See Remark 1. (Integer ≥ 0; Required)
NGROUP	Flag to indicate the number of pairs of “SECNDRY” and “PRIMARY” entries in the continuation lines. (Integer > 0; Required)
COPTS1, COPTM	Flag to indicate how secondary and primary surfaces may contact. See Remark 6. for the general contact.
“SECNDRY”	Indicates that this line defines the secondary or touching body and its parameters.
IDSEC1	Identification number of a BCBODY Bulk Data entry defining the touching body. (Integer > 0; Required)
ERROR	Distance below which a node is considered touching a body. When this field is left blank or 0.0, the value is taken from BCPARA = 0, ERROR, if it is specified. Otherwise, Nastran automatically calculates the value. See the Bulk Data entry <a href="#">BCPARA, 1333</a> for more details. (Real)

Describer	Meaning						
CINTERF	Interference closure amount, normal to the contact surface. For CINTERF > 0.0, overlap between bodies, CINTERF < 0.0, gap between bodies. (Real; Default = 0.0)						
IGLUE	<p>Flag to activate the glue options. See the descriptions of various options in BCTABLE for the general contact. This field must be specified for the glued contact. See Remark 4. (Integer &gt; 0; Required).</p> <ol style="list-style-type: none"> <li>1. Activates the glue option. In the glue option, all degrees-of- freedom of the contact nodes are tied in case of deformable-deformable contact once the node comes in contact. The relative tangential motion of a contact node is zero in case of deformable-rigid contact. This option is recommended when there is no gap or overlap between contact surfaces or initial stress free contact is specified.</li> <li>2. Activates a special glue option to insure that there is no relative tangential and normal displacement when a node comes into contact. An existing initial gap or overlap between the node and the contacted body will not be removed, as the node will not be projected onto the contacted body. To maintain an initial gap, ERROR should be set to a value slightly larger than the physical gap.</li> <li>3. Insures full moment carrying glue when shells contact. This option is recommended when moments are important and there is no gap or overlap between contact surfaces or initial stress free contact is specified.</li> <li>4. Insures full moment carrying glue when shells contact. The node will not be projected onto the contact body and an existing initial gap or overlap between the node and the contacted body will not be removed, as the node will not be projected onto the contacted body.</li> </ol>						
ISEARCH	<p>Option for contact searching order, from a secondary (touching) to a primary (touched) body or visca versa, for deformable contact. See the options in BCTABLE for the general contact. (Integer; Default = 0)</p> <table border="0"> <tr> <td data-bbox="482 1211 571 1237">0</td> <td data-bbox="571 1211 1330 1307">(Double orders search) 0(Double orders search) the search order is from lower BCBODOY ID's to higher ones first. Then it searches the opposite order. See Remark 19. in BCTABLE.</td> </tr> <tr> <td data-bbox="482 1315 571 1341">1</td> <td data-bbox="571 1315 1330 1341">(Single order search) the searching order is from Secondary to Primary</td> </tr> <tr> <td data-bbox="482 1350 571 1376">2</td> <td data-bbox="571 1350 1330 1428">(Single order search) let the program decide which search order. See Remark 19. in BCTABLE.</td> </tr> </table>	0	(Double orders search) 0(Double orders search) the search order is from lower BCBODOY ID's to higher ones first. Then it searches the opposite order. See Remark 19. in BCTABLE.	1	(Single order search) the searching order is from Secondary to Primary	2	(Single order search) let the program decide which search order. See Remark 19. in BCTABLE.
0	(Double orders search) 0(Double orders search) the search order is from lower BCBODOY ID's to higher ones first. Then it searches the opposite order. See Remark 19. in BCTABLE.						
1	(Single order search) the searching order is from Secondary to Primary						
2	(Single order search) let the program decide which search order. See Remark 19. in BCTABLE.						
ICOORD	Enter 1 to modify the coordinates of a node in contact with a deformable body so that stress-free initial contact can be obtained. Enter 2 to extend the tangential error tolerance at sharp corners of deformable bodies to delay sliding off a contacted segment. Enter 3 to have both 1 and 2 active. (Integer; Default = 0)						
"FBSH"	Character string used to introduce BIAS, COPTS1, and COPTM1.						

Describer	Meaning
BIAS	Contact tolerance bias factor. If this field is left blank, the default is the BIAS of the BCPARA entry. A nonblank entry will override the BIAS entered on the BCPARA entry. Note 0.0 is not default, and will override the BIAS on BCPARA. SYSTEM(758)=1 will set 0.0 same as blank. ( $0.0 \leq \text{Real} \leq 1.0$ )
SLIDE	Delayed slide off distance. This entry should not be made unless ICOORD $\geq 2$ (see above). When using the delayed slide off option, a node sliding on a segment will slide off this segment only if it passes the node (2-D) or edge (3-D) at a sharp corner over a distance larger than the delayed slide off distance. By default, the delayed slide off distance is related to the dimensions of the contacted segment by a 20 percent increase of its isoparametric domain. (Real; Default = 0.2)
COPTS1, COPTM1	Flag to indicate how individual pair of secondary and primary contact surfaces may contact. These two fields override COPTS and COPTM. See Remark 6.
“PRIMARY”	Indicates the start of the list of bodies touched by touching body IDSEC1.
IDPRIMi	Identification numbers of BCBODY Bulk Data entries defining touched bodies. (Integer > 0; Required)

#### Remarks:

1. This BCTABLE entry is tailored specifically for what we called the permanently-glued contact (or tied contact), from the entry of BCTABLE for the general contact, where the glued is an option in the approaching-and-touched contact. Most of the descriptions and remarks on the fields in this entry can be found in the BCTABLE for the general contact.
2. Permanent glued contact for small rotation condition is defined when all IGLUE fields of BCTABLE, reference by the very first loadcase, (the 1st STEP of the 1st SUBCASE in SOL 400 or the 1st SUBCASE in others) is set to larger than 0, IGLUE(>0). In BCPARA with ID=0, the value of NLGLUE may not be 1.

For large deformation and large rotation condition, permanent glued contact is activated by negative IGLUE (<0) and works in corresponding subcase or step in the corresponding subcase or step where it is defined, no matter what is set (1 or 0). This type of permanent glued contact with large deformation and large rotation may be applied together with combination of general glued contact and touching contact. IGLUE will be changed to negative automatically if SYSTEM(758)=2 when Permanently Glued setting is found with large rotation/deformation effect turned on.

3. The MPC equations internally created for the glued contact can be printed out in Nastran standard punch file by using Case Control command, NLOPRM MPCPCH=BEGN.
4. IGLUE= $\pm 2$  or  $\pm 4$  is favorable to passing the GROUNDCHECK. The initial stress-free contact is also available to preserve the six rigid-body modes with IGLUE = 1 or 3.
5. For SOLs 101 and 400, the BCTABLE with ID=0 will be used in loadcase automatically that does not need a corresponding Case Control command BCONTACT=0. The loadcase 0 is purely elastic and it can also be used to (1) move rigid contact bodies so that they just touch flexible contact bodies, and/or (2) remove any prestressed condition by adjusting the coordinates of the active nodes, which

are the Grid Points on the surface of all deformable BCBODY's. To place an entry in any physical loadcase (SUBCASE or STEP), the ID must be selected by the Case Control command BCONTACT=ID. When BCONTACT=ALLBODY, there is no ID of BCTABLE specified; therefore, the default values of all entries of BCTABLE are assumed.

- COPTS, COPTM COPTS1 and COPTM1 are packed numbers designating how the surfaces may contact using the formula

$$COP_{xxx}=A+10*B+1000*C$$

where the following codes apply:

A: the outside of the solid elements in the body

- = 1: the outside will be in the contact description (Default)

B (flexible bodies): the outside of the shell elements in the body

- = 1: both top and bottom faces will be in the contact description, thickness offset will be included (Default)
- = 2: only bottom faces will be in the contact description, thickness offset will be included
- = 3: only bottom faces will be in the contact description, shell thickness will be ignored
- = 4: only top faces will be in the contact description, thickness offset will be included
- = 5: only top faces will be in the contact description, shell thickness will be ignored
- = 6: both top and bottom faces will be in the contact description, shell thickness will be ignored

Note: The choice B = 6 for both bodies in a contact combination is only meaningful for glued contact. If in such cases separation is allowed, separated nodes will not come into contact anymore, unless a new CONTACT TABLE is defined to reset the value of B.

B (rigid bodies): the rigid surface

- = 1: the rigid surface should be in the contact description (Default)

C (flexible bodies): the edges of the body

- = 1: only the beam/bar edges are included in the contact description (Default)
- = 10: only the free and hard shell edges are included in the contact description
- = 11: both the beam/bar edges and the free and hard shell edges are included in the contact description

Note that C has no effect if beam-to-beam contact is **not** switched on (BEAMB ≠ 1 on BCPARA)

- It is not supported that a permanently-glued contact is used to glue a deformable body to a rigid one. If it is a SOL 101 or SOL 400 job, the general contact with glued option must be performed.

## BCTABL1 Defines a Contact Table

BCTABL1 specifies a list of contact pairs through the BCONECT option for SOLs 101, 103, 105, 107, 108, 109, 110, 111, 112, 200, 400 and 700. Only SOL 101, 400 and 700 can support all contact types: touching contact, glued, step glue and permanent glue (see [Chapter 7: Contact Types](#) of *Nastran SOL 400 Getting Started Guide*). Note that SOL 700 calls it “tie” contact to glue (also step glue or permanent glue). SOL 103, 105, 107 - 112 and standard 200 can only support permanent glue. When SOL 400 optimization, it can support all contact types. This contact table is activated in the BCONTACT Case Control command.

Format:

1	2	3	4	5	6	7	8	9	10
BCTABL1	BCID	ID1	ID2	ID3	ID4	ID5	ID6	ID7	
	ID8	ID9	-etc.-						

Examples:

BCTABL1	2	198	62	75	8	159	31	82	
	17								

BCTABL1	0	23	56						
---------	---	----	----	--	--	--	--	--	--

BCTABL1	5	31	35	THRU	40	163	THRU	169	
	1077	1088							

Describer	Meaning
BCID	Unique identification number referenced by a BCONTACT Case Control command.  See Remark 3. (Integer ≥ 0; default=0)
IDi	Identification number of BCONECT entry (Integer > 0 or “THRU”; ID1 is required). See Remark 4. and 5.

Remarks:

1. BCTABL1 defines surface contact. If BCTABL1 does not exist, the Case Control command BCONTACT=BCID may refer to the BCONECT Bulk Data entry directly.
2. If neither BCTABL1 nor BCONECT is given, the default for contact analysis is assumed, every body detects the possibility of contact relative to all other bodies and itself if it is a deformable body. If BCTABL1 or BCONECT is given, the default for every body is overwritten. The touching body does not contact itself unless requested. When the touched body is deformable, double-sided contact is applied by default. BCTABL1 or BCONECT is useful for deactivating or activating bodies to reduce computational effort and to change contact conditions between subcases.

3. For SOLs 101 and 400, the BCTABL1 or BCONECT with ID=0 will be used in loadcase 0 automatically that does not need a corresponding Case Control command BCONTACT=0. The loadcase 0 is purely elastic and it can also be used to (1) move rigid contact bodies so that they just touch flexible contact bodies, and/or (2) remove any prestressed condition by adjusting the coordinates of the active nodes, which are the Grid Points on the surface of all deformable BCBODY1's. To place an entry in any physical loadcase (SUBCASE or STEP), the BCID must be selected by the Case Control command BCONTACT=BCID or BCONECT=BCID. When BCONTACT=ALLBODY, there is no BCID of BCTABL1 or BCONECT specified; therefore, the default values of all entries of BCONPRG and BCONPRP are assumed. Case Control command BCONTACT=ALLBODY cannot be used for permanently glued contact.
4. When the "THRU" option is used, all BCONECT entries associated with intermediate BCONECT IDs must exist. The word "THRU" may not appear in field 3 or 9 (2 or 9 for continuations).
5. If Modules are present then this entry may only be specified in the main Bulk Data section.

**BCTRIM****Defines the Geometry of a Trimming Curve**

Defines the geometry of a trimming curve used to specify a NURBS for a rigid contact body.

Format:

1	2	3	4	5	6	7	8	9	10
BCTRIM	IDtrim	NPTUtrim	NORUtrim	NSUBtrim					
	“COORD”	Xisoparam1	Yisoparam1	Xisoparam2	Yisoparam2	-etc.-			
	“HOMO”	Homot1	Homot2	Homot3	-etc.-				
	“KNOT”	Knott1	Knott2	Knott3	-etc.-				

Examples:

BCTRIM	202	2	2	50					
	COORD	0.0	0.0	1.0	0.0				
	HOMO	1.	1.						
	KNOT	0.0	0.0	1.	1.				

Describer	Meaning
IDtrim	Unique trimming vector identification number referenced by a BCNURBS entry. (Integer > 0)
NPTUtrim	Number of control points for this trimming vector. (Integer > 0)
NORUtrim	Order for this trimming vector. (Integer > 0)
NSUBtrim	Number of subdivisions for this trimming vector. (Integer > 0)
“COORD”	Indicate the start of the list of isoparametric coordinates of points.
Xisoparam1, Yisoparam1, Xisoparam2, Yisoparam2, etc.	First and second coordinates of point in isoparametric space. There must be NPTUtrim set of (Xisoparam, Yisoparam) entries. (Real)
“HOMO”	Indicate the start of the list of homogeneous coordinates of this trimming vector.
Homot1, Homot2, Homot3, etc.	Homogeneous coordinates of this trimming vector. There must be NPTUtrim entrie. (Real; 0.0 to 1.0)
“KNOT”	Indicate the start of the list of knot vectors of this trimming vector.
Knot1, Knot2, Knot3, etc.	Knot vectors of this trimming vector. There must be (NPTUtrim+NORUtrim) entries. (Real; 0.0 to 1.0)

Remarks:

1. BCTRIM is referenced by a BCNURBS entry to define the trimming curve of a NURBS for a rigid contact body.

## BDYLIST Fluid Boundary List

Defines the boundary between a fluid and a structure.

Format:

1	2	3	4	5	6	7	8	9	10
BDYLIST	RHO	IDF1	IDF2	IDF3	IDF4	IDF5	IDF6	IDF7	
	IDF8	-etc.-							

Example:

BDYLIST	.037	AXIS	432	325	416	203	256	175	
---------	------	------	-----	-----	-----	-----	-----	-----	--

Describer	Meaning
RHO	Fluid mass density at boundary. (Real $\geq 0.0$ or blank; Default is DRHO on the AXIF entry)
IDF1	Identification number of a RINGFL entry. (Integer $> 0$ or Character = "AXIS" or "LAXIS") See Remark 7.
IDF2-IDFi	Identification number of additional RINGFL entries. (Unique Integers $> 0$ )

Remarks:

1. This entry is allowed only if an AXIF entry is also present.
2. Each entry defines a boundary if  $RHO \neq 0.0$ . The order of the points must be sequential with the fluid on the right with respect to the direction of travel.
3. The word "AXIS" defines an intersection with the polar axis of the fluid coordinate system.
4. There is no limit to the number of BDYLIST entries specified. If the fluid density varies along the boundary, there must be one BDYLIST entry for each interval between fluid points.
5. The BDYLIST entry is not required and should not be used to specify a rigid boundary where structural points are not defined. Such a boundary is automatically implied by the omission of a BDYLIST.
6. If  $RHO=0.0$ , no boundary matrix terms will be generated to connect the GRIDB points to the fluid. This option is a convenience for structural plotting purposes. GRIDB points may be located on a fluid ring (RINGFL entry) only if the rings are included in a BDYLIST.
7. If the polar axis of the fluid coordinate system is to occur at the first point use AXIS. If the polar axis of the fluid coordinate system is to occur at the last point use LAXIS.

## BDYOR

### CHBDYi Entry Default Values

Defines default values for the CHBDYP, CHBDYG, and CHBDYE entries.

Format:

1	2	3	4	5	6	7	8	9	10
BDYOR	TYPE	IVIEWF	IVIEWB	RADMIDF	RADMIDB		PID	GO	
	CE	E1	E2	E3					

Example:

BDYOR	AREA4	2	2	3	3		10		
-------	-------	---	---	---	---	--	----	--	--

Describer	Meaning
TYPE	Default surface type. See Remark 2. (Character)
IVIEWF	Default identification number of front VIEW entry. (Integer > 0 or blank)
IVIEWB	Default identification number of back VIEW entry. (Integer > 0 or blank)
RADMIDF	Default identification number of a RADM entry for front face. (Integer ≥ 0 or blank)
RADMIDB	Default identification number of a RADM entry for back face. (Integer ≥ 0 or blank)
PID	Default PHBDY property entry identification number. (Integer > 0 or blank)
GO	Default orientation grid point. (Integer ≥ 0; Default = 0)
CE	Default coordinate system for defining the orientation vector. (Integer ≥ 0 or blank)
E1, E2, E3	Default components of the orientation vector in coordinate system CE. The origin of this vector is grid point G1 on a CHBDYP entry. (Real or blank)

Remarks:

1. Only one BDYOR entry may be specified in the Bulk Data Section.
2. TYPE specifies the type of CHBDYi element surface; allowable values are: POINT, LINE, REV, AREA3, AREA4, ELCYL, FTUBE, AREA6, AREA8, and TUBE.
3. IVIEWF and IVIEWB are specified for view factor calculations only (see VIEW entry).
4. GO is only used from BDYOR if neither GO nor the orientation vector is defined on the CHBDYP entry and GO is > 0.
5. E1, E2, E3 is not used if GO is defined on either the BDYOR entry or the CHBDYP entry.

## BEADVAR Topography Design Variable

Defines design region for topography (bead or stamp) optimization.

Format:

1	2	3	4	5	6	7	8	9	10
BEADVAR	ID	PTYPE	PID	MW	MH	ANG	BF	SKIP	
	“DESVAR”	NORM/XD	YD	ZD	CID	XLB	XUB	DELXV	
	“GRID”	NGSET	DGSET						

Example using NORM:

BEADVAR	10	PSHELL	101	10.0	20.0	70.0			
---------	----	--------	-----	------	------	------	--	--	--

Example using “DESVAR” and “GRID”:

BEADVAR	10	PSHELL	101	10.0	20.0	70.0		NONE	
	DESVAR	2.0	3.0	4.0		-1.0	1.0		
	GRID	100							

Descriptor	Meaning
ID	Unique topography design region identification number. (Integer > 0)
PTYPE	Property entry type. Used with PID to identify the element nodes to be designed. (Character: “PSHELL”, “PSHEAR”, “PCOMP”, or “PCOMPG”.)
PID	Property entry identifier. See Remark 1. (Integer > 0)
MW	Minimum bead width. This parameter controls the width of the beads. The recommended value is between 1.5 and 2.5 times the average element width. See Remark 2. (Real > 0.0)
MH	Maximum bead height (Real > 0.0). This parameter sets the maximum height of the beads when XUB=1.0 (as Default). See Remark 2.
ANG	Draw angle in degrees (0.0 < Real < 90.0). This parameter controls the angle of the sides of the beads. The recommended value is between 60 and 75 degrees.
BF	Buffer zone ('yes' or 'no'; Default='yes'). This parameter creates a buffer zone between elements in the topography design region and elements outside the design region when BF='yes'. See Remark 3.

Describer	Meaning
SKIP	Boundary skip (“bc”, “load”, “both”, or “none”; Default = “both”). This parameter indicates which element nodes are excluded from the design region. “bc” indicates all nodes referenced by “SPC” and “SPC1” are omitted from the design region. “load” indicates all nodes referenced by “FORCE”, “FORCE1”, “FORCE2”, “MOMENT”, “MOMENT1”, “MOMENT2”, and “SPCD” are omitted from the design region. “both” indicates nodes with either “bc” or “load” are omitted from the design region. “none” indicates all nodes associated with elements referencing PID specified in field 4 are in the design region.
“DESVAR”	Indicates that this line defines bead design variables that are automatically generated.
NORM/XD, YD, ZD	Bead vector (draw direction). Norm indicates the shape variables are created in the normal directions to the elements. If XD, YD, and ZD are provided, the shape variables are created in the direction specified by the xyz vector defined by XD/YD/ZD that is given in the basic coordinate system or CID. See Remark 4. (Character or Real; Default = blank = norm).
CID	Coordinate system ID used for specifying draw direction (Blank or Integer > 0; Default = blank = basic coordinate system)
XLB	Lower bound. (Real < XUB or blank; Default = blank=0.0). This ensures the lower bound on grid movement equal to XLB*MH. See Remark 5.
XUB	Upper bound. (Real > XLB or blank; Default = 1.0). This sets the upper bound of the beads equal to XUB*MH. See Remark 5.
DELXV	Fractional change allowed for the design variable during approximate optimization. See Remark 3. (Real > 0.0; Default = 0.2)
“GRID”	Indicates this line defines what element nodes can be added and/or removed from topography design regions.
NGSET	All grids listed on a Bulk Data entry SET1 = NGSET are removed from topography design regions.
DGSET	All grids listed on a Bulk Data entry SET1 = DGSET are added to topography design regions.

#### Remarks:

1. Multiple BEADVAR’s are allowed in a single file. Combined topometry, topology, topography, sizing, and shape optimization is supported in a single file.

2. The user can provide allowable bead dimensions.

Bead Dimensions

3. It is recommended to set buffer zone = yes to maintain a good quality of mesh during topography optimization.

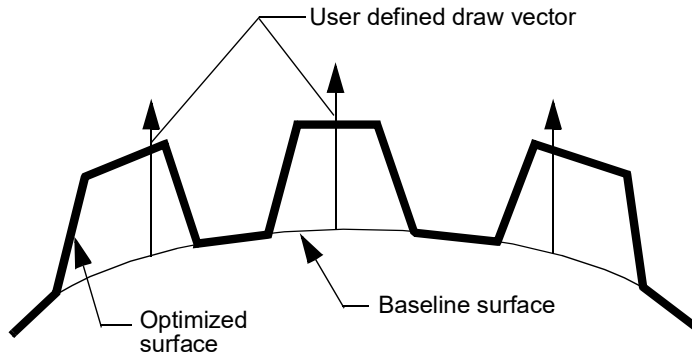

4. The grids moves in the normal direction. All element grids referenced by one BEADVAR entry must follow the right hand rule.

Element Normal

User's Provided Draw Direction

- To force the grids to move only in the positive bead vector direction (one side of the surface), use  $XLB = 0.0$ . To force the grids to move only in the negative bead vector direction (another side of the surface), use  $XUB = 0.0$ . To allow grids to move in both positive and negative bead vector directions, use  $XLB < 0.0$  and  $XUB > 0.0$ . For example,

(a)  $XLB = 0.0$  and  $XUB = 1.0$     (b)  $XLB = -1.0$  and  $XUB = 0.0$     (c)  $XLB = -1.0$  and  $XUB = 1.0$

- The jobname.h5 file (created by specifying MDLPRM,HDF5,0 in the bulk data input) has topography optimization results (shape changes) that can be viewed in Patran. The text file jobname.pch also has updated grid coordinates that can be copied to the original file, replace the original grids, and imported to Patran and other post-processors to view topography optimization results.
- The BEADVAR entry cannot be used with thermal loads.

## BEAMOR CBEAM Entry Default Values

Defines default values for field 3 and fields 6 through 9 of the CBEAM entry.

Format:

1	2	3	4	5	6	7	8	9	10
BEAMOR		PID			X1	X2	X3	OFFT	

Example:

BEAMOR		39			0.6	2.9	-5.87	GOG	
--------	--	----	--	--	-----	-----	-------	-----	--

Alternate Format and Example:

BEAMOR		PID			G0			OFFT	
--------	--	-----	--	--	----	--	--	------	--

BEAMOR		39			86			GOG	
--------	--	----	--	--	----	--	--	-----	--

Describer	Meaning
PID	Property identification number of the PBEAM or PBCOMP entry. (Integer > 0 or blank)
X1, X2, X3	Components of orientation vector $\vec{v}$ , from GA, in the displacement coordinate system at GA (default), or in the basic coordinate system. See Remark 5. (Real)
G0	Alternate method to supply the orientation vector $\vec{v}$ , using grid point G0. Direction of $\vec{v}$ is from GA to G0. $\vec{v}$ is then translated to End A. (Integer > 0; G0 ≠ GA or GB on CBEAM entry)
OFFT	Offset vector interpretation flag. See Remark 5. (Character or blank)

Remarks:

1. The contents of fields on this entry will be assumed for any CBEAM entry with corresponding fields that are blank.
2. Only one BEAMOR entry is allowed.
3. For an explanation of beam element geometry, see the CBEAM entry description.
4. If X1 or G0 is integer, G0 is used. If X1 or G0 is blank or real, then X1, X2, X3 is used.
5. OFFT in field 9 is a character string code that describes how the offset and orientation vector components are to be interpreted. By default (string input is GGG or blank), the offset vectors are measured in the displacement coordinate systems at grid points A and B and the orientation vector is measured in the displacement coordinate system of grid point A. At user option, the offset vectors can be measured in an offset system relative to grid points A and B, and the orientation vector can be measured in the basic system as indicated in the following table:

String	Orientation Vector	End A Offset	End B Offset
GGG	Global	Global	Global
BGG	Basic	Global	Global
GGO	Global	Global	Offset
BGO	Basic	Global	Offset
GOG	Global	Offset	Global
BOG	Basic	Offset	Global
GOO	Global	Offset	Offset
BOO	Basic	Offset	Offset

Any attempt to specify invalid combinations results in a bulk data entry input error message. For example, a value of OOO (indicating offset and orientation vectors are specified in an offset reference system) results in a fatal error since the orientation vector cannot be specified in an offset system. The offset system x-axis is defined from GA to GB. The orientation vector  $\hat{v}$  and the offset system x-axis are then used to define the z and y axes of the offset system. (Note: The character “O” in the table replaces the obsolete character “E”.)

## BFRIC

## Contact Friction

Defines frictional properties between two bodies in contact using the slideline contact in SOL 106 and SOL 129. SOL 400 is the recommended approach for contact analysis.

Format:

1	2	3	4	5	6	7	8	9	10
BFRIC	FID		FSTIF	MU1					

Example:

BFRIC	33			0.3					
-------	----	--	--	-----	--	--	--	--	--

Descriptor	Meaning
FID	Friction identification number. See Remark 1. (Integer > 0)
FSTIF	Frictional stiffness in stick. See Remarks 2. and 3. (Real > 0.0; Default = automatically selected by the program)
MU1	Coefficient of static friction. (Real > 0.0)

Remarks:

1. This identification number must be unique with respect to all other friction identification numbers. This is used in the FRICID field of BCONP Bulk Data entry.
2. The value of frictional stiffness requires care. A method of choosing its value is to divide the expected frictional strength ( $MU1 \cdot \text{expected normal force}$ ) by a reasonable value of the relative displacement that may be allowed before slip occurs. The relative value of displacement before slip occurs must be small compared to expected relative displacements during slip. A large stiffness value may cause poor convergence, while too small a value may cause poor accuracy.  
Frictional stiffness specified by the user is selected as the initial value. If convergence difficulties are encountered during the analysis, the frictional stiffness may be reduced automatically to improve convergence.
3. The stiffness matrix for frictional slip is unsymmetric. However, the program does not use the true unsymmetric matrix. Instead the program uses only the symmetric terms. This is to avoid using the unsymmetric solver to reduce CPU time.

BIAS

MESH Bias Definition

Specifies a variation of the mesh-size in one direction for use in the MESH entry in SOL 700. The MESH entry can create a biased or non-uniform mesh. A uniform mesh consists of a number of planes separated by a fixed distance, but for a biased mesh the distance between subsequent planes can differ. The BIAS definition allows specifying the locations of planes in one direction. For a number of intervals the density of planes can be specified.

Format:

1	2	3	4	5	6	7	8	9	10
BIAS	BID								
	X0	GROWTH0	N0	DXS0	DXE0				
	X1	GROWTH1	N1	DXS1	DXE1				
	Xi	GROWTHi	Ni	DXSi	DXEi				

Example:

BIAS	100								
	-4.5	0.2	15						
	-1	1	20						
	1			0.1	0.46				

Describer	Meaning
BID	Unique bias number. Must be referenced from MESH entry. (Integer; Required)
Xi	Begin coordinate of an interval. The interval ends at the $X_{i+1}$ entry. (Real; Default = 0.0)
GROWTHi	GROWTHi is the ratio between the step size at the beginning of the interval and at the end of the interval. If it is smaller than 1.0 then the mesh refines when going from the beginning of the interval to the end of the interval. (Real>0) See Remarks 1.- 3.
Ni	Ni is the number of elements inside the interval. (Integer>0) See Remarks 1.- 3.
DXSi	DXSi is the start element size of the interval. (Real>0) See Remarks 1.- 3.
DXEi	DXEi is the end element size of the interval. (Real>0) See Remarks 1.- 3.

Remarks:

1. The begin point of the first interval has to be equal to the X0 field of the MESH entry and may be left unspecified. The end point of the last interval is given by X0 + DX as specified by the MESH entry. In the example above, the first interval is given by [-4.5,-1], the second one by [-1,1] and the last one by [1,4.5], assuming that X0 + DX = 4.5 on the MESH entry that references the bias definition from IBIDX.

2. To define the bias in an interval four fields are available. These are GROWTHi, Ni, DXSi and DXEi. To specify the bias inside an interval two of these four variables have to be specified. The other two variables have to be left blank. In addition the mesh size can be chosen constant by defining Ni and leaving GROWTHi, DXSi and DXEi blank.

This gives seven methods of specifying a bias;

1. Define GROWTHi and Ni. DXSi and DXEi have to be left blank.
2. Define DXSi and DXEi. GROWTHi and Ni have to be left blank.
3. Define DXSi and Ni. GROWTHi and DXEi have to be left blank.
4. Define DXEi and Ni. GROWTHi and DXSi have to be left blank.
5. Define GROWTHi and DXSi. Ni and DXEi have to be left blank.
6. Define GROWTHi and DXEi. Ni and DXSi have to be left blank.
7. Only define Ni and leave GROWTHi, DXSi and DXEi blank.

For method 2 it can happen that the biased elements do not exactly fit into the interval.

To get a good fit a small change to defined start and end step sizes is made. These changes in general amount to a few percents.

For method 5 and 6 a small change to the specified growth factor can be made so that the biased elements fit into the interval.

3. The algorithm for each method first determines an appropriate growth factor so that the biased elements fit into the interval. In addition the number of planes is determined. For method 2, 3 and 4 this is done by using bisection. The location of the planes is given by:

$$X(i) = X(i - 1) + \Delta X(i - 1)$$

$$\Delta X(i) = GROWFAC \times \Delta X(i - 1)$$

$$GROWTHi = GROWFAC^{N-1}$$

Here X(i) denotes the location of the Euler plane,  $\Delta X_i$  denotes the step size of the interval and N denotes the number of Euler planes. The index i runs across the Euler planes. The variable GROWFAC denotes the grow factor between planes within the interval. The locations of the planes X(i) are written to the OUT file as part of MESH output. In addition, the growth of the element sizes is written out in the next column. This is given as the ratio in element size between the layer of elements to the right of the plane and to the left of the plane. Let x0, x1 and x2 denote three subsequent planes, then the element size to the left of the x1-plane is given x1-x0 and to the right it is given by x2-x1. The ratio by which the element size grows if one goes across the x1-plane is:

$$\frac{X2 - X1}{X1 - X0}$$

To get physically meaningful results, this value should not exceed 1.3 or be smaller than 0.7 .

Within each interval the ratio in element size equals GROWFAC. But the element size between two adjacent elements that are in two different intervals can differ from GROWFAC. Here each interval has a distinct GROWFAC variable.

For both method 2, 5 and 6 The growth factor GROWFAC and start and end step sizes that are actually used can be obtained from this plane summary in the OUT file. In this summary for each plane a growth factor and step size is specified.

Also the total number of elements is written out.

## BJOIN

Defines (multiple) pairs of grid points of one-dimensional and/or shell elements to be joined during the analysis in SOL 700. When the failure criterion for a grid-point pair is satisfied, the grid-point pair is removed from the join and the grid-point motion is computed for the separate grid points. The join ceases to exist when all pairs of the join have failed, after which all of the grid points of the join are treated as separate grid points.

Format:

1	2	3	4	5	6	7	8	9	10
BJOIN	BID	SID	TOL	TYPE		SN		SS	
					MULTI				
		TF							

Example:

BJOIN	1	2		SPOTWELD		1.E3		1.E3	
-------	---	---	--	----------	--	------	--	------	--

Describer	Meaning	Type	Default
BID	BJOIN number.	Integer > 0	Required
SID	BCGRID ID of set of grid points.	Integer > 0	Required
TOL	Tolerance used in matching grid point pairs.	Real > 0.0	1.E-4
TYPE	Type of failure criterion. SPOTWELD Spotweld-type failure.	C	SPOTWELD
SN	Failure force in tension.	Real > 0.0	No failure
SS	Failure force in shear.	Real > 0.0	No failure
MULTI	Multiple breakable joins, where the grid points must be entered as a sequence of BJOIN pairs. YES The grid points are entered on the BCGRID entry as a sequence of BJOIN pairs. NO The code creates BJOIN pairs for every two grid points entered on the BCGRID entry when the grid point positions fall within the tolerance (TOL).	C	YES
TF	Failure time for nodal constraint set.	Real	1.0E20

**Remarks:**

1. Nodes connected by a spot weld cannot be members of another constraint set that constrain the same degrees-of-freedom, a tied interface, or a rigid body, i.e., nodes cannot be subjected to multiple, independent, and possibly conflicting constraints. Also, care must be taken to ensure that single point constraints applied to nodes in a constraint set do not conflict with the constraint sets constrained degrees-of-freedom.
2. When the failure time,  $TF$ , is reached the spot weld becomes inactive and the constrained nodes may move freely.
3. Note that the shell elements do not have rotary stiffness in the normal direction and, therefore, this component cannot be transmitted.
4. For MULTI=YES, a spotweld or rivet will always be created, regardless if their distance is larger than the value of TOL. TOL will only be used for MULTI=NO.

## BLSEG                      Boundary Line Segments

Defines a curve that consists of a number of line segments via grid numbers that may come in contact with another body.

Format:

1	2	3	4	5	6	7	8	9	10
BLSEG	ID	G1	G2	G3	G4	G5	G6	G7	

Alternate Format:

BLSEG	ID	G1	"THRU"	G2	"BY"	INC			
-------	----	----	--------	----	------	-----	--	--	--

The Continuation Entry formats may be used more than once and in any order. They may also be used with either format above.

Continuation Entry Format 1:

	G8	G9	G10	G11	-etc.-				
--	----	----	-----	-----	--------	--	--	--	--

Continuation Entry Format 2:

	G8	"THRU"	G9	"BY"	INC				
--	----	--------	----	------	-----	--	--	--	--

Example:

BLSEG	15	5	THRU	21	BY	4			
	27	30	32	33					
	35	THRU	44						
	67	68	72	75	84	93			

Describer	Meaning
ID	Line segments identification number. See Remark 2. (Integer > 0)
Gi	Grid point identification numbers on a curve in a continuous topological order so that the normal to the segment points toward the other curve. See Remark 3. (Integer > 0)
INC	Grid point identification number increment. See Remark 3. (Integer or blank)

Remarks:

1. A line segment is defined between every two consecutive grid points. Thus, the number of line segments defined is equal to the number of grid points specified minus 1. A corresponding BWIDTH Bulk Data entry may be required to define the width/thickness of each line segment. If the corresponding BWIDTH is not present, the width/thickness for each line segment is assumed to be unity.

2. ID must be unique with respect to all other BLSEG entries. Each line segment has a width in 3-D sideline and a thickness in a 2-D slideline contact to calculate contact stresses. The width/thickness of each line segment is defined via BWIDTH Bulk Data entry. The ID in BLSEG must be same as the ID specified in the BWIDTH. That is, there must be a one to one correspondence between BLSEG and BWIDTH. BWIDTH Bulk Data entry may be omitted only if the width/thickness of each segment is unity.
3. For automatic generation of grid numbers, the default increment value is 1 if grid numbers are increasing or -1 if grid numbers are decreasing (i.e., the user need not specify BY and the increment value).
4. The normal to the segment is determined by the cross product of the slideline plane vector (i.e., the Z direction of the coordinate system defined in the 'CID' field of BCONP Bulk Data entry) and the tangential direction of the segment. The tangential direction is the direction from node 1 to node 2 of the line segment.
5. A curve may be closed or open. A closed curve is specified by having the last grid point identification number the same as the first grid number.
6. See BCBODY for use of BLSEG in 3D contact.

**BNDFIX****Fixed Boundary Degrees-of-Freedom**

Defines analysis set (a-set) degrees-of-freedom to be fixed (b-set) during generalized dynamic reduction or component mode synthesis calculations.

Format:

1	2	3	4	5	6	7	8	9	10
BNDFIX	ID1	C1	ID2	C2	ID3	C3	ID4	C4	

Example:

BNDFIX	2	135	14	6					
--------	---	-----	----	---	--	--	--	--	--

Describer	Meaning
IDi	Grid or scalar point identification number. (Integer > 0)
Ci	Component number. (Integer zero or blank for scalar points, or any unique combinations of the Integers 1 through 6 for grid points. No embedded blanks.)

Remarks:

1. BNDFIX and BSET entries are equivalent to each other. Either one of them or any combination of them may be employed.
2. If there are no BSETi/BNDFIXi or CSETi/BNDFREEi/BNDFRE1 entries present, all a-set points are considered fixed during component mode analysis. If there are only BSETi/BNDFIXi entries present, any a-set degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are only CSETi/BNDFREEi/BNDFRE1 entries present or both BSETi/BNDFIXi and CSETi/BNDFREEi/BNDFRE1 entries present, the c-set degrees-of-freedom are defined by the CSETi/BNDFREEi/BNDFRE1 entries, and any remaining a-set points are placed in the b-set.
3. Degrees-of-freedom specified on BSETi/BNDFIXi entries form members of the mutually exclusive b-set. They may not be specified on other entries that define mutually exclusive sets. See the [Degree-of-Freedom Sets](#) for a list of these entries.
4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.

## BNDFIX1 Fixed Boundary Degrees-of-Freedom, Alternate Form of BNDFIX Entry

Defines analysis set (a-set) degrees-of-freedom to be fixed (b-set) during generalized dynamic reduction or component mode synthesis calculations.

Format:

1	2	3	4	5	6	7	8	9	10
BNDFIX1	C	ID1	ID2	ID3	ID4	ID5	ID6	ID7	
	ID8	ID9	ID10	-etc.-					

Example:

BNDFIX1	2	135	14	6	23	24	25	26	
	122	127							

Alternate Format and Example:

BNDFIX1	C	ID1	“THRU”	ID2					
BNDFIX1	3	6	THRU	32					

Describer	Meaning
C	Component numbers. (Integer zero or blank for scalar points, or any unique combinations of the Integers 1 through 6 for grid points with no embedded blanks.)
IDi	Grid or scalar point identification numbers. (Integer > 0; For “THRU” option, ID1 < ID2)

Remarks:

1. BNDFIX1 and BSET1 entries are equivalent to each other. Either one of them or any combination of them may be employed.
2. If there are no BSETi/BNDFIXi or CSETi/BNDFREE/BNDFRE1 entries present, all a-set points are considered fixed during component mode analysis. If there are only BSETi/BNDFIXi entries present, any a-set degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are only CSETi/BNDFREE/BNDFRE1 entries present or both BSETi/BNDFIXi and CSETi/BNDFREE/BNDFRE1 entries present, the c-set degrees-of-freedom are defined by the CSETi/BNDFREE/BNDFRE1 entries, and any remaining a-set points are placed in the b-set.
3. Degrees-of-freedom specified on BSETi/BNDFIXi entries form members of the mutually exclusive b-set. They may not be specified on other entries that define mutually exclusive sets. See the [Degree-of-Freedom Sets](#) for a list of these entries.

4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.

## BNDFREE

## Free Boundary Degrees-of-Freedom

Defines analysis set (a-set) degrees-of-freedom to be free (c-set) during generalized dynamic reduction or component modes calculations.

Format:

1	2	3	4	5	6	7	8	9	10
BNDFREE	ID1	C1	ID2	C2	ID3	C3	ID4	C4	

Example:

BNDFREE	124	1	5	23	6	16			
---------	-----	---	---	----	---	----	--	--	--

Describer	Meaning
ID <sub>i</sub>	Grid or scalar point identification number. (Integer > 0)
C <sub>i</sub>	Component numbers. (Integer zero or blank for scalar points, or any unique combination of the Integers 1 through 6 for grid points with no embedded blanks.)

Remarks:

1. BNDFREE and CSET entries are equivalent to each other. Either one of them or any combination of them may be employed.
2. If there are no BSET<sub>i</sub>/BNDFIX<sub>i</sub> or CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present, all a-set points are considered fixed during component mode analysis. If there are only BSET<sub>i</sub>/BNDFIX<sub>i</sub> entries present, any a-set degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are only CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present or both BSET<sub>i</sub>/BNDFIX<sub>i</sub> and CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present, the c-set degrees-of-freedom are defined by the CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries, and any remaining a-set points are placed in the b-set.
3. Degrees-of-freedom specified on CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries form members of the mutually exclusive c-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.

**BNDFRE1** Free Boundary Degrees-of-Freedom, Alternate Form of BNDFREE Entry

Defines analysis set (a-set) degrees-of-freedom to be free (c-set) during generalized dynamic reduction or component modes calculations.

Format:

1	2	3	4	5	6	7	8	9	10
BNDFRE1	C	ID1	ID2	ID3	ID4	ID5	ID6	ID7	
	ID8	ID9	-etc.-						

Example:

BNDFRE1	124	1	5	7	6	9	12	122	
	127								

Alternate Formats and Examples:

BNDFRE1	C	ID1	“THRU”	ID2					
BNDFRE1	3	6	THRU	32					

BNDFRE1		“ALL”							
BNDFRE1		ALL							

Descriptor	Meaning
C	Component number. (Integer zero or blank for scalar points, or any unique combination of the Integers 1 through 6 for grid points with no embedded blanks)
IDI	Grid or scalar point identification number. (Integer > 0; For THRU option, ID1 < ID2)
ALL	All a-set degrees-of-freedom will be set free (included in c-set).

Remarks:

1. BNDFRE1 and CSET1 entries are equivalent to each other. Either one of them or any combination of them may be employed.
2. If there are no BSETi/BNDFIXi or CSETi/BNDFREE/BNDFRE1 entries present, all a-set points are considered fixed during component mode analysis. If there are only BSETi/BNDFIXi entries present, any a-set degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are only CSETi/BNDFREE/BNDFRE1 entries present or both BSETi/BNDFIXi and CSETi/BNDFREE/BNDFRE1 entries present, the c-set degrees-of-freedom are defined by the CSETi/BNDFREE/BNDFRE1 entries, and any remaining a-set points are placed in the b-set.
3. Degrees-of-freedom specified on CSETi/BNDFREE/BNDFRE1 entries form members of the mutually exclusive c-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.

4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.

**BNDGRID****Boundary Grid Points**

Specifies a list of grid point identification numbers on design boundaries or surfaces for shape optimization (SOL 200).

Format:

1	2	3	4	5	6	7	8	9	10
BNDGRID	C	GP1	GP2	GP3	GP4	GP5	GP6	GP7	
	GP8	-etc.-							

Example:

BNDGRID	123	41	42	43	44	45	46	47	
	49								

Alternate Format and Example:

BNDGRID	C	GP1	"THRU"	GP2					
BNDGRID	123	41	THRU	49					

Describer	Meaning
C	Component number (any unique combination of integers 1 through 6 with no embedded blanks). See Remark 1.
GPi	Shape boundary grid point identification number. (0 < Integer < 1000000; For THRU option, GP1 < GP2)

Remarks:

1. C specifies the components for the listed grid points for which boundary motion is prescribed.
2. Multiple BNDGRID entries may be used to specify the shape boundary grid point identification numbers.
3. Both fixed and free shape boundary grid point identification numbers are listed on this entry.
4. The degrees-of-freedom specified on BNDGRID entries must be sufficient to statically constrain the model.
5. Degrees-of-freedom specified on this entry form members of the mutually exclusive s-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
6. Fluid grids are not supported for BNDGRID.

## BOLT Defines the Multi-Point Constraints for a Bolt

Defines a rigid bolt by a set of MPC constraints.

Format:

1	2	3	4	5	6	7	8	9	10
BOLT	ID	GRIDC							
	TOP	GT1	GT2	GT3	GT4	GT5	GT6	GT7	
		GT8	GT9	etc.					
	BOTTOM	GB1	GB2	GB3	GB4	GB5	GB6	GB7	
		GB8	GB9	etc.					

Example:

BOLT	100	1025							
	TOP	101	102	103	104	105			
	BOTTOM	1	2	3	4	5			

Describer	Meaning
ID	Element ID of the bolt. (Integer; Required; no Default)
GRIDC	Control GRID ID where forces or displacements are applied. (Integer; no Default; Required)
TOP	Enter the character string TOP to define the start of the entry that defines all of the grids at the “top” of the bolt intersection with the structure. (Integer; no Default)
GT1, GT2, etc.	Grid IDs of the grid points at the top of the bolt intersection. (Integer; no Default)
BOTTOM	Enter the character string BOTTOM to define the start of the entry that defines all of the grids at the “bottom” of the bolt intersection with the structure (do not enter the ID for GRIDC). (Integer; no Default)
GB1, GB2, etc.	Grid IDs of the grid points at the bottom of the bolt intersection. (Integer; no Default)

Remarks:

1. The GRIDS entries of the TOP and BOTTOM keywords are open-ended.
2. GRIDC is the control grid point and usually not connected to any element.
3. (GT<sub>i</sub>, GB<sub>i</sub>) are pairs of grid on top and bottom.
4. To each pair of (GT<sub>i</sub>, GB<sub>i</sub>) and GRIDC, MPCs are created internally to all 6 DOFs. Since the GBs always belong to dependent-DOFs, they cannot be applied to any SPC, SPC1, SPCD and SPCR.
5. Same number of grid points in TOP and BOTTOM. They should be coincident but it is not required. Users who do otherwise do so at their own risk since the current design does not consider the initial offset between them.

6. Bolt loads, including enforced motion, are usually prescribed on GRIDC to represent the pre-tension, overlap or loading of the bolt. BOLT relative displacements are given in the global coordinate system of the control node.
7. Global Coordinate System may have to be defined at the Control Node if the bolt direction is not a Basic Coordinate direction and the user wants to apply the loads along the shaft of the bolt.
8. Loads in directions other than the shaft of the bolt direction are possible.
9. The internally written MPC relationship is of the form:

$$u_{GB} = u_{GT} + u_{GC}$$

10. In 3D Contact analysis, it replaces GBi (Bottom bolt segment) by GTi (Top bolt segment) on the internally generated contact surface, which makes contact surface continuous across the mesh split between them.
11. Force output is obtained through Case Control MPCFORCE.
12. The internal MPCs generated by the BOLT entry are valid for small rotations only.
13. The BOLT entry must be defined in the residual structure only.
14. Sufficient boundary conditions must be placed on the BOLT to prevent mechanisms.
15. In contact analysis, care should be taken that the preload displacement does not exceed the local element width.
16. Pretension of a BOLT is a three step process in SOL 400:

SUBCASE 1

STEP 1

- LOAD=n Applies a pretension load to the bolt on the control grid.
- SPC=m If any required to prevent motion of structure do not include the control grid.

STEP 2

- LOAD=p1 Load entry pointing to a SPCR (relative value of 0.0) and any other desired type of loading.
- SPC=q1 SPC or SPC1 includes control grid and any other desired SPC requirements.

STEP 3

- LOAD=p2 Load entry pointing to a SPCR and any other additional desired type of loading.
- SPC=q2 SPC or SPC1 includes control grid and any other additional desired SPC requirements.

17. The BOLT may also be used in SOL101 and SOL103. In this case PARAM, AUTOMSET, YES is recommended.

## BOLT1 Bolt Model

Defines an easy-to-use pre-tension bolt model that supports nonlinear analysis and large rotation. BOLT1 allows bolt forces or displacements to be applied at a layer of elements along a cross-section in the bolt, thus modeling the effect of bolt pre-tension without the need for duplicating grid points or splitting the bolt finite element mesh into top and bottom sections around the bolt cross-section. The bolt's local coordinate system and axial direction are continuously updated to track bolt rotation. Used in SOL 400 with advanced nonlinear elements only.

Format:

1	2	3	4	5	6	7	8	9	10
BOLT1	ID	GRIDC	FORM	N1	N2	N3	OFFSET	IDTYPE	
	"ELEM"	E1	E2	E3	E4	E5	E6	E7	
		E8	E9	etc.					
	"GRID"	G1	G2	G3	G4	G5	G6	G7	
		G8	G9	etc.					

Example: Simple Method using FORM = 0

BOLT1	1	10							
	ELEM	1	2	3	4	5	6		

Example: Cross-section method using FORM = 1

BOLT1	2	20	1	0.0	0.0	1.0		SET	
	ELEM	11							
	GRID	12							

Describer	Meaning
ID	Unique bolt ID. (Integer; Required; no Default)
GRIDC	Control grid ID where pre-tension loads or tightening displacements are applied. (Integer; Required; no Default)
FORM	Specify input format for bolt definition. ((Integer; Default = 0) 0: Simple method, enter the list of elements making the bolt, no need to enter bolt axial direction or grid points forming the bolt cross-section. 1: Cross-section method, enter vector defining bolt axis, enter the list of grid points forming the bolt cross-section and list of elements sharing cross-section grid points and lying on the opposite side of the normal vector.
Ni	Components of a vector defining bolt axis (direction normal to cross-section). (Real; Required only if FORM = 1)

Descriptor	Meaning
OFFSET	Cross-section offset in axial direction (fraction of bolt length). (Real; Used for FORM=0 only; Default = 0.0)
IDTYPE	Method for defining a list of element and grid IDs. (Character; Default = "LIST" or blank)  "LIST": Enter the character string LIST, or leave blank, to allow entering lists of element IDs $E_i$ and grid point IDs $G_i$ .  "SET": Enter the character string SET to allow entering lists of element and grid points as sets. E1 and G1 refer to SET3 entries with DES = "ELEM" and "GRID", respectively.
ELEM	Enter the character string ELEM to define a list of elements. (Character; Required)
$E_i$	Element IDs (Integer; no Default)  If FORM = 0, list of element IDs of the bolt (must enter at least 2 elements along the axis of the bolt).  If FORM = 1, list of element IDs sharing grid points in the bolt cross-section and lying on the opposite side of the cross-section normal vector.  IF IDTYPE = "SET", E1 is the ID of a SET3 entry with DES = "ELEM" used to define a list of element IDs other $E_i$ entries will be ignored.
GRID	Enter the character string GRID to define a list of grid points. (Character; Required only if FORM = 1)
$G_i$	Grid IDs for the bolt cross-section. (Integer; Required only if FORM = 1; no Default)  IF IDTYPE = "SET", G1 is the ID of a SET3 entry with DES = "GRID", other $G_i$ entries will be ignored.

#### Remarks:

1. The bolt control grid point GRIDC is unique to each bolt and should be used only to apply bolt pre-tension forces or enforced displacements. GRIDC is a special grid point that has a single degree-of-freedom only aligned along the bolt axial direction and should not be connected to any element or grid in the model. GRIDC should not have an associated displacement coordinate system CD defined on the GRID entry. Applied loads and displacements should always be along the first degree-of-freedom (T1) of the control grid.
2. For the cross-section input format of the bolt definition, FORM=1, user must enter the initial direction of the bolt axis, or bolt cross-section normal vector,  $N_i$ . User must give the list of grid points defining the bolt cross-section, where pre-tension is applied, using GRID. User must also specify the list of elements sharing grid points in the bolt cross-section and lying on the opposite side of the cross-section normal vector using ELEM.

3. Using the simple input format of bolt definition, FORM=0, the complete list of bolt elements is specified using ELEM. The bolt axial direction is automatically computed by the program to be along the principal axis of the bolt elements. The bolt cross-section is also internally selected by the program to pass by the bolt center of mass by default. User can move the position of the bolt cross-section along the bolt axis away from the center of mass using the OFFSET parameter if needed.
4. For FORM=1, the cross-section normal vector cannot be of zero length.
5. For FORM=0, the number of elements entered must be at least 2 in order to be able to compute the bolt axis. In addition, bolt elements are not allowed to have a negative Jacobian in this case. The order of element connectivity must follow element definition rules in order to correctly compute the bolt axis.
6. The method for entering bolt element and grid IDs under ELEM and GRID can be controlled using IDTYPE either as list of IDs or defining a list on SET3 entries.
7. BOLT1 is supported for advanced nonlinear elements in SOL 400 only. As such, nonlinear property extensions should be defined for bolt elements. The program will attempt to internally map the element properties used by BOLT1 elements to advanced nonlinear elements if possible. Alternatively, MDLPPRM,BOLTCNEL,1 can be used to search for all elements connected to BOLT1 elements and map their element properties. Automatic mapping is turned off if the user has set NLMOPTS,SPROPMAP,-1 in the Bulk Data section. In this case nonlinear property extensions must be defined for bolt elements.
8. Current limitations:
  - BOLT1 is currently supported for 3D solid elements only.
  - BOLT1 does not support Herrmann elements.
  - GPFORCE output for the control grid does not show contributions of cross-section elements.

## BOUTPUT

### Output for Slideline Contact

Defines secondary nodes at which output is requested.

Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
BOUTPUT	ID	G1	G2	G3	G4	G5	G6	G7	

Alternate Format:

BOUTPUT	ID	G1	“THRU”	G2	“BY”	INC			
---------	----	----	--------	----	------	-----	--	--	--

The Continuation Entry formats may be used more than once and in any order. They may also be used with either format above.

Continuation Entry Format 1:

	G8	G9	G10	G11	-etc.-				
--	----	----	-----	-----	--------	--	--	--	--

Continuation Entry Format 2:

	G8	“THRU”	G9	“BY”	INC				
--	----	--------	----	------	-----	--	--	--	--

Example:

BOUTPUT	15	5	THRU	21	BY	4			
	27	30	32	33					
	35	THRU	44						
	67	68	72	75	84	93			

Format and Example Using “ALL” (No continuation entry is allowed):

BOUTPUT	ID	ALL							
BOUTPUT	15	ALL							

Describer	Meaning
ID	Contact region identification number of a BCONP entry for which output is desired, or the contact Grid ID, in 3D contact. (Integer > 0)
Gi	Secondary node numbers for which output is desired. (Integer > 0)
INC	Grid point identification number increment. See Remark 1. (Integer or blank)

**Remark:**

1. For automatic generation of grid numbers, the default increment value is 1 if grid numbers are increasing or -1 if grid numbers are decreasing (i.e., the user need not specify BY and the increment value).

## BRKPROP

## Specifies Property of Brake System for Brake Squeal Analysis Using SOL 400

Defines property of brake system for brake squeal calculations.

Format:

1	2	3	4	5	6	7	8	9	10
BRKPROP	ID		Param_i	Value	Param_i	Value	Param_i	Value	
	Param_i	Value	Param_i	Value					

Example:

1	2	3	4	5	6	7	8	9	10
BRKPROP	28		AVSTIF	1.0E7	FRICT	0.25			

Describer	Meaning
ID	Identification ID of the Brake Property referred by the entry card <a href="#">BRKSYS</a>
AVSTIF	Approximate average stiffness per unit area between the two surfaces. AVSTIF is used as penalty contact stiffness, it needs to be a large value but not so large that numerical instabilities result. If AVSTIF is large enough, increasing it by a few orders of magnitude will not appreciably affect the squeal modes. (Real; Required if TAVSTIF=0).
TAVSTIF	Table ID of a TABL3Di providing temperature or spatial variation of the average stiffness (Integer; Default = 0 which means AVSTIF should be defined).
FRICT	Enter the friction coefficient. If 0, the friction coefficient is obtained from the CONTACT TABLE option.

Remarks:

1. When TAVSTIF is 0, AVSTIF should be defined. Otherwise, Nastran will issue a fatal message and stop.

**BRKSQL****Specifies Data for Brake Squeal Calculations In SOL 600**

Specifies data for brake squeal calculations in SOL 600 only. Obsolete, please see [BSQUEAL](#) for an enhanced version.

Format:

1	2	3	4	5	6	7	8	9	10
BRKSQL	METH	AVSTIF				GLUE	ICORD		
	R1	R2	R3	X	Y	Z			
	NASCMD								
	RCFILE								

Example:

BRKSQL	1	5.34E6							
	0.0	0.0	1.0	2.0	3.0	4.0			
	tran								
	nastb								

Describer	Meaning
METH	Method flag corresponding to the type of brake squeal calculations to be performed. (Integer; Default = 1) 0 = Performs brake squeal calculations before any nonlinear analysis has taken place (corresponds to Marc feature, 4302). 1 = Performs brake squeal calculations after all nonlinear load cases (corresponds to Marc feature, 4304). -1 = Same as ID=0 except it corresponds to Marc feature, 4301 (not recommended).
AVSTIF	Approximate average stiffness per unit area between the pads and disk. Corresponds to Marc's PARAMETERS fifth datablock, field 1. This value is also known as the initial friction stiffness in Marc Volume C documentation. AVSTIF is used as a penalty contact stiffness for brake squeal, it needs to be a large value but not so large that numerical instabilities result. If AVSTIF is large enough, increasing it by a few orders of magnitude will not appreciably affect the squeal modes. (Real; no Default. Required field)
GLUE	Flag specifying whether MPC for non-pad/disk surfaces with glued contact are used or ignored. A value of 0 means ignore the MPC; a value of 1 means include the MPCs. See Remark 6. (Integer; Default = 1)

Describer	Meaning
ICORD	Flag indicating whether coordinates are updated or not. A value of 0 means coordinates are not updated. A value of 1 means coordinates are updated using the formula $C_{new} = C_{orig} + D_{efl}$ where $C_{new}$ are updated coordinates, $C_{orig}$ are original coordinates, and $D_{efl}$ are the final displacements from last Marc increment. (Integer; Default = 0)
R1	X direction cosine (basic coord system) of axis of rotation; corresponds to Marc ROTATION A second datablock. (Real; no Default. Required field)
R2	Y direction cosine (basic coord system) of axis of rotation; corresponds to Marc ROTATION A second datablock
R3	Z direction cosine (basic coord system); corresponds to Marc ROTATION A second datablock. (Real; no Default. Required field)
X	X coordinate in basic coord system of a point on the axis of rotation; corresponds to Marc ROTATION A third datablock. (Real; no Default. Required field)
Y	Y coordinate in basic coord system of a point on the axis of rotation; corresponds to Marc ROTATION A third datablock. (Real; no Default. Required field)
Z	Z coordinate in basic coord system of a point on the axis of rotation; corresponds to Marc ROTATION A third datablock. (Real; no Default. Required field)
NASCMD	Name of a command to run Nastran (limited to 64 characters) -- used in conjunction with the CONTINUE options on the SOL 600 entry. The full path of the command to execute Nastran should be entered. Enter the string entirely in lower case. The string will be converted to lower case. See Remark 2. (Character; Default=nastran)
RCFILE	Name of an RC file to be used with a secondary Nastran job (limited to 8 characters) -- used in conjunction with the CONTINUE options on the SOL 600 entry. An extension of ".rc" will automatically be added. Enter the string entirely in lower case. See Remark 2. (Character; Default=nastb.rc)

#### Remarks:

1. This entry is used to calculate complex eigenvalues for brake squeal using unsymmetric stiffness friction matrices calculated by Marc. Options exist to obtain the unsymmetric stiffness matrices using the undeformed geometry (initial contact) or after all specified nonlinear subcases.
2. SOL 600 performs brake squeal calculations, using the following approach. The main (original) Nastran job with input file `jid.dat` or `jid.bdf` spawns Marc just as it does for any other SOL 600 job. Marc calculates unsymmetric friction stiffness matrices that are saved on a file (`jid.marc.bde` with associated file `jid.marc.ccc`). The primary Nastran job then creates input data for a second Nastran job (`jid.nast.dat`) to use the unsymmetric stiffness matrices in a complex eigenvalue extraction. The primary Nastran job spawns a second Nastran job to calculate the complex eigenvalues. The complex eigenvalues and eigenvectors are found in `jid.nast.f06`, `jid.nast.op2`, etc.

NASCMD is the name of the command to execute the secondary Nastran job. NASCMD can be up to 64 characters long and must be left justified in field 2. The sting as entered will be used as is - except that it will be converted to lower case regardless of whether it is entered in upper or lower case.

RCFILE is the name of an RC file to be used for the secondary Nastran job. Normally it should be similar to the RC file used for the primary run except that additional memory will normally be necessary to calculate the complex eigenvalues and `batch=no` should also be specified for Linux systems. RCFILE is limited to 8 characters and an extension of “.rc” will be added automatically. This entry will be converted to upper case in Nastran but will be converted to lower case before spawning the complex eigenvalue run. This RC file must be located in the same directory as the Nastran input file. This entry is the same as specifying PARAM,MRRCFILE. Only one or the other should be used.

3. MPCs are produced for contact surfaces with glued contact. DMIGs are produced for contact surfaces without glued contact. The brakes and drums should not use glued contact; other regions of the structure can use glued contact.
4. The continuation lines may be omitted if defaults are appropriate.
5. When a BRKSQL entry is used, PARAM,MRMTXNAM and PARAM,MARCFIL1 should not be entered.
6. When brake squeal matrices are output by Marc, unsymmetric friction stiffness matrices are output for non-glued contact surfaces. For surfaces with glued contact, MPCs are output. The GLUE flag signals SOL 600 to look for these MPCs and combine them with other MPCs that might be in the model using MPCADD, or if no MPCs were originally used to add the MPCs due to glued contact. Glued contact surfaces may not be used for the disk-rotor interface. If IGLUE is zero or blank, the MPCs for glued contact in the Marc brake squeal bde file (if any) will be ignored. Sometimes, Marc puts out MPCs with only one degree-of-freedom defined. Such MPCs will be ignored; otherwise Nastran will generate a fatal error.
7. If METH=1, a Marc t19 file will be produced.
8. The names NASCMD and RCFILE must be entered in small fixed field and start in column 9 (i.e., left justified in the field).
9. The Nastran input file name used for a brake squeal analysis may only contain lower case letters and the underscore and/or dash characters.
10. Brake squeal is not available with DDM (parallel processing). Do not enter a PARAMARC when using the BRKSQL entry.

**BRKSYS**

Specifies Data for Brake System for Brake Squeal Analysis Using SOL 400

Defines data for brake system for brake squeal calculations involving one wheel or multiple wheels with one axis or multi-axes.

Format:

1	2	3	4	5	6	7	8	9	10
BRKSYS	ID	OMETH	IVEC	BSONLY	ISLIDEBS				
	Disk1	BD1_ID	BD2_ID	MT1_ID	MT2_ID	BProp_ID			
	Disk2	BD1_ID	BD2_ID	MT1_ID	MT2_ID	BProp_ID			
	Diski	BD1_ID	BD2_ID	MT1_ID	MT2_ID	BProp_ID			

Example:

1	2	3	4	5	6	7	8	9	10
BRKSYS	900	0.5	0	YES					
	INNER	8	9	18	19	28			
	OUTER	8	9	18	19	28			

Describer	Meaning
-----------	---------

- ID Identification ID of number of a corresponding BSQUEAL Case Control command
- OMETH Specifies the corresponding load factor (or time step) where the brake squeal analysis is to be performed. (Real; Default = 0.0)
- BSONLY Brake-Squeal-Only flag to control whether or not to continue nonlinear iterations after brake squeal analysis is performed. (Character; Default = YES)
  - YES: Means to perform brake squeal analysis only and exit nonlinear iteration immediately
  - NO: means to continue nonlinear analysis.
- IVEC Flag specifying whether friction vector at center of primary contact body is in the same direction as that of the secondary nodes; See [Figure 9-3](#). (Integer; Default = 0)
  - 0: In same direction
  - 1: In tangential direction
- ISLIDEBS Flag indicating whether contact status is treated as sliding or general static contact for brake disk/pad pairs. (Integer; Default = 0)
  - 0: Sliding contact for brake disk/pad pairs
  - 1: General static contact
- Disk<sub>i</sub> Name of the i<sup>th</sup> brake system
- BD1\_ID ID of **BCBODY1** of the first body which is defined in this brake system
- BD2\_ID ID of **BCBODY1** of the second body which is defined in this brake system

Descriptor	Meaning
MT1_ID	ID of <b>MOTION</b> which is defined for the first body with BD1_ID
MT2_ID	ID of <b>MOTION</b> which is defined for the second body with BD2_ID. If blank, MT1_ID will be used
BProp_ID	ID of <b>BRKPROP</b> which defines the property of this brake system

**Remark:**

- When modules are present, multiple BRKSYS entries with the same ID can be put in different modules and selected by BSQUEAL Case Control command. In addition with this, MDBKSYS in module 0 with the same ID can also be selected.  
MSC Nastran only uses one set of fields in the first line of those entries (fields OMETH, IVEC, BSONLY and ISLIDEBS).

- If not all the sets are identical:
  - When MDBKSYS is selected, its fields will be used.
  - If MDBKSYS doesn't exist or isn't selected and all the sets of those fields of BRKSYS entries are not identical, use the default values.

If all the sets are identical, use the specified values.

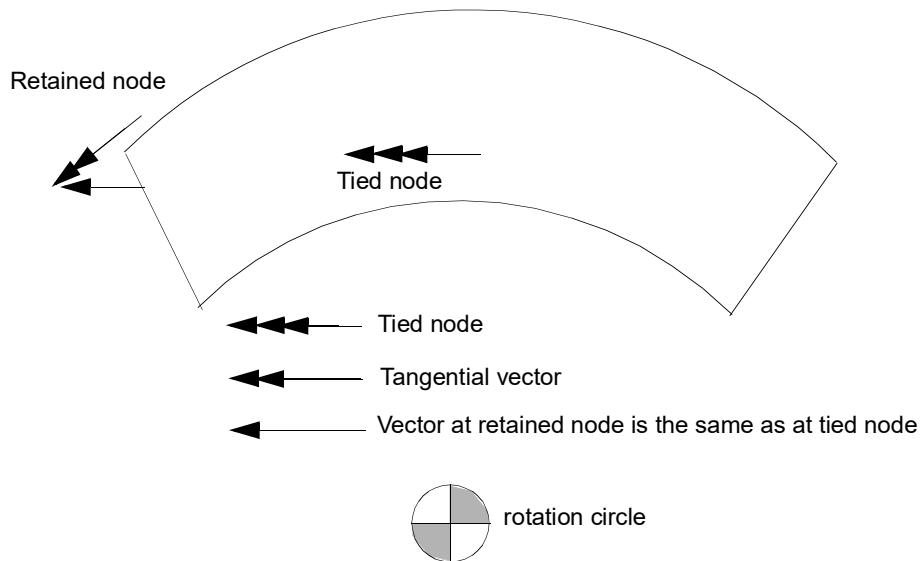

Figure 9-3 Vectors of frictional stiffness at tied and retained node.

## BSET Fixed Analysis Degrees-of-Freedom

Defines analysis set (a-set) degrees-of-freedom to be fixed (b-set) during generalized dynamic reduction or component mode synthesis calculations.

Format:

1	2	3	4	5	6	7	8	9	10
BSET	ID1	C1	ID2	C2	ID3	C3	ID4	C4	

Example:

BSET	2	135	14	6					
------	---	-----	----	---	--	--	--	--	--

Describer	Meaning
ID <sub>i</sub>	Grid or scalar point identification number. (Integer > 0)
C <sub>i</sub>	Component number. (Integer zero or blank for scalar points, or any unique combinations of the Integers 1 through 6 for grid points. No embedded blanks.)

Remarks:

1. BSET and BNDFIX entries are equivalent to each other. Either one of them or any combination of them may be employed.
2. If there are no BSET<sub>i</sub>/BNDFIX<sub>i</sub> or CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present, all a-set points are considered fixed during component mode analysis. If there are only BSET<sub>i</sub>/BNDFIX<sub>i</sub> entries present, any a-set degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are only CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present or both BSET<sub>i</sub>/BNDFIX<sub>i</sub> and CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present, the c-set degrees-of-freedom are defined by the CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries, and any remaining a-set points are placed in the b-set.
3. Degrees-of-freedom specified on BSET<sub>i</sub>/BNDFIX<sub>i</sub> entries form members of the mutually exclusive b-set. They may not be specified on other entries that define mutually exclusive sets. See the [Degree-of-Freedom Sets](#) for a list of these entries.
4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.
5. SOL 400 does not support ASET<sub>i</sub>, OMIT<sub>i</sub>, BSET<sub>i</sub>, CSET<sub>i</sub>, SUPORT<sub>i</sub>, and QSET<sub>i</sub> except in the following situations:

- a. Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
- b. Linear perturbation with:
  - i. EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
  - ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
- c. Superelements defined with BEGIN SUPER may contain ASETi, OMITi, BSETi, CSETi, and QSETi entries.

## BSET1 Fixed Analysis Degrees-of-Freedom, Alternate Form of BSET Entry

Defines analysis set (a-set) degrees-of-freedom to be fixed (b-set) during generalized dynamic reduction or component mode synthesis calculations.

Format:

1	2	3	4	5	6	7	8	9	10
BSET1	C	ID1	ID2	ID3	ID4	ID5	ID6	ID7	
	ID8	ID9	ID10	-etc.-					

Example:

BSET1	2	135	14	6	23	24	25	26	
	122	127							

Alternate Format and Example:

BSET1	C	ID1	“THRU”	ID2					
BSET1	3	6	THRU	32					

Describer	Meaning
C	Component numbers. (Integer zero or blank for scalar points, or any unique combinations of the Integers 1 through 6 for grid points with no embedded blanks.)
IDI	Grid or scalar point identification numbers. (Integer > 0; For “THRU” option, ID1 < ID2)

Remarks:

1. BSET1 and BNDFIX1 entries are equivalent to each other. Either one of them or any combination of them may be employed.
2. If there are no BSETi/BNDFIXi or CSETi/BNDFREE/BNDFRE1 entries present, all a-set points are considered fixed during component mode analysis. If there are only BSETi/BNDFIXi entries present, any a-set degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are only CSETi/BNDFREE/BNDFRE1 entries present or both BSETi/BNDFIXi and CSETi/BNDFREE/BNDFRE1 entries present, the c-set degrees-of-freedom are defined by the CSETi/BNDFREE/BNDFRE1 entries, and any remaining a-set points are placed in the b-set.
3. Degrees-of-freedom specified on BSETi/BNDFIXi entries form members of the mutually exclusive b-set. They may not be specified on other entries that define mutually exclusive sets. See the [Degree-of-Freedom Sets](#) for a list of these entries.

4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.
5. SOL 400 does not support ASETi, OMITi, BSETi, CSETi, SUPORTi, and QSETi except in the following situations:
  - a. Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
  - b. Linear perturbation with:
    - i. EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
    - ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
  - c. Superelements defined with BEGIN SUPER may contain ASETi, OMITi, BSETi, CSETi, and QSETi entries.

**BSQUEAL** Specifies Data for Brake Squeal Analysis Using SOLs 400 and 600

Defines data for brake squeal calculations involving one wheel (Primary Format) or multiple wheels (Alternate Format) as well as other rotating or stationary sliding objects used in SOLs 400 and 600.

Primary Format (One Wheel, SOL 400 and SOL 600):

1	2	3	4	5	6	7	8	9	10
BSQUEAL	ID	OMETH	AVSTIF			BSONLY	IGLUE	ICORD	
	RX	RY	RZ	X	Y	Z			
	NASCMD								
	RCFILE								

Alternate Format (Multiple Wheels, SOL 600 Only):

1	2	3	4	5	6	7	8	9	10
BSQUEAL	ID	OMETH	NGROUP	ICORD	ITYPE				
	"BODY"	ID1	ID2			AVSTIF	T(AVSTIF)		
		IVEC	IDRF1	IDRF2	IGLUE				
		RX1	RY1	RZ1	X1	Y1	Z1		
		RX2	RY2	RZ2	X2	Y2	Z2		
	"BODY"	ID1	ID2			AVSTIF	T(AVSTIF)		
		IVEC	IDRF1	IDRF2	IGLUE				
		RX1	RY1	RZ1	X1	Y1	Z1		
		RX2	RY2	RZ2	X2	Y2	Z2		
	NASCMD								
	RCFILE								

Example, Primary Format (SOL 400):

1	2	3	4	5	6	7	8	9	10
BSQUEAL	100	0.2	5.34E6			NO			
	0.0	0.0	1.0	2.0	3.0	4.0			

Example, Primary Format (SOL 600):

1	2	3	4	5	6	7	8	9	10
BSQUEAL		1.0	5.34E6						
	0.0	0.0	1.0	2.0	3.0	4.0			
	nastran								
	nastb.rc								

## Example, Alternate Format (SOL 600):

1	2	3	4	5	6	7	8	9	10
BSQUEAL		1.0	2	1	1				
	BODY	2	3			60000.	0		
		0			1				
		0.0	0.0	1.0	10.0	10.0	25.0		
		0.0	0.0	-1.0	10.0	10.0	30.0		
	BODY	6	8			1.0	5		
		0	110	120	1				
	nastran								
	nastb.rc								

Describer	Meaning
ID	Identification number of a corresponding BSQUEAL Case Control command (Integer > 0). Ignored by SOL 600.
OMETH	Specifies the corresponding load factor (or time step) where the brake squeal analysis is to be performed. (Real; Default = 0.0 in SOL 400, see Remark 5., for SOL 600 the value must be 0.0 or 1.0, Remark 11.)
NGROUP	Number of pairs of contact bodies (Integer > 0; Default = 1)
ICORD (SOL 600 Only)	Flag indicating whether coordinates are updated or not. A value of 0 means coordinates are not updated. A value of 1 means coordinates are updated using the formula $C_{new} = C_{orig} + Defl$ where $C_{new}$ are updated coordinates, $C_{orig}$ are original coordinates, $Defl$ are the final displacements from last Marc increment. (Integer; Default = 0)
ITYPE (SOL 600 Only)	Flag determining type of analysis. See Figure 9-4 and Figure 9-5 (Integer; Default = 1) 1 Brake squeal 2 Complex engenvalue analysis following general sliding contact analysis.
BSONLY (SOL 400 Only)	Brake-Squeal-Only flag to control whether or not to continue nonlinear iterations after brake squeal analysis is performed. BSONLY=YES means to perform brake squeal analysis only and exit nonlinear iteration immediately; BSONLY=NO means to continue nonlinear analysis. (Character; Default = YES)
“BODY”	Character string that signals the start of a pair of contact bodies for which instability calculations are to be made (Character; Required)
ID1	BCBODY ID of the first contact body. (Integer > 0; no Default; bcbody id1 must exist)
ID2	BCBODY ID of the second contact body. (Integer > 0; no Default; bcbody id2 must exist)

Descriptor	Meaning
AVSTIF	Approximate average stiffness per unit area between the two surfaces. AVSTIF is used a penalty contact stiffness, it needs to be a large value but not so large that numerical instabilities result. If AVSTIF is large enough, increasing it by a few orders of magnitude will not appreciably affect the squeal modes. (Real; no Default; Required field)
T(AVSTIF)	Table ID of a TABL3Di providing temperature or spatial variation of the average stiffness (Integer; Default = 0 which means FC is constant)
IVEC	Flag specifying whether friction vector at center of primary contact body is in the same direction as that of the secondary nodes; see <a href="#">Figure 9-4</a> . (Integer; Default = 0)
	0            In same direction
	1            In tangential direction
IDRFi (SOL 600 Only)	ID of a matching RFORCE entry (if any) for body 1 or 2. (Integer; Default = 0, which means this body is not rotating)
IGLUE (SOL 600 Only)	Flag specifying whether MPC's for non-pad/disk surfaces with glued contact are used or ignored. A value of 0 means ignore the MPC's, a value of 1 means include the MPC's. See <a href="#">Remarks 12</a> and <a href="#">14</a> . (Integer; Default = 1)
RXi	X direction cosine (basic coord system) of axis of rotation for body i if IDRFi is zero or blank (Real; or blank)
RYi	Y direction cosine (basic coord system) of axis of rotation for body i if IDRFi is zero or blank (Real; or blank)
RZi	Z direction cosine (basic coord system) of axis of rotation for body i if IDRFi is zero or blank (Real; or blank)
Xi	X coordinate in basic coord system of a point on the axis of rotation for body i if IDRFi is zero or blank (Real; or blank)
Yi	Y coordinate in basic coord system of a point on the axis of rotation for body i if IDRFi is zero or blank (Real; or blank)
Zi	Z coordinate in basic coord system of a point on the axis of rotation for body i if IDRFi is zero or blank (Real; or blank)
NASCMD (SOL 600 Only)	Name of a command to run Nastran (limited to 64 characters) - used in conjunction with the CONTINUE options on the SOL 600 statement. The full path of the command to execute Nastran should be entered. Enter the string entirely in lower case. (Character; Default = nastran) If the string exceeds 8 characters, do not enter this string using free-field also see <a href="#">Remark 9</a> .
RCFILE (SOL 600 Only)	Name of a RC file to be used with a secondary Nastran job (limited to 8 characters) - used in conjunction with the CONTINUE options on the SOL 600 statement. An extension of ".rc" will automatically be added. Enter the string entirely in lower case. (Character; Default=nastb.rc) If the string exceeds 8 characters, do not enter this string using free-field also see <a href="#">Remark 9</a> .

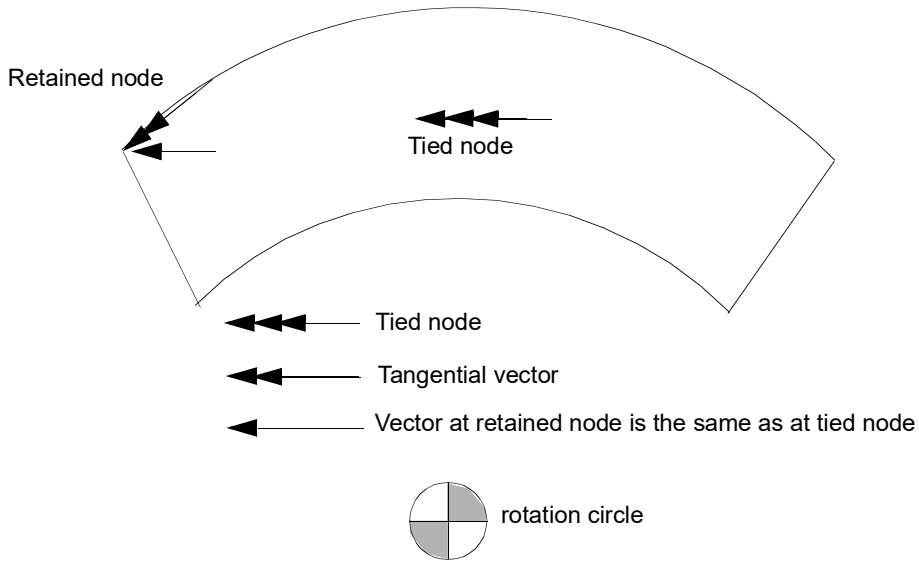

Figure 9-4 Vectors of frictional stiffness at tied and retained node.

Figure 9-5 Sliding model

Remarks:

1. This entry is used to perform multiple-body brake squeal analysis or other contact with friction sets of bodies using unsymmetric stiffness friction matrices.

2. One or more pairs of bodies may be specified. Each pair of bodies is described by the four lines beginning with the header "BODY". For example, there may be one rotating body, such as brake disk or rotor, and one contact body or bodies, such as brake pad under each "BODY" keyword. There may be other bodies or parts in the assembly.
3. The disks should not be glued with pads. When bodies are intended to be glued, turn on BCTABLE / IGLUE or BCONPRG/IGLUE for those contact bodies.
4. Entries ICORD, ITYPE, IDBFi, IGLUE, NASCMD and RCFILE are used by SOL 600 only.
5. Entry BSONLY is used by SOL 400 only.
6. Brake squeal is not available with segment-to-segment contact.

### SOL 400 Only

7. For nonlinear static analysis,  $0.0 < \text{OMETH} < 1.0$ , OMETH is overridden by the load factor from Case Control command, NLIC or its default, when a brake squeal analysis is performed in a separate SUBCASE-STEP other than ANALYSIS = NLSTATIC.
8. User subroutine UBSQUEAL is available using the BCONUDS entry.

### SOL 600 Only

9. SOL 600 performs brake squeal calculations as follows. The main (original) Nastran job with input deck jid.dat or jid.bdf spawns Marc just as done for any other SOL 600 job. Marc calculates unsymmetric friction stiffness matrices which are saved on a file (jid.marc.bde with associated file jid.marc.ccc). The primary Nastran job then creates input data for a second Nastran job (jid.nast.dat) to use the unsymmetric stiffness matrices in an complex eigenvalue extraction. The primary Nastran job spawns a second Nastran job to calculate the complex eigenvalues. The complex eigenvalues and eigenvectors are found in jid.nast.f06, jid.nast.op2, etc.  
 NASCMD is the name of the command to execute the secondary Nastran job. NASCMD can be up to 64 characters long and must be left justified in field 2. The sting as entered will be used as is - except that it will be converted to lower case regardless of whether it is entered in upper or lower case. RCFILE is the name of an RC file to be used for the secondary Nastran job. Normally it should be similar to the RC file used for the primary run except that additional memory will normally be necessary to calculate the complex eigenvalues and batch=no should also be specified. RCFILE is limited to 8 characters and an extension of ".rc" will be added automatically. This entry will be converted to upper case in Nastran but will be converted to lower case before spawning the complex eigenvalue run. This RC file must be located in the same directory as the Nastran input file. This entry is the same as specifying PARAM,MRRCFILE. Only one or the other should be used.
10. OMETH can only be one of the following two values in SOL 600.  
 0.0=Perform brake squeal calculations before any nonlinear analysis has taken place  
 1.0=Perform brake squeal calculations after all nonlinear load cases
11. Options exist to obtain the unsymmetric stiffness matrices using the undeformed geometry (initial contact) or after all specified nonlinear subcases.
12. MPC's are produced for contact surfaces with glued contact. DMIG's are produced for contact surfaces without glued contact. The brakes and drums may not use glued contact, other regions of the structure can used glued contact.

13. When the BSQUEAL entry is used, PARAM,MRMTXNAM and PARAM,MARCFIL1 should not be entered.
14. When brake squeal matrices are output by Marc, unsymmetric friction stiffness matrices are output for non-glued contact surfaces. For surfaces with glued contact, MPC's are output. The GLUE flag signals SOL 600 to look for these MPC's and combine them with other MPC's that might be in the model using MPCADD, or if no MPC's were originally used to add the MCP's. due to glued contact. Glued contact surfaces may not be used for the disk-rotor interface. If IGLUE is zero or blank, the MPC's for glued contact in the Marc brake squeal bde file (if any) will be ignored. Sometimes, Marc puts out MPC's with only one degree-of-freedom defined. Such MPC's will be ignored otherwise Nastran will generate a fatal error.
15. The names NASCMD and RCFILE must be entered in small fixed field and start in column 9 (i.e. left justified in the field).
16. The Nastran input file name used for a brake squeal analysis may only contain lower case letters and the underscore and/or dash characters.
17. Brake squeal is not available with DDM (parallel processing). Do not enter a PARAMARC when using the BSQUEAL entry.
18. The Bulk Data entry BRKSQL is the alternate format in SOL 600 when there is only one body.

## BSURF

## Contact Body or Surface

Defines a contact body or surface by Element IDs.

Format:

1	2	3	4	5	6	7	8	9	10
BSURF	ID	ELID1	ELID2	ELID3	ELID4	ELID5	ELID6	ELID7	
	ELID8	ELID9	etc.						

Alternate Format:

BSURF	ID	ELID1	THRU	ELID2	BY	INC			
	ELID3	THRU	ELID4	BY	INC2				

Example:

BSURF	15	5	THRU	21	BY	4			
	27	30	32	33					
	35	THRU	44						
	67	68	72	75	84	93			

Describer	Meaning
ID	Identification of a deformable surface corresponding to a BSID value on the BCBODY entry. See Remark 2. (Integer > 0)
ELIDi	Element identification numbers. If the curve or surface is defined with element ids only, the direction of the normal depends on the grid point numbering. Keywords THRU and BY can be used to assist the listing. For SOL 600 and SOL 700 the Alternate Format must be used with Remarks 6. and 7.
INC	Identification number increment. See Remark 3. (Integer or blank)

Remarks:

1. BSURF can be used in SOL101, 103, 105, 107, 108, 109, 110, 111, 112, 400, 600, and 700.
2. ID must be unique with respect to all other BSURF, BCBOX, BCPROP, and BCMATL entries.
3. For automatic generation of element IDs, the default increment value is 1 if element numbers are increasing or -1 if element numbers are decreasing (i.e., the user need not specify BY and the increment value).
4. The deformable surface may alternately be defined using BCBOX, BCPROP, or BCMATL entries.
5. Only one kind of entry (BSURF, BCBOX, BCPROP, or BCMATL) may be used to define a particular deformable surface.

6. For SOLs 600 and 700, Format 1 and the Alternate Format cannot be mixed for a particular BSURF entry.
7. For SOLs 600 and 700 if the Alternate Format is used, THRU must be in column 4 for entries with the BSURF header and in column 3 for continuation entries. If BY is not used, columns 6-9 of the BSURF entry and columns 5-9 of continuation entries must be blank.

**BWIDTH**                      Boundary Line Segment Width or Thickness

Defines widths or thicknesses for line segments in 3-D or 2-D sideline contact defined in the corresponding BLSEG Bulk Data entry for SOL 106 or SOL 129. SOL 400 general contact capability, defined with BCONTACT, BCTABL1, etc. is the recommended approach for contact analysis.

Format:

1	2	3	4	5	6	7	8	9	10
BWIDTH	ID	W1	W2	W3	W4	W5	W6	W7	

Alternate Format:

BWIDTH	ID	W1	"THRU"	W2	"BY"	INC			
--------	----	----	--------	----	------	-----	--	--	--

The continuation entry formats may be used more than once and in any order. They may also be used with either format above.

Continuation Entry Format 1:

	W8	W9	W10	W11	-etc.-				
--	----	----	-----	-----	--------	--	--	--	--

Continuation Entry Format 2:

	W8	"THRU"	W9	"BY"	INC				
--	----	--------	----	------	-----	--	--	--	--

Example:

BWIDTH	15	2.0	THRU	5.0	BY	1.0			
	2.0	2.0	2.0	2.0					
	35.	THRU	44.						
	1.5	3.4	7.6	0.4	0.7				

Descriptor	Meaning
------------	---------

ID	BLSEG entry identification number. (Integer > 0)
Wi	Width values for the corresponding line segments defined in the BLSEG entry. See Remark 1. (Real > 0.0)
INC	Width value increment. See Remark 2. (Real or blank)

Remarks:

1. BWIDTH may be omitted if the width of each segment defined in the BLSEG entry is unity. The number of widths to be specified is equal to the number of segments defined in the corresponding BLSEG entry.

2. The default value for INC is 1.0 if the width is increasing or -1.0 if the width is decreasing. That is, the user need not specify BY and the increment value. If the number of widths specified is less than the number of segments defined in the corresponding BLSEG entry, the width for the remaining segments is assumed to be equal to the last width specified.
3. If there is only one grid point in the corresponding BLSEG entry, there is no contributory area associated with the grid point. To compute correct contact stresses an area may be associated with the single grid point by specifying the area in field W1.

## Entries CA - CM

### CAABSF

### Frequency-Dependent Acoustic Absorber Element

Defines a frequency-dependent acoustic absorber element in coupled fluid-structural analysis.

Format:

1	2	3	4	5	6	7	8	9	10
CAABSF	EID	PID	G1	G2	G3	G4			

Example:

CAABSF	44	38	1	10	20				
--------	----	----	---	----	----	--	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number that matches a PAABSF entry. (Integer > 0; Default = EID)
Gi	Grid point identification number of fluid connection points. (Integer ≥ 0 or blank)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. If only G1 is specified then a point impedance is assumed. If G1 and G2 are specified then a line impedance is assumed. If G1, G2, and G3 are specified, then an impedance is associated with the area of the triangular face. If G1 through G4 are specified, then an impedance is associated with the quadrilateral face. See [Figure 9-6](#).
3. The CAABSF element must connect entirely to fluid points on the fluid-structure boundary.
4. This element is used only in frequency response and is ignored in all other solutions.

Figure 9-6 Four Types of CAABSF Elements

## CACINF3

## Acoustic Conjugate Infinite Element Base Connection

Defines an acoustic conjugate infinite element with triangular base.

Format:

1	2	3	4	5	6	7	8	9	10
CACINF3	EID	PID	G1	G2	G3				

Example:

CACINF3	111	10	1004	1008	1011				
---------	-----	----	------	------	------	--	--	--	--

Describer	Meaning
EID	Element Identification Number. (0 < Integer < 100,000,000)
PID	Property Identification Number of a PACINF entry. (Integer > 0)
Gi	Grid Point Identification Numbers of Element Base Connection Points. (Integer > 0)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. The element must be connected to acoustic grid points.
3. The element normal is defined by the right-hand rule. If the normal does not point into the exterior domain, the element orientation will be changed automatically, and an information message will be written to the .f06 file.

## CACINF4 Acoustic Conjugate Infinite Element Base Connection

Defines an acoustic conjugate infinite element with quadrilateral base.

Format:

1	2	3	4	5	6	7	8	9	10
CACINF4	EID	PID	G1	G2	G3	G4			

Example:

CACINF4	275	10	1027	1032	1056	1021			
---------	-----	----	------	------	------	------	--	--	--

Describer	Meaning
EID	Element Identification Number. (0 < Integer < 100,000,000)
PID	Property Identification Number of a PACINF entry. (Integer > 0)
Gi	Grid Point Identification Numbers of Element Base Connection Points. (Integer > 0)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. The element must be connected to acoustic grid points.
3. The element normal is defined by the right-hand rule. If the normal does not point into the exterior domain, the element orientation will be changed automatically, and an information message will be written to the .f06 file.

## CAERO1

## Aerodynamic Panel Element Connection

Defines an aerodynamic macro element (panel) in terms of two leading edge locations and side chords. This is used for Doublet-Lattice theory for subsonic aerodynamics and the ZONA51 theory for supersonic aerodynamics.

Format:

1	2	3	4	5	6	7	8	9	10
CAERO1	EID	PID	CP	NSPAN	NCHORD	LSPAN	LCHORD	IGID	
	X1	Y1	Z1	X12	X4	Y4	Z4	X43	

Example:

CAERO1	1000	1		3			2	1	
	0.0	0.0	0.0	1.0	0.2	1.0	0.0	0.8	

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PAERO1 entry; used to specify associated bodies. Required even if there are no associated bodies. (Integer > 0)
CP	Coordinate system for locating points 1 and 4. (Integer ≥ 0; Default = 0)
NSPAN	Number of spanwise boxes; if a positive value is given NSPAN, equal divisions are assumed; if zero or blank, a list of division points is given at LSPAN, field 7. (Integer ≥ 0)
NCHORD	Number of chordwise boxes; if a positive value is given NCHORD, equal divisions are assumed; if zero or blank, a list of division points is given at LCHORD, field 8. (Integer ≥ 0)
LSPAN	ID of an AEFAC data entry containing a list of division points for spanwise boxes. Used only if NSPAN, field 5 is zero or blank. (Integer > 0)
LCHORD	ID of an AEFAC data entry containing a list of division points for chordwise boxes. Used only if NCHORD, field 6 is zero or blank. (Integer > 0)
IGID	Interference group identification; aerodynamic elements with different IGIDs are uncoupled. (Integer > 0)
X1, Y1, Z1 X4, Y4, Z4	} Location of points 1 and 4, in coordinate system CP. (Real)
X12, X43	

Remarks:

1. The boxes and corner point nodes are numbered sequentially, beginning with EID. The user should be careful to ensure that all box and corner point node numbers are unique. There can be overlapping IDs between the structural and aerodynamic model, but MSC Patran will not then be able to display any results. Also, non-unique corner IDs are allowed, but results cannot be visualized in MSC Patran.
2. The number of division points is one greater than the number of boxes. Thus, if NSPAN=3, the division points are 0.0, 0.333, 0.667, 1.000. If the user supplies division points, the first and last points need not be 0. and 1. (In which case the corners of the panel would not be at the reference points.)
3. A triangular element is formed if X12 or X43=0.0
4. The element coordinate system is right-handed as shown in [Figure 9-7](#).
5. The continuation is required.
6. It is recommended that NCHORD or LCHORD be chosen so that the typical box chord length  $\Delta x$  satisfies the condition  $\Delta x < 0.08 V/f$  (recent studies indicate that  $.02 V/f$  is needed to get converged stability derivatives) where  $V$  is the minimum velocity and  $f$ , in hertz, is the maximum frequency to be analyzed (see the [MSC Nastran Aeroelastic Analysis User's Guide](#)).

Figure 9-7 Element Coordinate System for Aerodynamic Panel

7. This entry can be used for two different aerodynamic theories: Doublet-Lattice for subsonic and ZONA51 for supersonic. The proper theory is selected based on the specification of Mach number on the MKAEROi or TRIM entry.

## CAERO2

## Aerodynamic Body Connection

Defines aerodynamic slender body and interference elements for Doublet-Lattice aerodynamics.

Format:

1	2	3	4	5	6	7	8	9	10
CAERO2	EID	PID	CP	NSB	NINT	LSB	LINT	IGID	
	X1	Y1	Z1	X12					

Example:

CAERO2	1500	2	100		4	99		1	
	-1.0	100.	-30.	175.					

Describer	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Property identification number of a PAERO2 entry. ( $\text{Integer} > 0$ )
CP	Coordinate system for locating point 1. ( $\text{Integer} \geq 0$ ; Default = 0)
NSB	Number of slender body elements. If $\text{NSB} > 0$ , then NSB equal divisions are assumed; if zero or blank, specify a list of divisions in LSB. ( $\text{Integer} \geq 0$ )
NINT	Number of interference elements. If $\text{NINT} > 0$ , then NINT equal divisions are assumed; if zero or blank, specify a list of divisions in LINT. ( $\text{Integer} \geq 0$ )
LSB	ID of an AEFACCT Bulk Data entry for slender body division points; used only if NSB is zero or blank. ( $\text{Integer} \geq 0$ )
LINT	ID of an AEFACCT data entry containing a list of division points for interference elements; used only if NINT is zero or blank. ( $\text{Integer} \geq 0$ )
IGID	Interference group identification. Aerodynamic elements with different IGIDs are uncoupled. ( $\text{Integer} \geq 0$ )
X1, Y1, Z1	Location of point 1 in coordinate system CP. (Real)
X12	Length of body in the x-direction of the aerodynamic coordinate system. ( $\text{Real} > 0.0$ )

Remarks:

1. Point 1 is the leading point of the body.
2. All CAERO1 (panels) and CAERO2 (bodies) in the same group (IGID) will have aerodynamic interaction.
3. At least one interference element is required for the aerodynamic body specified by this entry.

4. The beams and connection points are numbered sequentially beginning with EID. The user should be careful to ensure that all aero elements and connection point IDs are unique. Overlapping IDs between structure and aerodynamic models are allowed, but will prevent results visualization in Patran.

Old rules regarding numbering among Z, ZY, Y bodies and CAERO1 no longer apply: arbitrary ordering is allowed.

5. At least two slender body elements are required for each aerodynamic body.
6. Interference elements are only intended for use with panels.
7. Determining the size of the j-set (i.e., the number of aerodynamic elements) is essential to input D1JE and D2JE matrices. Use the following expressions for locating the proper row in the two matrices:

$$\begin{aligned} J = & \text{Number of boxes} + \text{Number of I-elements, z} \\ & + 2 * (\text{Number of I-elements, zy}) \\ & + \text{Number of I-elements, y} \\ & + \text{Number of S-elements, z} \\ & + 2 * (\text{Number of S-elements, zy}) \\ & + \text{Number of S-elements, y} \end{aligned}$$

where I-elements denote interference and S-elements denote slender body.

## CAERO3

## Aerodynamic Panel Element Configuration

Defines the aerodynamic edges of a Mach Box lifting surface. If no cranks are present, this entry defines the aerodynamic Mach Box lifting surface.

Format:

1	2	3	4	5	6	7	8	9	10
CAERO3	EID	PID	CP	LISTW	LISTC1	LISTC2			
	X1	Y1	Z1	X12	X4	Y4	Z4	X43	

Example:

CAERO3	2000	2001	0	22	33				
	1.0	0.0	0.0	100.	17.	130.	0.	100.	

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PAERO3 entry. (Integer > 0)
CP	Coordinate system for locating points 1 and 4. (Integer ≥ 0; Default = 0)
LISTW	Identification number of an AEFACCT entry that lists (x,y) pairs for structural interpolation of the wing. (Integer > 0)
LISTC1, LISTC2	Identification number of AEFACCT entries that list (x,y) pairs for control surfaces, if they exist. (Integer ≥ 0)
X1, Y1, Z1 X4, Y4, Z4	} Location of points 1 and 4 in coordinate system CP. (Real)
X12, X43	

Remarks:

1. EID must be unique with respect to all other element identification numbers.
2. The (x,y) pairs on LISTW, LISTC1 and LISTC2 AEFACCT entries are in the aero element coordinate system (see [Figure 9-8](#)). The (x,y) pairs define a set of aerodynamic grid points that are independent of Mach number and are selected by the user to be representative of the planform and motions of interest. The (x,y) pairs must be sufficient in number and distribution such that: the surface spline provides an accurate interpolation between them and the Mach Box centers that are variously located on the planform as a function of Mach number (a complete description of the Mach Box Method is given in the [MSC Nastran Aeroelastic Analysis User's Guide](#)).

3. The (x,y) pairs are numbered sequentially, beginning with EID for LISTW, then LISTC1, and finally for LISTC2. On SPLINEi entries, the box numbers (BOX1 and BOX2 on SPLINE1, ID1 and ID2 on SPLINE2, and UKID on SPLINE3) refer to the (x,y) pair sequence number appropriate for the surface (primary, or first or second control) being splined.
4. If cranks and/or control surfaces exist, their locations are given on the PAERO3 entry.
5. The numbering system and coordinate system are shown below:

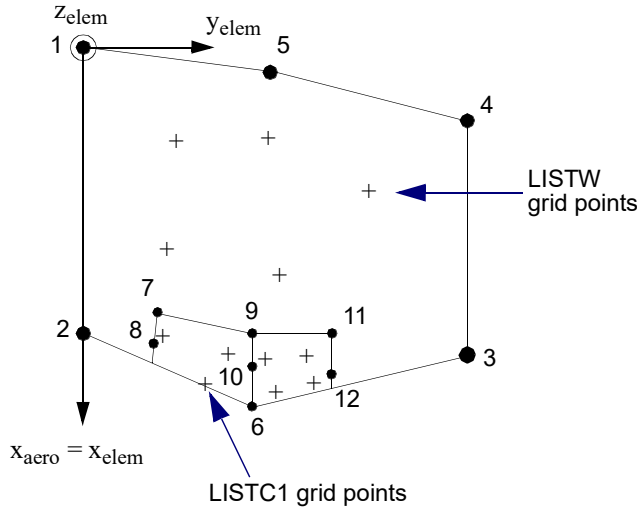

Figure 9-8 CAERO3 Element Configuration

Platform Corners		Control	
1	Leading edge, inboard	7	Hinge line, inboard
2	Trailing edge, inboard	8	On inboard edge (usually at trailing edge)
3	Trailing edge, outboard	9	Hinge line, outboard
4	Leading edge, outboard	10	On outboard edge (usually at trailing edge)
Cranks		Control (if two)	
5	Leading edge	9	Hinge line, inboard
6	Trailing edge	10	On inboard edge (usually at trailing edge)
		11	Hinge line, outboard
		12	On outboard edge (usually at trailing edge)

6. The CAERO3 entry is only supported in SOL 145, SOL 200 with ANALYSIS=FLUT and in SOL 146 with mechanical loads. Gust response in SOL 146 is not supported for the CAERO3.

## CAERO4 Aerodynamic Macro-Strip Element Connection

Defines an aerodynamic macro element for Strip theory.

Format:

1	2	3	4	5	6	7	8	9	10
CAERO4	EID	PID	CP	NSPAN	LSPAN				
	X1	Y1	Z1	X12	X4	Y4	Z4	X43	

Example:

CAERO4	6000	6001	100		315				
	0.0	0.0	0.0	1.0	0.2	1.0	0.0	0.8	

Describer	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Property identification number of a PAERO4 entry. ( $\text{Integer} > 0$ )
CP	Coordinate system for locating points 1 and 4. ( $\text{Integer} \geq 0$ ; Default = 0)
NSPAN	Number of strips; if a positive value is given, NSPAN equal strips are assumed. If zero or blank, LSPAN must be specified. ( $\text{Integer} \geq 0$ )
LSPAN	ID of an AEFACCT entry containing a list of division points for strips. Used only if NSPAN is zero or blank. ( $\text{Integer} > 0$ )
X1, Y1, Z1 X4, Y4, Z4	Location of points 1 and 4 in coordinate system CP. (Real)
X12, X43	

Remarks:

1. The strips are numbered sequentially, beginning with EID. The user must ensure that all strip numbers are unique and greater than structural grid, scalar, and extra point IDs.
2. The number of division points is one greater than the number of boxes. Thus, if NSPAN = 3, the division points are 0.0, 0.333, 0.667, and 1.000. If the user supplies division points, the first and last points need not be 0.0 and 1.0 (in which case the corners of the panel would not be at the reference points).
3. A triangular element is formed if X12 or X43 = 0.

Figure 9-9 CAERO4 Element Connection

4. The CAERO4 entry is only supported in SOL 145, SOL 200 with ANALYSIS=FLUT and in SOL 146 with mechanical loads. Gust response in SOL 146 is not supported for the CAERO4.

## CAERO5

## Aerodynamic Panel Element Configuration

Defines an aerodynamic macro element for Piston theory.

Format:

1	2	3	4	5	6	7	8	9	10
CAERO5	EID	PID	CP	NSPAN	LSPAN	NTHRY	NTHICK		
	X1	Y1	Z1	X12	X4	Y4	Z4	X43	

Example:

CAERO5	6000	6001	100		315	0	0		
	0.0	0.0	0.0	1.0	0.2	1.0	0.	0.8	

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PAERO5 entry. (Integer > 0)
CP	Coordinate system for locating points 1 and 4. (Integer ≥ 0; Default = 0)
NSPAN	Number of strips. (Integer. If a positive value is given, equal strips are assumed. If zero or blank, then LSPAN must be specified.)
LSPAN	ID of an AEFAC T entry containing a list of division points for strips. Used only if NSPAN is zero or blank. (Integer > 0)
NTHRY	Parameter to select Piston or van Dyke's theory. (Integer = 0, 1, or 2; Default = 0) Blank or 0   Piston theory is used to compute $\bar{C}_1$ and $\bar{C}_2$ 1            van Dyke's theory is used to compute $\bar{C}_1$ and $\bar{C}_2$ with no sweep correction (secΛ = 1.0). 2            van Dyke's theory is used to compute $\bar{C}_1$ and $\bar{C}_2$ with a sweep correction based on the actual Λ.
NTHICK	Parameter to select thickness integrals input. (Integer ≥ 0; Default = 0) Blank or 0   Thickness integrals are computed internally. > 0           Thickness integrals are input directly and are the ID number of an AEFAC T entry that lists the <i>I</i> and/or <i>J</i> integrals.
X1,Y1, Z1 X4,Y4, Z4	} Location of points 1 and 4 in coordinate system CP. (Real)
X12, X43	Edge chord lengths in aerodynamic coordinate system. (Real ≥ 0; X12 and X43 cannot both be zero.)

Figure 9-10 CAER05 Element Configuration

Remarks:

1. The strips are numbered sequentially, beginning with EID. The user must ensure that all strip numbers are unique and different from structural grid IDs.
2. The number of division points is one greater than the number of boxes. Thus, if NSPAN=3, the division points are 0.0, 0.333, 0.667, 1.000. If the user supplies division points, the first and last points need not be 0.0 and 1.0 (in which case the corners of the panel would not be at the reference points).
3. A triangular element is formed if X12 or X43 = 0.0.

$$\bar{C}_1 = m / (m^2 - \sec^2 \Lambda)^{1/2}$$

$$\bar{C}_2 = [m^4 (\gamma + 1) - 4 \sec^2 \Lambda (m^2 - \sec^2 \Lambda)] / [4 (m^2 - \sec^2 \Lambda)^2]$$

where:

- m = Mach number
- $\gamma$  = Specific heat ratio
- $\Lambda$  = Leading edge sweep angle

When  $\sec \Lambda = 0.0$ , Piston theory coefficients are obtained (NTHRY = 1)

When  $\sec \Lambda = 1.0$ , van Dyke's coefficients are obtained (NTHRY = blank or 0)

When  $\sec \Lambda \neq 0.0$  or  $\neq 1.0$ , sweep corrections are included (NTHRY = 2)

5.  $I$  and  $J$  thickness integral definitions:

$g_\xi \equiv \frac{dg}{d\xi}$  = slope of airfoil semithickness

$$\begin{aligned}
 I_1 &= \int_0^1 g_\xi d\xi & J_1 &= \int_{\xi_h}^1 g_\xi d\xi \\
 I_2 &= \int_0^1 \xi g_\xi d\xi & J_2 &= \int_{\xi_h}^1 \xi g_\xi d\xi \\
 I_3 &= \int_0^1 \xi^2 g_\xi d\xi & J_3 &= \int_{\xi_h}^1 \xi^2 g_\xi d\xi \\
 I_4 &= \int_0^1 g_\xi^2 d\xi & J_4 &= \int_{\xi_h}^1 g_\xi^2 d\xi
 \end{aligned}$$

$$I_5 = \int_0^1 \xi g_\xi^2 d\xi \quad J_5 = \int_{\xi_h}^1 \xi g_\xi^2 d\xi$$

$$I_6 = \int_0^1 \xi^2 g_\xi^2 d\xi \quad J_6 = \int_{\xi_h}^1 \xi^2 g_\xi^2 d\xi$$

Figure 9-11 CAERO5  $I$  and  $J$  Thickness Integral Definitions

- The CAERO5 entry is only supported in SOL 145, SOL 200 with ANALYSIS=FLUT and in SOL 146 with mechanical loads. Gust response in SOL 146 is not supported for the CAERO5.

## CAMPBLL

## Campbell Diagram Parameters

Specifies the parameters for Campbell Diagram generation and mode tracking analysis.

Formats:

1	2	3	4	5	6	7	8	9	10
CAMPBLL	CID	VPARM	DDVALID	TYPE					
	MODTRK	CORU	SWITR	NUMMOD	PRTCOR				

Examples:

CAMPBLL	15	SPEED	22	RPM					
	1	0.75	1		1				

Describer	Meaning
CID	Identification number of entry (Integer > 0; Required).
VPARM	Variable parameter, allowable entry is: 'SPEED'. 'SPEED', reference rotor speed will be varied (rotordynamic option only).
DDVALID	Identification number of DDVAL entry that specifies the values for the variable parameter (Integer > 0; Required).
TYPE	Allowable entries are: 'FREQ' and 'RPM'.
MODTRK	Perform mode tracking using either numerical approach (default) or eigenvector based approach or both. (Default = 0). See remark 4.
CORU	Threshold for mode correlation.
SWITR	Option to use updated mode for mode tracking in case of failure. See remark 7.
NUMMODE	Number of modes to track (Should be less than $0.5 * Neig$ , where $Neig$ is the number of eigenvalues extracted in EIGC). See remark 4.
PRTCOR	Option to print correlation matrix at each rotor speed (Default = 0). See remark 9.

Remarks:

1. CAMPBLL option is supported for SOL 107, SOL110, SOL200 and SOL400 analysis.
2. CAMPBLL option is supported in SOL 200 and SOL 400 for ANALYSIS = DCEIG/MCEIG.
3. Only the modes with positive imaginary part are used for mode tracking (to avoid repeated eigenvalues.)
4. Following methods are available in MSC Nastran for mode tracking:
  - a. Numerical Mode tracking based on second derivative.

Obtain second derivative for the variation of eigenvalue with rotor speed and determine the eigenfrequency with minimum slope.

- b. Mode tracking based on orthogonality of left and right eigenvectors.

This feature is available for analysis in fixed reference frame only.

MODTRK = 0: Perform numerical mode tracking only. (Default)

MODTRK = 1: Perform BOTH numerical and eigenvector based mode tracking.

MODTRK = 2: Perform eigenvector based mode tracking only.

- 5. The variables specified in the second row are relevant for eigenvector-based mode tracking only.
- 6. Ideally, for tracked pair of modes, the value of Normalized Cross Complex Orthogonality (NC2O) parameter is very close to 1. However, for complex models involving large stator component and dynamic reduction, this value can be significantly lower. Thus, the default value for CORU is set to 0.7. Based on the model complexity and NC2O matrix obtained for two rotor speeds, user may change this value.
- 7. In case of mode tracking failure at a particular rotor speed, user has the option to continue mode tracking for rest of the rotors speed by:
  - SWITR = 1: Updating modes corresponding to rotor speed with failed mode tracking, or
  - SWITR = 0: Using the modes from last rotor speed with successful mode tracking. (Default)

In case the Campbell diagram includes multiple mode switching and there are new modes entering the analysis, use of SWITR=1 is recommended.
- 8. Only the complex eigenvalues with positive imaginary part are considered for mode tracking analysis. As a result, the number of eigenvalues available for mode tracking may not be same at all the rotor speeds considered in the analysis. This may lead to mode tracking failure. One way to avoid this issue is to pick NUMMODE to be less than half of the number of complex eigenvalues extracted using EIGC bulk data entry. Thus, the analysis uses only the first NUMMODE frequencies with positive imaginary part for mode tracking at each rotor speed.
- 9. When PRTCOR parameter is turned to 1, the code prints NC2O matrix corresponding to each rotor speed in the F06 file. This information can be very useful in identifying reasons for mode tracking failure.
- 10. For both approaches, damping ratio is also tracked while tracking eigenfrequencies. The results produced from mode tracking can be extracted in OP4 using following assign statements:

```
$ Extract results for numerical mode tracking
ASSIGN OUTPUT4='freq_nmt.op4',UNIT=71,FORM=FORMATTED,DELETE $ MODE FREQS
ASSIGN OUTPUT4='rot_nmt.op4',UNIT=72,FORM=FORMATTED,DELETE $ ROTOR SPEED
ASSIGN OUTPUT4='dmp_nmt.op4',UNIT=73,FORM=FORMATTED,DELETE $ DAMPING RATIO
$ Extract results for eigenvector based mode tracking
ASSIGN OUTPUT4='freq_evmt.op4',UNIT=81,FORM=FORMATTED,DELETE $ MODE FREQS
ASSIGN OUTPUT4='rot_evmt.op4',UNIT=82,FORM=FORMATTED,DELETE $ ROTOR SPEED
ASSIGN OUTPUT4='dmp_evmt.op4',UNIT=83,FORM=FORMATTED,DELETE $ DAMPING RATIO
```

These OP4 files can be imported in MSC PATRAN to produce Campbell Diagram.

- 11. DMP>1 is not supported for SOL 110 for generating Campbell diagram when ACMS option is not used.

## CAXIFI

## Fluid Element Connections

Defines an axisymmetric fluid element that connects  $i = 2, 3,$  or  $4$  fluid points.

Formats:

1	2	3	4	5	6	7	8	9	10
CAXIF2	EID	IDF1	IDF2			RHO	B		
CAXIF3	EID	IDF1	IDF2	IDF3		RHO	B		
CAXIF4	EID	IDF1	IDF2	IDF3	IDF4	RHO	B		

Examples:

CAXIF2	11	23	25			0.25E-3			
CAXIF3	105	31	32	33		6.47E-3			
CAXIF4	524	421	425	424	422	0.5E-3	2.5+3		

Describer	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ )
IDFi	Identification numbers of connected GRIDF points. ( $\text{Integer} > 0$ )
RHO	Fluid density in mass units. ( $\text{Real} > 0.0$ or blank)
B	Fluid bulk modulus. ( $\text{Real} \geq 0.0$ or blank)

Remarks:

1. CAXIFI is allowed only if an AXSLOT entry is also present.
2. The element identification number (EID) must be unique with respect to all other fluid or structural elements.
3. If RHO or B is blank, then the corresponding RHOD and BD fields must be specified on the AXSLOT entry.
4. Plot elements are generated for these elements. Because each plot element connects two points, one is generated for the CAXIF2 element, three are generated for the CAXIF3 element, and four plot elements are generated for the CAXIF4 element. In the last case the elements connect the pairs of points (1-2), (2-3), (3-4), and (4-1).
5. If  $B = 0.0$ , the fluid is incompressible.

## CAXISYM

## Axisymmetric Line Elements Connection - SOL 400

Defines two or three node axisymmetric thick shell elements.

Formats:

1	2	3	4	5	6	7	8	9	10
CAXISYM	EID	PID	G1	G2	G3	NOFF			

Example:

CAXISYM	22	98	8	16					
---------	----	----	---	----	--	--	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of PAXISYM entry. (Integers > 0)
G1, G2	Identification numbers at the two end grid points. Required data. (Unique; Integers > 0)
G3	Identification number of the one grid in between G1 and G2. See Remark 2. (Unique Integer ≥ 0 or blank). If G3=0; this is a straight two node element.
NOFF	Offset from the surface of the grid points to the element reference plane. (Real)

Remarks:

1. Element identification numbers should be unique with respect to all other identification numbers.
2. It is recommended that G3 be located within the middle third of the element.
3. The element must lie in the x-y plane of the basic system and is oriented as shown below.

## CBAR Simple Beam Element Connection

Defines a simple beam element.

Format:

1	2	3	4	5	6	7	8	9	10
CBAR	EID	PID	GA	GB	X1	X2	X3	OFFT	
	PA	PB	W1A	W2A	W3A	W1B	W2B	W3B	

Example:

CBAR	2	39	7	3	0.6	18.	26.	GOG	
		513							

Alternate Format and Example:

CBAR	EID	PID	GA	GB	G0			OFFT	
	PA	PB	W1A	W2A	W3A	W1B	W2B	W3B	
CBAR	2	39	7	6	105			GOG	
		513							

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PBAR, PBARL or PBRSECT entry. (Integer > 0 or blank*; Default = EID unless BAROR entry has nonzero entry in field 3.)
GA, GB	Grid point identification numbers of connection points. (Integer > 0; GA ≠ GB)
X1, X2, X3	Components of orientation vector $\vec{v}$ , from GA, in the displacement coordinate system at GA (Default), or in the basic coordinate system. See Remark 8. (Real)
G0	Alternate method to supply the orientation vector $\vec{v}$ using grid point G0. The direction of $\vec{v}$ is from GA to G0. $\vec{v}$ is then translated to End A. (Integer > 0; G0 ≠ GA or GB)
OFFT	Offset vector interpretation flag. (character or blank) See Remark 8.

Descriptor	Meaning
PA, PB	Pin flags for bar ends A and B, respectively. Used to remove connections between the grid point and selected degrees-of-freedom of the bar. The degrees-of-freedom are defined in the element's coordinate system (see Figure 9-12). The bar must have stiffness associated with the PA and PB degrees-of-freedom to be released by the pin flags. For example, if PA = 4 is specified, the PBAR entry must have a value for J, the torsional stiffness. (Up to 5 of the unique Integers 1 through 6 anywhere in the field with no embedded blanks; Integer > 0.) Pin flags combined with offsets are not allowed for SOL 600. Pin flags are not allowed in SOL 700.
W1A, W2A, W3A W1B, W2B, W3B	Components of offset vectors $\vec{w}_a$ and $\vec{w}_b$ , respectively (see Figure 9-12) in displacement coordinate systems (or in element system depending upon the content of the OFFT field), at points GA and GB, respectively. See Remark 7. and 8. (Real; Default = 0.0) Offsets are not allowed in SOL 700.

\*See the BAROR entry for default options for field 3 and fields 6 through 9.

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Figure 9-12 and Figure 9-13 define bar element geometry with and without offsets:

Figure 9-12 CBAR Element Geometry with Offsets

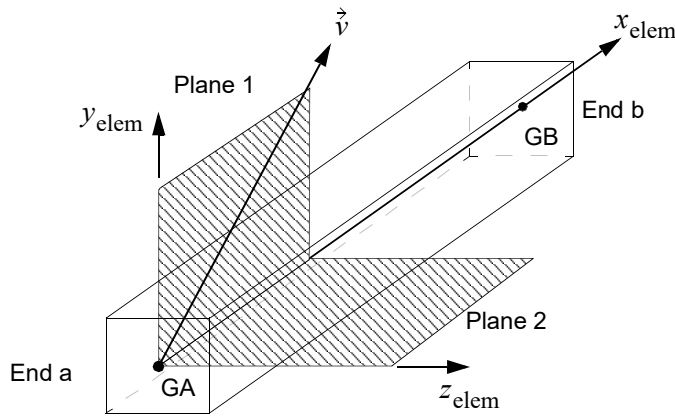

Figure 9-13 CBAR Element Geometry without Offsets

3. Figure 9-14 and Figure 9-15 define the elemental force and moment sign convention.

Figure 9-14 CBAR Element Internal Forces and Moments (x-y Plane)

Figure 9-15 CBAR Element Internal Forces and Moments (x-z Plane)

4. The continuation may be omitted if there are no pin flags or offsets.  
 5. For the case where field 9 is blank and not provided by the BAROR entry, if an integer is specified in field 6, then G0 is used; if field 6 is blank or real, then X1, X2, X3 is used.

6. See [Grid Point and Coordinate System Definition](#) in the *MSC Nastran Reference Guide* for a definition of coordinate system terminology.
7. Offset vectors are treated internally like rigid elements. For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, the user is required to use MDLPRM, OFFDEF, LROFF.
  - Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.
  - The length of offset vectors is not affected by thermal loads. But the thermal load changes due to location changes by offsets are correctly computed if the enhanced method is used.
  - BAR elements with offsets will give correct buckling results if the enhanced method is used.
  - Masses are correctly transformed for offset effects if MDLPRM, OFFDEF, LROFF is used. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by MDLPRM, OFFDEF, NOMASS.
  - In nonlinear solution sequences, such as SOL 106 or SOL 400, BAR is treated as linear element. If geometric nonlinear effects are required, please use Bulk Data entry MDLPRM,BRTOBM,1 to convert BAR to BEAM.
8. OFFT is a character string code that describes how the offset and orientation vector components are to be interpreted. By default (string input is GGG or blank), the offset vectors are measured in the displacement coordinate systems at grid points A and B and the orientation vector is measured in the displacement coordinate system of grid point A. At user option, the offset vectors can be measured in an offset coordinate system relative to grid points A and B, and the orientation vector can be measured in the basic system as indicated in the following table:

String	Orientation Vector	End A Offset	End B Offset
GGG	Global	Global	Global
BGG	Basic	Global	Global
GGO	Global	Global	Offset
BGO	Basic	Global	Offset
GOG	Global	Offset	Global
BOG	Basic	Offset	Global
GOO	Global	Offset	Offset
BOO	Basic	Offset	Offset

Any attempt to specify invalid combinations results in a bulk data entry input error message. For example, a value of OOO (indicating offset and orientation vectors are specified in an offset reference system) results in a fatal error since the orientation vector cannot be specified in an offset system. The offset system x-axis is defined from GA to GB. The orientation vector  $\vec{v}$  and the offset system x-axis are then used to define the z and y axes of the offset system. A vector is formed from a cross product of a vector going from Grid A to Grid B and the orientation vector to create the offset coordinate z-direction. To obtain a nonzero cross product the orientation vector must not be parallel to both vectors from Grid A to Grid B for the offset coordinate system and End A and End B for the element coordinate system. (Note: The character “O” in the table replaces the obsolete character “E”.)

9. For SOL 600, the BIT field is ignored unless param,MAROFSET is 1 or 2. An extra flag
10. For SOL 700, the BIT field is ignored and a warning is issued.
11. For RC network solver in thermal analysis, the G0, OFFT, PA, PB, W1A, W2A, W3A, W1B, W2B and W3B are ignored.

## CBARAO

### Auxiliary Output Points Along Bar Element Axis (CBAR Entry)

Defines a series of points along the axis of a bar element (CBAR entry) for stress and force recovery output. This entry is applicable in static and normal modes analysis only.

Format:

1	2	3	4	5	6	7	8	9	10
CBARAO	EID	SCALE	X1	X2	X3	X4	X5	X6	

Example:

CBARAO	1065	FR	0.2	0.4	0.6	0.8			
--------	------	----	-----	-----	-----	-----	--	--	--

Alternate Format and Example:

CBARAO	EID	SCALE	NPTS	X1	DELTA				
CBARAO	1065	FR	4	0.2	0.2				

Descriptor	Meaning
EID	Element identification of a CBAR entry. (0 < Integer < 100,000,000)
SCALE	Defines scale of Xi values. (Character = "LE" or "FR")
Xi	Series of locations along element axis for stress and force data recovery. (Real > 0.0)
DELTA	Incremental distance along element axis. (Real)
NPTS	Number of stress recovery points, not including the end points. (Integer > 0)

Remarks:

1. This entry defines intermediate locations on the axis of selected CBAR elements for additional data recovery. The values of Xi are actual distances along the length if SCALE = "LE". If SCALE = "FR", the values of Xi are ratios of actual distances to the bar length. A PLOAD1 Bulk Data entry for the CBAR element in question must be present to obtain intermediate data recovery.
2. When the alternate format is used, a series of locations  $X_i = X_{[i-1]} + \text{DELTA}$ ,  $i = 1, 2, \dots, \text{NPTS}$  is generated.
3. If a CBARAO or PLOAD1 entry is specified and stress and/or force output is requested, then the stresses and/or forces will be calculated at each location Xi and output as a separate line. The force and stress values at the end points of the beam will always be output. This output format will be used for all beam and bar elements.
4. Intermediate loads on the element defined by the PLOAD1 entry will be accounted for in the calculation of element stresses and forces. If no PLOAD1 entry is defined for the element, the shear forces are constant, the moments are linear, and it is not necessary that the user define additional points.

5. For each bar element, either the basic format or the alternate format, but not both, may be used. A maximum of six internal points can be specified with the basic form. The end points must not be listed because data will be generated for them, as explained in Remark 3. If more than six unequally spaced internal points are desired, it is advisable to subdivide the bar into two or more elements.

## CBEAM

### Beam Element Connection

Defines a beam element.

Format:

1	2	3	4	5	6	7	8	9	10
CBEAM	EID	PID	GA	GB	X1	X2	X3	OFFT	
	PA	PB	W1A	W2A	W3A	W1B	W2B	W3B	
	SA	SB							

Example:

CBEAM	2	39	7	13	8.2	6.1	-5.6	GOG	
		513		3.0					
	8	5							

Alternate Format and Example:

CBEAM	EID	PID	GA	GB	G0			OFFT	
	PA	PB	W1A	W2A	W3A	W1B	W2B	W3B	
	SA	SB							

CBEAM	2	39	7	13	105			GOG	
		513							

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of PBEAM, PBCOMP, PBEAML or PBMSECT entry. (Integer > 0; Default = EID)*
GA, GB	Grid point identification numbers of connection points. (Integer > 0; GA ≠ GB)
X1, X2, X3	Components of orientation vector $\vec{v}$ , from GA, in the displacement coordinate system at GA (Default), or in the basic coordinate system. See Remark 8. (Real)
G0	Alternate method to supply the orientation vector $\vec{v}$ using grid point G0. Direction of $\vec{v}$ is from GA to G0. $\vec{v}$ is then transferred to End A. (Integer > 0; G0 ≠ GA or GB)
OFFT	Offset vector interpretation flag. See Remark 8. (Character or blank)

Describer	Meaning
PA, PB	Pin flags for beam ends A and B, respectively; used to remove connections between the grid point and selected degrees-of-freedom of the beam. The degrees-of-freedom are defined in the element's coordinate system and the pin flags are applied at the offset ends of the beam (see <a href="#">Figure 9-16</a> ). The beam must have stiffness associated with the PA and PB degrees-of-freedom to be released by the pin flags. For example, if PA = 4, the PBEAM entry must have a nonzero value for J, the torsional stiffness. (Up to five of the unique Integers 1 through 6 with no embedded blanks.) Pin flags combined with offsets are not allowed for SOL 600. Pin flags are not presently allowed in SOL 700. Also, Pig flags should not be used in nonlinear analysis when there is large displacement.
W1A, W2A, W3A W1B, W2B, W3B	Components of offset vectors from the grid points to the end points of the axis of the shear center. See Remarks 7., 8. and 8. (Real; Default = 0.0)
SA, SB	Scalar or grid point identification numbers for the ends A and B, respectively. The degrees-of-freedom at these points are the warping variables $d\theta/dx$ . (Integers $\geq 0$ or blank)

\*See the BEAMOR entry for default options for field 3 and fields 6 through 9.

**Remarks:**

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. For an additional explanation of the beam element, see the [Beam Element \(CBEAM\)](#) in the *MSC Nastran Reference Guide*. [Figure 9-16](#) defines beam element geometry:

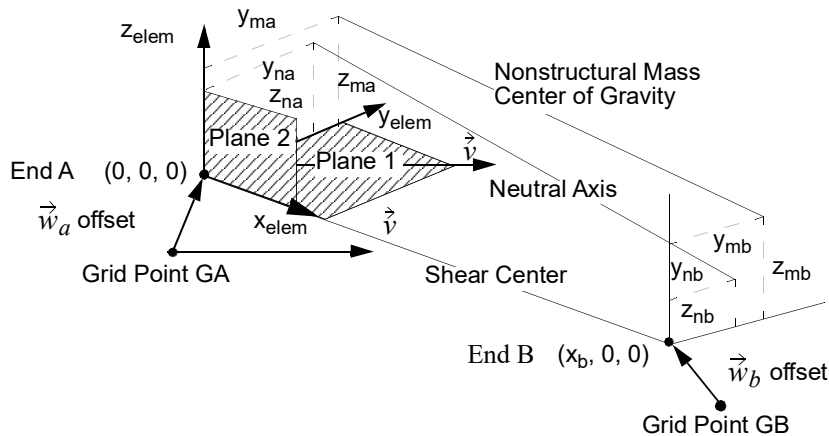

Figure 9-16 CBEAM Element Geometry System

Figure 9-17 CBEAM Internal Element Forces and Moments

3. If field 6 is an integer, then G0 is used. If field 6 is blank or real, then X1, X2, X3 is used.
4. G0 cannot be located at GA or GB.
5. The rules for the continuations entries are:
  - Both continuations may be omitted if there are no pin flags, offsets, or warping variables.
  - If the second continuation is used, then the first continuation must be included, even if all fields are blank.
  - If the second continuation is omitted, torsional stiffness due to warping of the cross section will not be considered.
6. If warping is allowed ( $SA$  and  $SB > 0$ ), then  $SA$  and  $SB$  must be defined with SPOINT or GRID entries. If GRID entries are used, the warping degree-of-freedom is attached to the first (T1) component. In addition, SPOINT ID is recommended for  $SA$  and  $SB$  if GROUNDCHECK is requested in case control.
7. Offset vectors are treated internally like rigid elements. Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.

For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, the user is required to use MDLPRM, OFFDEF, LROFF. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by MDLPRM, OFFDEF, NOMASS.

For SOLs 106, 129, 153, and 159 the differential stiffness for offset vectors will give incorrect results with PARAM, LGDISP, 1.

8. OFFT in field 9 is a character string code that describes how the offset and orientation vector components are to be interpreted. By default (string input is GGG or blank), the offset vectors are measured in the displacement coordinate systems at grid points A and B and the orientation vector is measured in the displacement coordinate system of grid point A. At user option, the offset vectors can be measured in an offset system relative to grid points A and B, and the orientation vector can be measured in the basic system as indicated in the following table:

String	Orientation Vector	End A Offset	End B Offset
GGG	Global	Global	Global
BGG	Basic	Global	Global
GGO	Global	Global	Offset
BGO	Basic	Global	Offset
GOG	Global	Offset	Global
BOG	Basic	Offset	Global
GOO	Global	Offset	Offset
BOO	Basic	Offset	Offset

Any attempt to specify invalid combinations results in a bulk data entry input error message. For example, a value of OOO (indicating offset and orientation vectors are specified in an offset reference system) results in a fatal error since the orientation vector cannot be specified in an offset system. The offset system x-axis is defined from GA to GB. The orientation vector  $\vec{v}$  and the offset system x-axis are then used to define the z and y axes of the offset system. A vector is formed from a cross product of a vector going from Grid A to Grid B and the orientation vector to create the offset coordinate z-direction. To obtain a nonzero cross product the orientation vector must not be parallel to both vectors from Grid A to Grid B for the offset coordinate system and End A and End B for the element coordinate system. (Note: The character “O” in the table replaces the obsolete character “E”.)

9. For RC network solver in thermal analysis, the X1, X2, X3, OFFT, PA, PB, W1A, W2A, W3A, W1B, W2B, W3B, SA and SB are ignored.

## CBEAM3

### Three-Node Beam Element Connection

Defines a three-node beam element.

Format:

1	2	3	4	5	6	7	8	9	10
CBEAM3	EID	PID	GA	GB	GC	X1	X2	X3	
	W1A	W2A	W3A	W1B	W2B	W3B	W1C	W2C	
	W3C	TWA	TWB	TWC	SA	SB	SC		

Example:

CBEAM3	101	2	201	332	1000	1.0	3.5	-2.0	
		3.0		3.0	2.2	-1.0			
	2.5	10.	15.	20.0	206	301	312		

Alternate Format and Example:

CBEAM3	EID	PID	GA	GB	GC	G0			
	W1A	W2A	W3A	W1B	W2B	W3B	W1C	W2C	
	W3C	TWA	TWB	TWC	SA	SB	SC		

CBEAM3	101	2	201	332	1000	105			
		3.0			2.2	1.0			
	2.5	10.	15.	20.0	206	301	312		

Descriptor	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of PBEAM3 or PBMSECT entries. See Remark 8. (Integer > 0; Required)
GA, GB, GC	Grid point identification numbers of connection points. GA and GB are grid point identification numbers at the two ends of the beam element while GC is the one at the grid point in between. (Integer > 0 or blank; GA, GB and GC must be distinct from each other. See Remark 6.)
X1, X2, X3	Components of orientation vector $\vec{v}$ , from GA, in the displacement coordinate system at GA. (Real)
G0	Alternate method to supply the orientation vector $\vec{v}$ using grid point G0. The direction of $\vec{v}$ is from GA to G0. $\vec{v}$ is then transferred to End A. (Integer > 0; G0 ≠ GA or GB or GC)

Describer	Meaning
WiA, WiB, WiC	Components of offsets vectors, measured in the displacement coordinate systems at grid points A, B, and C, from the grid points to the points on the axis of shear center. See Remark 9. (Real; Default = 0.0)
TWA, TWB, TWC	Pretwist angles in degrees at A, B, and C, respectively. (Real; Default = 0.0)
SA, SB, SC	Scalar or grid point identification numbers for A, B, and C, respectively. The degrees of freedom at these points are warping variables. (Integer > 0 or blank)

#### Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. If field 7 is an integer, then G0 is used. If field 7 is blank or real, then X1, X2, X3 are used.
3. G0 cannot be located at GA or GB or GC.
4. If warping effect is included in the analysis (SA, SB and SC > 0), then SA, SB, and SC must be defined with either SPOINT or GRID entries. If GRID entries are used, the warping degree of freedom is attached to the first (T1) component. In addition, SPOINT ID is recommended for SA, SB and SC if GROUNDCHECK is requested in case control.
5. BEAMOR cannot be used to set up default options for field 3 and fields 6 through 8 for CBEAM3 entries.
6. If GC is left blank, then the element degenerates to a formulation similar to the two-node straight beam element. The two-node straight beam formulation is not the CBEAM formulation and will result in overly stiff results with warping and shear center offset. This is because the CBEAM3 is a Variational Asymptotic Beam Section that generalizes Timoshenko beam theory and requires the mid node for accuracy.
7. This entry is not available in SOL 600.
8. For CBEAM3 referencing PBMSECT, the CORE/LAYER keywords are required or a Fatal message is issued. For this composite case, it is recommended that CBEAM3 has 3 nodes and 3 warping DOFs.

Figure 9-18 CBEAM3 Element Geometry System

Figure 9-19 Local Coordinate System on Beam Cross-Section

- Offset vectors are treated internally like rigid elements. Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.

For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, the user is required to use MDLPRM, OFFDEF, LROFF. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by MDLPRM, OFFDEF, NOMASS.

## CBEND Curved Beam or Pipe Element Connection

Defines a curved beam, curved pipe, or elbow element.

Format:

1	2	3	4	5	6	7	8	9	10
CBEND	EID	PID	GA	GB	X1	X2	X3	GEOM	

Example:

CBEND	32	39	17	19	6.2	5.1	-1.2	3	
-------	----	----	----	----	-----	-----	------	---	--

Alternate Format and Example:

CBEND	EID	PID	GA	GB	G0			GEOM	
CBEND	32	39	17	19	106			3	

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PBEND entry. (Integer > 0; Default = EID)
GA, GB	Grid point identification numbers of connection points. (Integer > 0; GA ≠ GB)
X1, X2, X3	Components of orientation vector $\vec{v}$ , from GA, in the displacement coordinate system at GA. (Real)
G0	Alternate method to supply the orientation vector $\vec{v}$ using grid point G0. Direction of $\vec{v}$ is from GA to G0. $\vec{v}$ is then translated to End A. (Integer > 0; G0 ≠ GA or GB)
GEOM	Flag to select specification of the bend element. See Remark 3. (1 ≤ Integer ≤ 4; No Default)

Remarks:

1. Element identification numbers must be unique with respect to all other element identification numbers.

2. For an additional explanation of the CBEND element, see the PBEND entry description. [Figure 9-20](#) and [Figure 9-21](#) define the element coordinate system and internal forces and moments.

Figure 9-20 CBEND Element Coordinate System

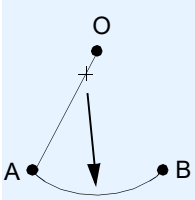

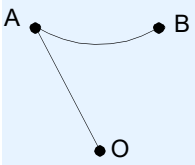

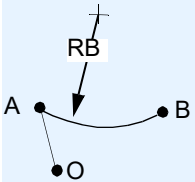

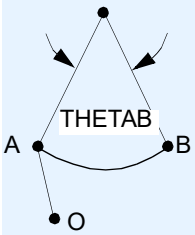

Figure 9-21 CBEND Element Internal Forces and Moments

3. The options for element connection to GA, GB using GEOM are the following.

Table 2 GEOM Options

Configuration	GEOM	Description
	1	The center of curvature lies on the line AO (or its extension) or vector $\vec{v}$ .
	2	The tangent of centroid arc at end A is parallel to line AO or vector $\vec{v}$ . Point O (or vector $\vec{v}$ ) and the arc AB must be on the same side of the chord AB.
	3	The bend radius (RB) is specified on the PBEND entry: Points A, B, and O (or vector $\vec{v}$ ) define a plane parallel or coincident with the plane of the element arc. Point O (or vector $\vec{v}$ ) lies on the opposite side of line AB from the center of the curvature.
	4	THETAB is specified on the PBEND entry. Points A, B, and O (or vector $\vec{v}$ ) define a plane parallel or coincident with the plane of the element arc. Point O (or vector $\vec{v}$ ) lies on the opposite side of line AB from the center of curvature.

4. For RC network solver in thermal analysis, the X1, X2, X3 and GEOM are ignored.

## CBUSH Generalized Spring-and-Damper Connection

Defines a generalized spring-and-damper structural element that may be nonlinear or frequency dependent.

Format:

1	2	3	4	5	6	7	8	9	10
CBUSH	EID	PID	GA	GB	GO/X1	X2	X3	CID	
	S	OCID	S1	S2	S3				

**Example 1:** Noncoincident grid points.

CBUSH	39	6	1	100	75				
-------	----	---	---	-----	----	--	--	--	--

**Example 2:** GB not specified.

CBUSH	39	6	1					0	
-------	----	---	---	--	--	--	--	---	--

**Example 3:** Coincident grid points ( $GA \neq GB$ ).

CBUSH	39	6	1					6	
-------	----	---	---	--	--	--	--	---	--

**Example 4:** Noncoincident grid points with fields 6 through 9 blank and a spring-damper offset.

CBUSH	39	6	1	600					
	0.25	10	0.	10.	10.				

Describer	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Property identification number of a PBUSH entry. ( $\text{Integer} > 0$ ; Default = EID)
GA, GB	Grid point identification number of connection points. See Remark 6. ( $GA > 0$ , $GB \geq 0$ or blank)
Xi	Components of orientation vector $\vec{v}$ , from GA, in the displacement coordinate system at GA. (Real)
GO	Alternate method to supply vector $\vec{v}$ using grid point GO. Direction of $\vec{v}$ is from GA to GO. $\vec{v}$ is then transferred to End A. See Remark 3. ( $\text{Integer} > 0$ )
CID	Element coordinate system identification. A 0 value means the basic coordinate system will be used. If CID is blank, then the element coordinate system is determined from GO or Xi. See Figure 9-22 and Remark 3. ( $\text{Integer} \geq 0$ or blank)
S	Location of spring damper. See Figure 9-22. (Real; Default = 0.5)

Describer	Meaning
OCID	Coordinate system identification of spring-damper offset. See Remark 9. (Integer $\geq -1$ ; Default = -1, which means the offset point lies on the line between GA and GB according to Figure 9-22)
S1, S2, S3	Components of spring-damper offset in the OCID coordinate system if OCID $\geq 0$ . See Figure 9-23 and Remark 9. (Real)

#### Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Figure 9-22 shows the bush element geometry. In geometric nonlinear analysis (SOL400), the element axis (line GA to GB) follows the deformation of grids GA and GB.
3.  $CID \geq 0$  overrides GO and Xi. Then the element x-axis is along T1, the element y-axis is along T2, and the element z-axis is along T3 of the CID coordinate system. If the CID refers to a cylindrical coordinate system or a spherical coordinate system, then grid GA is used to locate the system. If for cylindrical or spherical coordinate, GA falls on the z-axis used to define them, it is recommended that another CID be selected to define the element x-axis.
4. For noncoincident grids ( $GA \neq GB$ ), when GO or (X1, X2, X3) is given and no CID is specified, the line AB is the element x-axis and the orientation vector  $\vec{v}$  lies in the x-y plane (similar to the CBEAM element).
5. For noncoincident grids ( $GA \neq GB$ ), if neither GO or (X1, X2, X3) is specified and no CID is specified, then the line AB is the element x-axis. This option is valid only when K1 (or B1) or K4 (or B4) or both on the PBUSH entry are specified (but K2, K3, K5, K6 or B2, B3, B5, B6 are not specified). If K2, K3, K5, or K6 (or B2, B3, B5, or B6) are specified, a fatal message will be issued.
6. If the distance between GA and GB is less than .0001, or if GB is blank, then CID must be specified. GB blank implies that B is a grounded terminal, a grounded terminal is a point with a displacement that is constrained to zero.
7. If PID references a PBUSHT entry, then the CBUSH element may only be defined in the residual structure and cannot be attached to any omitted degrees-of-freedom.
8. Element impedance output is computed in the CID coordinate system. The impedances in this system are uncoupled.
9. If OCID = -1 or blank (default) then S is used and S1, S2, S3 are ignored. If OCID  $\geq 0$ , then S is ignored and S1, S2, S3 are used.

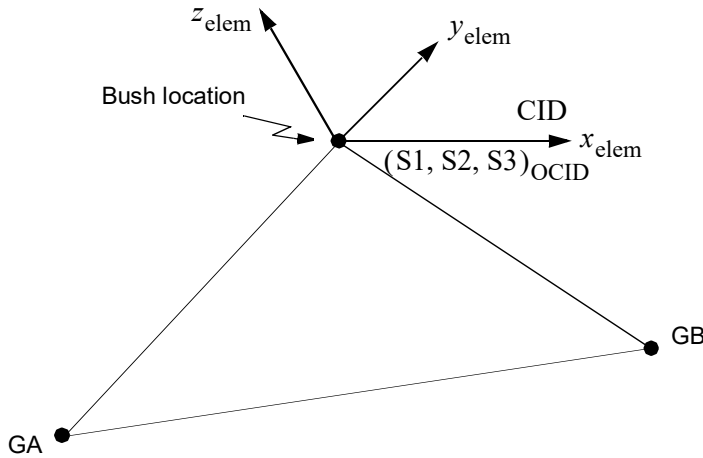

Figure 9-22 CBUSH Element

The material stiffness and damping properties of the elastomer are located at  $(S1, S2, S3)$ .

Figure 9-23 Definition of Offset S1, S2, S3

- When  $CID \geq 0$ , the element x-axis is set as in Remark 3. This means that the element force is always computed as  $K_e \cdot (UB - UA)$ ; if  $UA > UB$ , a compressive force will result. This is unlike the GO or Xi options, where relative positive elongation in tension and relative negative elongation is compression.

11. The CBUSH element is designed to satisfy rigid body equilibrium requirements. For noncoincident grids, internal rigid links connect the bush location to the grid locations. This results in coupling between translational and rotational degrees-of-freedom at the grids even when no rotational springs or dampers are specified on the PBUSH.
12. CBUSH elements are not supported in thermal analysis.

## CBUSH1D

### Rod Type Spring-and-Damper Connection

Defines the connectivity of a one-dimensional spring and viscous damper element.

Format:

1	2	3	4	5	6	7	8	9	10
CBUSH1D	EID	PID	GA	GB	CID				

Example:

CBUSH1D	35	102	108	112					
---------	----	-----	-----	-----	--	--	--	--	--

Describer	Meaning	Default Values
EID	Element identification number. (0 < Integer < 100,000,000)	Required
PID	Property identification number of a PBUSH1D entry. (Integer > 0)	EID
GA	Grid point id of first grid.	Required
GB	Grid point id of second grid	blank
CID	Coordinate system id. (Integer ≥ 0)	blank

Remarks:

1. For noncoincident grids  $GA \neq GB$  and if CID is blank, the line GA to GB is the element axis. In geometric nonlinear analysis, the element axis (line GA to GB) follows the deformation of grids GA and GB. See [Figure 9-24](#).
2. If  $CID \geq 0$  is specified, the x-axis of the CID coordinate system is the element axis. In geometric nonlinear analysis, the element axis (x-axis of CID) remains fixed.
3. If GA and GB are coincident or if GB is blank, then  $CID \geq 0$  must be specified and the element axis is the x-axis of CID.

Figure 9-24 Spring and Damper Element

## CBUSH2D

## 2-D Linear-Nonlinear Connection

Defines the connectivity of a two-dimensional Linear-Nonlinear element.

Format:

1	2	3	4	5	6	7	8	9	10
CBUSH2D	EID	PID	GA	GB	CID	PLANE			

Example:

CBUSH2D	100	101	1001	2001	0	XY			
---------	-----	-----	------	------	---	----	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000; Required)
PID	Property identification number of a PBUSH2D. (Integer > 0; Required)
GA	Inner grid. (Integer > 0; Required)
GB	Outer grid. (Integer > 0; Required)
CID	Coordinate system used to define 2-D plane. (Integer ≥ 0; Default = 0)
PLANE	Orientation plane in CID: XY, YZ, ZX, see Remark 1. (Character; Default = 'XY')

Remarks:

1. The XY, YZ, and ZX planes are relative to the displacements coordinates of GA and GB. The planes correspond to directions 1 and 2. GA and GB should be coincident grids with parallel displacement coordinate systems. The coordinate systems are not checked. Wrong answers will be produced if this rule is not followed.
2. The behavior is different if there is no rotor in the model and a CBUSH2D is used. When this happens, for most cases, if there is no rotor the nominal stiffness values from the PBUSH2D will be used, with no frequency-dependence. However, if an ELEMUDS is used, the CBUSH2D will be ignored if there is no rotor in the model. Also, an ELEMUDS with CBUSH2DA call will require to have a rotor in the model. A FATAL message will be used if there is no rotor, for ELEMUDS having CBUSH2DA call.

## CCONEAX

### Axisymmetric Shell Element Connection

Defines a conical shell element.

Format:

1	2	3	4	5	6	7	8	9	10
CCONEAX	EID	PID	RA	RB					

Example:

CCONEAX	1	2	3	4					
---------	---	---	---	---	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PCONEAX entry. (Integer > 0; Default = EID)
RA	Identification number of a RINGAX entry. (Integer > 0; RA ≠ RB)
RB	Identification number of a RINGAX entry. (Integer > 0; RA ≠ RB)

Remarks:

1. This element has limited capabilities. See the *MSC Nastran Reference Guide*, Section 5.3.3.
2. This entry is allowed only if an AXIC entry is also present.
3. In order to reference this entry on a SET Case Control command, the ID must be modified by

$$ID_n = ID \cdot 1000 + n$$

where n is the harmonic number plus one and ID<sub>n</sub> is the value specified on the SET entry.

## CDAMP1 Scalar Damper Connection

Defines a scalar damper element.

Format:

1	2	3	4	5	6	7	8	9	10
CDAMP1	EID	PID	G1	C1	G2	C2			

Example:

CDAMP1	19	6	0		23	2			
--------	----	---	---	--	----	---	--	--	--

Describer	Meaning
EID	Unique element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Property identification number of a PDAMP property entry. ( $\text{Integer} > 0$ ; Default = EID)
G1, G2	Geometric grid point identification number. ( $\text{Integer} \geq 0$ )
C1, C2	Component number. ( $0 \leq \text{Integer} \leq 6$ ; blank or zero if scalar point.)

Remarks:

- Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero.
- Element identification numbers should be unique with respect to all other element identification numbers.
- The two connection points (G1, C1) and (G2, C2), must be distinct.
- For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
- When CDAMP1 is used in heat transfer analysis, it generates a lumped heat capacity.
- A scalar point specified on this entry need not be defined on an SPOINT entry.
- If Gi refers to a grid point then Ci refers to degrees-of-freedom(s) in the displacement coordinate system specified by CD on the GRID entry.

## CDAMP1D

## Scalar Damper Connection for SOL 700 Only

Defines a scalar damper connection for use in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CDAMP1D	EID	PID	G1	C1	G2	C2			
	CORD	FOLLOW							

Example:

CDAMP1D	1001	101	55	1					
---------	------	-----	----	---	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PDAMPn entry. (Integer > 0; Default = EID)
G1, G2	Geometric grid point identification number. (Integer ≥ 0)
C1, C2	Component number. (0 ≤ Integer ≤ 6; 0 or up to six unique integers, 1 through 6 may be specified in the field with no embedded blanks. 0 applies to scalar points and 1 through 6 applies to grid points.)
CORD	Number of a coordinate system in which the degree-of-freedom (C1,C2) is defined. (Integer ≥ 0)
FOLLOW	Method to update the direction vector in which the damper acts: FOLLOW=CORD: direction vector follows the motion of the coordinate system as specified under CORD.

Remark:

- Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero.
- Element identification numbers should be unique with respect to all other element identification numbers.
- The two connection points (G1, C1) and (G2, C2), must be distinct.
- For a discussion of the scalar elements, see [Scalar Elements \(CELASI, CMASSI, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
- When CDAMP1 is used in heat transfer analysis, it generates a lumped heat capacity.
- A scalar point specified on this entry need not be defined on an SPOINT entry.
- If Gi refers to a grid point then Ci refers to degrees-of-freedom(s) in the displacement coordinate system specified by CD on the GRID entry. Available in SOL 700 only.

## CDAMP2

## Scalar Damper Property and Connection

Defines a scalar damper element without reference to a material or property entry.

Format:

1	2	3	4	5	6	7	8	9	10
CDAMP2	EID	B	G1	C1	G2	C2			

Example:

CDAMP2	16	2.98	32	1					
--------	----	------	----	---	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
B	Value of the scalar damper. (Real)
G1, G2	Geometric grid point identification number. (Integer ≥ 0)
C1, C2	Component number. (0 ≤ Integer ≤ 6; blank or zero if scalar point.)

Remarks:

1. Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. The two connection points (G1, C1) and (G2, C2), must be distinct.
4. For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
5. When CDAMP2 is used in heat transfer analysis, it generates a lumped heat capacity.
6. A scalar point specified on this entry need not be defined on an SPOINT entry.
7. If Gi refers to a grid point then Ci refers to degrees-of-freedom(s) in the displacement coordinate system specified by CD on the GRID entry.
8. RC network solver does not support CDAMP2 for thermal analysis.

## CDAMP2D

## Scalar Damper Connection for SOL 700 Only

Defines a scalar damper connection for use in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CDAMP2D	EID	B	G1	C1	G2	C2			
	CORD	FOLLOW							

Example:

CDAMP2D	1001	101	55	1					
---------	------	-----	----	---	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. ( $0 < \text{Integer} < 100,000,000$ )
B	Value of the scalar damper. (Real)
G1, G2	Geometric grid point identification number. ( $\text{Integer} \geq 0$ )
C1, C2	Component number. ( $0 \leq \text{Integer} \leq 6$ ; 0 or up to six unique integers, 1 through 6 may be specified in the field with no embedded blanks. 0 applies to scalar points and 1 through 6 applies to grid points.)
CORD	Number of a coordinate system in which the degree-of-freedom (C1,C2) is defined. ( $\text{Integer} \geq 0$ )
FOLLOW	Method to update the direction vector in which the damper acts: FOLLOW=CORD: direction vector follows the motion of the coordinate system as specified under CORD.

Remark:

- Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero.
- Element identification numbers should be unique with respect to all other element identification numbers.
- The two connection points (G1, C1) and (G2, C2), must be distinct.
- For a discussion of the scalar elements, see [Scalar Elements \(CELASI, CMASSI, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
- When CDAMP2 is used in heat transfer analysis, it generates a lumped heat capacity.
- A scalar point specified on this entry need not be defined on an SPOINT entry.
- If Gi refers to a grid point then Ci refers to degrees-of-freedom(s) in the displacement coordinate system specified by CD on the GRID entry. Available in SOL 700 only.

## CDAMP3 Scalar Damper Connection to Scalar Points Only

Defines a scalar damper element that is connected only to scalar points.

Format:

1	2	3	4	5	6	7	8	9	10
CDAMP3	EID	PID	S1	S2					

Example:

CDAMP3	16	978	24	36					
--------	----	-----	----	----	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PDAMP entry. (Integer > 0; Default = EID)
S1, S2	Scalar point identification numbers. (Integer ≥ 0; S1 ≠ S2)

Remarks:

1. S1 or S2 may be blank or zero, indicating a constrained coordinate.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. Only one scalar damper element may be defined on a single entry.
4. For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
5. When CDAMP3 is used in heat transfer analysis, it generates a lumped heat capacity.
6. A scalar point specified on this entry need not be defined on an SPOINT entry.
7. RC network solver does not support CDAMP3 for thermal analysis.

## CDAMP4

## Scalar Damper Property and Connection to Scalar Points Only

Defines a scalar damper element that connected only to scalar points and without reference to a material or property entry.

Format:

1	2	3	4	5	6	7	8	9	10
CDAMP4	EID	B	S1	S2					

Example:

CDAMP4	16	-2.6	4	9					
--------	----	------	---	---	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
B	Scalar damper value. (Real)
S1, S2	Scalar point identification numbers. (Integer $\geq$ 0; S1 $\neq$ S2 )

Remarks:

1. S1 or S2 may be blank or zero, indicating a constrained coordinate.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. Only one scalar damper element may be defined on a single entry.
4. For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
5. If this entry is used in heat transfer analysis, it generates a lumped heat capacity.
6. A scalar point specified on this entry need not be defined on an SPOINT entry.
7. RC network solver does not support CDAMP4 for thermal analysis.

## CDAMP5 Scalar Damper with Material Property

Defines a damping element that refers to a material property entry and connection to grid or scalar points. This element is intended for heat transfer analysis only.

Format:

1	2	3	4	5	6	7	8	9	10
CDAMP5	EID	PID	G1	G2					

Example:

CDAMP5	1	4	10	20					
--------	---	---	----	----	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Identification number of a PDAMP5 property entry. ( $\text{Integer} > 0$ ; Default = EID)
G1, G2	Grid or scalar point identification numbers. ( $\text{Integer} \geq 0$ and $G1 \neq G2$ )

Remarks:

1. G1 or G2 may be blank or zero indicating a constraint.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. CDAMP5 generates a lumped heat capacity in heat transfer analysis.
4. A scalar point specified on CDAMP5 need not be defined on an SPOINT entry.
5. This entry is not supported in SOL 600.
6. RC network solver does not support CDAMP5 for thermal analysis.

## CDUMi Dummy Element Connection

Defines a dummy element ( $3 \leq i \leq 7$ ).

Format:

1	2	3	4	5	6	7	8	9	10
CDUMi	EID	PID	G1	G2	G3	G4	-etc.-		
	A1	A2	-etc.-						

Example:

CDUM3	114	108	2	5	6	8	11		
	2.4		3.E4	2		50			

Describer	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Property identification number of a PDUMi entry. See Remark 2. ( $\text{Integer} > 0$ )
Gi	Grid point identification numbers of connection points. ( $\text{Integer} > 0$ ; $G1 \neq G2$ $\dots \neq GN$ )
Ai	Additional fields. (Real or Integer)

Remarks:

1. The user must write the associated element subroutines for matrix generation, stress recovery, etc., and perform a link edit to replace the dummy routines. See the *MSC Nastran Programmer's Manual*.
2. If no property entry is required, PID may contain the material identification number.
3. Additional entries are defined in the user-written element routines.
4. The fields on this entry are required to be defined on the corresponding ADUMi entry. This entry requires a license for "USER MODIFIABLE Nastran" Other than the EID field, all field checking is the responsibility of the user supplied code.

## CELAS1      Scalar Spring Connection

Defines a scalar spring element.

Format:

1	2	3	4	5	6	7	8	9	10
CELAS1	EID	PID	G1	C1	G2	C2			

Example:

CELAS1	2	6			8	1			
--------	---	---	--	--	---	---	--	--	--

Describer	Meaning
EID	Unique element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Property identification number of a PELAS entry. ( $\text{Integer} > 0$ ; Default = EID)
G1, G2	Geometric grid point identification number. ( $\text{Integer} \geq 0$ )
C1, C2	Component number. ( $0 \leq \text{Integer} \leq 6$ ; blank or zero if scalar point.)

Remarks:

- Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero. If only scalar points and/or ground are involved, it is more efficient to use the CELAS3 entry.
- Element identification numbers should be unique with respect to all other element identification numbers.
- The two connection points (G1, C1) and (G2, C2) must be distinct.
- For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
- A scalar point specified on this entry need not be defined on an SPOINT entry.
- If Gi refers to a grid point then Ci refers to degrees-of-freedom(s) in the displacement coordinate system specified by CD on the GRID entry.
- It is recommended that for most applications the grids connected by CELAS1 entries be coincident and the displacement coordinate systems of each grid be congruent. Connecting non-coincident grids and/or non-congruent coordinate systems can lead to models that do not pass strain energy checks (see the [GROUNDCHECK \(Case\)](#) Case Control command).

## CELAS1D

## Scalar Spring Connection for SOL 700 Only

Defines a scalar spring connection for use in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CELAS1D	EID	PID	G1	C1	G2	C2			
	CORD	FOLLOW							

Example:

CELAS1D	1001	101	55	1	8	1			
---------	------	-----	----	---	---	---	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PELAS entry. (Integer > 0; Default = EID)
G1, G2	Geometric grid point identification number. (Integer ≥ 0)
C1, C2	Component number. (0 ≤ Integer ≤ 6; 0 or up to six unique, 1 through 6 may be specified in the field with no embedded blanks. 0 applies to scalar points and 1 through 6 applies to grid points.)
CORD	Number of a coordinate system in which the degree-of-freedom (C1,C2) is defined. (Integer ≥ 0) (SOL 700 only)
FOLLOW	Method to update the direction vector in which the spring acts: For SOL 700: FOLLOW=CORD: Direction vector follows the motion of the coordinate system as specified under CORD.

Remarks:

1. Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero. If only scalar points and/or ground are involved, it is more efficient to use the CELAS3 entry.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. The two connection points (G1, C1) and (G2, C2) must be distinct.
4. For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
5. A scalar point specified on this entry need not be defined on an SPOINT entry.

6. If  $G_i$  refers to a grid point then  $C_i$  refers to degrees-of-freedom(s) in the displacement coordinate system specified by CD on the GRID entry.
7. Available in SOL 700 only.
8. It is recommended that for most applications the grids connected by CELAS1D entries be coincident and the displacement coordinate systems of each grid be congruent. Connecting non-coincident grids and/or non-congruent coordinate systems can lead to models that do not pass strain energy checks (see the [GROUNDCHECK \(Case\)](#) Case Control command).

## CELAS2      Scalar Spring Property and Connection

Defines a scalar spring element without reference to a property entry.

Format:

1	2	3	4	5	6	7	8	9	10
CELAS2	EID	K	G1	C1	G2	C2	GE	S	

Example:

CELAS2	28	6.2+3	32		19	4			
--------	----	-------	----	--	----	---	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
K	Stiffness of the scalar spring. (Real)
G1, G2	Geometric grid point or scalar identification number. (Integer ≥ 0)
C1, C2	Component number. (0 ≤ Integer ≤ 6; 0 blank or zero if scalar point.)
GE	Damping coefficient. See Remarks 6. and 8. (Real)
S	Stress coefficient. (Real)

Remarks:

- Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero. If only scalar points and/or ground are involved, it is more efficient to use the CELAS4 entry.
- Element identification numbers should be unique with respect to all other element identification numbers.
- The two connection points (G1, C1) and (G2, C2) must be distinct.
- For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
- A scalar point specified on this entry need not be defined on an SPOINT entry.
- If PARAM,W4 is not specified, GE is ignored in transient analysis. See [Parameters](#).
- If Gi refers to a grid point then Ci refers to degrees-of-freedom in the displacement coordinate system specified by CD on the GRID entry.
- To obtain the damping coefficient GE, multiply the critical damping ratio  $C/C_0$  by 2.0.

## CELAS2D

## Scalar Spring Connection for SOL 700 Only

Defines a scalar spring connection for use in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CELAS2D	EID	K	G1	C1	G2	C2			
	CORD	FOLLOW							

Example:

CELASD2	1001	101	55	1	8	1			
---------	------	-----	----	---	---	---	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
K	Stiffness of the scalar spring. (Real)
G1, G2	Geometric grid point identification number. (Integer ≥ 0)
C1, C2	Component number. (0 ≤ Integer ≤ 6; 0 or up to six unique, 1 through 6 may be specified in the field with no embedded blanks. 0 applies to scalar points and 1 through 6 applies to grid points.)
CORD	Number of a coordinate system in which the degree-of-freedom (C1,C2) is defined. (Integer ≥ 0)
FOLLOW	Method to update the direction vector in which the spring acts: FOLLOW=CORD: Direction vector follows the motion of the coordinate system as specified under CORD.

Remarks:

- Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero. If only scalar points and/or ground are involved, it is more efficient to use the CELAS4 entry.
- Element identification numbers should be unique with respect to all other element identification numbers.
- The two connection points (G1, C1) and (G2, C2) must be distinct.
- For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
- A scalar point specified on this entry need not be defined on an SPOINT entry.
- If Gi refers to a grid point then Ci refers to degrees-of-freedom in the displacement coordinate system specified by CD on the GRID entry.

7. It is recommended that for most applications the grids connected by CELAS2D entries be coincident and the displacement coordinate systems of each grid be congruent. Connecting non-coincident grids and/or non-congruent coordinate systems can lead to models that do not pass strain energy checks (see the [GROUNDCHECK \(Case\)](#) Case Control command).

## CELAS3      Scalar Spring Connection to Scalar Points Only

Defines a scalar spring element that connects only to scalar points.

Format:

1	2	3	4	5	6	7	8	9	10
CELAS3	EID	PID	S1	S2					

Example:

CELAS3	19	2	14	15					
--------	----	---	----	----	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PELAS entry. (Integer > 0; Default = EID)
S1, S2	Scalar point identification numbers. (Integer ≥ 0; S1 ≠ S2)

Remarks:

1. S1 or S2 may be blank or zero, indicating a constrained coordinate.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. Only one scalar spring element may be defined on a single entry.
4. For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
5. A scalar point specified on this entry need not be defined on an SPOINT entry.

**CELAS4**

Scalar Spring Property and Connection to Scalar Points Only

Defines a scalar spring element that is connected only to scalar points, without reference to a property entry.

Format:

1	2	3	4	5	6	7	8	9	10
CELAS4	EID	K	S1	S2					

Example:

CELAS4	42	6.2-3	2						
--------	----	-------	---	--	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
K	Stiffness of the scalar spring. (Real)
S1, S2	Scalar point identification numbers. (Integer ≥ 0; S1 ≠ S2)

Remarks:

1. S1 or S2, but not both, may be blank or zero indicating a constrained coordinate.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. A structural damping coefficient is not available with CELAS4. The value of g is assumed to be 0.0.
4. No stress coefficient is available with CELAS4.
5. Only one scalar spring element may be defined on a single entry.
6. For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
7. A scalar point specified on this entry need not be defined on an SPOINT entry.

## CFAST A Shell Patch Fastener Connection

Defines a fastener with material orientation connecting two surface patches. Large displacement and large rotational effects are supported when in SOL 600 and SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
CFAST	EID	PID	TYPE	IDA	IDB	GS	GA	GB	
	XS	YS	ZS						

Example using PROP:

CFAST	3	20	PROP	21	24	206			
-------	---	----	------	----	----	-----	--	--	--

Example using ELEM:

CFAST	7	70	ELEM	27	74	707			
-------	---	----	------	----	----	-----	--	--	--

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PFAST entry. (Integer > 0; Default = EID)
TYPE	Specifies the surface patch definition: (Character) If TYPE = 'PROP', the surface patch connectivity between patch A and patch B is defined with two PSHELL (or PCOMP) properties with property ids given by IDA and IDB. See Remark 1. and Figure 9-25. If TYPE = 'ELEM', the surface patch connectivity between patch A and patch B is defined with two shell element ids given by IDA and IDB. See Remark 1. and Figure 9-25.
IDA,IDB	Property id (for PROP option) or Element id (for ELEM option) defining patches A and B. IDA ≠ IDB (Integer > 0)
GS	Grid point defining the location of the fastener. See Remark 2. (Integer > 0 or blank)
GA,GB	Grid ids of piercing points on patches A and B. See Remark 2. (Integer > 0 or blank)
XS,YS,ZS	Location of the fastener in basic. Required if neither GS nor GA is defined. See Remark 2. (Real or blank)

Remarks:

1. The CFAST defines a flexible connection between two surface patches. The number of unique physical grids connected depends on the location for the piercing points GA and GB and the size of the diameter D (see PFAST).

Figure 9-25 Patches Defined with TYPE= 'PROP' or TYPE = 'ELEM'

- GS defines the approximate location of the fastener in space. GS is projected onto the surface patches A and B. The resulting piercing points GA and GB define the axis of the fastener. GS does not have to lie on the surfaces of the patches. GS must be able to project normals to the two patches. GA can be specified in lieu of GS, in which case GS will be ignored. If neither GS nor GA is specified, then (XS, YS, ZS) in basic must be specified.

If both GA and GB are specified, they must lie on or at least have projections onto surface patches A and B respectively. If GA and GB are both specified, GS is ignored. By default, the locations of user specified GA and GB will not be changed. If the user specifies "SWLDPRM, MOVGAB, 1," then the locations will be corrected so that they lie on the surface patches A and B within machine precision. The length of the fastener is the final distance between GA and GB. If the length is zero, the normal to patch A is used to define the axis of the fastener.

Diagnostic printouts, checkout runs and control of search and projection parameters are requested on the SWLDPRM Bulk Data entry.

- The use of param,cfdiagp,yes and param,cfrandel,real\_fraction\_value allows for the random removal of a percentage of CFAST elements for failure studies.
- This entry is not supported in SOL 700.
- If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
- In SOL400, the behavior of this element in regard to large rotation is affected by the Case Control Command Rigid.
- If partitioned superelements are present, then CFAST is supported in the main Bulk Data section only.

**CFLUIDi****Fluid Element Connections**

Defines three types of fluid elements for an axisymmetric fluid model.

Formats:

1	2	3	4	5	6	7	8	9	10
CFLUID2	EID	IDF1	IDF2			RHO	B		
CFLUID3	EID	IDF1	IDF2	IDF3		RHO	B		
CFLUID4	EID	IDF1	IDF2	IDF3	IDF4	RHO	B		

Examples:

CFLUID2	100	11	14			.025	0.0		
CFLUID3	110	15	13	12		1.2			
CFLUID4	120	11	15	12	14				

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
IDFi	Identification number of a RINGFL entry. (Integer > 0; IDF1 ≠ IDF2 ≠ IDF3 ≠ IDF4; all IDF <sub>i</sub> < 500000)
RHO	Mass density. (Real > 0.0; Default is the value of DRHO on the AXIF entry)
B	Bulk modulus, pressure per volume ratio. (Real; Default is the value of DB on the AXIF entry)

Remarks:

1. CFLUIDi is allowed only if an AXIF entry is also present.
2. Element identification number must be unique with respect to all other fluid, scalar, and structural elements.

- The volume defined by IDFi is a body of revolution about the polar axis of the fluid coordinate system defined by AXIF. CFLUID2 defines a thick disk with IDF1 and IDF2 defining the outer corners as shown in [Figure 9-26](#):

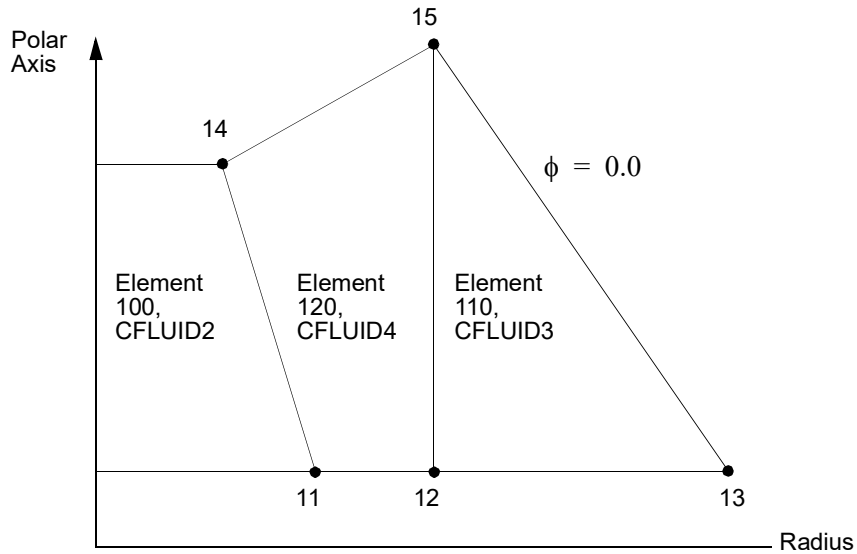

Figure 9-26 CFLUIDi Examples

- All interior angles must be less than  $180^\circ$ .
- The order of connected RINGFL points is arbitrary.
- If  $B = 0.0$ , the fluid is incompressible.

## CGAP

## Gap Element Connection

Defines a gap or friction element.

Format:

1	2	3	4	5	6	7	8	9	10
CGAP	EID	PID	GA	GB	X1	X2	X3	CID	

Example:

CGAP	17	2	110	112	5.2	0.3	-6.1		
------	----	---	-----	-----	-----	-----	------	--	--

Alternate Format and Example:

CGAP	EID	PID	GA	GB	GO			CID	
CGAP	17	2	110	112	13				

Describer	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Property identification number of a PGAP entry. (Integer $> 0$ ; Default = EID)
GA, GB	Connected grid points at ends A and B. (Integers $> 0$ ; $GA \neq GB$ )
X1, X2, X3	Components of the orientation vector $\bar{v}$ , from GA, in the displacement coordinate system at GA. (Real)
GO	Alternate method to supply the orientation vector $\bar{v}$ using grid point GO. Direction of $\bar{v}$ is from GA to GO. (Integer $> 0$ )
CID	Element coordinate system identification number. CID must be specified if GA and GB are coincident (distance from GA to GB $< 10^{-4}$ ). See Remark 6. (Integer $\geq 0$ or blank)

Remarks:

1. The CGAP element is intended for the nonlinear solution sequences 106, 129, 153, 159, and 400. However, it will produce a linear stiffness matrix for the other solutions, but remains linear with the initial stiffness. The stiffness used depends on the value for the initial gap opening (U0 field in the PGAP entry).
2. The gap element coordinate system is defined by one of two following methods:
  - If the coordinate system (CID field) is specified, the element coordinate system is established using that coordinate system, in which the element x-axis is in the T1 direction and the y-axis in the T2 direction. The orientation vector  $\bar{v}$  will be ignored in this case.
  - If the CID field is blank and the grid points GA and GB are not coincident (distance from A to B  $\geq 10^{-4}$ ), then the line AB is the element x-axis and the orientation vector  $\bar{v}$  lies in the x-y plane (like the CBEAM element).

3. The element coordinate system does not rotate as a result of deflections.
4. Initial gap openings are specified on the PGAP entry and not derived from the separation distance between GA and GB.
5. Forces are requested with the FORCE or NLSTRESS Case Control command. The NLSTRESS command is only for nonlinear solutions, and the output also includes the gap STATUS. Forces are output in the element coordinate system. The force  $F_x$  is positive for compression.
6. If CID is being used to define the element coordinate system and the CID refers to either a cylindrical or spherical coordinate system then grid GA will be used to locate the system. If grid GA lies on the z-axis of the cylindrical or spherical coordinate system it is recommended that a different coordinate system be used for this element.
7. See PARAM,CDITER for an alternative approach.

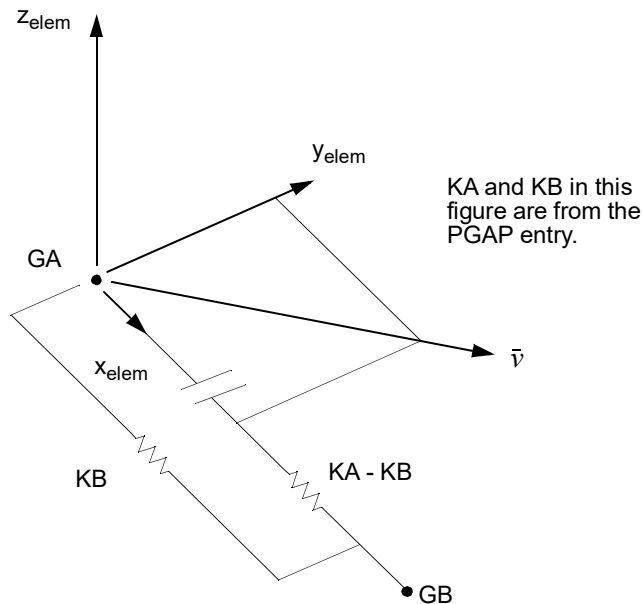

Figure 9-27 CGAP Element Coordinate System

8. Since a large stiffness is used for KA (the closed GAP stiffness), param,g damping should be avoided. Instead damping should be specified on the MATi entries and PARAM,W4 set.

## CHACAB

## Acoustic Absorber Element Connection

Defines the acoustic absorber element in coupled fluid-structural analysis.

Format:

1	2	3	4	5	6	7	8	9	10
CHACAB	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12			
			G17	G18	G19	G20			

Example:

CHACAB	95	12	1	2	5	7	8	9	
	24	23							

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PACABS entry. (Integer > 0)
Gi	Grid point identification numbers of connection points. (Integer ≥ 0 or blank)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Grid points G1 through G4 must be given in consecutive order about one quadrilateral face. G5 through G8 must be on the opposite face with G5 opposite G1, G6 opposite G2, etc.
3. The edge points, G9 to G20, are optional. Any or all of them may be deleted. If the ID of any edge connection point is left blank or set to zero (as for G9 and G10 in the example), the equations of the element are adjusted to give correct results for the reduced number of connections. Corner grid points cannot be deleted.
4. It is recommended that the edge points be located within the middle third of the edge.
5. The face consisting of grid points G1 through G4 and G9 through G12 is assumed to be in contact with the structure.

Figure 9-28 CHACAB Element Connection

6. The mass is lumped to the face formed by grid points G5 through G8 and G17 through G20 and defined to be in contact with the fluid. The opposite face has no mass contribution due to the absorber element. Also, the face in contact with the fluid has only translational stiffness in the direction normal to the face.

## CHACBR

## Acoustic Barrier Element Connection

Defines the acoustic barrier element.

Format:

1	2	3	4	5	6	7	8	9	10
CHACBR	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12			
			G17	G18	G19	G20			

Example:

CHACBR	95	12	1	2	5	7	8	9	
	24	23							

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PACBAR entry. (Integer > 0)
Gi	Grid point identification numbers of connection points. (Integer > 0)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Grid points G1 through G4 must be given in consecutive order about one quadrilateral face. G5 through G8 must be on the opposite face with G5 opposite G1, G6 opposite G2, etc.
3. The edge points, G9 to G20, are optional. Any or all of them may be deleted. If the ID of any edge connection point is left blank or set to zero (as for G9 and G10 in the example), the equations of the element are adjusted to give correct results for the reduced number of connections. Corner grid points cannot be deleted.
4. It is recommended that the edge points be located within the middle third of the edge.
5. The face consisting of grids G1 through G4 and G9 through G12 is assumed to be the backing that corresponds to MBACK on the PACBAR entry.
6. The face consisting of grid points G5 through G8 and G17 through G20 is assumed to be the septum that corresponds to MSEPTM on the PACBAR entry.

Figure 9-29 CHACBR Element Connection

7. The face in contact with the fluid is defined to be the face formed by grid points G5 through G8 and G17 through G20 and has only translational stiffness in the direction normal to the face.

## CHBDYE

## Geometric Surface Element Definition (Element Form)

Defines a boundary condition surface element with reference to a heat conduction element.

Format:

1	2	3	4	5	6	7	8	9	10
CHBDYE	EID	EID2	SIDE	IVIEWF	IVIEWB	RADMIDF	RADMIDB		

Example:

CHBDYE	2	10	1	3	3	2	2		
--------	---	----	---	---	---	---	---	--	--

Describer	Meaning
EID	Surface element identification number for a specific side of a particular element. See Remarks 1. and 9. (Unique (0 < Integer < 100,000,000) among all elements.)
EID2	A heat conduction element identification number. (Integer > 0)
SIDE	A consistent element side identification number. See Remark 6. ( $1 \leq \text{Integer} \leq 6$ )
IVIEWF	A VIEW entry identification number for the front face of surface element. See Remark 2. for default. (Integer $\geq 0$ )
IVIEWB	A VIEW entry identification number for the back face of surface element. See Remark 2. for default. (Integer $\geq 0$ )
RADMIDF	RADM identification number for front face of surface element. See Remark 2. for default. (Integer $\geq 0$ )
RADMIDB	RADM identification number for back face of surface element. See Remark 2. for default. (Integer $\geq 0$ )

Remarks:

1. EID is a unique elemental ID associated with a particular surface element. EID2 identifies the general heat conduction element being considered for this surface element.
2. The defaults for IVIEWF, IVIEWB, RADMIDF, and RADMIDB may be specified on the BDYOR entry. If a particular field is blank both on the CHBDYE entry and the BDYOR entry, then the default is zero.
3. For the front face of shell elements, the right-hand rule is used as one progresses around the element surface from G1 to G2 to ... Gn. For the edges of shell elements or the ends of line elements, an outward normal is used to define the front surface.
4. If the surface element is to be used in the calculation of view factors, it must have an associated VIEW entry.
5. All conduction elements to which any boundary condition is to be applied must be individually identified with the application of one of the surface element entries: CHBDYE, CHBDYG, or CHBDYP.

6. Side conventions for solid elements.

The sides of the solid elements are numbered consecutively according to the order of the grid point numbers on the solid element entry. The sides of solid elements are either quadrilaterals or triangles. For each element type, tabulate the grid points (gp) at the corners of each side.

**8-node or 20-node CHEXA**

side	gp	gp	gp	gp
1	4	3	2	1
2	1	2	6	5
3	2	3	7	6
4	3	4	8	7
5	4	1	5	8
6	5	6	7	8

**CPENTA**

side	gp	gp	gp	gp
1	3	2	1	
2	1	2	5	4
3	2	3	6	5
4	3	1	4	6
5	4	5	6	

**CTETRA**

side	gp	gp	gp
1	3	2	1
2	1	2	4
3	2	3	4
4	3	1	4

**CPYRAM**

side	gp	gp	gp	gp
1	3	2	5	
2	1	4	5	
3	2	1	5	
4	3	5	4	
5	4	1	2	3

7. Side conventions for shell elements.

Side 1 of shell elements (top) are of an AREA type, and additional sides (2 through a maximum of 5 for a QUAD) are of LINE type. (See CHBDYG for surface type definition.)

Area Type Sides -- The first side is that given by the right-hand rule on the shell elements grid points.

Line Type Sides -- The second side (first line) proceeds from grid point 1 to grid point 2 of the shell element, and the remaining lines are numbered consecutively. The thickness of the line is that of the shell element, and the normal to the line is outward from the shell element in the plane of the shell. Note that any midside nodes are ignored in this specification.

For 3-D heat shell elements when used in combination with linear or quadratic nodal temperature (see option TEMPP of the NLMOPTS entry), SIDE=6 refers to BOT surface. SIDE=1 refers to TOP surface. The IVIEW and RADM should be filled in consistently in relation with the SIDE entry. E.g., when SIDE=1 or 6 then only IVIEWF makes sense.

8. Side conventions for line elements.

LINE elements have one linear side (side 1) with geometry that is the same as that of the element and two POINT-type sides corresponding to the two points bounding the linear element (first grid point-side 2; second grid point-side 3).

The TUBE-type element has two linear sides of type TUBE. The first side represents the outside with diameters equal to that of the outside of the tube. The second side represents the inside with diameters equal to that of the inside of the tube.

Point Sides -- Point sides may be used with any linear element. The direction of the outward normals of these points is in line with the element axis, but pointing away from the element. The area assigned to these POINT-type sides is consistent with the element geometry.

Rev Sides -- The CTIRAX6 element has associated with it three REV sides. The first side is associated with Grid Points G1, G2, and G3. The positive face identification normals point away from the element.

9. Application of boundary conditions to CHBDYE is referenced through the EID. Boundary conditions can reference either the front or back face of the CHBDYE by specifying +EID or -EID respectively. Correspondingly, the back face is minus the normal vector of the front face. Similarly, IVIEWF and RADMIDF are associated with +EID and IVIEWB and RADMIDB with -EID. For radiation problems, if the RADMIDF or RADMIDB is zero, default radiant properties assume perfect black body behavior.
10. Starting with MSC Nastran 2004, axisymmetric view factors are supported CHBDYG of TYPE=REV, but not supported CHBDYE. If CHBDYE is used for this, axisymmetric view factors are not calculated.

## CHBDYG Geometric Surface Element Definition (Grid Form)

Defines a boundary condition surface element without reference to a property entry.

Format:

1	2	3	4	5	6	7	8	9	10
CHBDYG	EID		TYPE	IVIEWF	IVIEWB	RADMIDF	RADMIDB		
	G1	G2	G3	G4	G5	G6	G7	G8	

Example:

CHBDYG	2		AREA4	3	3	2	2		
	100	103	102	101					

Describer	Meaning
EID	Surface element identification number. (Unique (0 < Integer < 100,000,000) among all elemental entries)
TYPE	Surface type. See Remark 3. (Character)
IVIEWF	A VIEW entry identification number for the front face. See Remark 2. for default. (Integer ≥ 0)
IVIEWB	A VIEW entry identification number for the back face. See Remark 2. for default. (Integer ≥ 0)
RADMIDF	RADM identification number for front face of surface element. See Remark 2. for default. (Integer ≥ 0)
RADMIDB	RADM identification number for back face of surface element. See Remark 2. for default. (Integer ≥ 0)
Gi	Grid point IDs of grids bounding the surface. (Integer > 0)

Remarks:

- EID is a unique ID associated with a particular surface element as defined by the grid points.
- The defaults for TYPE, IVIEWF, IVIEWB, RADMIDF, and RADMIDB may be specified on the BDYOR entry. If a particular field is blank on both the CHBDYG entry and the BDYOR entry, then the default is zero.
- TYPE specifies the kind of element surface; allowed types are: REV, REV1, AREA3, AREA4, AREA6, and AREA8. See [Figure 9-30](#), [Figure 9-31](#), and [Figure 9-32](#).
  - TYPE = REV

The “REV” type has two primary grid points that must lie in the x-z plane of the basic coordinate system with  $x > 0$ . A midside grid point G3 is optional and supports convection or heat flux from the edge of the six-noded CTRIAX6 element. The defined area is a conical section with z as the axis of symmetry. A property entry is required for convection, radiation, or thermal vector flux.

Figure 9-30 Normal Vector for CHBDYG Element of Type “REV”

The unit normal lies in the x-z plane, and is given by

$$\vec{n} = (\vec{e}_y \times \vec{T}) / |\vec{e}_y \times \vec{T}|.$$

$\vec{e}_y$  is the unit vector in the y direction.

- TYPE = REV1. The “REV1” type has two primary grid points that must lie in the x-y plane of the basic coordinate system with  $x > 0$ . A midside grid point G3 is optional and supports convection or heat flux from the edge of the CQUADX (4 or 8 node) and CTRIAX (3 or 6 node) element. The defined area is a conical section with y as the axis of symmetry. A property entry is required for convection, radiation, or thermal vector flux.
- TYPE = AREA3, AREA4, AREA6, or AREA8

These types have three and four primary grid points, respectively, that define a triangular or quadrilateral surface and must be ordered to go around the boundary. A property entry is required for convection, radiation, or thermal vector flux.

AREA3

AREA4

AREA6  
(Grid points G4 through G6 optional)

AREA8  
(Grid points G5 through G8 optional)

Figure 9-31 TYPE Examples

Figure 9-32 Normal Vector for CHBDYG Element of Types "AREAi"

The unit normal vector is given by

$$\vec{n} = \frac{(\vec{T}_{12} \times \vec{T}_{1x})}{|\vec{T}_{12} \times \vec{T}_{1x}|}$$

(G3 is used for triangles, and G4 is used for quadrilaterals.)

- For defining the front face, the right-hand rule is used on the sequence G1 to G2 to ... Gn of grid points.

5. If the surface element is to be used in the calculation of view factors, it must have an associated VIEW entry.
6. All conduction elements to which any boundary condition is to be applied must be individually identified with one of the surface element entries: CHBDYE, CHBDYG, or CHBDYP.
7. See Remark 9. of CHBDYE for application of boundary conditions using CHBDYG entries and a discussion of front and back faces.

## CHBDYP

## Geometric Surface Element Definition (Property Form)

Defines a boundary condition surface element with reference to a PHBDY entry.

Format:

1	2	3	4	5	6	7	8	9	10
CHBDYP	EID	PID	TYPE	IVIEWF	IVIEWB	G1	G2	G0	
	RADMIDF	RADMIDB	GMID	CE	E1	E2	E3		

Example:

CHBDYP	2	5	POINT	2	2	101		500	
	3	3			0.0	0.0	1.0		

Describer	Meaning
EID	Surface element identification number. (Unique (0 < Integer < 100,000,000) among all element identification numbers.)
PID	PHBDY property entry identification numbers. (Integer > 0)
TYPE	Surface type. See Remark 3. (Character)
IVIEWF	VIEW entry identification number for the front face. (Integer ≥ 0 or blank)
IVIEWB	VIEW entry identification number for the back face. (Integer ≥ 0 or blank)
G1, G2	Grid point identification numbers of grids bounding the surface. (Integer > 0)
G0	Orientation grid point. (Integer ≥ 0; Default = 0)
RADMIDF	RADM entry identification number for front face. (Integer ≥ 0 or blank)
RADMIDB	RADM entry identification number for back face. (Integer ≥ 0 or blank)
GMID	Grid point identification number of a midside node if it is used with the line type surface element.
CE	Coordinate system for defining orientation vector. (Integer ≥ 0; Default = 0)
Ei	Components of the orientation vector in coordinate system CE. The origin of the orientation vector is grid point G1. (Real or blank)

Remarks:

1. EID is a unique ID associated with a particular surface element as defined by the grid point(s).
2. The defaults for PID, TYPE, IVIEWF, IVIEWB, GO, RADMIDF, RADMIDB, CE, and Ei may be specified on the BDYOR entry. If a particular field is blank on both the CHBDYP entry and the BDYOR entry, then the default is zero.

3. TYPE specifies the kind of element surface; the allowed types are: “POINT,” “LINE,” “ELCYL,” “FTUBE,” and “TUBE.” For TYPE = “FTUBE” and TYPE = “TUBE,” the geometric orientation is completely determined by G1 and G2; the GO, CE, E1, E2, and E3 fields are ignored.

- TYPE = “POINT”

TYPE = “POINT” has one primary grid point, requires a property entry, and the normal vector  $\vec{V}_i$  must be specified if thermal flux is to be used.

Figure 9-33 Normal Vector for CHBDYP Element of Type “POINT”  
(See Remarks 4. and 5.)

The unit normal vector is given by  $\vec{n} = \vec{V} / |\vec{V}|$  where  $\vec{V}$  is specified in the Ei field and given in the basic system at the referenced grid point. See Remarks 4. and 5. for the determination of  $\vec{V}$ .

- TYPE = “LINE,” “FTUBE,” or “TUBE”

The TYPE = “LINE” type has two primary grid points, requires a property entry, and the vector is required. TYPE = “FTUBE” and TYPE = “TUBE” are similar to TYPE = “LINE” except they can have linear taper with no automatic view factor calculations. GMID is an option for the TYPE = “LINE” surface element only and is ignored for TYPE = “FTUBE” and “TUBE”.

Figure 9-34 Normal Vector for CHBDYP Element with TYPE=“LINE”,  
TYPE=“FTUBE”, or TYPE=“TUBE” (See Remarks 4. and 5.)

The unit normal lies in the plane  $\vec{V}$  and  $\vec{T}$ , is perpendicular to  $\vec{T}$ , and is given by:

$$\vec{n} = \frac{\vec{T} \times (\vec{V} \times \vec{T})}{|\vec{T} \times (\vec{V} \times \vec{T})|}$$

- TYPE = “ELCYL”

TYPE = “ELCYL” (elliptic cylinder) has two connected primary grid points and requires a property entry. The vector must be nonzero.

Figure 9-35 Normal Vector for CHBDYP Element of TYPE=“ELCYL”  
(See Remarks 4. and 5.)

The same logic is used to determine  $\vec{n}$  as for TYPE = LINE. The “radius”  $R_1$  is in the  $\vec{n}$  direction, and  $R_2$  is the perpendicular to  $\vec{n}$  and  $\vec{T}$  (see fields 7 and 8 of PHBDY entry).

4. For TYPE = “POINT,” TYPE = “LINE,” and TYPE = “ELCYL,” geometric orientation is required. The required information is sought in the following order:
  - If  $GO > 0$  is found on the CHBDYP entry, it is used.
  - Otherwise, if a nonblank CE is found on the CHBDYP continuation entry, this CE and the corresponding vectors E1, E2, and E3 are used.
  - If neither of the above, the same information is sought in the same way from the BDYOR entry.
  - If none of the above apply, a warning message is issued.
5. The geometric orientation can be defined by either GO or the vector E1, E2, E3.
  - If  $GO > 0$ :  
For a TYPE = “POINT” surface, the normal to the front face is the vector from G1 to GO. For the TYPE = “LINE” surface, the plane passes through G1, G2, GO and the right-hand rule is used on this sequence to get the normal to the front face. For TYPE = “ELCYL” surface the first axis of the ellipse lies on the G1, G2, GO plane, and the second axis is normal to this plane. For TYPE = “FTUBE” or “TUBE” surface, no orientation is required, and GO is superfluous.
  - If GO is zero:  
For a TYPE = “POINT” surface, the normal to the front face is the orientation vector. For the TYPE = “LINE” surface, the plane passes through G1, G2, and the orientation vector; the front face is based on the right-hand rule for the vectors G2-G1 and the orientation vector. For TYPE = “ELCYL” surface, the first axis of the ellipse lies on the G1, G2, orientation vector plane, and the second axis is normal to this plane.
6. The continuation entry is optional.

7. If the surface element is to be used in the calculation of view factors, it must have an associated VIEW entry.
8. All conduction elements to which any boundary condition is to be applied must be individually identified with the application of one of the surface element entries: CHBDYE, CHBDYG, or CHBDYP entries.
9. For RC network solver in thermal analysis, the G0, GMID, CE, E1, C2 and E3 are ignored.

## CHEXA Six-Sided Solid Element Connection

Defines the connections of the six-sided solid element with eight to twenty grid points or the six-sided solid shell element with eight grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CHEXA	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12	G13	G14	
	G15	G16	G17	G18	G19	G20			

Example:

CHEXA	71	4	3	4	5	6	7	8	
	9	10	0	0	30	31	53	54	
	55	56	57	58	59	60			

Descriptor	Meaning	Type	Default
EID	Element identification number.	(0 < Integer < 100,000,000)	Required
PID	Property identification number of a PSOLID, PLSOLID or PCOMPLS entry.	Integer > 0	Required
Gi	Grid point identification numbers of connection points.	Integer ≥ 0 or blank	Required

Figure 9-36 CHEXA Element Connection

**Remarks:**

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Grid points G1 through G4 must be given in consecutive order about one quadrilateral face. G5 through G8 must be on the opposite face with G5 opposite G1, G6 opposite G2, etc.
3. For Nastran conventional element, the edge points, G9 to G20, are optional. Any or all of them may be deleted. If the ID of any edge connection point is left blank or set to zero (as for G9 and G10 in the input example), the equations of the element are adjusted to give correct results for the reduced number of connections. Corner grid points cannot be deleted. The element is an isoparametric element (with shear correction) in all cases.  
Note that for advanced nonlinear elements, partial specification of mid-points is not allowed. i.e. Either none of the mid-points should be specified or all of the mid points should be specified.
4. Components of stress are output in the material coordinate system except for hyperelastic elements, which are output in the basic coordinate system. The material coordinate system is defined on the PSOLID entry.
5. The second continuation is optional.
6. For nonhyperelastic and non-composite elements, the element coordinate system for the CHEXA element is defined in terms of the three vectors R, S, and T, which join the centroids of opposite faces.  
R vector joins the centroids of faces G4-G1-G5-G8 and G3-G2-G6-G7.  
S vector joins the centroids of faces G1-G2-G6-G5 and G4-G3-G7-G8.  
T vector joins the centroids of faces G1-G2-G3-G4 and G5-G6-G7-G8.

The origin of the coordinate system is located at the intersection of these vectors. The X, Y, and Z axes of the element coordinate system are chosen as close as possible to the R, S, and T vectors and point in the same general direction. (Mathematically speaking, the coordinate system is computed in such a way that if the R, S, and T vectors are described in the element coordinate system a 3 x 3 positive-definite symmetric matrix would be produced.)

Solid elements have both a material and an element coordinate system. Both systems are defined for the initial geometry, and for geometric nonlinear analysis they will rotate with the element. The material coordinate system is used to input anisotropic material properties and for stress output. The material coordinate system is defined by the CORDM field of the PSOLID entry. The element coordinate system is used for element stiffness integration (reduced shear for example) and optionally to define the material coordinate system (only if PSOLID,CORDM=-1).

Figure 9-37 CHEXA Element R, S, and T Vectors

7. It is recommended that the edge points be located within the middle third of the edge.
8. For hyperelastic elements, the plot codes are specified under the CHEXAFD element name in [Item Codes](#).
9. By default, all the twelve edges of the element are considered straight unless, any of G9 through G20 are specified.
10. This element may be used:

Element Type	Property	BEHi Code	Integration Scheme	Solution Type
Solid	PSOLID	N/A	Refer to IN and ISOP	All Solution Sequences
	Nastran conventional element. Typically used for small strain, small / large displacement solutions.			
Below are advanced nonlinear elements.				
Solid	PSOLID+ PSLDN1	SOLID	L, Q, LRIH and QRI	SOL 400
	Typically used for large strain, large displacement solutions in conjunction with MATEP, MATS1, MATHE, etc.			
Solid Shell	PSOLID+ PSLDN1	SLCOMP	ASTN	SOL 400
	Typically used for bending dominated large strain, large displacement solutions.			
3D Solid Gasket	PSOLID+ PSLDN1	SLCOMP	L	SOL 400
	Used for gaskets with MATG.			

Element Type	Property	BEHi Code	Integration Scheme	Solution Type
Solid Composite	PCOMPLS	SLCOMP	L and Q	SOL 400 and SOL 101 to SOL 112
	Typically used for solid composite small strain / large strain / small displacement / large displacement solutions.			
Solid Shell Composite	PCOMPLS	SLCOMP	L and Q	SOL 400 and SOL 101 to SOL 112
	Typically used for bending dominated solid composite small strain / large strain / small displacement / large displacement solutions.			

- When this element is used as a three-dimensional eight-node solid shell element or three-dimensional eight-node composite solid shell element, the user should keep in mind that the layer orientation is required to be in the element T-direction, when specifying grid order.
- The internal coordinate system of the element is used internally and is based on eigenvalue techniques to insure non bias in the element formulation. For stress/strain output this internal coordinate system (CORDM=-1 on PSOLID entry) is hard to visualize. Thus a CORDM=-2 on the PSOLID is available as shown in [Figure 9-38](#).

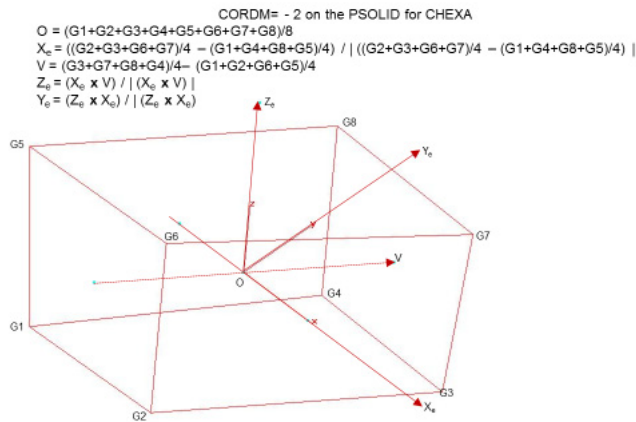

Figure 9-38 PSOLID for CHEXA

## CIFHEX

## Solid InterFace Cohesive Zone Modeling Element

Linear/Quadratic, twenty-node, three-dimensional interface element used to simulate the onset and progress of delamination in SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
CIFHEX	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12	G13	G14	
	G15	G16	G17	G18	G19	G20			

Example:

CIFHEX	700	701	456	357	882	889	443	447	
	162	911							

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property number of a PCOHE entry. (Integer > 0)
G1-G8	Identification number of connected corner grid points. Required data for all eight corner grid points. (Unique Integer > 0)
G9-G12 G17-G20	Identification number of connected edge grid points. Optional data for bottom and top edge grid points. (Unique Integer > 0)
G13-G16	Identification number of connected midside grid points. Optional data for midside grid points used only to make the element compatible with twenty-noded hexahedral elements. (Unique Integer > 0)

Remarks:

1. Element identification numbers should be unique with respect to all other element ID's of any kind.
2. Grid points  $G_i$  must be numbered as shown in the following figure. Specify either G1-G8, or all G1-G20.
3. The element is typically used to model the interface between different materials, where G1, G9, G2, G10, G3, G11, G4 and G12 correspond to one side (called the bottom) and G5, G17, G6, G18, G7, G19, and G20 correspond to the other side (called the top). The stress components are one normal and two shear tractions. When only G1-G8 are specified, the element is linear. When in addition to G1-G8, G9-G12, G17-G20 are specified, the element is quadratic.
4. The corresponding deformations are relative displacements between the top and bottom edge of the element.

- The element is allowed to be infinitesimally thin; in which case edges defined by grids G1-G4 and G5-G8 may coincide.

- This element does not support thermal load. No thermal strain will be generated.

## CIPENT

## Solid InterFace Cohesive Zone Modeling Element

Linear/Quadratic, fifteen-node, three-dimensional interface element used to simulate the onset and progress of delamination in SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
CIPENT	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12	G13	G14	
	G15								

Example:

CIPENT	700	701	456	357	882	889	443	447	
--------	-----	-----	-----	-----	-----	-----	-----	-----	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property number of a PCOHE entry. (Integer > 0)
G1-G6	Identification number of connected corner grid points. Required data for all four corner grid points. (Unique Integer > 0)
G7-G9 G13-G15	Identification number of connected edge grid points. Optional data for bottom and top edge grid points. (Unique Integer > 0)
G10-G12	Identification number of connected midside grid points. Optional data for midside grid points used only to make the element compatible with fifteen-noded pentahedral elements. (Unique Integer > 0)

Remarks:

1. Element identification numbers should be unique with respect to all other element ID's of any kind.
2. Grid points  $G_i$  must be numbered as shown in the following figure. Specify either G1-G6 or all G1-G15.
3. The element is typically used to model the interface between different materials, where G1, G7, G2, G8, G3 and G9 correspond to one side (called the bottom) and G4, G13, G5, G14, G6, and G15 correspond to the other side (called the top). The stress components are one normal and one shear tractions. When only G1-G6 are specified, the element is linear. When in addition to G1-G6, G7-G9, G13-G15 are specified, the element is quadratic.
4. The corresponding deformations are relative displacements between the top and bottom edge of the element.

- The element is allowed to be infinitesimally thin; in which case edges defined by grids G1-G3 and G4-G6 may coincide.

- This element does not support thermal load. No thermal strain will be generated.

## CIFQDX

## Axisymmetric InterFace Cohesive Zone Modeling Element

Linear/Quadratic, eight-node, axisymmetric interface element used to simulate the onset and progress of delamination in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
CIFQDX	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8							

Example:

CIFQDX	700	701	456	357	882	889	443	447	
	1612	911							

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property number of a PCOHE entry. (Integer > 0)
G1-G4	Identification number of connected corner grid points. Required data for all four corner grid points. (Unique Integer > 0)
G5, G7	Identification number of connected edge grid points. Optional data for bottom and top edge grid points. (Unique Integer > 0)
G6, G8	Identification number of connected edge grid points. Optional data for side grid points used only to make the element compatible with eight-noded quadrilateral axisymmetric elements. (Unique Integer > 0)

Remarks:

1. Element identification numbers should be unique with respect to all other element ID's of any kind.
2. Grid points  $G_i$  must be numbered as shown in the following figure.
3. The element is typically used to model the interface between different materials, where  $G_1$ ,  $G_5$ , and  $G_2$  correspond to one side (called the bottom) and  $G_3$ ,  $G_7$ , and  $G_4$  correspond to the other side (called the top). The stress components are one normal and one shear traction. Then only  $G_1$ - $G_4$  are specified, the element is linear. When in addition to  $G_1$ - $G_4$ ,  $G_5$  and  $G_7$  are specified, the element is quadratic.
4. The corresponding deformation are relative displacements between the top and bottom edge of the element.
5. The element is allowed to be infinitesimally thin; in which case edges  $G_1$ - $G_5$ - $G_2$  and  $G_3$ - $G_7$ - $G_4$  may coincide.
6. The element must lie in the x-y plane of the basic system. Coordinate  $r$  is parallel to the x-basic and coordinate  $z$  is parallel to y-basic.

7. This element does not support thermal load. No thermal strain will be generated.

## CIFQUAD

## Planar InterFace Cohesive Zone Modeling Element

Linear/Quadratic, eight-noded planar interface element used to simulate the onset and progress of delamination in SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
CIFQUAD	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8							

Example:

CIFQUAD	700	701	456	357	882	889	443	447	
	1612	911							

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property number of a PCOHE entry. (Integer > 0)
G1-G4	Identification number of connected corner grid points. Required data for all four corner grid points. (Unique Integer > 0)
G5, G7	Identification number of connected edge grid points. Optional data for bottom and top edge grid points. (Unique Integer > 0)
G6, G8	Identification number of connected edge grid points. Optional data for side grid points used only to make the element compatible with eight-noded quadrilateral elements. (Unique Integer > 0)

Remarks:

1. Element identification numbers should be unique with respect to all other element ID's of any kind.
2. Grid points  $G_i$  must be numbered as shown in the following figure.
3. The element is typically used to model the interface between different materials, where  $G_1$ ,  $G_5$ , and  $G_2$  correspond to one side (called the bottom) and  $G_3$ ,  $G_7$ , and  $G_4$  correspond to the other side (called the top). The stress components are one normal and one shear traction. Then only  $G_1$ - $G_4$  are specified, the element is linear. When in addition to  $G_1$ - $G_4$ ,  $G_5$  and  $G_7$  are specified, the element is quadratic.
4. The corresponding deformation are relative displacements between the top and bottom edge of the element.
5. The element is allowed to be infinitesimally thin; in which case edges  $G_1$ - $G_5$ - $G_2$  and  $G_3$ - $G_7$ - $G_4$  may coincide.

- The element must lie in the x-y plane of the basic system.

- This element does not support thermal load. No thermal strain will be generated.

## CINTC Line Interface Element Connection

Defines a line interface element with specified boundaries.

Format:

1	2	3	4	5	6	7	8	9	10
CINTC	EID	TYPE							
LIST = (BID1(INTP1), BID2(INTP2),...,BIDn(INTPn))									

Example:

CINTC	1001	GRDLIS T							
LIST=(101,102(Q),-103(Q),104(L))									

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
TYPE	Connectivity. If TYPE = "GRDLIST" or blank (Default), the user will specify the boundaries via Bulk Data entry, GMBNDC. See Remark 2. (Character; Default = "GRDLIST")
BIDi	Boundary curve identification number, referenced to Bulk Data entry, GMBNDC. See Remark 2. (Integer ≠ 0)
INTPi	Interpolation scheme. (Character; Default = "L") INTP = "L": Linear interpolation; INTP = "Q": Quadratic interpolation.

Remarks:

1. Line interface element identification numbers must be unique with respect to all other line interface elements.
2. There must be at least two BIDi specified. If all BIDi are positive, by default, the degrees of freedom associated with the grids on the boundary represented by the first BID will be taken as the independent (n-set), and the degrees of freedom with the grids on the rest of boundaries are taken as the dependent (m-set). If there is a single negative BID, the degrees of freedom associated with the grids on the boundary represented by this BID will be taken as the independent (n-set), and the rest of the degrees of freedom with other boundaries are used as the dependent (m-set). If there are two or more negative BIDs, the degrees of freedom with the first negative one will be taken as the independent.
3. Forces of multipoint constraints may be recovered with the MPCFORCE Case Control command.
4. The m-set degrees of freedom specified on the boundary grids by this entry may not be specified by other entries that define mutually exclusive sets.

**CLOAD****Static Load Combination for Superelement Loads (Superposition)**

Defines a static load as a linear combination of previously calculated superelement loads defined by the LSEQ entry in nonlinear static analysis (SOLs 106 or 153).

Format:

1	2	3	4	5	6	7	8	9	10
CLOAD	CID	S	S1	IDV1	S2	IDV2	S3	IDV3	
	S4	IDV4	-etc.-						

Example:

CLOAD	25	1.0	25.0	10	-1.0	101	2.2-1	604	
	-62.0	62							

Describer	Meaning
CID	Combination identification number. (Integer > 0)
S	Scale factor. (Real)
Si	Scale factors. (Real)
IDVi	Identification numbers of load vectors (EXCITEID of a selected LSEQ entry) calculated for a superelement loads entry. (Integer > 0)

Remarks:

- The CLOAD entry must be selected in the residual solution subcases of the Case Control with CLOAD = CID and must be used if loads are applied to upstream superelements in SOL 106 or 153.
- The load vector defined is given by  $\{P\} = S \sum_i S_i \{P_{IDV_i}\}$
- The IDVi field refers to a previously calculated load vector for the superelement via the LSEQ approach. That is, a LOADSET keyword must have been selected in Case Control that in turn refers to one or more LSEQ entries in the Bulk Data Section. The IDVi refers to the EXCITEID of such LSEQ entries. For more details, see the Case Control commands [LSEQ](#) Bulk Data entry and the [LOADSET \(Case\)](#).
- In the CID or IDV fields, a CLOAD entry may not reference an identification number defined by another CLOAD entry.

## CMARKB2

## Two-Noded Marker Connectivity Definition

Defines a 2-noded marker beam element by means of connecting two grid points. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CMARKB2	ID	PID	G1	G2					

Example:

CMARKB2	7	1	9	10					
---------	---	---	---	----	--	--	--	--	--

Describer	Meaning
ID	Unique element number. (Integer > 0; Required)
PID	Property ID referring to a PMARKER entry. (Integer > 0; Required)
G1	Grid point number connectivity 1. (Integer > 0; Required)
G2	Grid point number connectivity 2. (Integer > 0; Required)

Remarks:

1. A CMARKB2 element may refer to two types of grid points:
  - a. Structural grid points, thus grid points that are part of the connectivity of an element
  - b. Free grid points in space. These grid points do not have mass associated with them. The motion of these grid points is specified by the PMARKER property
2. The ID must be unique in the model and may not be used as structural element ID.

## CMARKN1

## One-Noded Marker Connectivity Definition

Defines a 1-noded marker element on a grid point. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CMARKN1	ID	PID	G1						

Example:

CMARKN1	7	1	9						
---------	---	---	---	--	--	--	--	--	--

Describer	Meaning
ID	Unique element number. (Integer > 0; Required)
PID	Property ID referring to a PMARKER entry. (Integer > 0; Required)
G	Grid point number. (Integer > 0; Required)

Remarks:

1. A CMARKB2 element may refer to two types of grid points:
  - a. Structural grid points, thus grid points that are part of the connectivity of an element
  - b. Free grid points in space. These grid points do not have mass associated with them. The motion of these grid points is specified by the PMARKER property
2. The ID must be unique in the model and may not be used as structural element ID.

## CMASS1      Scalar Mass Connection

Defines a scalar mass element.

Format:

1	2	3	4	5	6	7	8	9	10
CMASS1	EID	PID	G1	C1	G2	C2			

Example:

CMASS1	32	6	2	1					
--------	----	---	---	---	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. ( $0 < \text{Integer} < 100,000,000$ )
PID	Property identification number of a PMASS entry. ( $\text{Integer} > 0$ ; Default = EID)
G1, G2	Geometric grid or scalar point identification number. ( $\text{Integer} \geq 0$ )
C1, C2	Component number. ( $0 \leq \text{Integer} \leq 6$ ; blank or zero if scalar point)

Remarks:

- Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero. If only scalar points and/or ground are involved, it is more efficient to use the CMASS3 entry.
- Element identification numbers should be unique with respect to all other element identification numbers.
- The two connection points (G1, C1) and (G2, C2) must not be coincident.
- For a discussion of the scalar elements, see the *MSC Nastran Reference Guide*, Section 5.6.
- A scalar point specified on this entry need not be defined on an SPOINT entry.
- If Gi refers to a grid point then Ci refers to degrees-of-freedom(s) in the displacement coordinate system specified by CD on the GRID entry.
- Scalar elements input coupled mass matrices when the second pair of fields is entered. When uncoupled point masses are desired input only the first pair of fields. When a coupled mass matrix is requested the submatrix added has M on the diagonal, and -M on the off-diagonal. The element is not checked for internal constraints, which is the user's responsibility if desired. There are instances where elements with internal constraints are desired, although not frequently. To identify the presence of internal constraints caused by coupled mass, inspect GPWG output, OLOAD output due to GRAV loads, and rigid body modes of free structures. Some forms of coupled mass will cause coupling of rigid body translational mass terms in GPWG output, and poor rigid body modes in modal analysis.

## CMASS2      Scalar Mass Property and Connection

Defines a scalar mass element without reference to a property entry.

Format:

1	2	3	4	5	6	7	8	9	10
CMASS2	EID	M	G1	C1	G2	C2			

Example:

CMASS2	32	9.25	6	1					
--------	----	------	---	---	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. ( $0 < \text{Integer} < 100,000,000$ )
M	Value of the scalar mass. (Real)
G1, G2	Geometric grid or scalar point identification number. ( $\text{Integer} \geq 0$ )
C1, C2	Component number. ( $0 \leq \text{Integer} \leq 6$ ; blank or zero if scalar point)

Remarks:

- Scalar points may be used for G1 and/or G2, in which case the corresponding C1 and/or C2 must be zero or blank. Zero or blank may be used to indicate a grounded terminal G1 or G2 with a corresponding blank or zero C1 or C2. A grounded terminal is a point with a displacement that is constrained to zero. If only scalar points and/or ground are involved, it is more efficient to use the CMASS4 entry.
- Element identification numbers should be unique with respect to all other element identification numbers.
- The two connection points (G1, C1) and (G2, C2) must be distinct. Except in unusual circumstances, one of them will be a grounded terminal with blank entries for Gi and Ci.
- For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
- A scalar point specified on this entry need not be defined on an SPOINT entry.
- If Gi refers to a grid point then Ci refers to degrees-of-freedom(s) in the displacement coordinate system specified by CD on the GRID entry.
- See Remark 7 for [CMASS1](#).

## CMASS3 Scalar Mass Connection to Scalar Points Only

Defines a scalar mass element that is connected only to scalar points.

Format:

1	2	3	4	5	6	7	8	9	10
CMASS3	EID	PID	S1	S2					

Example:

CMASS3	13	42	62						
--------	----	----	----	--	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PMASS entry. (Integer > 0; Default = EID)
S1, S2	Scalar point identification numbers. (Integer ≥ 0; S1 ≠ S2)

Remarks:

1. S1 or S2 may be blank or zero, indicating a constrained coordinate.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. Only one scalar mass element may be defined on a single entry.
4. For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
5. A scalar point specified on this entry need not be defined on an SPOINT entry.

## CMASS4      Scalar Mass Property and Connection to Scalar Points Only

Defines a scalar mass element that is connected only to scalar points, without reference to a property entry.

Format:

1	2	3	4	5	6	7	8	9	10
CMASS4	EID	M	S1	S2					

Example:

CMASS4	23	14.92		23					
--------	----	-------	--	----	--	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
M	Scalar mass value. (Real)
S1, S2	Scalar point identification numbers. (Integer ≥ 0; S1 ≠ S2)

Remarks:

1. S1 or S2 may be blank or zero, indicating a constrained coordinate. This is the usual case.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. Only one scalar mass element may be defined on a single entry.
4. For a discussion of the scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
5. A scalar point specified on this entry need not be defined on an SPOINT entry.

**CMREBAI** Defines Rebar Elements and Matching "Matrix" Solid Elements using the Marc REBAR with INSERT Method in SOL 600

In some cases, particularly for modeling of concrete or tires, it is beneficial to add rebar or cord material to a matrix. The resulting combined material is similar to a composite but it is sometimes easier to postprocess the stresses of the rebar and matrix separately to determine failure conditions. Unlike the CMREBAR element, this element can span multiple matrix CHEXA elements (for example, could be allied to all elements on the bottom of a flat surface modeled with several layers of CHEXA matrix elements through the thickness).

**Format:**

1	2	3	4	5	6	7	8	9	10
CMREBAI	ID	IP	G1	G2	G3	G4	G5	G6	
	G7	G8							

**Example:**

CMREBAI	100	2	31	32	88	87			
CMREBAI	250	8	1	2	3	4	5	6	
	7	8							

Describer	Meaning
ID	Rebar element ID should be distinct between all element ID's. (Integer; Required; no Default)
IP	Property identification of a matching PMRBAR entry. (Integer; Required; no Default)
G1-G4	Grid point identification numbers of the four corner points. (Integer > 0; all unique)
G5-G8	Grid point identification numbers of the four mid-side nodes similar to G5-G8 for the CQUAD8 element. (Integer > 0, or blank. If any of G5-G8 are not blank, all nodes in the range G5 to G8 must be defined and must be unique among the range G1-G8.)

**Remarks:**

1. This entry makes use of Marc's REBAR and INSERT capabilities for membrane element types 147 and 148. If G5-G8 are blank, Marc element 147 with 4 nodes is used. If G5-G8 are not blank, Marc element 148 with 4 corner nodes and 4 mid-side nodes is used. Entry CMREBAR makes use of Marc's REBAR capability (without INSERT) and uses rebar elements 23 and 146.
2. The grid ID's do not have to correspond to those of any matrix CHEXA element. The PMREABI entry is used to describe the matrix CHEXA elements that these rebar elements will be inserted into.
3. Cord-reinforced composites are characterized by a group of reinforcing cords with arbitrary spatial orientations embedded in various matrix materials. The different constituents may have different mechanical properties. Two typical examples of the cord-reinforced composites are tires and cord-reinforced concretes. In modeling such materials, the rebar technique is very useful. The basic idea

of rebar layer concept contains (1) the reinforcing cords and the matrix materials of the composites are represented independently by different types of elements along with different constitutive models, (2) the reinforcing cords within the elements modeling these cords (the so-called rebar elements) are assumed to be in the form of layers, and (3) the rebar elements are then embedded into the matrix elements. The compatibility between the cord elements and the matrix elements is enforced by embedding membrane rebar elements into solid matrix elements using Marc's INSERT option. Membrane rebar elements types 147 and 148 are available with this option. They are empty 4-node or 8-node quadrilaterals. You can place reinforcing cord layers within these empty elements. These elements are then embedded into their corresponding solid elements representing the matrix materials. Independent meshes can be used for the rebar membrane elements and the matrix elements. Marc's INSERT option is automatically invoked by the CMREBAI elements and used to enforce the compatibility between two different meshes.

4. The major difference between the CMREBAR and CMREBAI elements is that CMREBAR elements share the same grids as the matrix CHEXA elements while CMREBAI elements typically have different grid ID's than the matrix CHEXA elements. Marc's INSERT option automatically adds tyings (MPC's) between the CMREBAI grids and the CHEXA grids.
5. CMREBAI elements are preferred over the CMREBAR elements when re-meshing is involved.
6. See MPREBAI for additional information and figures defining these rebar elements.
7. Only CHEXA elements may be used for the matrix elements.

**CMREBAR**

Defines Rebar Elements and Matching "Matrix" Solid Elements using the Marc REBAR without INSERT Method in SOL 600

In some cases, particularly for modeling of concrete or tires, it is beneficial to add rebar or cord material to a matrix. The resulting combined material is similar to a composite but it is sometimes easier to postprocess the stresses of the rebar and matrix separately to determine failure conditions. CMREBAR elements require that the rebar be placed in matching CHEXA matrix elements on a one-to-one basis. For a similar capability where the rebar can span multiple CEHXA matrix elements, see the CMREBAI entry.

Format:

1	2	3	4	5	6	7	8	9	10
CMREBAR	ID	IP	ID2	IDD	ID22				

Example:

CMREBAR	100	2	1						
CMREBAR	1001	50	101	1100	200				

Describer	Meaning
EID	Rebar element ID should be distinct between all element ID's. (Integer; Required; no Default)
IP	Property identification of a matching PMRBAR entry. (Integer; Required; no Default)
ID2	CHEXA (8 node or 20 node) "matrix" element that the rebar will be added to. (Integer; Required; no Default)
IDD	If more than one rebar element in a continuous range is to be added to a continuous range of rebar elements, IDD represents the first rebar element identification number in the range. (Integer; Required; Default = 0, IDD must be larger than ID)
ID22	If more then one rebar element in a continuous range is to be added to a continuous range of "matrix" elements, ID22 represents the last CHEXA matrix element identification number in the range. (Integer; Required; Default = 0, ID22 must be larger then ID2)

Remarks:

1. This entry makes use of Marc's REBAR capability for element types 23 and 146. Entry CMREBAI makes use of Marc's REBAR and INSERT capabilities and uses membrane rebar elements 147 and 148.
2. If IDD is entered, IDD2 must also be entered and the difference IDD-ID must match the difference IDD2-ID2.

3. The same grid ID's are used to define element ID and ID2. Similarly the same grid ID's define the other elements if a range of elements are used. Element ID is an "empty shell element" and up to 5 rebar layers (each containing multiple rebar) are placed in the empty shell as specified by the PMREBAR property entries.
4. Cord-reinforced composites are characterized by a group of reinforcing cords with arbitrary spatial orientations embedded in various matrix materials. The different constituents may have different mechanical properties. Two typical examples of the cord-reinforced composites are tires and cord-reinforced concretes. In modeling such materials, the rebar technique is very useful. The basic idea of rebar layer concept contains that (1) the reinforcing cords and the matrix materials of the composites are represented independently by different types of elements along with different constitutive models, (2) the reinforcing cords within the elements modeling these cords (the so-called rebar elements) are assumed to be in the form of layers, and (3) the rebar elements are then embedded into the matrix elements. The compatibility between the cord elements and the matrix elements is enforced by superimposing solid rebar elements on corresponding solid matrix elements using the same element connectivity. The rebar elements are empty 8-node or 20-node CHEXA elements derived from the matching matrix elements. The reinforcing cord layers are placed within the elements. Each solid rebar element is then superimposed on a solid matrix element. The two elements share the same space with the same element connectivity (therefore, the same element nodes). The compatibility condition between the reinforcements and the matrix materials is then automatically enforced.
5. The major difference between the CMREBAR and CMREBAI elements is that CMREBAR elements share the same grids as the matrix CHEXA elements while CMREBAI elements typically have different grid ID's than the matrix CHEXA elements. Marc's INSERT option automatically adds tyings (MPC's) between the CMREBAI grids and the CHEXA grids.
6. CMREBAI elements are preferred over the CMREBAR elements when re-meshing is involved.
7. See PMREBAR for additional information and figures defining these rebar elements.
8. Only CHEXA elements may be used for the matrix elements.

## Entries CO - CY

### COHESIV

Defines Data for Cohesive Materials in SOL 600

This option allows you to define material properties for interface elements, that may be used to simulate the onset or progress of delamination, and to associate these material properties with a list of element numbers. The cohesive material is defined using the cohesive energy (also called critical energy release rate), that equals the area below the equivalent traction versus equivalent relative displacement curve. The shape of this curve can be bilinear, exponential, or combined linear-exponential. Mixed mode delamination is incorporated by converting the normal and shear components of the relative displacements into an equivalent using the normal shear weighting factor.

As an alternative to the standard linear, exponential, and liner-exponential model, the user can also utilize this option to trigger the call to the UCOHESIVE user-subroutine. Used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
COHESIV	MID	ITYPE	IACT	NAME					
	EN	COD	MOD	NSW	SNW	DECAY			
	VISC	RATE	STIFF						
	ISET								

Example:

COHESIV	101	1	1	material	number10	1			
	2000.	.01	.015	23.	24.	1.			
	.05	0.0	1.0						
	101								

Describer	Meaning
MID (3,1)	Material ID - Must match a MATXXX entry. (Integer; no Default)
ITYPE (3,2)	Type of cohesive model. (Integer > 0; Default = 1) 1 Bilinear model (Default) 2 Exponential modes 3 Combined linear-exponential model -1 User-defined using user-subroutine UCOHESIVE
IACT (3,3)	Option to deactivate elements and output to t16 file. (Integer; Default = 0) 0 Elements remain active regardless of the damage level. 1 Deactivate the elements if the maximum damage in all the element integration points has been reached. Do not remove the elements from the t16 file.

Describer	Meaning
	2 Deactivate the elements if the maximum damage in all the element integration points has been reached. Remove the elements from the t16 file.
NAME (3,5)	Name of the material. (Character up to 40 characters; no Default; optional entry)
EN (4,1)	Cohesive energy. (Real; no Default; Required value)
COD (4,2)	Critical opening displacement. (Real; no Default; Required value)
MOD (4,3)	Maximum opening displacement (Bilinear model only). (Real; no Default)
NSW (4,4)	Normal-shear weighting factor, beta. (Real; no Default; Required value)
SNW (4,5)	Shear-normal weighting factor. (Real; Default = 1.0)
DECAY (4,6)	Exponential decay factor. (Linear-Exponential model only).(Real; Default = 1.0)
VISC (4,7)	Viscous energy dissipation factor (zero implies no viscous energy dissipation). (Real; Default = 0.0)
RATE (4,8)	Relative displacement reference rate. Only used if viscous energy dissipation is by setting VISC to a non-zero value. (Real; Default = 0.0)
STIFF (4,9)	Stiffening factor in compression. (Real; Default = 1.0)
ISET (5)	ID of a SET3 entry defining the elements associated with this cohesive material. (Integer, no Default, Required value)

#### Remarks:

1. Values in parenthesis (i,j) refer to Marc's COHESIVE entry. (Datablock, field)
2. For solid elements, this entry may be used to add a "layer" or interface between the solid elements (CHEXA, CTETRA or CPENTA). This interface can fail or delaminate depending on the properties entered. It is used in conjunction with Marc element types 188, 192 and 193 and provides the material properties for these element types.
3. For shell elements (CQUADi, CTRIAi) this entry may be used to add a layer between the edges of adjacent shells. It is used in conjunction with Marc element types 186 and 187 and provides the material properties for these element types.
4. Solid or shell elements with a COHESIV MID will automatically be assigned Marc element types 186, 187, 188, 189, 192, 193 as appropriate to the type and number of grids defined for that element. These solid elements must either only have corner nodes or have the full parabolic number of nodes (for example, CHEXA must either have 8 nodes or 20 nodes).
5. For SOL 600, cohesive behavior is not available for axisymmetric or plane strain analyses.
6. MID must not be used by any other material such as MAT1, MAT2, etc.
7. All continuation lines are required.

**COHFRIC****Cohesive Friction**

Allows friction and sticking during tensile conditions at the coupling surface. Use SOL700 only.

Format:

COHFRIC	CID	MAXSTRS	FRIC	REFVEL					
---------	-----	---------	------	--------	--	--	--	--	--

Example:

COHFRIC	112	8e+10	8e+5	2					
---------	-----	-------	------	---	--	--	--	--	--

Describer	Meaning
CID	Unique number of a COHFRIC entry. (Integer>0; required)
MAXSTRS	Maximal normal stress. Allows tensile stresses at the coupling surface as long as the normal stress does not exceed MAXSTRS. (Real ≥ 0.0; default=0.0)
FRIC	Friction stress under tensile conditions. (Real ≥ 0.0; default=0.0)
REFVEL	Reference value for velocity. (Real ≥ 0.0; default=0.0)

Remarks:

1. If the cohesive friction parameters is uniform across the coupling surface then DYPARAM, COHESION can be used instead.
2. During tension any relative tangential velocity between coupling surface and Eulerian material will yield a shear stress whose magnitude equals  $Fric \times \min\left(1, \frac{V_{REL, tangential}}{REFVEL}\right)$ . This is a viscous-like friction law.
3. This shear force opposes the relative tangential movement along the coupling surface.

**COMPUDS**

Orthotropic Failure Model that allows to model Property Degradation

Defines an orthotropic failure model for shell composites specified by a user subroutine. Used in SOL700 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
COMPUDS	MID	GROUP	UNAME						+
+	E1	E2	N12	G12	G1,Z	G2,Z	RHO		+
+	NV	S	ALPHA	TRSFAL	F12				+
+	XT	XT	YT	YC	PFD	VALUE	PFDST		+
+	FBTEN	FBCOM	MXTEN	MXCOM	MXSHR				+
+	PRDFT	PRDFC	PRDMT	PRDMC	PRDSH				+

**Example:**

In FMS Section of the MSC Nastran input stream:

```
CONNECT SERVICE excomp1 'SCA.MDSolver.Obj.Uds.Dytran.Materials'
In Bulk Data:
```

COMPUDS	1	EXCOMP1							+
+	30E6	1.0E6	0.3	2.0E6	3.0E6	1.5E6	0.056		+
+	5	100							
+	200	150	100	110					

Field	Contents
MID	Unique material identification number. (Integer > 0; required)
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; required).
UNAME	User subroutine name associated with the entry. (Character; default = blank).
E1	Modulus of elasticity in longitudinal direction (also defined as fiber direction or one-direction). (Real > 0.0; required)
E2	Modulus of elasticity in lateral direction (also defined as matrix direction or two-direction). (Real > 0.0; required)
N12	Poisson's ratio ( $\nu$ / 1 for uniaxial loading in one-direction). Note that $\nu_{21} = \nu_{12} E_2 / E_1$ for uniaxial loading in two-direction is related to $\nu_{12}$ , E1, E2 by the relation $\nu_{12} E_2 = \nu_{21} E_1$ . (Real > 0.0; required)
G12	In-plane shear modulus R. (Real > 0.0; required)
G1,Z	Transverse shear modulus for shear in 1-Z plane. (Real > 0.0; default= G12)
RHO	Mass density. (R > 0.0; required)

Field	Contents
NV	Number of additional history variables for a user model. See Remark 8. ( $0 < \text{Integer} < 10$ ; default=0)
S	Failure stress for in-plane shear. (Real $\geq 0.0$ ; default=0.0)
ALPHA	Nonlinear shear coefficient. (Real $\geq 0.0$ ; default=0.0)
TRSFAIL	Transverse shear failure. (Character; default = SUBL)
	ELEM: Failure if element fails
	SUBL: Failure if sublayer fails
F12	Interaction term in Tsai-Wu theory. (Real; default=0.0)
XT, XC	Tensile compressive failure stress in the large structural direction. (Real $> 0.0$ ; required)
YT, YC	Tensile compressive failure stress in the lateral direction. (Real $> 0.0$ ; required)
PFD	Post-failure degradation model. (Character; default = STEPS)
	STEPS: Degrade stresses by time steps
	TIME: Degrade stresses by time
	VELOC: Degrade stresses by velocity
VALUE	Depending on PFD, VALUE gives the number of time steps, time interval, or propagation velocity. (Integer or Real; default=100)
PFDST	Post-failure degradation start. (Character; default=INDV)
	INDV Stresses are degraded per distinct failure mode.
	ALL Stresses are degraded if all elastic constants are zero.
FBTEN,FBCO N,MXTEN,M XCOM,MXS HR	Failure modes in fiber, matrix direction, and theory failure. (Character; default=blank)
PRDFT	Property degradation due to fiber-tension failure. (Integer; default=1111)
PRDFC	Property degradation due to fiber-compression failure. (Integer; default=1010)
PRDMT	Property degradation due to matrix-tension failure. (Integer; default=0110)
PRDMC	Property degradation due to matrix-compression failure. (Integer; default=0110)
PRDSH	Property degradation due to in-plane shear failure. (Integer; default=0001)

Remarks:

11. Please check MAT8 and MAT8A cards about the details of each field. The field definition is identical as MAT8 and MAT8A.
12. UNAME can be:

Subroutine Name	Function
EXCOMP	User defined orthotropic material models for shell composite

**CONCTL** Parameter SWLDPRM override for CFAST, CSEAM, and CWELD Connector Elements

This entry provides local connector search algorithm control to override SWLDPRM values.

Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
CONCTL	SET3ID		PARAM1	VALUE1	PARAM2	VALUE2	PARAM3	VALUE3	
	PARAM4	VALUE5	PARAM4	VALUE5	-etc.-				

Example:

CONCTL	75		PROJTOL	0.2	PRTSW	1	GSMOVE	3	
	NREDIA	2							
CONCTL	83		MOVGAB	1					

Describer	Meaning
SET3ID	The ID of a SET3 entry using (DES= ELEM) to identify a group of connector elements. (Integer>0)
PARAMi	Name of the connector parameter. Allowable names are listed in Table 8-62 of SWLDPRM. (Character)
VALUEi	Value of the parameter. See Table 8-62 of SWLDPRM (Real or Integer)

Remarks:

- Multiple CONCTL entries are allowed and ALL appearing will be used. If the user supplies a PARAMi, VALUEi that refers to specific Element on one CONCTL entry and a same PARAMi with VALUEj that refers to the same specific Element on another CONCTL, a fatal message will be issued.
- For a given connector element ID, this entry will override the global default set by the SWLDPRM entry.
- The parameter CHKRUN can only be set on SWLDPARM and will be ignored on CONCTL entries.
- A user fatal will be issued if DES on the SET3 entry is not "ELEM".

## CONM1 Concentrated Mass Element Connection, General Form

Defines a 6 x 6 symmetric mass matrix at a geometric grid point.

Format:

1	2	3	4	5	6	7	8	9	10
CONM1	EID	G	CID	M11	M21	M22	M31	M32	
	M33	M41	M42	M43	M44	M51	M52	M53	
	M54	M55	M61	M62	M63	M64	M65	M66	

Example:

CONM1	2	22	2	2.9	6.3				
	4.8	28.6							
		28.6						28.6	

Descriptor	Meaning
EID	Unique element identification number. ( $0 < \text{Integer} < 100,000,000$ ). See Remark 2.
G	Grid point identification number. ( $\text{Integer} > 0$ ). See Remark 3.
CID	Coordinate system identification number for the mass matrix. ( $\text{Integer} \geq 0$ )
Mij	Mass matrix values. (Real)

Remarks:

1. For a less general means of defining concentrated mass at grid points, see the CONM2 entry description.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. Unlike the CONM2 entry, the CONM1 entry does not allow for the specification of concentrated mass at harmonic structural grid points. Therefore, grid point G must necessarily be a non-harmonic structural grid point.

**CONM2** Concentrated Mass Element Connection, Rigid Body Form

Defines a concentrated mass at a grid point.

Format:

1	2	3	4	5	6	7	8	9	10
CONM2	EID	G	CID	M	X1	X2	X3		
	I11	I21	I22	I31	I32	I33			

Example:

CONM2	2	15	6	49.7					
	16.2		16.2			7.8			

Describer	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ ). See Remark 1.
G	Grid point identification number. ( $\text{Integer} > 0$ ). See Remark 7.
CID	Coordinate system identification number. For CID of -1; see X1, X2, X3 below. ( $\text{Integer} \geq -1$ ; Default = 0). See Remarks 4., 6. and 7.
M	Mass value. (Real). See Remarks 5. and 7.
X1, X2, X3	Offset distances from the grid point to the center of gravity of the mass in the coordinate system defined in field 4, unless CID = -1, in which case X1, X2, X3 are the coordinates, not offsets, of the center of gravity of the mass in the basic coordinate system. (Real). See Remarks 4., 5., 6. and 7.
Iij	Mass moments of inertia measured at the mass center of gravity in the coordinate system defined by field 4. If CID = -1, the basic coordinate system is implied. (Real). See Remarks 4., 5. and 7.

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. For a more general means of defining concentrated mass at grid points, see the CONM1 entry description.
3. The continuation is optional.
4. If CID = -1, offsets are internally computed as the difference between the grid point location and X1, X2, X3. The grid point locations may be defined in a nonbasic coordinate system. In this case, the values of Iij must be in a coordinate system that parallels the basic coordinate system.
5. The form of the inertia matrix about its center of gravity is taken as:

$$\begin{bmatrix} M & & & & & & & & \\ & M & & & & & & & \\ & & \text{symmetric} & & & & & & \\ & & & I_{11} & & & & & \\ & & & -I_{21} & & I_{22} & & & \\ & & & -I_{31} & & -I_{32} & & I_{33} & \\ & & & & & & & & \end{bmatrix}$$

where

$$M = \int \rho dV$$

$$I_{11} = \int \rho(x_2^2 + x_3^2) dV$$

$$I_{22} = \int \rho(x_1^2 + x_3^2) dV$$

$$I_{33} = \int \rho(x_1^2 + x_2^2) dV$$

$$I_{21} = \int \rho x_1 x_2 dV$$

$$I_{31} = \int \rho x_1 x_3 dV$$

$$I_{32} = \int \rho x_2 x_3 dV$$

and  $x_1, x_2, x_3$  are components of distance from the center of gravity in the coordinate system defined in field 4. The negative signs for the off-diagonal terms are supplied automatically. A warning message is issued if the inertia matrix is non-positive definite, since this may cause fatal errors in dynamic analysis modules.

6. If  $CID \geq 0$ , then X1, X2, and X3 are defined by a local Cartesian system, even if CID references a spherical or cylindrical coordinate system. This is similar to the manner in which displacement coordinate systems are defined.
7. MSC Nastran contains two kinds of structural grid points, namely, non-harmonic structural grid points and harmonic structural grid points. The former have the standard three translational and three rotational degrees of freedom while the latter have three symmetric components and three anti-symmetric components dependent on the harmonic value.

Harmonic grid points are identified automatically as the grid points listed on CQUADX and CTRIAX element entries that are associated with PAXSYMH entries.

For a harmonic grid point, the mass value  $M$  is the total mass. This value is not to be multiplied by  $2\pi$ . The mass matrix computed for harmonic grids is dependent on the harmonic value associated with the PAXSYMH entry and will be automatically determined by the code. Only harmonic values of 0 and 1 have contributions to grid point weight generator type calculations.

Any values specified in the CID, X1, X2, X3, I11, I21, I22, I31, I32, or I33 fields are ignored for a harmonic grid.

**CONROD****Rod Element Property and Connection**

Defines a rod element without reference to a property entry.

Format:

1	2	3	4	5	6	7	8	9	10
CONROD	EID	G1	G2	MID	A	J	C	NSM	

Example:

CONROD	2	16	17	4	2.69				
--------	---	----	----	---	------	--	--	--	--

Describer	Meaning
EID	Unique element identification number. (0 < Integer < 100,000,000)
G1, G2	Grid point identification numbers of connection points. (Integer > 0; G1 ≠ G2)
MID	Material identification number. (Integer > 0)
A	Area of the rod. (Real)
J	Torsional constant. (Real)
C	Coefficient for torsional stress determination. (Real)
NSM	Nonstructural mass per unit length. (Real)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. For structural problems, MID must reference a MAT1 material entry.
3. For heat transfer problems, MID must reference a MAT4 or MAT5 material entry.
4. For RC network solver in thermal analysis, the J, C and NSM are ignored.

Figure 9-39 CONROD Element Forces and Moments

## CONTRLT Thermal Control Element for Heat Transfer Analysis

Defines the control mechanism for QVECT, QVOL, QBDY3, RADBC, CONV, and CONVM in heat transfer analysis (SOL 159 and SOL 400 with analysis=htran).

Format:

1	2	3	4	5	6	7	8	9	10
CONTRLT	ID	SENSOR	SFORM	CTYPE	PL	PH	PTYPE	PZERO	
	DT	DELAY	TAUC				FCTMIN	FCTMAX	
	GAIN1	GAIN2	GAIN3						

Example:

CONTRLT	100	20	T	TSTAT	68.	73.	7	1.	
	0.1	0.01	0.				0.	1.	
	0.	0.	0.						

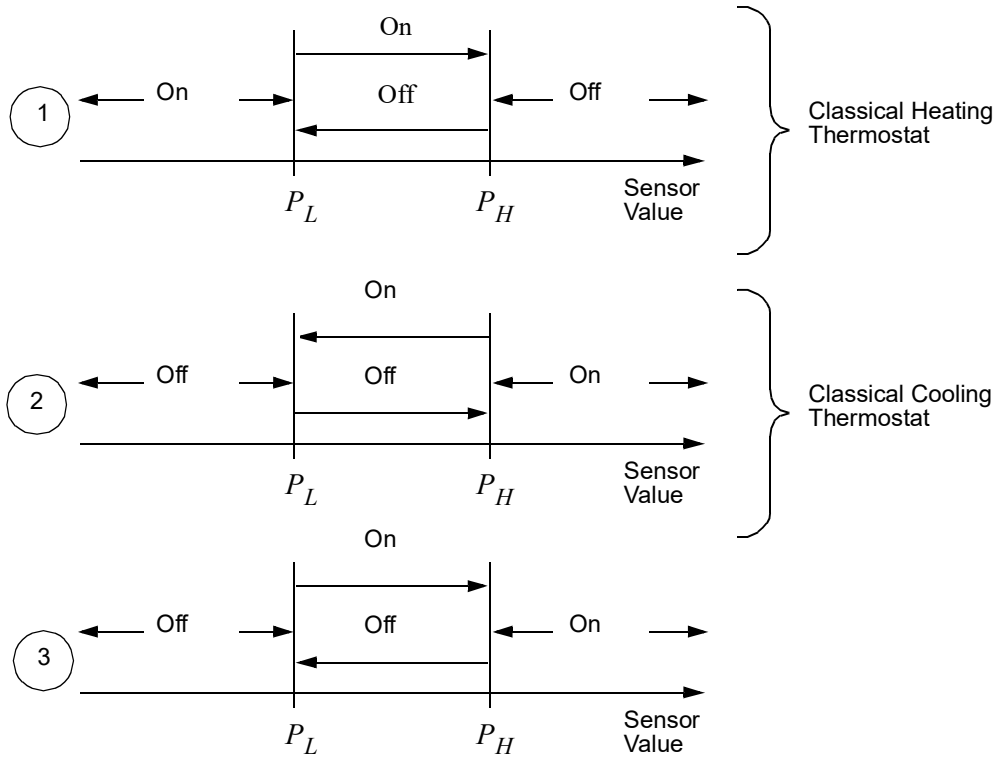

Describer	Meaning
ID	Controller identification node. See Remark 1. (Integer > 0; Required)
SENSOR	Grid or scalar point ID of sensor. See Remark 2. (Integer > 0; Required)
SFORM	Sensor output form. See Remark 3. (Character, T; Default = T)
CTYPE	Control type. See Remark 4. (Character, Default TSTAT)
PL	Minimum temperature. For PTYPE 9 through 11, set temperature. See Remark 5. (Real; Required)
PH	Maximum temperature. For PTYPE 9 through 11, unused. See Remark 5. (Real; Required)
PTYPE	Process type. See Remark 5. (Integer 1 through 11, 1 through 6 already defined; no Default)
	7      Bang-bang (a thermostat that is either on or off, a special case of a bang-bang controller)
	8      Proportional
	9      Steady-state (special routine for steady state models)
	10     Classical PID (proportional-integral-differential) and does not include the time derivative of the set point )
	11     Standard PID (Includes the time derivative of the set point)
PZERO	Initial controller value. See Remark 4. (0. < Real < 1.; Default = 0)
DT	Monitoring time interval or sampling period. (Real > 0.; Default = 0)

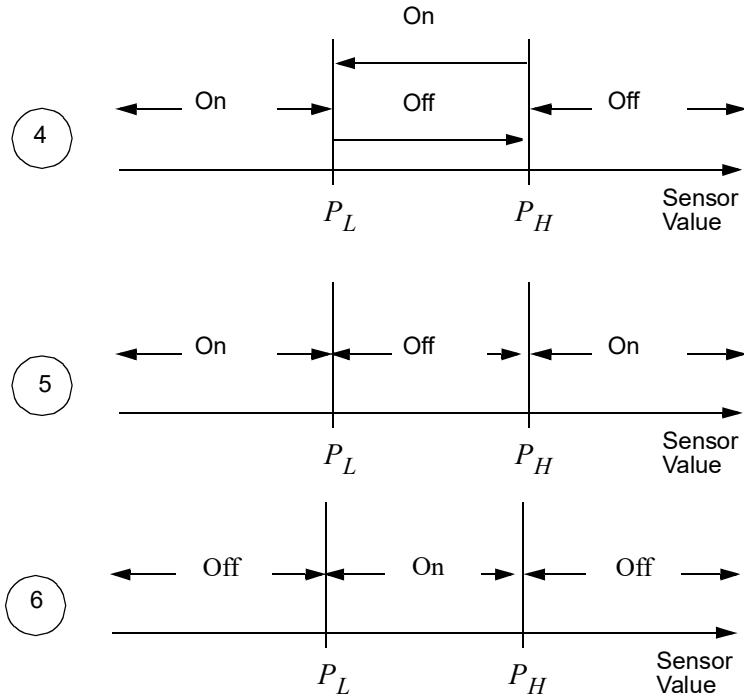

Describer	Meaning
DELAY	Time delay after the switch is triggered or time for delayed control action in PID control. (Real > 0.; Default = 0.0)
TAUC	Decay time constant for actuator response. (Real > 0.; Default = 0.0)
FCTMIN/MAX	Minimum factor/Maximum factor on load to apply. (Real; Default = 0.0)
GAINx	Gain variables for heat controller. Use GAIN1 for P value, GAIN2 for I value, and GAIN3 for D value. (Real; Default = 0.0)

**Remarks:**

1. The CONTRLT ID is referenced by CNTRLND entry identified on any of the CONV, CONVM, RADBC, QVECT, QVOL, and QBDY3 Bulk Data entries. If any grid or scalar point ID is the same as the CONTRLT ID, then the combined logic associated with the controller and the control node will be in force for the LBC referenced. Any number of CONTRLT statements may exist in a single model.
2. Sensor point, where a feedback temperature or rate of change of temperature is measured. May be a dependent DOF in a MPC relationship.
3. Sensor output may only be temperature (T)
4. Control type can only be TSTAT. The PZERO field cannot have any other value but 0.0 or 1.0.
5. The upper and lower limit values (PL and PH) define a dead band for a thermostat. The available thermostat controller (TSTAT) formats are (PTYPE = 1 through 6).
6. RC network solver only supports PTYPE=1 and PTYPE=2 thermostat controller, SFORM, CTYPE, PZERO, DT, DELAY, TAUC and TA8 are ignored.

7. The last 5 parameters are for RC Network solver only.
8. RC Network solver only supports controllers (thermostats) on source data. This entry can be used in either steady-state (static) or transient state (dynamic). For more details about these parameters, please reference the *MSC SINDA User's Guide and Library Reference*.

## CONV Heat Boundary Element Free Convection Entry

Specifies a free convection boundary condition for heat transfer analysis through connection to a surface element (CHBDYi entry).

Format:

1	2	3	4	5	6	7	8	9	10
CONV	EID	PCONID	FLMND	CNTRLND	TA1	TA2	TA3	TA4	
	TA5	TA6	TA7	TA8					

Example:

CONV	2	101	3	201	301				
------	---	-----	---	-----	-----	--	--	--	--

Describer	Meaning
EID	CHBDYG, CHBDYE, or CHBDYP surface element identification number. (0 < Integer < 100,000,000)
PCONID	Convection property identification number of a PCONV entry. (Integer > 0)
FLMND	Point for film convection fluid property temperature. (Integer ≥ 0; Default = 0)
CNTRLND	Control point for free convection boundary condition. (Integer ≥ 0; Default = 0)
TAi	Ambient points used for convection. (Integer > 0 for TA1 and Integer ≥ 0 for TA2 through TA8; Default for TA2 through TA8 is TA1.)

Remarks:

- The basic exchange relationship can be expressed in one of the following forms:
  - $q = H \cdot (T - T_{AMB})^{EXPF} (T - T_{AMB})$ , CNTRLND = 0
  - $q = (H \cdot u_{CNTRLND})(T - T_{AMB})^{EXPF} (T - T_{AMB})$ , CNTRLND ≠ 0
  - $q = H(T^{EXPF} - T_{AMB}^{EXPF})$ , CNTRLND = 0
  - $q = (H \cdot u_{CNTRLND})(T^{EXPF} - T_{AMB}^{EXPF})$ , CNTRLND ≠ 0

EXPF is specified on the PCONV entry.  
(See [PCONV](#) entry for additional clarification of forms.)
- The continuation entry is not required.
- CONV is used with an CHBDYi (CHBDYG, CHBDYE, or CHBDYP) entry having the same EID.

4. The temperature of the film convection point provides the look up temperature to determine the convection film coefficient. If  $FLMND=0$ , the reference temperature has several options. It can be the average of surface and ambient temperatures, the surface temperature, or the ambient temperature, as defined in the FORM field of the PCONV Bulk Data entry.
5. If only one ambient point is specified then all the ambient points are assumed to have the same temperature. If midside ambient points are missing, the temperature of these points is assumed to be the average of the connecting corner points.
6. See the Bulk Data entry, [PCONV](#), for an explanation of the mathematical relationships involved in free convection and the reference temperature for convection film coefficient.
7. RC network solver only supports CNTRLND node defined by SPC or SPCD entries, FLMND is ignored.

## CONVM Heat Boundary Element Forced Convection Entry

Specifies a forced convection boundary condition for heat transfer analysis through connection to a surface element (CHBDYi entry).

Format:

1	2	3	4	5	6	7	8	9	10
CONVM	EID	PCONID	FLMND	CNTMDOT	TA1	TA2	Mdot		

Example:

CONVM	101	1	201	301	20	21			
-------	-----	---	-----	-----	----	----	--	--	--

Describer	Meaning
EID	CHBDYP element identification number. (0 < Integer < 100,000,000)
PCONID	Convection property identification number of a PCONVM entry. (Integer > 0)
FLMND	Point used for fluid film temperature. (Integer ≥ 0; Default = 0)
CNTMDOT	Control point used for controlling mass flow. (Integer ≥ 0 or Blank). Blank or zero is only allowed when Mdot > 0.0. See Remark 3.
TA1, TA2	Ambient points used for convection. (Integer > 0 for TA1 and Integer ≥ 0 for TA2; Default for TA2 is TA1.)
Mdot	A multiplier for mass flow rate in case there is no point associated with the CNTRLND field. (Real > 0.0; Default = 1.0 if CNTMDOT > 0). See Remark 3.)

Remarks:

1. CONVM is used with an CHBDYP entry of type FTUBE having the same EID.
2. The temperature of the fluid film point may be specified to determine the material properties for the fluid. If FLMND=0, the reference temperature has several options. It can be the average of surface and ambient temperatures, the surface temperatures, or the ambient temperature, as defined in the FORM field of the PCONVM Bulk Data entry.
3. The CNTMDOT has a dual function. It can reference the ID of the CONTRLT Bulk Data entry to activate a thermostat controlled flux transfer. It can also reference a GRID or a scalar point which is set to the desired mass flow rate (mdot) to effect the advection of energy downstream at an  $mdot \cdot C_p \cdot T$  rate. If CNTMDOT is zero or is not specified (blank field), then the mass flow rate must be specified on the Mdot field (8th field).

Case 1: Define a thermostat controller using the CONTRLT Bulk Data entry.

Total mass flow rate = CONTRLT · Mdot · CNTMDOT

where CONTRLT is the grid ID on the 2nd field of the CONTRLT Bulk Data entry that ties the mass flow rate through this sensor grid.

Mdot is the 8th field of the CONVM Bulk Data entry.

CNTMDOT is the grid ID that has a mass flow rate associated with it.

Example: The thermostat controller controls GRID 5 (sensor grid) from 250 degrees to 300 degrees. If the temperature exceeds 300 degrees, then the mass flow is turned ON. If the temperature is below 250 degrees, then the mass flow is turned OFF.

```
CONTRLT, 5, 2, T, TSTAT, 250.0, 300.0, 1, 1.0 +
+, 0.0, 0.0, 0.0
CONVM, 100001, 1, , 5, 4
```

Note that GRID 5 is also specified on the 5th field of the CONVM Bulk Data entry.

Case 2: There is no CONTRLT Bulk Data entry (more general case).

Total mass flow rate = Mdot · CNTMDOT

If the CNTMDOT (the 5th field of the CONVM Bulk Data entry) is specified, then the default Mdot value is 1.0 and the mass flow rate is defined through CNTMDOT.

Example: Define a constant mass flow rate of 0.5 through CNTMDOT.

```
CONVM, 100001, 1, , 5, 4
SPC, 1, 5, 1, 0.5
```

To specify a time-varying mass flow rate, replace the SPC Bulk Data entry by TEMPBC,TRAN for SOL 159 or by SPC1 and SPCD for SOL 400.

For SOL 159:

```
TEMPBC, 2, TRAN, 1.0, 5
DLOAD, 700, 1.0, 1.0, 9
TLOAD1, 9, 2, , , 121
TABLED1, 121
, 0.0, 0.3, 100.0, 0.5, endt
```

For SOL 400:

```
SPC = 111 (Case Control command)
SPC1, 111, , 5
SPCD, 2, 5, , 1.0
DLOAD, 700, 1.0, 1.0, 9
TLOAD1, 9, 2, , 1, 121
TABLED1, 121
, 0.0, 0.3, 100.0, 0.5, endt
```

If the CNTMDOT is not specified (zero or blank), then the mass flow rate must be constant and must be defined on Mdot (the 8th field of the CONVM Bulk Data entry).

Example: Define a mass flow rate of 0.5 directly on Mdot without specifying CNTMDOT.

CONVM,100001,1,,,,99,,0.5

4. If only the first ambient point is specified then, the second ambient point is assumed to have the same temperature.
5. See the Bulk Data entry, [PCONVM](#), for an explanation of the mathematical relationships available for forced convection and the reference temperature for fluid material properties.
6. RC network solver does not support CONVM for thermal analysis, it uses PRJCON for forced convection.

## CORD1C

## Cylindrical Coordinate System Definition, Form 1

Defines a cylindrical coordinate system using three grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CORD1C	CIDA	G1A	G2A	G3A	CIDB	G1B	G2B	G3B	

Example:

CORD1C	3	16	32	19					
--------	---	----	----	----	--	--	--	--	--

Descriptor	Meaning
CIDA, CIDB	Coordinate system identification number. (Integer > 0)
GiA, GiB	Grid point identification numbers. (Integer > 0; G1A ≠ G2A ≠ G3A ; G1B ≠ G2B ≠ G3B )

Remarks:

1. Coordinate system identification numbers on all CORD1R, CORD1C, CORD1S, CORD2R, CORD2C, CORD2S and CORD3G entries must be unique.
2. One or two coordinate systems may be defined on a single entry.
3. GiA and GiB must be defined in coordinate systems with definitions that do not involve the coordinate system being defined. The first point is the origin, the second lies on the z-axis, and the third lies in the plane of the azimuthal origin. The three grid points GiA (or GiB) must be noncolinear and not coincident.
4. The location of a grid point (P in [Figure 9-40](#)) in this coordinate system is given by (R, θ, Z) where θ is measured in degrees.

Figure 9-40 CORD1C Definition

5. The displacement coordinate directions at P are dependent on the location of P as shown above by  $(u_r, u_\theta, u_z)$ .
6. It is recommended that points on the z-axis not have their displacement directions defined in this coordinate system. See the discussion of cylindrical coordinate systems in [Grid Point and Coordinate System Definition](#) in the *MSC Nastran Reference Guide*.

If CYLINDRICAL and point exactly on z-axis ( $r = 0.0$  exactly) then R,  $\theta$ , Z triad coordinates are exactly aligned with the local defining system triad. User caution: if  $r \approx 0.0$  but not exactly 0.0 should be avoided as unexpected direction cosine matrix may result.

## CORD1R Rectangular Coordinate System Definition, Form 1

Defines a rectangular coordinate system using three grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CORD1R	CIDA	G1A	G2A	G3A	CIDB	G1B	G2B	G3B	

Example:

CORD1R	3	16	32	19					
--------	---	----	----	----	--	--	--	--	--

Describer	Meaning
CIDA, CIDB	Coordinate system identification number. (Integer > 0)
GiA, GiB	Grid point identification numbers. (Integer > 0; G1A ≠ G2A ≠ G3A and G1B ≠ G2B ≠ G3B)

Remarks:

1. Coordinate system identification numbers on all CORD1R, CORD1C, CORD1S, CORD2R, CORD2C, CORD2S and CORD3G entries must be unique.
2. One or two coordinate systems may be defined on a single entry.
3. GiA and GiB must be defined in coordinate systems with definitions that do not involve the coordinate system being defined. The first point is the origin, the second lies on the z-axis, and the third lies in the x-z plane. The three grid points GiA (or GiB) must be noncolinear and not coincident.
4. The location of a grid point (P in [Figure 9-41](#)) in this coordinate system is given by (X, Y, Z).

## Figure 9-41 CORD1R Definition

5. The displacement coordinate directions at P are shown above by  $(u_x, u_y, u_z)$ .

## CORD1S

## Spherical Coordinate System Definition, Form 1

Defines a spherical coordinate system by reference to three grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CORD1S	CIDA	G1A	G2A	G3A	CIDB	G1B	G2B	G3B	

Example:

CORD1S	3	16	32	19					
--------	---	----	----	----	--	--	--	--	--

Describer	Meaning
CIDA, CIDB	Coordinate system identification numbers. (Integer > 0)
GiA, GiB	Grid point identification numbers. (Integer > 0; G1A ≠ G2A ≠ G3A and G1B ≠ G2B ≠ G3B)

Remarks:

1. Coordinate system identification numbers on all CORD1R, CORD1C, CORD1S, CORD2R, CORD2C, CORD2S and CORD3G entries must be unique.
2. One or two coordinate systems may be defined on a single entry.
3. GiA and GiB must be defined in coordinate systems with a definition that does not involve the coordinate system being defined. The first point is the origin, the second lies on the z-axis, and the third lies in the plane of the azimuthal origin. The three grid points GiA (or GiB) must be noncolinear and not coincident.
4. The location of a grid point (P in [Figure 9-42](#)) in this coordinate system is given by (R, θ, φ) where θ and φ are measured in degrees.

Figure 9-42 CORD1S Definition

5. The displacement coordinate directions at P are dependent on the location of P as shown above by  $(u_r, u_\theta, u_\phi)$ .
6. It is recommended that points on the z-axis not have their displacement directions defined in this coordinate system. See the discussion of spherical coordinate systems in [Grid Point and Coordinate System Definition](#) in the *MSC Nastran Reference Guide*.

If SPHERICAL and  $R = 0.0$  (point at origin) then  $R, \theta, \phi$  triad coordinates are exactly aligned with the local defining system triad. User caution: if  $R \approx 0.0$  but not exactly 0.0 should be avoided as unexpected direction cosine matrix may result.

If SPHERICAL and r in azimuth plane is  $r = 0.0$  and  $z \neq 0.0$  then the coordinate system is defined as  $R$  global along  $\pm Z$ - local defining system triad according if  $z > 0.$  or  $z < 0.$ ,  $\theta$  -global along X-local defining system triad and  $\phi$  -global along Y-local defining system triad. User caution: if  $r \approx 0.0$  but not exactly 0.0 should be avoided as unexpected direction cosine matrix may result.

## CORD2C

## Cylindrical Coordinate System Definition, Form 2

Defines a cylindrical coordinate system using the coordinates of three points.

Format:

1	2	3	4	5	6	7	8	9	10
CORD2C	CID	RID	A1	A2	A3	B1	B2	B3	
	C1	C2	C3						

Example:

CORD2C	3	17	-2.9	1.0	0.0	3.6	0.0	1.0	
	5.2	1.0	-2.9						

Describer	Meaning
CID	Coordinate system identification number. (Integer > 0)
RID	Identification number of a coordinate system that is defined independently from this coordinate system. (Integer ≥ 0; Default = 0 is the basic coordinate system.)
Ai, Bi, Ci	Coordinates of three points given with respect to the coordinate system defined by RID. (Real)

Remarks:

- Coordinate system identification numbers on all CORD1R, CORD1C, CORD1S, CORD2R, CORD2C, CORD2S and CORD3G entries must be unique.
- The three points [(A1, A2, A3), (B1, B2, B3), (C1, C2, C3)] must be unique and noncolinear. Noncolinearity is checked by the geometry processor. The first point defines the origin. The second point defines the direction of the z-axis. The third lies in the plane of the azimuthal origin. The reference coordinate system must be independently defined.
- The continuation entry is required.
- If RID is zero or blank, the basic coordinate system is used.
- The location of a grid point (P in [Figure 9-43](#)) in this coordinate system is given by (R, θ, Z), where θ is measured in degrees.

Figure 9-43 CORD2C Definition

6. The displacement coordinate directions at P are dependent on the location of P as shown above by  $(u_r, u_\theta, u_z)$ .
7. It is recommended that points on the z-axis not have their displacement directions defined in this coordinate system. See the discussion of cylindrical coordinate systems in [Grid Point and Coordinate System Definition](#) in the *MSC Nastran Reference Guide*. If CYLINDRICAL and point exactly on z-axis ( $r = 0.0$  exactly) then R,  $\theta$ , Z triad coordinates are exactly aligned with the local defining system triad. User caution: if  $r \approx 0.0$  but not exactly 0.0 should be avoided as unexpected direction cosine matrix may result.
8. If any CORD2C, CORD2R, or CORD2S entry is changed or added on restart, then a complete re-analysis is performed. Therefore, CORD2C, CORD2R, or CORD2S changes or additions are not recommended on restart.
9. An example of defining a coordinate system with respect to another coordinate system (RID) may be found in the Linear Static Analysis manual [Example](#).

## CORD2R

## Rectangular Coordinate System Definition, Form 2

Defines a rectangular coordinate system using the coordinates of three points.

Format:

1	2	3	4	5	6	7	8	9	10
CORD2R	CID	RID	A1	A2	A3	B1	B2	B3	
	C1	C2	C3						

Example:

CORD2R	3	17	-2.9	1.0	0.0	3.6	0.0	1.0	
	5.2	1.0	-2.9						

Describer	Meaning
CID	Coordinate system identification number. (Integer > 0)
RID	Identification number of a coordinate system that is defined independently from this coordinate system. (Integer ≥ 0; Default = 0; which is the basic coordinate system.)
Ai, Bi, Ci	Coordinates of three points given with respect to the coordinate system defined by RID. (Real)

Remarks:

1. Coordinate system identification numbers on all CORD1R, CORD1C, CORD1S, CORD2R, CORD2C, CORD2S, and CORD3G entries must be unique.
2. The three points [(A1, A2, A3), (B1, B2, B3), (C1, C2, C3)] must be unique and noncolinear. Noncolinearity is checked by the geometry processor. The first point defines the origin. The second defines the direction of the z-axis. The third point defines a vector which, with the z-axis, defines the x-z plane. The reference coordinate system must be independently defined.
3. The continuation entry is required.
4. If RID is zero or blank, the basic coordinate system is used.
5. An example of defining a coordinate system with respect to another coordinate system (RID) may be found in the Linear Static Analysis manual [Example](#).
6. The location of a grid point (P in the [Figure 9-44](#)) in this coordinate system is given by (X, Y, Z).

Figure 9-44 CORD2R Definition

7. The displacement coordinate directions at P are shown by  $(u_x, u_y, u_z)$ .
8. If any CORD2C, CORD2R, or CORD2S entry is changed or added on restart, then a complete re-analysis is performed. Therefore, CORD2C, CORD2R, or CORD2S changes or additions are not recommended on restart.

## CORD2S

## Spherical Coordinate System Definition, Form 2

Defines a spherical coordinate system using the coordinates of three points.

Format:

1	2	3	4	5	6	7	8	9	10
CORD2S	CID	RID	A1	A2	A3	B1	B2	B3	
	C1	C2	C3						

Example:

CORD2S	3	17	-2.9	1.0	0.0	3.6	0.0	1.0	
	5.2	1.0	-2.9						

Describer	Meaning
CID	Coordinate system identification number. (Integer > 0)
RID	Identification number of a coordinate system that is defined independently from this coordinate system. (Integer $\geq$ 0; Default = 0 is the basic coordinate system.)
Ai, Bi, Ci	Coordinates of three points given with respect to the coordinate system defined by RID. (Real)

Remarks:

1. Coordinate system identification numbers on all CORD1R, CORD1C, CORD1S, CORD2R, CORD2C, CORD2S, and CORD3G entries must all be unique.
2. The three points [(A1, A2, A3), (B1, B2, B3), (C1, C2, C3)] must be unique and noncolinear. Noncolinearity is checked by the geometry processor. The first point defines the origin. The second point defines the direction of the z-axis. The third lies in the plane of the azimuthal origin. The reference coordinate system must be independently defined.
3. The continuation entry is required.
4. If RID is zero or blank, the basic coordinate system is used.
5. An example of defining a coordinate system with respect to another coordinate system (RID) may be found in the Linear Static Analysis manual [Example](#).
6. The location of a grid point (P in [Figure 9-45](#)) in this coordinate system is given by (R,  $\theta$ ,  $\phi$ ), where  $\theta$  and  $\phi$  are measured in degrees.

Figure 9-45 CORD2S Definition

7. The displacement coordinate directions at P are shown above by  $(u_r, u_\theta, u_\phi)$ .
8. It is recommended that points on the z-axis not have their displacement directions defined in this coordinate system. See the discussion of spherical coordinate systems in [Grid Point and Coordinate System Definition](#) in the *MSC Nastran Reference Guide*.

If SPHERICAL and  $R = 0.0$  (point at origin) then  $R, \theta, \phi$  triad coordinates are exactly aligned with the local defining system triad. User caution: if  $R \approx 0.0$  but not exactly 0.0 should be avoided as unexpected direction cosine matrix may result.

If SPHERICAL and  $r$  in azimuth plane is  $r = 0.0$  and  $z \neq 0.0$  then the coordinate system is defined as  $R$  global along  $\pm Z$ -local defining system triad according if  $z > 0.$  or  $z < 0.$ ,  $\theta$ -global along  $X$ -local defining system triad and  $\phi$ -global along  $Y$ -local defining system triad. User caution: if  $r \approx 0.0$  but not exactly 0.0 should be avoided as unexpected direction cosine matrix may result.

9. If any CORD2C, CORD2R, or CORD2S entry is changed or added on restart, then a complete re-analysis is performed. Therefore, CORD2C, CORD2R, or CORD2S changes or additions are not recommended on restart.

## CORD3G

## General Coordinate System

Defines a general coordinate system using three rotational angles as functions of coordinate values in the reference coordinate system. The CORD3G entry is used with the MAT9 entry to orient material principal axes for 3-D composite analysis.

Format:

1	2	3	4	5	6	7	8	9	10
CORD3G	CID	METHOD	FORM	THETAID1	THETAID2	THETAID3	CIDREF		

Example:

CORD3G	100	E313	EQN	110	111	112	0		
--------	-----	------	-----	-----	-----	-----	---	--	--

Descriptor	Meaning
CID	Coordinate system identification number. See Remark 1. (Integer > 0)
METHOD	E313 or S321 for Euler angle rotation in 313 sequence or space-fixed rotation in 321 sequence. See Remark 2. (Character; Default = "E313")
FORM	Specifies the Bulk Data entry which defines angles. FORM = "EQN" for DEQATN entry or FORM = "TABLE" for TABLE3D entry. (Character; Default = "EQN")
THETAID	Identification number for DEQATN or TABLE3D Bulk Data entry which defines the three angles (in radians) measured from reference coordinates to the general material coordinate system. See Remark 3. (Integer > 0)
CIDREF	Identification number for the coordinate system from which the orientation of the general coordinate system is defined. (Integer ≥ 0; Default = 0)

Remarks:

1. CID must be unique with respect to all other coordinate systems. CID cannot be referenced on GRID entries.
2. Three Euler angles specify the rotation of the CORD3G coordinate axes (xyz) with respect to the local Cartesian coordinate axes (XYZ) in CIDREF as follows: first rotate about Z-axis by  $\theta_1$ , next rotate about rotated x-axis by  $\theta_2$ , and then rotate about rotated z-axis by  $\theta_3$ . On the other hand, the space-fixed rotations in 321 sequence specify all the rotations about the fixed coordinate axes: first rotate about Z by  $\theta_1$ , next about Y by  $\theta_2$ , then about X by  $\theta_3$ .
3. The three rotations define a coordinate transformation which transforms position vectors in the reference coordinate system into the general coordinate system.
4. The DEQATN option must have three arguments representing the three axes of CIDREF, although not all arguments are necessarily needed in the equation.

5. If FORM = EQN is used with CIDREF pointing to any CORD1k or CORD2k,  $k = C, S$ , and a spatial relationship is required, then the equations are written using  $R, \theta, \varphi$  as input variables. Non spatial fixed values such as THETA1 (A,B,C)=PI(1.) may of course be entered for any type of coordinate defined by the CIDREF.

If FORM = TABLE3D is used with CIDREF pointing to any CORD1k or CORD2k,  $k = C, S$ , and a spatial relationship is required then the equations are written using the variables X,Y, Z defined at the origin of the CIDREF as input values and not the variables  $R, \theta, Z$  or  $R, \theta, \varphi$  input values. For example, if a CORD1S is used then the table input value is X internally computed as  $R \cdot \sin \theta \cdot \cos \varphi$ .

Whether the EQN or TABLE3D FORM is used, the equation must return an angle measure in radians to have any meaning.

## CORD3R

## Moving Rectangular Coordinate System

Defines a moving rectangular coordinate system using three points in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CORD3R	CID	N1	N2	N3	CID	N1	N2	N3	

Example:

CORD3R	1001	1	144	300					
--------	------	---	-----	-----	--	--	--	--	--

Describer	Meaning
CID	Unique coordinate system number. (Integer > 0)
N1, N2, N3	Grid point numbers (must be unique). (Integer > 0)

Remarks:

1. Available in SOL 700 only.
2. Two different coordinate systems may be defined on one entry.
3. The grid points must be defined in an independent coordinate system.
4. The first grid point is the origin, the second lies on the z-axis and the third lies in the x-z plane.
5. The position and orientation of the coordinate system is updated as the grid points move.
6. The three grid points must not be colinear.

## COSMGRP

## Define the coupled area in Co-Simulation service

COSMGRP defines the coupled area where Nastran will exchange input and output data with co-simulation partner in Co-simulation analysis. It is supported in SOL 400 only.

### Format 1: TYPE=SURFACE

1	2	3	4	5	6	7	8	9	10
COSMGRP	GRPID	TYPE							
	EID	FaceID	EID	FaceID	EID	FaceID	EID	FaceID	
	EID	FaceID	...						

### Examples 1: TYPE=SURFACE

1	2	3	4	5	6	7	8	9	10
COSMGRP	202	SURFACE							
	1001	5	1002	4					

### Format 2: TYPE=POINT

1	2	3	4	5	6	7	8	9	10
COSMGRP	GRPID	TYPE							
	GridID1	GridID2	...						
	GridIDi		...						

### Examples 2: TYPE=POINT

1	2	3	4	5	6	7	8	9	10
COSMGRP	202	POINT							
	2001	2002	31002	31003					

Describer	Meaning
GRPID	Identification number of COSMGRP referenced by a COSMSRV Bulk Data Entry. (Integer > 0)
TYPE	The definition type of coupled area (Character; Default is SURFACE) SURFACE: the couple area is defined by the element ID and its face ID POINT: the coupled area is defined by a list of grid IDs
EID	Element identification number
FACEID	Face identification number of element. Refer to the remarks 6. and 7. for the element face identification of CHBDYE entry.
GRIDID	Grid point identification numbers

**COSMINP**

## Define the physical quantities of input in Co-Simulation service

Defines the physical quantities of input which Nastran will receive from the co-simulation partner in Co-simulation analysis. It is supported in SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
COSMINP	PHYIN								
	PHYQUA1	PHYQUA2							

Example:

1	2	3	4	5	6	7	8	9	10
COSMINP	405								
	FORCE								

Describer	Meaning
PHYIN	Identification number of COSMINP referenced by a COSMSRV Bulk Data Entry (Integer > 0).
PHYQUAi	Name of physical quantities which will be provided to Nastran as input in co-simulation analysis (Character; Default: FORCE)

Remarks:

1. Currently, it supports FORCE and TEMP (temperature load) from CoSIM only.

## COSMOUT

### Define the physical quantities of output in Co-Simulation service

Defines the physical quantities of output which Nastran will yield and provide to the co-simulation partner in Co-simulation analysis. It is supported only in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
COSMOUT	PHYOUT								
	PHYQUA1	PHYQUA2	PHYQUA3						

Example:

1	2	3	4	5	6	7	8	9	10
COSMOUT	506								
	DISP	ACCE							

Describer	Meaning
PHYOUT	Identification number of COSMOUT referenced by a COSMSRV Bulk Data Entry (Integer > 0).
PHYQUAi	Name of physical quantities which will be provided to partner software as input in co-simulation analysis (Character)

One or any combination of the following physical quantities can be used:

- DISP
- VELO
- ACCE

Remarks:

1. Currently, it supports only one or combination of DISP, VELO, and ACCE.
2. The displacement, velocity and acceleration from Nastran to co-simulation are always in basic coordinate system, even these degree of freedom are defined in local rectangular coordinate system like CORD2R. Note that only rectangular local coordinate system is supported; the cylindrical and spherical local coordinate systems are not supported in co-simulation analysis.

## COSMSEL

## Specify the Co-Simulation service

Specifies the selected co-simulation service for analysis through the COSMSRV. It is supported only in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
COSMSEL	SID								
	CSRVID1	CSRVID2	CSRVID3						

Example:

1	2	3	4	5	6	7	8	9	10
COSMSEL	1								
	21								

Describer	Meaning
-----------	---------

SID Identification number referenced by a COSMSEL Case Control command (Integer > 0).

CSRVIDi Identification number of COSMSRV entry (Integer > 0).

Remarks:

1. Currently, it supports only one COSMSRV.

## COSMSRV

## Define the Co-Simulation service

Defines the co-simulation service for analysis on a coupled group and exchanged physical quantities. It is supported only in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
COSMSRV	CSRVID	SERV							
	GRPID1	PHYINP	GRPID2	PHYOUT					

Example:

1	2	3	4	5	6	7	8	9	10
COSMSRV	21	scFlow							
	202	305	202	406					

Describer	Meaning
CSRVID	Identification number referenced by a COSMSEL Bulk Data Entry (Integer > 0).
SERV	Cosim service identifier (Character) (support scFLOW only now).
GRPID1	Identification number of COSMGRP Bulk Data Entry (Integer > 0). It defines the coupled area in which Nastran receives the input from co-simulation partner.
GRPID2	Identification number of COSMGRP Bulk Data Entry (Integer > 0). It defines the coupled area in which Nastran provides output of analysis to co-simulation partner.
PHYINP	Identification number of COSMINP Bulk Data Entry (Integer > 0). It defines the physical quantities which Nastran receives from co-simulation partner.
PHYOUT	Identification number of COSMOUT Bulk Data Entry (Integer > 0). It defines the physical quantities which Nastran provides to co-simulation partner.

Remarks:

1. Currently, it supports one set of coupled area only.
2. At present, GRPID1 should be same as GRPID2.
3. SERV is a mandatory input. Currently, any characters are acceptable; scFLOW is recommended.

## COUCOHF

## Cohesive Friction Model To Be Used For a COUPLE Entry

Defines a cohesive friction model suited for Euler Coupled analyses. The friction model is defined as part of the coupling surface. Use SOL700 only.

Format:

COUCOHF	CID	COHFRID	SUBID	COHFRICID					
---------	-----	---------	-------	-----------	--	--	--	--	--

Example:

COUCOHF	112	14	12	12					
---------	-----	----	----	----	--	--	--	--	--

Describer	Meaning
CID	Unique number of a COUCOHF entry. (Integer $\geq 0$ ; required)
COHFRID	Number of a set of COUCOHF entries. COUCOHF must be referenced from a COUPLE entry. (Integer $\geq 0$ ; required)
SUBID	BSURF, BCSEG or BCPROP id, which must be a part of the BSID field of the COUPLE entry. See Remark 2. (Integer $\geq 0$ ; default = blank)
COHFRICID	Cohesive friction ID (Integer $\geq 0$ ; required)

Remarks:

1. One couple entry can reference more than one COUCOHF entry. This allows a cohesive friction that varies along the coupling surface.
2. When SUBID is left blank, then the cohesive friction applies to the whole coupling surface.
3. A coupling surface segment can only have one porosity or one cohesive friction definition assigned.

## COUOPT

## Coupling Surface Pressure Definition

Defines the interaction factor and a pressure load from the covered side acting on a BSURE, BCPROP, BCMATL, BCSEG, BCBOX. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
COUOPT	CID	OPTID	SUBID	FACTOR	FACTORV				
	PLCOVER	PLCOVERV							

Example:

COUOPT	1	80	42	CONSTANT					
	CONSTANT	1.E5							

Describer	Meaning
CID	Unique number of a COUOPT entry. (Integer > 0; Required)
OPTID	Number of a set of COUOPT entries. OPTID must be referenced from a COUPLE entry. (Integer > 0; Required)
SUBID	<p>&gt; 0            Number of a BSURE, BCBOX, BCPROP, BCMATL or BCSEG, which must be part of the surface as defined in the COUPLE entry. (Integer <math>\geq</math> 0, 0)</p> <p>= 0            COUOPT definitions used for the entire surface as defined in the COUPLE entry.</p>
FACTOR	<p>Method of defining the interaction FACTORV with which the Eulerian pressure acting on the surface is multiplied. (Character, CONSTANT)</p> <p>CONSTANT    The FACTOR is constant and specified in FACTORV</p>
FACTORV	The interaction factor. (Real, 1.)
PLCOVER	<p>Method of defining the pressure load exerted on the faces of the surface from the covered side. The pressure load is applied only when the Eulerian pressure is greater than zero. (Character, CONSTANT)</p> <p>CONSTANT    The PLCOVER is constant and specified in PLCOVERV.</p> <p>TABLE        The PLCOVER varies with time. PLCOVERV is the number of a TABLED1 entry giving the variation of the PLCOVER (y-value) with time (x-value).</p>
PLCOVERV	The pressure load or the number of a TABLED1 entry depending on the PLCOVER entry. (Real $\geq$ 0, 0.)

Remarks:

1. The effect of specifying an interaction FACTOR is similar to specifying a porosity coefficient on a COUPOR entry. The difference is that in this case the surface still acts as a wall boundary for the Eulerian material.
2. Applying a PLCOVER instead of applying a pressure load on the faces through either a PLOAD, PLOAD4, or DAREA entry gives the following differences:
  - a. PLCOVER is applied only when there is a balancing Eulerian pressure greater than zero.
  - b. Possible porosity as defined on a COUPOR entry is taken into account when applying the PLCOVER.
  - c. With PARAM,PLCOVCUT you can define a cut-off time that is applied to PLCOVER.
3. The covered side of a surface lies on the side where there is no Eulerian material.

## COUP1FL

## Coupling Surface Failure

Defines the surrounding variables when a segment of a coupling surface fails. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
COUP1FL	CFID	RHO	SIE	XVEL	YVEL	ZVEL	PRESSURE	MATERIAL	

Example:

COUP1FL	3	1.225	204082.	900.					
---------	---	-------	---------	------	--	--	--	--	--

Describer	Meaning
CFID	Unique ID of a COUP1FL entry referenced from the COUPLE entry. (Integer > 0; Required)
RHO	Surrounding density. See Remark 2. (Real > 0)
SIE	Surrounding specific internal energy. See Remark 2. (Real)
XVEL	Surrounding x-velocity. See Remark 2. (Real)
YVEL	Surrounding y-velocity. See Remark 2. (Real)
ZVEL	Surrounding z-velocity. See Remark 2. (Real)
PRESSURE	Surrounding pressure. See Remark 4. (Real)
MATERIAL	MATDEUL ID. Only used when the multi-material Euler solver is active. (Blank)

Remarks:

1. This entry can only be used in combination with DYPARAM,FASTCOUP, ,FAIL and with either the HYDRO, MMHYDRO or MMSTREN Euler Solver. For restrictions on the use of COUP1FL refer to param,flow-method. The coupling surface failure is associated with the element failure of the structure to which the surface is connected. Therefore, you have to define a failure model for the structure for the entry to take effect in the analysis.
2. For the first order Euler solvers no restriction apply to the values of the surrounding variables. For the Roe solver at least one of the surrounding variables should be defined. The default value of the density (RHO) will be set equal to the reference density as defined on the MATDEUL entry. By default, the other variables (SIE, XVEL, YVEL and ZVEL) are set equal to zero.
3. The coupling surface must only consist of CQUAD and/or CTRIA elements.
4. The field PRESSURE has to be left blank in combination with the Roe solver.
5. In combination with multi-material Euler only outflow of material is allowed. Each material in an outflow Euler element is transported. The materials are transported in proportion to their relative volume fractions.

## COUPINT

## Coupling Surface Interaction

Defines the surrounding variables when a segment of a coupling surface fails. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
COUPINT	CID	CID1	CID2						

Example:

COUPINT	33	2							
---------	----	---	--	--	--	--	--	--	--

Describer	Meaning
CIID	Unique number of a COUPINT entry.
CID1	Number of COUPLE entry 1.
CID2	Number of COUPLE entry 2.

Remarks:

1. This entry can only be used in combination with DYPARAM,FASTCOUP, ,FAIL and with either the HYDRO, MMHYDRO or MMSTREN Euler Solver. The interaction will be activated when failure of a Lagrangian structure with which the coupling surface is associated occurs. Therefore, you have to define a failure model for the material of the structure.
2. The coupling surface must consist of CQUAD and/or CTRIA elements.

## COUPLE

## General Euler-Lagrange Coupling Surface

Defines a coupling surface that acts as the interface between an Eulerian (finite volume) and a Lagrangian (finite element) domain. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
COUPLE	CID	BSID	COVER	REVERSE	CHECK	PORID	OPTID	CTYPE	
	INFID	HTRID	FS	FK	EXP	INTID			
	SET1ID	MESHID	TDEAC	COUP1FL	HYDSTAT	SKFRIC	COHFRI D		

Example:

COUPLE	100	37	INSIDE	ON	ON				
				0.3	0.0				

Describer	Meaning
CID	Unique number of a COUPLE entry. (Integer > 0; Required)
BSID	Number of a BSURE, BCBOX, BCPROP, BCMATL or BCSEG entry defining the coupling surface. (Integer > 0; Required)
COVER	The processing strategy for Eulerian elements inside and outside of the coupling surface. (Character, INSIDE)
	INSIDE      The Eulerian elements inside the closed volume of the coupling surface are not processed.
	OUTSIDE     The Eulerian elements outside the closed volume of the coupling surface are not processed
	NONE        The Eulerian elements on both sides of the coupling surface are processed.
REVERSE	Auto-reverse switch for the coupling surface segments. (Character, ON)
	ON            If required, the normals of the coupling surface segments are automatically reversed so that they all point in the same general direction as to give a positive closed volume.
	OFF          The segments are not automatically reversed. The user is responsible for defining the correct general direction of the segment normals.
CHECK	Check switch for coupling surface segments. (Character, ON)
	ON            The normals of the segments are checked to verify that they all point in the same general direction and yield a positive closed volume.

Describer	Meaning
	<p>OFF The segments are not checked. It the responsibility of the user to ensure that the direction of the segment normals yield a positive closed volume.</p> <p>When “REVERSE” is set to “ON”, the “CHECK” option will be automatically activated.</p>
PORID	Number of a set of “LEAKAGE” entries that define the porosity for the BSURF entries. (Integer > 0, 0 (no porosity))
OPTID	Not available for the Roe solver Number of a set of “COUOPT” entries that define special options for the BSURF entries (Integer ≥ 0, 0 (no special options))
CTYPE	Not available for the Roe solver Coupling surface type definition. (Character, STANDARD)
	<p>STANDARD Standard Euler-Lagrange interaction.</p> <p>AIRBAG Coupling for airbag applications. It is equivalent to the standard coupling algorithm with the following exceptions that tailor the solution for airbag applications: Inflow through a porous (sub)-surface will only occur when there is already some material (gas) in the Eulerian element. Almost empty Eulerian elements will be automatically eliminated. The standard algorithm redistributes the small mass to the most suitable neighbor elements.</p>
INFID	Number of a set of “ABINFL” entries that define the inflator(s) on the subsurface(s) of the coupling surface. Not available for the Roe solver. (Integer > 0, 0 (no inflators))
HTRID	Number of a set of “HEATLOS” entries that define the heat transfer definition(s) on the subsurface(s) of the coupling surface. Not available for the Roe solver. (Integer ≥ 0, 0 (no heat transfer))
FS	Static friction coefficient. See Remark 6. Not available for the Roe solver. (Real ≥ 0.0, 0.0)
FK	Kinetic friction coefficient. See Remark 6. Not available for the Roe solver. (Real ≥ 0.0, 0.0)
EXP	Exponential decay coefficient. See Remark 6. Not available for the Roe solver. (Real ≥ 0.0, 0.0)
INTID	ID of an INITGAS entry specifying initial gas composition for the Euler mesh. See Remark 7. (Integer ≥ 0, 0 (no initial gas composition))
SET1ID	The number of a SET1 entry, which defines the Eulerian elements associated with this coupling surface. See Remark 8. (Integer ≥ 0; Default = blank)
MESHID	ID of a MESH entry, which defines the Eulerian mesh associated with this coupling surface. See Remark 8. (Integer ≥ 0; Default = blank)

Describer	Meaning
TDEAC	Time of deactivation of the coupling surface and the associated Eulerian mesh. (Real $\geq$ 0.0, 1.E20)
COUP1FL	The number of a COUP1FL entry, which defines the surrounding variables for the coupling surface when its segments fail. See Remark 9. (Integer $\geq$ 0; Default = blank)
HYDSTAT	The number of a HYDSTAT entry, which specifies a hydrostatic preset. The preset is applied to all Euler element specified by the SET1ID and MESHID. See Remark 11. (Integer $\geq$ 0, 0 (no hydrostatic preset))
SKFRIC	Skin friction value. See Remark 13. (Real $\geq$ 0.0, 0.0)
COHFRID	Number of a set of COUCOHF entries that define the cohesive friction on the subsurface(s) of the coupling surface. ( $I \geq 0$ Default = blank)

Remarks:

1. All coupling surfaces must form a multi-faceted closed volume. If necessary, additional segments must be defined to achieve the closed volume. The closed volume must intersect at least one Euler element initially.
2. All segments must be attached to the face of an element. Dummy elements can be used to define any additional segments that are required to create the closed volume.
3. The normals of all segments that form the coupling surface must point in the same general direction and result in a positive closed volume. Setting the “REVERSE” option to “ON” ensures that this condition is satisfied, regardless of the initial definition of the segments.
4. The “COVER” field determines how Eulerian elements that are inside and outside of the coupling surface are processed. The default setting of INSIDE is appropriate for most of the problems. In the majority of analyses, the Eulerian material flows around the outside of the coupling surface. Therefore, the Eulerian elements that fall within the coupling surface do not contain material. For some specific applications, such as airbag inflation, the Eulerian material (gas) is completely contained within the coupling surface. In these cases, the “COVER” definition should be set to OUTSIDE.
5. By default the fast coupling algorithm is used. The algorithm then used is substantially faster than the general coupling. The restriction is that you cannot use an arbitrarily shaped Euler mesh with the fast coupling algorithm. All element faces of the Euler mesh must have their normal pointing in any of the three basic coordinate directions. If you want to use the general coupling algorithm, you can define the parameter “DYPARAM,FASTCOUP,NO” in the input file.
6. The friction model implemented for the coupling algorithm is a simple Coulomb friction definition. The friction coefficient  $\mu$  is defined as:

$$\mu = \mu_k + (\mu_s - \mu_k) \cdot e^{-(\beta \cdot v)}$$

where  $\mu_s$  is the static friction coefficient,  $\mu_k$  is the kinetic friction coefficient,  $\beta$  the exponential decay coefficient and  $v$  the relative sliding at the point of contact.

7. An initial gas composition is for use with the single-material hydrodynamic Euler solver and an ideal-gas equation of state (EOSGAM) only.
8. Multiple coupling surfaces are available when you associate one Eulerian domain with a single coupling surface by either using the SETIID or the MESHID option. Note that only one of the two options may be set and will work only in combination with the fast coupling algorithm.
9. The COUP1FL option is available and valid only in combination with the fast coupling algorithm with the failure option (DYPARAM,FASTCOUP, ,FAIL). If no number is given, the default values of the surrounding variables will be used; the density (RHO) is set equal to the reference density as defined on the MATDEUL entry. By default, the other variables (SIE, XVEL, YVEL and ZVEL) are set equal to zero.
10. If an ACTIVE entry is present, its definition is ignored in case the TDEAC value is defined in combination with the fast coupling algorithm.
11. If there is only one coupling surface and no adaptive meshing is used, the HYDSTAT field can be left blank. To impose a boundary condition that matches the hydrostatic initialization, the PORHYDS entry can be used.
12. A mixture of BSURF, BCBOX, BCPROP, BCMATL or BCSEG with the same BSID is allowed. However multiple BSID of the same type is not allowed. When using this option, special care must be taken to assure the same element is not part of multiple BSID definitions.
13. The skin friction is defined as:

$$C_f = \frac{\tau_w}{0.5 \cdot \rho u^2}$$

Here,  $\tau_w$  denotes the shear friction in an Euler element adjacent to a couple surface segment where  $\rho$  is the density and  $u$  is the tangential relative velocity in the Euler element that is adjacent to a couple surface segment.

SKFRIC will only be used when VISC has been set on either an EOSGAM or an EOSPOL entry. If VISC has been set and if SKFRIC has not been set then a no slip condition will be prescribed at the interface between fluid and structure.

14. If the coupling surface is a structural solid then Sol700 can automatically create a coupling surface for the solid. This coupling surface consists of the boundary faces of the solid. To activate this, a BCPROP has to be created for the solid and the BCPROP has to be used for the BSID of the COUPLE entry.
15. Option NONE requires the use of DYPARAM, AUTCOUP. For details refer to this DYPARAM.
16. When BSID refers to a ID of a BCPROP or BCMATL, only properties of shell elements can be referenced. All solid elements referenced with the same PID or MID will be ignored. Use BCSEG to reference faces of solid elements.

## CPENTA

### Five-Sided Solid Element Connection

Defines the connections of a five-sided solid element with six to fifteen grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CPENTA	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12	G13	G14	
	G15								

Example:

CPENTA	112	2	3	15	14	4	103	115	
	5	16	8				120	125	
	130								

Describer	Meaning	Type	Default
EID	Element identification number.	$0 < \text{Integer} < 100,000,000$	Required
PID	Property identification number of a PSOLID or PLSOLID entry.	Integer > 0	Required
Gi	Identification numbers of connected grid points.	Integer $\geq 0$ or blank	Required

Figure 9-46 CPENTA Element Connection

**Remarks:**

1. Element ID numbers must be unique with respect to all other element ID numbers.
2. The topology of the diagram must be preserved; i.e., G1, G2, and G3 define a triangular face, G1, G10, and G4 are on the same edge, etc.
3. For Nastran conventional element, the edge grid points, G7 to G15, are optional. Any or all of them may be deleted. In the example shown, G10, G11, and G12 have been deleted. The continuations are not required if all edge grid points are deleted.  
Note that for advanced nonlinear elements, partial specification of mid-points is not allowed. i.e. either none of the mid-points should be specified or all of the mid points should be specified.
4. Components of stress are output in the material coordinate system except for hyperelastic elements, which are output in the basic coordinate system.
5. For nonhyperelastic elements the element coordinate system for the CPENTA element is derived accordingly. The origin of the coordinate system is located at the midpoint of the straight line connecting the points G1 and G4. The Z axis points toward the triangle G4-G5-G6 and is oriented somewhere between the line joining the centroids of the triangular faces and a line perpendicular to the midplane. The midplane contains the midpoints of the straight lines between the triangular faces. The X and Y axes are perpendicular to the Z axis and point in a direction toward, but not necessarily intersecting, the edges G2 through G5 and G3 through G6, respectively.

Solid elements have both a material and an element coordinate system. Both systems are defined for the initial geometry, and for geometric nonlinear analysis they will rotate with the element. The material coordinate system is used to input anisotropic material properties and for stress output. The material coordinate system is defined by the CORDM field of the PSOLID entry. The element coordinate system is used for element stiffness integration (reduced shear for example) and optionally to define the material coordinate system (only if PSOLID,CORDM=-1).

Figure 9-47 CPENTA Element Coordinate System

6. We recommend that the edge grid points be located within the middle third of the edge.
7. For hyperelastic elements, the plot codes are specified under the CPENTAFD element name in [Item Codes](#).
8. By default, all the nine edges of the element are considered straight unless, any of G7 through G15 are specified.
9. The internal coordinate system of the element is used internally and is based on eigenvalue techniques to insure non bias in the element formulation. For stress/strain output this internal coordinate system (CORDM=-1 on PSOLID entry) is hard to visualize. Thus a CORDM=-2 on the PSOLID is available as shown in [Figure 9-48](#).

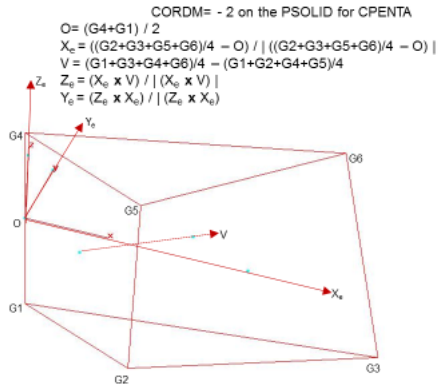

Figure 9-48 PSOLID for CPENTA

## CPYRAM

## Five-Sided Solid Element Connection

Defines the connections of the five-sided solid element with five or thirteen grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CPYRAM	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12	G13		

Example:

CPYRAM	7	4	15	16	17	18	40	21	
	22	23	24	31	32	33	34		

Describer	Meaning	Type	Default
EID	Element identification number.	0 < Integer < 100,000,000	Required
PID	Property identification number of a PSOLID entry.	Integer > 0	Required
Gi	Identification numbers of connected grid points.	Integer ≥ 0 or blank	Required

Figure 9-49

CPYRAM Element Connection

**Remarks:**

1. Element ID numbers must be unique with respect to all other element ID numbers.
2. The topology of the diagram must be preserved, that is, G1, G2, G3, G4 define the quadrilateral base, G5 defines the apex, G1, G5, G10 are on the same edge, etc.
3. For a 5 noded CPYRAM element, only G1 - G5 should be provided. For a 13 noded CPYRAM element, all the corner and mid-side nodes (G1 - G13) should be provided. Note that partial specification of mid-points is not allowed. i.e. either none of the mid-points should be specified or all of the mid points should be specified.
4. The pyramid elements use the basic coordinate system as the element coordinate system. They can use a material coordinate system defined by the CORDM field of the corresponding PSOLID entry. CORDM = 0, -1, -2 or blank is the same as the basic coordinate system.
5. For CORDM > 0, the material coordinate system is defined with respect to the initial geometry and is used to input orthotropic or anisotropic material properties and for stress output. For geometric nonlinear analysis, the material coordinate system rotates with the element. Component of stresses are output in the material coordinate system referenced by the CORDM field of PSOLID entry (CORDM > 0).

## CQUAD

## Fully Nonlinear Plane Strain Element

Defines a plane strain quadrilateral element with up to nine grid points for use in fully nonlinear (i.e., large strain and large rotation) hyperelastic analysis.

Format:

1	2	3	4	5	6	7	8	9	10
CQUAD	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	THETA or MCID					

Example:

CQUAD	111	203	31	74	75	32			
-------	-----	-----	----	----	----	----	--	--	--

Describer	Meaning	
EID	Element identification number. (0 < Integer < 100,000,000)	
PID	Property identification number of a PLPLANE or PLCOMP entry. (Integer > 0)	
G1, G2, G3, G4	Identification numbers of connected corner grid points. Required data for all four grid points. (Unique Integers > 0)	
G5, G6, G7, G8	Identification numbers of connected edge grid points. Optional data for any or all four grid points. (Integer ≥ 0 or blank)	
G9	Identification number of center grid point. Optional. (Integer ≥ 0 or blank)	
THETA	Material property orientation angle in degrees. THETA is only applicable if PLCOMP referenced, or the PLPLANE entry has an associated PSHLN2 entry which is honored only in SOL 400. For PSHLN2 BEHi=PSTRS or PLSTRN codes, THETA is measured relative to the line defined from G1-G2. For PSHLN2 or PLCOMP BEHi=COMPS code the THETA value on the element connection entry will be ignored. (Real; Default = 0.0)	
MCID	Material coordinate system identification number MCID is only applicable if the PLPLANE entry has an associated PSHLN2 entry which is honored only in SOL 400. The x-axis of the material coordinate system is determined by projecting the T1-axis of the MCID coordinate system onto the surface of the shell element as follows:	
CORD1R,	x -axis of MCID the coordinate is projected onto shell surface and the	
CORD2R	material angle is measured from the G1-G2 line to the to the projected x-axis	

Describer	Meaning
CORD1C, CORD2C CORD1S, CORD2S	r-axis of MCID the coordinate is projected onto shell surface through the element center and the material angle is measured from the G1-G2 line to the to the projected r-axis
	For PSHLN2 (or PLCOMP) BEHi=COMPS code the MCID value on the element connection entry will be ignored. (Integer $\geq 0$ ; if blank, then THETA = 0.0 is assumed.)

Remarks:

1. Element identification numbers should be unique with respect to all other element IDs of any kind.
2. Grid points G1 to G9 must be numbered as shown and must lie on a plane. G5 - G9 are Optional data for any or all four grid points for Nastran conventional element only.  
Note that for advanced nonlinear elements, partial specification of mid-points is not allowed. i.e. either none of the mid-points should be specified or all of the mid points should be specified.
3. It is recommended that the edge points be located within the middle third of the edge.
4. The plot codes are specified under the CQUADFD element name in [Item Codes](#).
5. Stresses and strains are output in the coordinate system identified by the CID field of the PLPLANE entry.

Figure 9-50 CQUAD Element Coordinate System

## CQUAD4 Quadrilateral Plate Element Connection

Defines an isoparametric membrane-bending or plane strain quadrilateral plate element.

Format:

1	2	3	4	5	6	7	8	9	10
CQUAD4	EID	PID	G1	G2	G3	G4	THETA or MCID	ZOFFS	
		TFLAG	T1	T2	T3	T4			

Example:

CQUAD4	111	203	31	74	75	32	2.6	0.3	
			1.77	2.04	2.09	1.80			

Describer	Meaning	
EID	Element identification number. (0 < Integer < 100,000,000)	
PID	Property identification number of a PSHELL, PCOMP, PCOMPG or PLPLANE or PLCOMP entry. (Integer > 0; Default = EID)	
Gi	Grid point identification numbers of connection points. (Integers > 0, all unique.)	
THETA	Material property orientation angle in degrees. THETA is ignored for hyperelastic elements. See <a href="#">Figure 9-52</a> . See Remark 9. (Real; Default = 0.0)	
MCID	Material coordinate system identification number. The x-axis of the material coordinate system is determined by projecting the T1-axis of the MCID coordinate system onto the surface of the shell element as follows:	
	CORD1R, x -axis of MCID the coordinate is projected onto shell surface and the	
	CORD2R material angle is measured from the G1-G2 line to the to the projected x-axis	
	CORD1C, r-axis of MCID the coordinate is projected onto shell surface through the	
	CORD2C element center and the material angle is measured from the G1-G2 line	
	CORD1S, to the to the projected r-axis	
	CORD2S	
	Use DIAG 38 to print the computed THETA values. MCID is ignored for hyperelastic elements. For SOL 600, only CORD2R is allowed. See Remark 9. (Integer ≥ 0; If blank, then THETA = 0.0 is assumed.)	

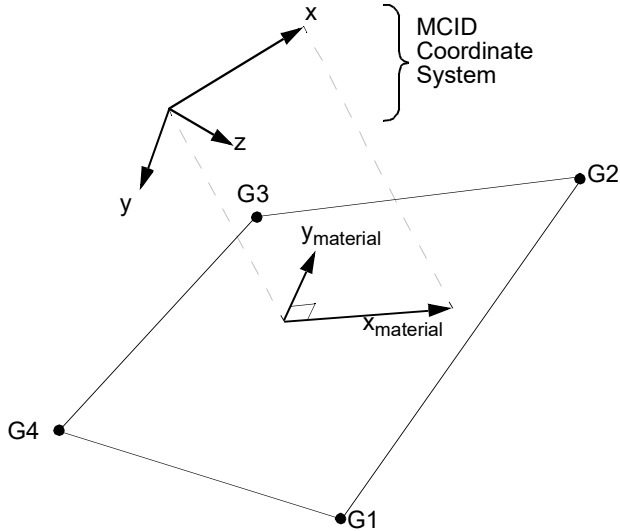

Figure 9-51 MCID Coordinate System Definition

ZOFFS	Offset from the surface of grid points to the element reference plane. ZOFFS is ignored for hyperelastic elements. See Remark 6. (Real)
TFLAG	An integer flag, signifying the meaning of the $T_i$ values. (Integer 0, 1, or blank)
$T_i$	Membrane thickness of element at grid points G1 through G4. If “TFLAG” is zero or blank, then $T_i$ are actual user specified thicknesses. See Remark 4. for default. (Real $\geq 0.0$ or blank, not all zero.) If “TFLAG” is one, then the $T_i$ are fractions relative to the T value of the PSHELL. (Real $> 0.0$ or blank, not all zero. Default = 1.0) $T_i$ are ignored for hyperelastic elements.

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Grid points G1 through G4 must be ordered consecutively around the perimeter of the element.
3. All interior angles must be less than  $180^\circ$ .
4. The continuation is optional. If it is not supplied, then T1 through T4 will be set equal to the value of T on the PSHELL entry.

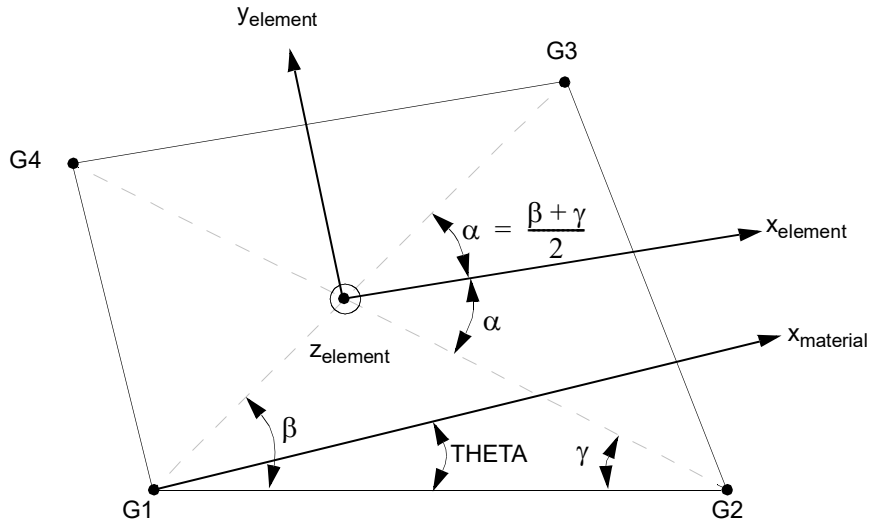

Figure 9-52 CQUAD4 Element Geometry and Coordinate Systems

5. The reference coordinate system for the output of stress, strain and element force depends on the element type.
  - For CQUAD4 elements which are not hyperelastic, the reference coordinate system for the output is the element coordinate system. See PARAM,OMID for output in the material system.
  - For hyperelastic elements the stress and strain are output according to CID on the PLPLANE entry.
6. Elements may be offset from the connection points by means of ZOFFS. Other data, such as material matrices and stress fiber locations, are given relative to the reference plane. A positive value of ZOFFS implies that the element reference plane is offset a distance of ZOFFS along the positive Z-axis of the element coordinate system. If the ZOFFS field is used, then the MID1 and MID2 fields must be specified on the PSHELL entry referenced both by PID.

Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.

For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, it is **highly recommended** to use MDLPRM, OFFDEF, LROFF. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by MDLPRM, OFFDEF, NOMASS.

For SOLs 106, 129, 153, and 159 the differential stiffness for offset vectors will give incorrect results with PARAM, LGDISP, 1. In addition in SOLs 106 and 129 offset vectors will produce incorrect results with thermal loading.

7. For finite deformation hyperelastic analysis, the plot codes are given by the CQUADFD element name in [Item Codes](#).
8. By default, all of the four edges of the element are considered straight.
9. If element has an associated PSHLN2 or PLCOMP entry with BEHi=COMPS code, the THETA/MCID value on the element connection entry will be ignored.
10. For RC network solver in thermal analysis, the ZOFFS is ignored.
11. In SOL 600, when PCOMP is used, one must define the material property with orientation, MCID>0.

**CQUAD8****Curved Quadrilateral Shell Element Connection**

Defines a curved quadrilateral shell or plane strain element with eight grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CQUAD8	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	T1	T2	T3	T4	THETA or MCID	ZOFFS	
	TFLAG								

Example:

CQUAD8	207	3	31	33	73	71	32	51	
	53	72	0.125	0.025	0.030	.025	30.	.03	

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PSHELL, PCOMP, PCOMPG or PLPLANE or PLCOMP entry. (Integer > 0)
G1, G2, G3, G4	Identification numbers of connected corner grid points. Required data for all four grid points. (Unique Integers > 0)
G5, G6, G7, G8	Identification numbers of connected edge grid points. Optional data for any or all four grid points for Nastran conventional element only. (Integer > 0 or blank). Note that for advanced nonlinear elements, partial specification of mid-points is not allowed. i.e. either none of the mid-points should be specified or all of the mid points should be specified.
Ti	Membrane thickness of element at grid points G1 through G4. If "TFLAG" zero or blank, then Ti are actual user specified thickness. See Remark 4. for default. (Real ≥ 0.0 or blank, not all zero.) If "TFLAG" one, then the Ti are fraction relative to the T value of the PSHELL. (Real > 0.0 or blank, not all zero. Default = 1.0) Ti are ignored for hyperelastic elements.
THETA	Material property orientation angle in degrees. See Figure 9-53. THETA is ignored for hyperelastic elements. See Remark 10. (Real; Default = 0.0)
MCID	Material coordinate system identification number. The x-axis of the material coordinate system is determined by projecting the T1-axis of the MCID coordinate system onto the surface of the shell element as follows:  CORD1R, x -axis of MCID the coordinate is projected onto shell surface and the CORD2R material angle is measured from the G1-G2 line to the to the projected x-axis

Describer	Meaning
	<p>CORD1C, r-axis of MCID the coordinate is projected onto shell surface through the CORD2C element center and the material angle is measured from the G1-G2 line CORD1S, to the to the projected r-axis CORD2S</p> <p>(see Remark 3.) MCID is ignored for hyperelastic elements. For SOL 600, only CORD2R is allowed. See Remark 10. (Integer <math>\geq 0</math>; if blank, then THETA = 0.0 is assumed.)</p>
ZOFFS	Offset from the surface of grid points to the element reference plane. See Remark 6. ZOFFS is ignored for hyperelastic elements. (Real)
TFLAG	An integer flag, signifying the meaning of the Ti values. (Integer 0, 1, or blank)

#### Remarks:

1. Element identification numbers should be unique with respect to all other element IDs of any kind.
2. Grid points G1 to G8 must be numbered as shown in [Figure 9-53](#).
3. The orientation of the material property coordinate system is defined locally at each interior integration point by THETA, which is the angle between  $x_{\text{material}}$  and the line of constant  $\eta$ .

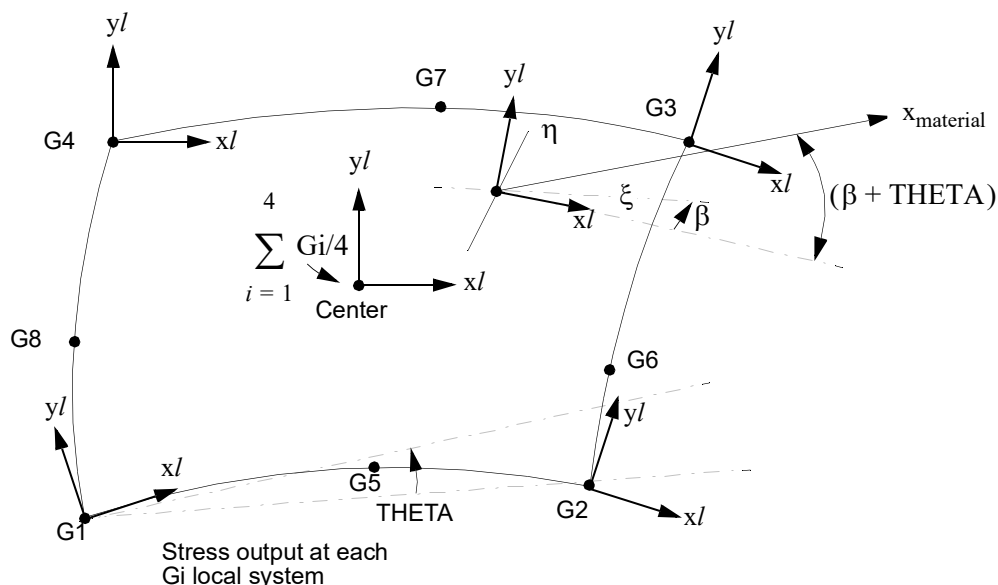

The definition of the material coordinate system by projection is used to calculate an angle THETA. Please note that since xi changes directions throughout the element based on element shape, the material coordinate system varies similarly. Because of this an orthotropic or anisotropic material will cause the CQUAD8's stiffness to be biased by both it's shape and grid ordering. Use the QUAD4 element if a constant material coordinate system direction is desired with orthotropic and anisotropic materials.

4. T1, T2, T3 and T4 are optional. If they are not supplied and no TFLAG, then T1 through T4 will be set to the value of T on the PSHELL entry.
5. It is recommended that the midside grid points be located within the middle third of the edge. If the edge point is located at the quarter point, the program may fail with a divide-by-zero error or the calculated stresses will be meaningless.
6. Elements may be offset from the connection points by means of the ZOFFS field. Other data, such as material matrices and stress fiber locations, are given relative to the reference plane. A positive value of ZOFFS implies that the element reference plane is offset a distance of ZOFFS along the positive z-axis of the element coordinate system. If the ZOFFS field is used, then both the MID1 and MID2 fields must be specified on the PSHELL entry referenced by PID.

Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.

For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, it is **highly recommended** to use MDLPRM, OFFDEF, LROFF. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by **MDLPRM, OFFDEF, NOMASS**.

- If all midside grid points are deleted, then the element will be excessively stiff and the transverse shear forces incorrect. A User Warning Message is printed, and a CQUAD4 element is recommended instead. If the element is hyperelastic, then it is processed identically to the hyperelastic CQUAD4 element.
- For a description of the element coordinate system, see [Shell Elements \(CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, CQUADR\)](#) in the *MSC Nastran Reference Guide*. Stresses and strains are output in the local coordinate system identified by  $x_l$  and  $y_l$  in [Figure 9-53](#). However, for hyperelastic elements the stress and strain are output in the coordinate system identified by the CID field on the PLPLANE entry.
- For hyperelastic elements the plot codes are specified under the CQUADFD element name in [Item Codes](#).

where

- $\vec{e}_\eta$  is tangent to  $\eta$  at  $G_i$
- $\vec{e}_\xi$  is tangent to  $\xi$  at  $G_i$
- $\vec{A}$  is formed by bisection of  $\vec{e}_\eta$  and  $\vec{e}_\xi$
- $\vec{B}$  and  $\vec{A}$  are perpendicular

$y_l$  is formed by bisection of  $\vec{A}$  and  $\vec{B}$   
 $x_l$  is perpendicular to  $y_l$

**Figure 9-53 CQUAD8 Element Geometry and Coordinate Systems**

10. If element has an associated PSHLN2 or PLCOMP entry with BEHi=COMPS code, the THETA/MCID value on the element connection entry will be ignored.
11. For RC network solver in thermal analysis, the ZOFFS is ignored.
12. In SOL 600, when PCOMP is used, one must define the material property with orientation, MCID>0.

**CQUADR****Quadrilateral Plate Element Connection**

Defines an isoparametric membrane and bending quadrilateral plate element. This element has a normal rotational (drilling) degrees-of-freedom. It is a companion to the CTRIAR element.

Format:

1	2	3	4	5	6	7	8	9	10
CQUADR	EID	PID	G1	G2	G3	G4	THETA or MCID	ZOFFS	
		TFLAG	T1	T2	T3	T4			

Example:

CQUADR	82	203	31	74	75	32	2.6		
			1.77	2.04	2.09	1.80			

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PSHELL, PCOMP or PCOMPEntry. (Integer > 0; Default = EID)
Gi	Grid point identification numbers of connection points. (Integers > 0, all unique)
THETA	Material property orientation angle in degrees. See <a href="#">Figure 9-55</a> . (Real; Default = 0)
MCID	Material coordinate system identification number. The x-axis of the material coordinate system is determined by projecting the T1-axis of the MCID coordinate system onto the surface of the shell element as follows:  CORD1R, x -axis of MCID the coordinate is projected onto shell surface and the CORD2R material angle is measured from the G1-G2 line to the to the projected x-axis  CORD1C, r-axis of MCID the coordinate is projected onto shell surface through the CORD2C element center and the material angle is measured from the G1-G2 line CORD1S, to the to the projected r-axis CORD2S  Use DIAG 38 to print the computed THETA values. For SOL 600, only CORD2R is allowed. (Integer ≥ 0; If blank, then THETA = 0.0 is assumed.)
ZOFFS	Offset from the surface of grid point to the element plane. See Remark 8.

Figure 9-54 MCID Coordinate System Definition

TFLAG	An integer flag, signifying the meaning of the $T_i$ values. (Integer 0, 1, or blank)
$T_i$	Membrane thickness of element at grid points G1 through G4. If “TFLAG” zero or blank, then $T_i$ are actual user specified thickness. (Real $\geq 0.0$ or blank, not all zero. See Remark 4. for default.) If “TFLAG” one, then the $T_i$ are fraction relative to the T value of the PSHELL. (Real $> 0.0$ or blank, not all zero. Default = 1.0) $T_i$ are ignored for hyperelastic elements.

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Grid points G1 through G4 must be ordered consecutively around the perimeter of the element.
3. All the interior angles must be less than  $180^\circ$ .
4. The continuation is optional. If it is not supplied, then T1 through T4 will be set equal to the value of T on the PSHELL entry.
5. Stresses and strains are output in the element coordinate system at the centroid and grid points G1 through G4.
6. Inaccurate results will be obtained if interior grids have the rotation normal (drilling) to the element constrained. At the boundary of a model, the drilling degrees-of-freedom must be constrained if the user wants a fixed boundary. Also, for this element it is critical that consistent membrane (in plane) edge loads be applied. Reference the [PLOAD4](#) entry (SORL option) and the [Consistent Surface and Edge Loads](#) in the *MSC Nastran Reference Guide* for additional information.

7. The CTRIAR element is the triangular companion to the CQUADR element and should be used instead of CTRIA3 or CTRIA6.

Figure 9-55 CQUADR Element Geometry and Coordinate Systems

8. Elements may be offset from the connection points by means of ZOFFS. Other data, such as material matrices and stress fiber locations, are given relative to the reference plane. A positive value of ZOFFS implies that the element reference plane is offset a distance of ZOFFS along the positive Z-axis of the element coordinate system. If the ZOFFS field is used, then the MID1 and MID2 fields must be specified on the PSHELL entry referenced both by PID.

Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.

For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, it is **highly recommended** to use MDLPRM, OFFDEF, LROFF. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by MDLPRM, OFFDEF, NOMASS.

For SOLs 106, 129, 153, and 159 the differential stiffness for offset vectors will give incorrect results with PARAM, LGDISP, 1. In addition in SOLs 106 and 129 offset vectors will produce incorrect results with thermal loading.

9. In SOL 600, when PCOMP is used, one must define the material property with orientation, MCID>0.

## CQUADX Axisymmetric Quadrilateral Element (Fully Nonlinear or Linear Harmonic)

Defines an axisymmetric quadrilateral element with up to nine grid points for use in fully nonlinear (i.e., large strain and large rotations) analysis or a linear harmonic or rotordynamic analysis. The element has between four and nine grid points

Format:

1	2	3	4	5	6	7	8	9	10
CQUADX	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	THETA or MCID					

Example:

CQUADX	111	203	31	74	75	32			
--------	-----	-----	----	----	----	----	--	--	--

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000). See Remark 1.
PID	Property identification number of a PLPLANE or PAXSYMH or PLCOMP entry. (Integer > 0). See Remark 2.
G1, G2 G3, G4	Identification numbers of connected corner grid points. Required data for all four grid points. (Unique Integers > 0). See Remark 3., 6., 7.
G5, G6 G7, G8	Identification numbers of connected edge grid points. Optional data for any or all four grid points. (Integer ≥ 0 or blank). See Remark 3., 4., 6., 7.
G9	Identification number of center grid point. Optional. (Integer ≥ 0 or blank). Not used for linear harmonic elements. See Remark 3., 6., 7.
THETA	Material property orientation angle in degrees. THETA is only applicable if PLCOMP referenced, or the PLPLANE entry has an associated PSHLN2 entry which is honored only in SOL 400. For PSHLN2 BEHi=AXSOLID code, THETA is measured relative to the R axis of the element. For PSHLN2 or PLCOMP BEHi=AXCOMP code the THETA value on the element connection entry will be ignored. (Real; Default = 0.0). THETA is ignored if PID refers to a PAXSYMH entry.
MCID	Material coordinate system identification number, MCID is only applicable if PLCOMP referenced, or the PLPLANE entry has an associated PSHLN2 entry which is honored only in SOL 400. The x-axis of the material coordinate system is determined by projecting the x-axis of the MCID coordinate system onto the surface of the element. For PSHLN2 BEHi=AXSOLID the resulting angle is measured relative to the R axis of the element. For PSHLN2 (or PLCOMP) BEHi=AXCOMP code the MCID value on the element connection entry will be ignored. (Integer ≥ 0; If blank, then THETA = 0.0 is assumed.)

## Remarks:

1. Element identification numbers should be unique with respect to all other element IDs of any kind.
2. If PID refers to a PLPLANE or PLCOMP entry, CQUADX defines an element for use in fully nonlinear analysis. If PID refers to a PAXSYMH entry, CQUADX defines a linear harmonic element for use in rotordynamic or harmonic analysis.
3. Gi must be numbered as shown in [Figure 9-56](#).
4. It is recommended that the edge points be located within the middle third of the edge.
5. The plot codes are specified under the CQUADXFD element name in [Item Codes](#).
6. All Gi must lie on the x-y plane of the basic coordinate system. Stress and strain are output in the basic coordinate system.
7. A concentrated load (e.g., FORCE entry) at Gi is multiplied by the radius to Gi and then applied as a force per unit circumferential length. For example, in order to apply a load of 100 N/m on the circumference at G1, which is located at a radius of 0.5 m, then the magnitude specified on the static load entry must result in:

$$(100 \text{ N/m}) \cdot (0.5 \text{ m}) = 50 \text{ N}$$

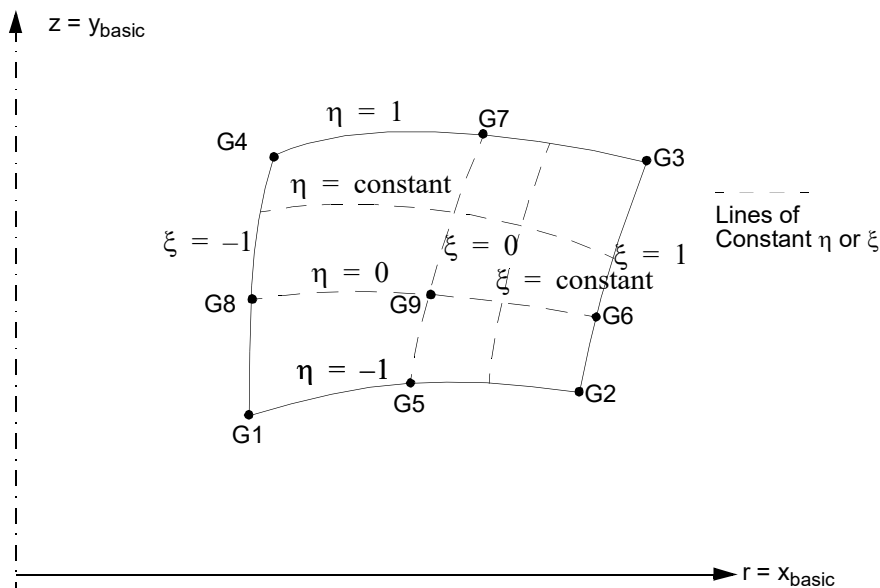

Figure 9-56 CQUADX Element Coordinate System

## CRAC2D Two-Dimensional Crack Tip Element

Defines a two-dimensional crack tip element.

Format:

1	2	3	4	5	6	7	8	9	10
CRAC2D	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12	G13	G14	
	G15	G16	G17	G18					

Example:

CRAC2D	114	108	2	5	6	8	7	11	
	12	14	16	17		20	22		

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PRAC2D entry. (Integer > 0)
Gi	Grid point identification numbers of connection points. (Integer ≥ 0; G11 through G18 may be blank.)

Remarks:

1. CRAC2D is a dummy element and requires the presence of this Bulk Data entry:

ADUM8	18	0	5	0	CRAC2D				
-------	----	---	---	---	--------	--	--	--	--

2. The element should be planar. Significant deviations will produce fatal errors.
3. Grid points G1 through G10 are required while grid points G11 through G18 are optional for the quadrilateral form of the element.
4. The stresses and stress intensity factors are calculated assuming that G2 and G10 are coincident. Deviations from this will produce erroneous results.
5. For the symmetric half-crack option, grid points G1 through G7 are required while grid points G11 through G14 are optional. Grid points G8 through G10 and G15 through G18 must not be present for this option.
6. The ordering conventions for the full-crack and half-crack options are shown in [Figure 9-57](#).
7. The ratio of the element dimensions in the y to x axis shown for the element coordinate system in [Figure 9-57](#) should be in the range 2.0 to 0.5.
8. The stress output is interpreted as shown in [Crack Tip Elements \(CRAC2D, CRAC3D\)](#) in the *MSC Nastran Reference Guide*.

(a) Full Crack Option

(b) Symmetric Half-Crack Option

Figure 9-57 CRAC2D Element Connection for Full and Symmetric Options

## CRAC3D

## Three-Dimensional Crack Tip Element

Defines a three-dimensional crack tip element.

Format:

1	2	3	4	5	6	7	8	9	10
CRAC3D	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10	G11	G12	G13	G14	
	G15	G16	G17	G18	G19	G20	G21	G22	
	G23	G24	G25	G26	G27	G28	G29	G30	
	G31	G32	G33	G34	G35	G36	G37	G38	
	G39	G40	G41	G42	G43	G44	G45	G46	
	G47	G48	G49	G50	G51	G52	G53	G54	
	G55	G56	G57	G58	G59	G60	G61	G62	
	G63	G64							

Example:

CRAC3D	113	101	2	5	7	8	4	10	
	11	14	15	17		3	6	9	
	12		16		102	105	107	108	
	104	110	111	114	115	117		103	
	106	109	112		116		202	205	
	207	208	204	210	211	214	215	217	
	225	226							

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PRAC3D entry. (Integer < 0)
Gi	Grid point identification numbers of connection points. (Integer ≥ 0)

Remarks:

1. CRAC3D is a dummy element and requires the presence of this Bulk Data entry:

ADUM9	64	0	6	0	CRAC3D				
-------	----	---	---	---	--------	--	--	--	--

2. Element identification numbers should be unique with respect to all other element identification numbers.

3. This element, including grid point numbering conventions, is shown in [Figure 9-58](#) and [Figure 9-59](#). Grid points G1 through G10, and G19 through G28 are required; midside and surface grid points G11 through G18, G29 through G36, and G37 through G64 are optional. Either all or none of grid points G37 through G46 should be present. A fatal error message will be issued for partial connectivity.
4. The ratio of the element dimensions in the y to x axis shown for the element coordinate system in [Figure 9-58](#) should be in the range 2.0 to 0.5.
5. For the symmetric half-crack option Grid Points G1 through G7, and G19 through G25 are required, whereas grid points G11 through G14, G29 through G32, and G37 through G42 are optional. Grid points G8 through G10, G15 through G18, G26 through G28, G33 through G36, G43 through G46, G51 through G55, and G60 through G64 should not be specified to invoke this option.
6. It is recommended that both the faces (formed by grid points G2 through G18 and grid points G20 through G36) and the midplane (formed by grid points G37 through G46 and grid points G37 through G46) be planar. It is also recommended that midside grid points G37 through G46 be located within the middle third of the edges.
7. The midside nodes on both the faces should be defined in pairs. For example, if grid point G11 is not defined, then grid point G29 should not be defined and vice versa.
8. The stresses and stress intensity factors are calculated with the assumptions that grid points G2 and G10, G20 and G28, and G38 and G46 are coincident. Deviation from this condition will produce erroneous results.
9. The stress output is interpreted as shown in [Crack Tip Elements \(CRAC2D, CRAC3D\)](#) in the *MSC Nastran Reference Guide*.
10. As depicted in [Figure 9-58](#) and [Figure 9-59](#), the element is a right-handed element. Thus define the vectors  $\overline{G1G9}$  and  $\overline{G1G3}$ , then the cross-product  $\overline{G1G9} \times \overline{G1G3}$  points to the face defined by G19, G20, ...

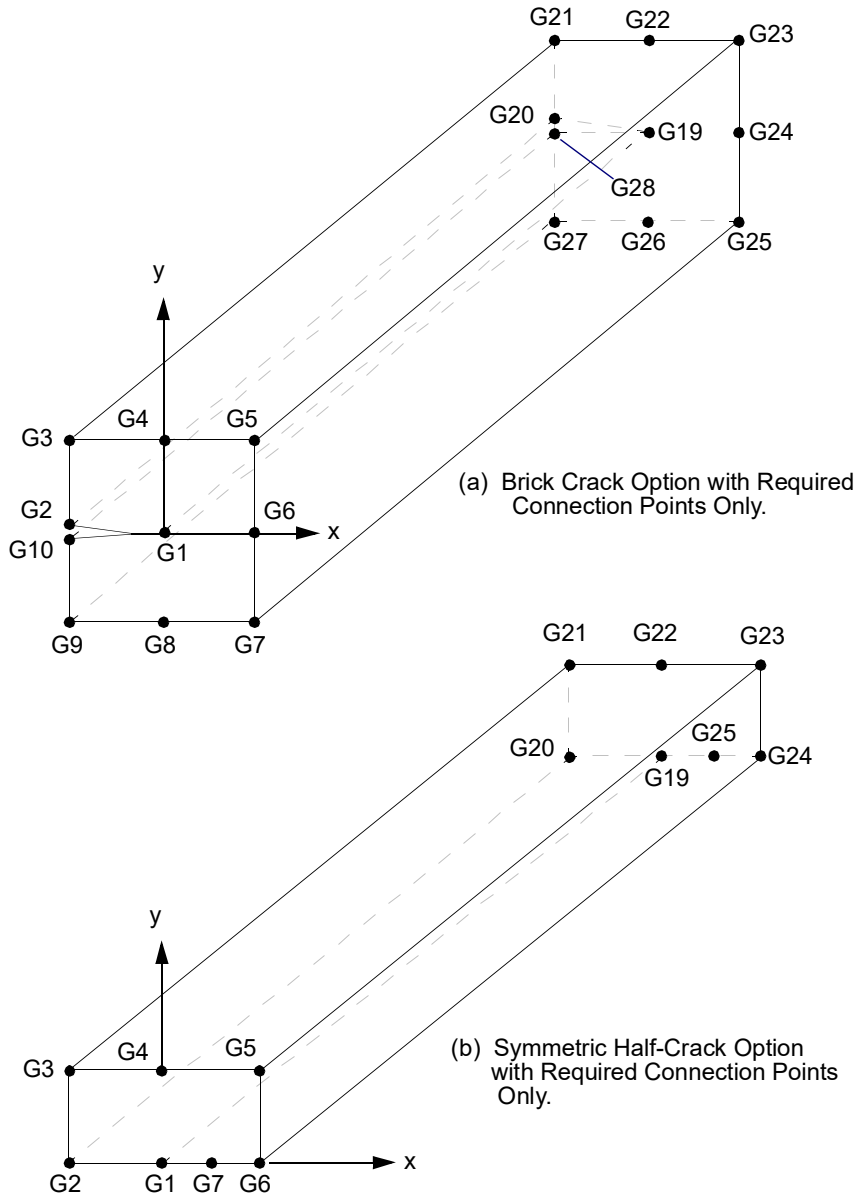

Figure 9-58 CRAC3D Solid Crack Tip Element with Required Connection Points Only

Figure 9-59 CRAC3D Solid Crack Tip Element with All Connection Points

## CREEP

## Creep Characteristics

Defines creep characteristics based on experimental data or known empirical creep law. This entry will be activated if a MAT1, MAT2, or MAT9 entry with the same MID is used and the NLPARM entry is prepared for creep analysis. The creep formulation is principally suited for isotropic materials and, in general, when used with anisotropic materials may produce incorrect results. However, slightly anisotropic materials may produce acceptable results.

Format:

1	2	3	4	5	6	7	8	9	10
CREEP	MID	T0	EXP	FORM	TIDKP	TIDCP	TIDCS	THRESH	
	TYPE	a	b	c	d	e	f	g	

Example:

CREEP	8	1100.		CRLAW					
	121	6.985-6	2.444	7.032-4	0.1072	6.73-9	0.1479	3.0	

Describer	Meaning
MID	Material identification number of a MAT1, MAT2, or MAT9 entry. (Integer > 0)
T0	Reference temperature at which creep characteristics are defined. See Remark 2. (Real; Default = 0.0)
EXP	Temperature-dependent term, $e^{(-\Delta H/(R \cdot T0))}$ , in the creep rate expression. See Remark 2. (0.0 < Real ≤ 1.0; Default = 1.0E-9)
FORM	Form of the input data defining creep characteristics. (Character: “CRLAW” for empirical creep law, or “TABLE” for tabular input data of creep model parameters.)
TIDKP, TIDCP, TIDCS	Identification number of a TABLES1 entry, which defines the creep model parameters $K_p(\sigma)$ , $C_p(\sigma)$ , and $C_s(\sigma)$ , respectively. See Remarks 3. through 4. (Integer > 0)
THRESH	Threshold limit for creep process. Threshold stress under which creep does not occur is computed as THRESH multiplied by Young’s modulus. (0.0 < Real < 1.0E-3; Default = 1.0E-5)
TYPE	Identification number of the empirical creep law type. See Remark 1. (Integer: 111, 112, 121, 122, 211, 212, 221, 222, or 300)
a through g	Coefficients of the empirical creep law specified in TYPE. Continuation should not be specified if FORM = “TABLE”. See Remark 1. (Real)

Remarks:

- Two classes of empirical creep law are available.

Creep Law Class 1

The first creep law class is expressed as:

$$\varepsilon^c(\sigma, t) = A(\sigma)[1 - e^{-R(\sigma)t}] + K(\sigma)t \tag{9-3}$$

Parameters  $A(\sigma)$ ,  $R(\sigma)$ , and  $K(\sigma)$  are specified in the following form, as recommended by Oak Ridge National Laboratory:

Parameter	Function 1	Digit	Function 2	Digit
$A(\sigma)$	$a\sigma^b$	i=1	$ae^{b\sigma}$	i=2
$R(\sigma)$	$ce^{d\sigma}$	j=1	$c\sigma^d$	j=2
$K(\sigma)$	$e \cdot [\sinh(f\sigma)]^g$	k=1	$ee^{f\sigma}$	k=2

TYPE=ijk where i, j, and k are digits equal to 1 or 2, according to the desired function in the table above. For example, TYPE=122 defines  $A(\sigma) = a\sigma^b$ ,  $R(\sigma) = c\sigma^d$ , and  $K(\sigma) = ee^{f\sigma}$ .

### Creep Law Class 2

The second creep law class (TYPE=300) is expressed as:

$$\varepsilon^c(\sigma, t) = a\sigma^b t^d \tag{9-4}$$

where the values of b and d must be defined as follows:

The above expression is determined by curve fitting using a Newton-Raphson procedure based on the expressions:

$$\lambda = C_p / K_{pi} = \left( \frac{\frac{-c}{\varepsilon}}{a\sigma^b} \right)^{1/d} \tag{9-5}$$

where  $\bar{\sigma}$  is the effective stress and the nonlinear equation:

$$\lambda^2(e^{t_0/\lambda} - 1) - \lambda t_0 - t_0^2 / d = 0$$

Then the creep model parameters are determined by:

$$\frac{1}{C_s} = \frac{\bar{\varepsilon}^c d}{t_0 \bar{\sigma}} \left[ 1 - \frac{\lambda(1-d)}{t_0} \right]$$

$$\frac{1}{K_p} = \left( \frac{\lambda}{t_0} \right)^2 \frac{\bar{\varepsilon}^c}{\bar{\sigma}} (1-d)d - \frac{t_0}{C_s} + \frac{\bar{\varepsilon}^c}{\bar{\sigma}}$$

$$C_p = \lambda K_p$$

To keep the solution of these expressions stable, the values of b and d are recommended to be defined as follows:

$$1.0 < b < 8.0$$

and

$$0.2 < d < 2.0$$

The coefficient g should be blank if TYPE = 112, 122, 222, or 212 and c, e, f, and g should be blank if TYPE = 300. The coefficients a through g are dependent on the structural units; caution must be exercised to make these units consistent with the rest of the input data.

- Creep law coefficients a through g are usually determined by least squares fit of experimental data, obtained under a constant temperature. This reference temperature at which creep behavior is characterized must be specified in the T0 field if the temperature of the structure is different from this reference temperature. The conversion of the temperature input (°F or °C) to °K (degrees Kelvin) must be specified in the PARAM,TABS entry as follows:

PARAM,TABS,273.16 (If Celsius is used.)

PARAM,TABS,459.69 (If Fahrenheit is used.)

When the correction for the temperature effect is required, the temperature distribution must be defined in the Bulk Data entries (TEMP, TEMPP1 and/or TEMPRB), which are selected by the Case Control command TEMP(LOAD) = SID within the subcase.

From the thermodynamic consideration, the creep rate is expressed as:

$$\dot{\varepsilon}^C = \dot{\varepsilon}_A (e^{-\Delta H/RT}) \quad (9-6)$$

where:

$\Delta H$  = energy of activation

$R$  = gas constant (= 1.98 cal/mole °K)

$T$  = absolute temperature (°K)

$\dot{\varepsilon}_A$  = strain/sec per activation

If the creep characteristics are defined at temperature T0, the creep rate at temperature T is corrected by a factor

$$\frac{\dot{\varepsilon}^c}{\dot{\varepsilon}_o^c} = \text{EXP} \left( \frac{T_0}{T} - 1 \right) \quad (9-7)$$

where:

$$\dot{\varepsilon}^c = \text{corrected creep rate}$$

$$\dot{\varepsilon}_o^c = \text{creep rate at } T_0$$

$$\text{EXP} \left( \frac{T_0}{T} - 1 \right) = \text{correction factor}$$

3. Creep model parameters  $K_p$ ,  $C_p$ , and  $C_s$  represent parameters of the uniaxial rheological model as shown in Figure 9-60.

Tabular values ( $X_i$ ,  $Y_i$ ) in the TABLES1 entry correspond to  $(\sigma_i, K_{pi})$ ,  $(\sigma_i, C_{pi})$ , and  $(\sigma_i, C_{si})$  for the input of  $K_p$ ,  $C_p$ , and  $C_s$ , respectively. For linear viscoelastic materials, parameters  $K_p$ ,  $C_p$ , and  $C_s$  are constant and two values of  $\sigma_i$  must be specified for the same value of  $K_{pi}$ ,  $C_{pi}$ , and  $C_{si}$ .

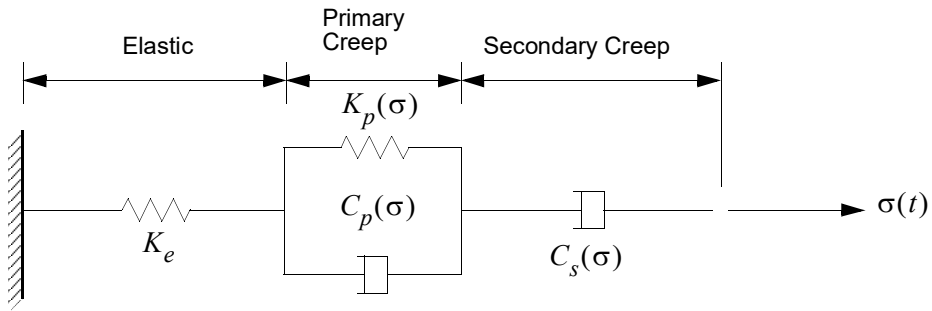

Figure 9-60 CREEP Parameter Idealization

Creep model parameters, as shown in Figure 9-61 through Figure 9-63, must have positive values. If the table look-up results in a negative value, the value will be reset to zero and a warning message (TABLE LOOK-UP RESULTS IN NEGATIVE VALUE OF CREEP MODEL PARAMETER IN ELEMENT ID=\*\*\*\*) will be issued.

Figure 9-61  $K_p$  Versus  $\sigma$  Example for CREEP

Figure 9-62  $C_p$  Versus  $\sigma$  Example for CREEP

Figure 9-63  $C_s$  Versus  $\sigma$  Example for CREEP

- Creep analysis requires an initial static solution at  $t = 0$ , which can be obtained by specifying a subcase that requests an NLPARM entry with  $DT = 0.0$ .

## CROD Rod Element Connection

Defines a tension-compression-torsion element.

Format:

1	2	3	4	5	6	7	8	9	10
CROD	EID	PID	G1	G2					

Example:

CROD	12	13	21	23					
------	----	----	----	----	--	--	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PROD entry. (Integer > 0; Default = EID)
G1, G2	Grid point identification numbers of connection points. (Integer > 0; G1 ≠ G2)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. See [CONROD](#) for alternative method of rod definition.
3. Only one element may be defined on a single entry.

Figure 9-64 CROD Element Internal Forces and Moments

## CSEAM A Shell Patch SEAM Connection

Defines a SEAM connecting two surface patches.

Format:

1	2	3	4	5	6	7	8	9	10
CSEAM	EID	PID	SMLN	CTYPE	IDAS	IDBS	IDAE	IDBE	
	GS	GE							

Alternate Format:

1	2	3	4	5	6	7	8	9	10
CSEAM	EID	PID		CTYPE	IDAS	IDBS	IDAE	IDBE	
	XS	YS	ZS	XE	YE	ZE			

Example:

CSEAM	552	297			43	48			
	30422	77987							

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PSEAM entry. (Integer > 0)
SMLN	SEAM line identification. See Remark 2. (CHAR or blank)
CTYPE	Connectivity search type. (Character) If CTYPE = "PSHELL", IDAS and IDBS are property identification numbers of PSHELL's. (Default) If CTYPE = "ELEM", IDAS and IDBS are element identification numbers.
IDAS, IDBS	Used to define patch A and B or the start of patch A or B for a tailored blank. See Remark 4. (Integer > 0) If CTYPE = "PSHELL", required property id defining patches A and B. If CTYPE = "PSHELL" and IDAS = IDBS or IDBS = blank the patch will be considered as two-sided and the property identification numbers of PSHELL's will be the same for both the top and bottom. See Remark 6. If CTYPE = "ELEM", required element id defining patches A and B. IDAS ≠ IDBS.
IDAE, IDBE	Used to define the end of patch A and the end of patch B for a tailored blank. See Remark 4. (Integer ≥ 0 or blank) If CTYPE = "PSHELL", property id defining patches A and B. If CTYPE = 'PSHELL' and IDAE = IDBE or IDBE=blank the patch will be considered as two-sided and the property identification numbers of PSHELL's will be the same for both the top and bottom. If CTYPE = "ELEM", element id defining patches A and B. IDAE ≠ IDBE.

Describer	Meaning
GS, GE	Grid ids of piercing points on patches A and B of the Start and End of the SEAM. (Integer > 0)
XS,YS,ZS	Location of the SEAM Start. (Real or blank)
XE,YE,ZE	Location of the SEAM End. (Real or blank)

**Remarks:**

1. Element ID numbers must be unique with respect to all other element ID numbers.
2. With no embedded blanks any combination of up to eight of the acceptable characters in MSC Nastran may be employed for the SMLN entry.

The seam line will be considered continuous between each connected element and where any two elements have a common face, the faces of the resulting internal CHEXA's will be adjusted to a single common face. If a CSEAM's GS or GE is not common to the GE or GS of any other CSEAM the faces will not be adjusted.

A SMLN cannot have a branch.

3. GS and GE define the start and end points of the SEAM element. At these points and using the value *W* specified on the PSEAM entry, surface patches A and B are determined. Points are projected onto the surface patches A and B with the four points at end GS and the four points at end GE then used to form faces of a CHEXA element.

The auxiliary points forming the faces of the CHEXA element are then connected to the physical grids of the patches. The number of unique physical grids per patch ranges from a possibility of 6 to 64 grids.

The auxiliary points must have a projection on patches A and B, but they do not have to lie on patch A or B.

A maximum of three shell elements of patch A and three shell elements of patch B can be connected with one CSEAM element, see [Figure 9-65](#).

Figure 9-65 Connected Shell Elements for a CSEAM Element

## 4. For CTYPE = 'PSHELL'

If patch A is uniform in thickness, then only its IDAS is needed to define it.

If patch B is uniform in thickness, then only its IDBS is needed to define it.

If patch A has stepped tapering, then IDAS and IDAE are used to define it.

If patch B has stepped tapering, then IDBS and IDBE are used to define it.

## 5. Projection Algorithms for the CSEAM Elements

Because of complex geometry, the user supplied start point GS may not have a projection SA and SB, and the end point GE may not have a projection EA and EB. Even though these four projection points are found, the program still has to find projections for the eight auxiliary points SA1, SA2, ..., EB2, and EB1 of the HEXA. The default projection strategy can be changed by overwriting the default values of the flags and parameters in the SWLDPRM Bulk Data entry.

## a. Find Projections for SA, SB, EA, and EB

For CTYPE = "PSHELL", the program finds the closest shell grids to GS and GE. The shell elements that are connected to these closest grids are defined as the candidate shell elements. While looping through each candidate shell element to compute the projection of GS and GE onto that element, the program always tries to get the most accurate projection. Even though a projection is found with PROJ TOL > 0.0, the program still continues the projection calculations using PROJ TOL=0.0. If a projection is found with PROJ TOL=0.0, that shell element will be selected as the connecting element. Otherwise, the shell element that gets projection with PROJ TOL>0.0 is selected as EIDSA, EIDSB, EIDEA, or EIDEB. For CTYPE = "ELEM", the above processes are skipped, because EIDSA, EIDSB, EIDEA, and EIDEB have already been specified by the user.

If GSTOL > 0.0 and the distance GS-SA, GS-SB, GE-EA, or GE-EB is greater than GSTOL, a UFM 7549 is issued and the CSEAM element is rejected.

If the projection of GS or GE lies outside the shell sheet, or the connected shell elements fail the geometry check with GMCHK > 0, the program will issue a UFM and the CSEAM element will be rejected.

If GMCHK > 0, the program checks errors of CSEAM across a cutout or over a corner with elements in plane. The program also computes the angle between the shell normal vectors of EIDSA and EIDEA and the angle between the shell normal vectors of EIDSB and EIDEB to check a corner with elements out of plane.

For CTYPE = "PSHELL", if there is an error detected, the program loops back to compute the other possibility of projection until a correct connection is found or all candidate shell elements are processed. In the latter case, either UFM 7638 (the seam spans a cutout) or UFM 7667 (the seam spans a corner) will be issued. If GMCHK=2, the program also lists all candidate shell elements with their projection status for each connecting type after issuing a UFM. This will help the user to select the correct shell elements for EIDSA, EIDSB, EIDEA, and EIDEB.

For CTYPE="ELEM", the program only checks errors and issues UFM 7638 or 7667 for the kind of error encountered. No looping back will be performed.

If  $GMCHK > 0$  and  $GSPROJ \geq 0.0$ , the program also computes the angle between the shell normal vectors of EIDSA and EIDSB and the angle between the shell normal vectors of EIDEA and EIDEB. A UFM 7595 is issued if the angle between the shell normal vectors is greater than  $GSPROJ$ . By default,  $GSPROJ = 20^\circ$ , that means the shell patches A and B can be tilted relative to each other by not more than  $20^\circ$ .

b. Find Projections of the Eight Auxiliary Points SA1, SA2, ..., EB2, and EB1

After the projections for SA, SB, EA, and EB have been found, eight auxiliary points for an internal hexagonal polygon are formed. If the GS or GE of a CSEAM element is connected to the GE or GS of another CSEAM element, then the internal HEXA elements are adjusted to a common face.

If  $GSPROJ \geq 0.0$  and the angle between the face vectors parallel to the thickness direction of the internal HEXA and the normal vector of the shell element that gets projection exceeds  $GSPROJ$ , the program will skip picking this shell element and will proceed to process next candidate shell element.

The most common error condition occurs when the seam lies on the edge of the shell patches. Under this situation, half of the seam hangs outside the shell sheets (Figure 9-66). It is required that each of the eight points has a projection. If at least one point does not have a projection and  $GSMOVE > 0$ , GS will be moved by  $W/2$ . Same algorithms apply to end E. The move will be repeated until either all projections are found or the number of moves reaches  $GSMOVE$ .

Figure 9-66 Seam Weld at an Edge

c. Error Checks by GMCHK Parameter

The GMCHK parameter specified in the SWLDPRM Bulk Data entry checks the errors of CSEAM elements across cutouts or over corners. There are three allowable values of GMCHK.

- GMCHK = 0 (Default) Do not check errors
- GMCHK = 1 Check errors
- GMCHK = 2 Check errors and output all candidate shell elements if there is an error encountered

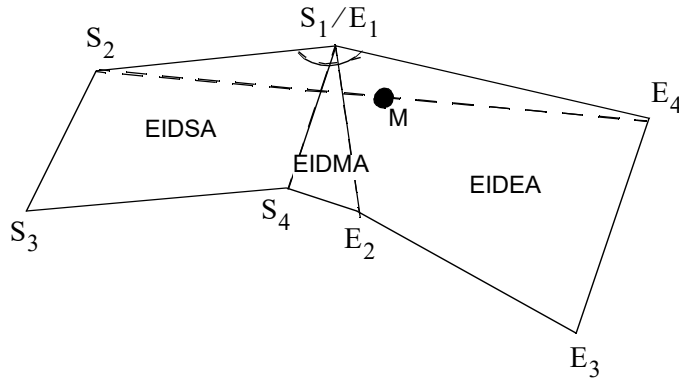

If GMCHK is turned on, Nastran will perform the following checking while searching for the projected shell elements. Note that EIDSA is the shell element that gets projection from GS on shell A; EIDEA is the shell element that gets projection from GE on shell A. Same algorithms are applied to EIDSB and EIDEB for shell B.

d. Check the CSEAM Across a Cutout or Over a Corner with Elements in Plane

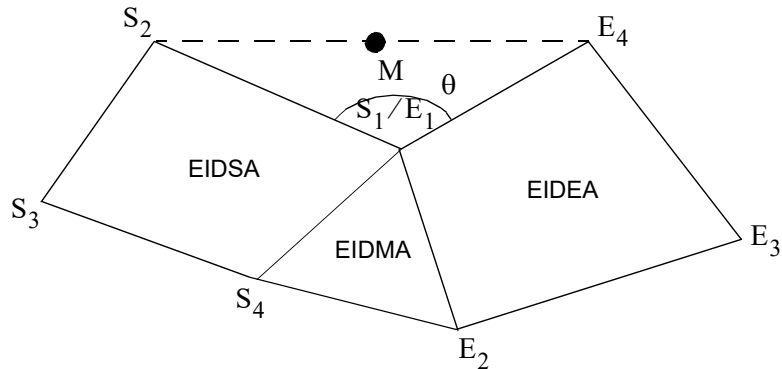

- If EIDSA is equal to EIDEA, the seam lies within one element. No checks are required.

- If EIDSA and EIDEA share two corner grids, these elements are adjacent. No checks are required.
- If EIDSA and EIDEA share only one corner grid, the seam is over a corner. There are two exceptions:

There exists a shell element (EIDMA) that shares two corner grids with EIDSA and EIDEA. Also, either the angle  $\theta$  between vector  $S_1S_2$  and vector  $E_1E_4$  is greater than CNRAGLI degrees or the middle point (M) of line segment  $S_2E_4$  projects to EIDSA, EIDMA, or EIDEA.

This model is acceptable - CONVEX ( $\theta > \text{CNRAGLI}$ ).

This model fails - not CONVEX ( $\theta < \text{CNRAGLI}$  and point M does not project to EIDSA, EIDMA or EIDEA).

This shared grid is a shell grid of another two different shell elements.

- If EIDSA and EIDEA do not share any corner grid, Nastran will check if there is an element (EIDMA) lying between EIDSA and EIDEA. EIDMA must share two corner grids with EIDSA and another different one corner grid with EIDEA, or vice versa. The following five examples demonstrate the acceptable and failed cases.

EIDMA shares one edge with EIDSA and shares one corner grid with EIDEA. This case is acceptable.

EIDMA shares one edge with IEDEA and shares one corner grid with EIDSA. This case is acceptable.

EIDMA shares one corner grid with EIDSA and shares another corner grid with EIDEA. An error is detected because the seam spans a cutout.

EIDMA shares one edge with EIDSA and shares another edge with EIDEA. This case is acceptable.

There does not exist a single element that shares an edge or corner grid with EIDSA or EIDEA. An error is detected because the length of the seam spans more than three elements.

- e. Check the CSEAM Over a Corner with Elements Out of Plane

The CNRAGLO parameter is used to check the error of a seam over a corner with EIDSA and EIDEA not lying on a same plane. An error is detected if the angle  $\varphi$  between the shell normal vectors of EIDSA and EIDEA is greater than CNRAGLO. The default value of CNRAGLO is  $20^\circ$ . No angles will be checked if CNRAGLO = -1.

This model fails. ( $\varphi > \text{CNRAGLO}$ )

f. Modeling Guidelines

When there exist multiple pairs of connections, it is recommended that either the GMCHK and GSPROJ flags be turned on to filter out tilted connections or the ELEM option be used to specify the IDs of the connected shell elements directly. For example, if EIDA1 is connected to EIDB2 or EIDA2 is connected to EIDB1, the element tangent vectors will be computed wrong and the auxiliary points will not be able to find connected shell elements.

- The projection algorithm for the two-sided option will be the same as in Remark 5. above once the two patches A and B have been established. The program will find the closest shell grids to GS and GE as usual for candidate shell elements for patch A.

It will compute the normal for the candidate patch A (similar for GE) and for the candidate patch B. If the normals are approximately aligned (within a tolerance) the algorithm will proceed as in Remark 5.

If the normals of the candidate patch's A and B do not align within a specified tolerance, the algorithm will use another set of pairs of grids for candidate patches to find a new patch A and B. If their normals align within a specified tolerance it will proceed as in Remark 5. If after processing all reasonable pairs of patches, no alignment of normals are found or the patches A and B at GE have different normal alignment from the patches A and B at GB, a user fatal will be issued.

**Note:** For the two-sided option, GS and GB must lie between patches A and B. Also, the shell elements that get projections from GS/GE cannot share a common shell grid. This option always selects the patch with the shell grids closest to GS/GE as patch A. Avoid having GS/GE exactly midway between the two patches.

7. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
8. The CSEAM contributes to MASS if its PSEAM entry has an associated MATi entry with a non-zero density. PARAM,COUPMASS effects the mass calculation. In SOL400, the behavior of this element in regard to large rotation is affected by the Case Control Command Rigid.
9. If partitioned superelements are present, then CSEAM is supported in the main Bulk Data section only.

## CSET Free Boundary Degrees-of-Freedom

Defines analysis set (a-set) degrees-of-freedom to be free (c-set) during generalized dynamic reduction or component mode synthesis calculations.

Format:

1	2	3	4	5	6	7	8	9	10
CSET	ID1	C1	ID2	C2	ID3	C3	ID4	C4	

Example:

CSET	124	1	5	23	6	16			
------	-----	---	---	----	---	----	--	--	--

Describer	Meaning
IDi	Grid or scalar point identification number. (Integer > 0)
Ci	Component number. (Integer zero or blank for scalar points, or any unique combinations of the Integers 1 through 6 for grid points. No embedded blanks.)

Remarks:

1. CSET and BNDFREE entries are equivalent to each other. Either one of them or any combination of them may be employed.
2. If there are no BSETi/BNDFIXi or CSETi/BNDFREE/BNDFRE1 entries present, all a-set points are considered fixed during component mode analysis. If there are only BSETi/BNDFIXi entries present, any a-set degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are only CSETi/BNDFREE/BNDFRE1 entries present or both BSETi/BNDFIXi and CSETi/BNDFREE/BNDFRE1 entries present, the c-set degrees-of-freedom are defined by the CSETi/BNDFREE/BNDFRE1 entries, and any remaining a-set points are placed in the b-set.
3. Degrees-of-freedom specified on CSETi/BNDFREE/BNDFRE1 entries form members of the mutually exclusive c-set. They may not be specified on other entries that define mutually exclusive sets. See the [Degree-of-Freedom Sets](#) for a list of these entries.
4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.
5. SOL 400 does not support ASETi, OMITi, BSETi, CSETi, SUPORTi, and QSETi except in the following situations:

- a. Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
- b. Linear perturbation with:
  - i. EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
  - ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
- c. Superelements defined with BEGIN SUPER may contain ASETi, OMITi, BSETi, CSETi, and QSETi entries.

## CSET1 Free Boundary Degrees-of-Freedom, Alternate Form of CSET Entry

Defines analysis set (a-set) degrees-of-freedom to be free (c-set) during generalized dynamic reduction or component mode synthesis calculations.

Format:

1	2	3	4	5	6	7	8	9	10
CSET1	C	ID1	ID2	ID3	ID4	ID5	ID6	ID7	
	ID8	ID9	ID10	-etc.-					

Example:

CSET1	124	1	5	7	6	9	12	122	
	127								

Alternate Formats and Examples:

CSET1	C	ID1	“THRU”	ID2					
CSET1	3	6	THRU	32					

CSET1		“ALL”							
CSET1		ALL							

Describer	Meaning
C	Component numbers. (Integer zero or blank for scalar points, or any unique combinations of the Integers 1 through 6 for grid points with no embedded blanks.)
ID <sub>i</sub>	Grid or scalar point identification numbers. (Integer > 0; For “THRU” option, ID <sub>1</sub> < ID <sub>2</sub> )

Remarks:

1. CSET1 and BDNFRE1 entries are equivalent to each other. Either one of them or any combination of them may be employed.
2. If there are no BSET<sub>i</sub>/BNDFIX<sub>i</sub> or CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present, all a-set points are considered fixed during component mode analysis. If there are only BSET<sub>i</sub>/BNDFIX<sub>i</sub> entries present, any a-set degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are only CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present or both BSET<sub>i</sub>/BNDFIX<sub>i</sub> and CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries present, the c-set degrees-of-freedom are defined by the CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries, and any remaining a-set points are placed in the b-set.
3. Degrees-of-freedom specified on CSET<sub>i</sub>/BNDFREE/BNDFRE1 entries form members of the mutually exclusive c-set. They may not be specified on other entries that define mutually exclusive sets. See the [Degree-of-Freedom Sets](#) for a list of these entries.

4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.
5. SOL 400 does not support ASETi, OMITi, BSETi, CSETi, SUPORTi, and QSETi except in the following situations:
  - a. Multidisciplinary (linear) analysis. See Remark 3-6. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
  - b. Linear perturbation with:
    - i. EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
    - ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
  - c. Superelements defined with BEGIN SUPER may contain ASETi, OMITi, BSETi, CSETi, and QSETi entries.

## CSHEAR Shear Panel Element Connection

Defines a shear panel element and effective extensional stiffener rods.

Format:

1	2	3	4	5	6	7	8	9	10
CSHEAR	EID	PID	G1	G2	G3	G4			

Example:

CSHEAR	3	6	1	5	3	7			
--------	---	---	---	---	---	---	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PSHEAR entry. (Integer > 0; Default = EID)
Gi	Grid point identification numbers of connection points. (Integer > 0; G1 ≠ G2 ≠ G3 ≠ G4)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Grid points G1 through G4 must be ordered consecutively around the perimeter of the element.
3. All interior angles must be less than 180°.

Figure 9-67 CSHEAR Element Connection and Coordinate System

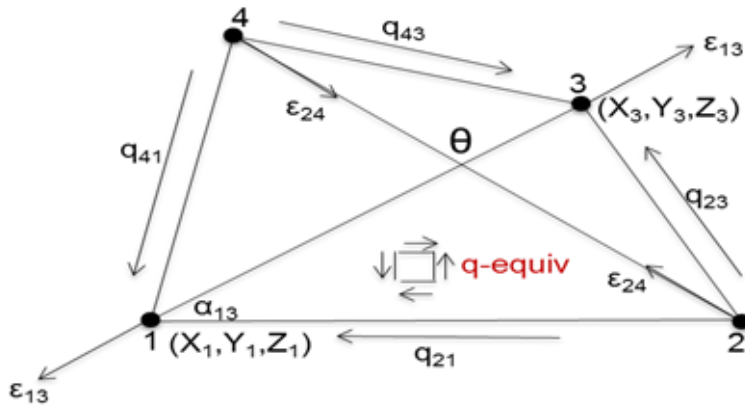

Figure 9-68 CSHEAR Element Corner Forces and Shear Flows

4. The parameter entry MDLPRM,SHEARP,GARVEY(default) selects the standard Garvey shear panel. MDLPRM,SHEARP,HARDER selects the Harder shear panel: The Harder panel is based on the following:  
Consider the following quadrilateral shear panel.

The shear stress  $\tau$  is related to the shear strain by the relationship  $\tau = G\gamma$  where G is the shear modulus.

Determining the value for shear for the general quadrilateral shown is a heuristic process. For the Harder element it is determined in the following manner. The strain along a diagonal such as L13 is found from the expression (or Mohr's circle):

$$\varepsilon_{13} = \varepsilon_x \cos^2 \alpha_{13} + \varepsilon_y \sin^2 \alpha_{13} + \gamma_{xy} \cos \alpha_{13} \sin \alpha_{13}$$

With a similar expression for  $\varepsilon_{24}$ , where  $\alpha_{24} = 180 - (\alpha_{13} + \theta)$ . For shear panels, the direct strains are negligible compared to the shear strain. For a rectangular shear panel  $\alpha_{24} = \alpha_{13}$  and we have

$$\Delta\varepsilon = \varepsilon_{13} - \varepsilon_{24} = \gamma \sin \theta \text{ or } \gamma = (\varepsilon_{13} - \varepsilon_{24}) / (\sin \theta).$$

In the above, the subscripts have been dropped from the term for shear strain. The Harder shear panel uses this definition for the measure of shear strain in the general quadrilateral. For a rectangular panel it is exact. For a reasonable panel it is within an error of < 1 degree. To insure reasonableness, all the geometry checks required by the Garvey element are still performed.

### Stress Recovery:

The output for either the Garvey or the Harder panel is the same with the following exception:

MAX SHEAR	AVG SHEAR	SHEARP
MAX( $\tau_1, \tau_2, \tau_3, \tau_4$ )	$(\tau_1 + \tau_2 + \tau_3 + \tau_4) / 4$	GARVEY
MAX( $\tau_1, \tau_2, \tau_3, \tau_4$ )	(q-Equiv) / $\tau$	HARDER

For both Garvey and Harder panels, q-Equiv is the shear flow on which all stress calculations are based.

## CSLOT3

## Three Point Slot Element Connection

Defines an element connecting three points that solve the wave equation in two dimensions. Used in the acoustic cavity analysis for the definition of evenly spaced radial slots.

Format:

1	2	3	4	5	6	7	8	9	10
CSLOT3	EID	IDS1	IDS2	IDS3		RHO	B	M	

Example:

CSLOT3	100	1	3	2		3.0-3		6	
--------	-----	---	---	---	--	-------	--	---	--

Descriptor	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ )
IDS <sub>i</sub>	Identification number of connected GRIDS points. ( $\text{Integer} > 0$ )
RHO	Fluid density in mass units. ( $\text{Real} > 0.0$ ; Default is the value of RHOD on the AXSLOT entry)
B	Fluid bulk modulus. ( $\text{Real} \geq 0.0$ ; Default is the value of BD on the AXSLOT entry)
M	Number of slots in circumferential direction. ( $\text{Integer} \geq 0$ ; Default is the value of MD on the AXSLOT entry)

Remarks:

1. CSLOT3 is allowed only if an AXSLOT entry is also present.
2. This element identification number (EID) must be unique with respect to all other fluid or structural elements.
3. If RHO, B, or M are blank, then the RHOD, BD, or MD fields on the AXSLOT entry must be specified.
4. This element generates three plot elements, connecting points IDS1 to IDS2, IDS2 to IDS3, and IDS3 to IDS1.
5. If B=0.0, then the slot is considered to be an incompressible fluid.
6. If M=0, then no matrices for CSLOT3 elements are generated.

## CSLOT4

## Four Point Slot Element Connection

Defines an element connecting four points that solve the wave equation in two dimensions. Used in acoustic cavity analysis for the definition of evenly spaced radial slots.

Format:

1	2	3	4	5	6	7	8	9	10
CSLOT4	EID	IDS1	IDS2	IDS3	IDS4	RHO	B	M	

Example:

CSLOT4	101	1	3	2	4		6.2+4	3	
--------	-----	---	---	---	---	--	-------	---	--

Descriptor	Meaning
EID	Element identification number. ( $0 < \text{Integer} < 100,000,000$ )
IDS <sub>i</sub>	Identification number of connected GRIDS points. ( $\text{Integer} > 0$ )
RHO	Fluid density in mass units. ( $\text{Real} > 0.0$ ; Default is the value of RHOD on the AXSLOT entry.)
B	Fluid bulk modulus. ( $\text{Real} \geq 0.0$ ; Default is the value of BD on the AXSLOT entry.)
M	Number of slots in circumferential direction. ( $\text{Integer} \geq 0$ ; Default is the value of MD on the AXSLOT entry.)

Remarks:

1. This entry is allowed only if an AXSLOT entry is also present.
2. This element identification number (EID) must be unique with respect to all other fluid or structural elements.
3. If RHO, B, or M are blank, then the RHOD, BD, or MD fields on the AXSLOT entry must be specified.
4. This element generates four plot elements connecting points IDS1 to IDS2, IDS2 to IDS3, IDS3 to IDS4, and IDS4 to IDS1.
5. If  $B = 0.0$ , then the slot is considered to be an incompressible fluid.
6. If  $M = 0$ , then no matrices for CSLOT4 elements are generated.

## CSPR

## Springs With Offsets

Springs for use in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CSPR	EID	PID	G1	G2					

Example:

CSPR	1	22	456	457					
------	---	----	-----	-----	--	--	--	--	--

Describer	Meaning	Type	Default
EID	Element ID. A unique number has to be used.	I > 0	Required
PID	Property ID of PSPRMAT entry	I > 0	Required
G1	Gridpoint 1	I > 0	Required
G2	Gridpoint 2.	I > 0	Required

## CSSCHD

## Aerodynamic Control Surface Schedule Input

Defines a scheduled control surface deflection as a function of Mach number and angle of attack.

Format:

1	2	3	4	5	6	7	8	9	10
CSSCHD	SID	AESID	LALPHA	LMACH	LSCHD				

Example:

CSSCHD	5	50	12	15	25				
--------	---	----	----	----	----	--	--	--	--

Describer	Meaning
SID	Set identification number. (Integer > 0)
AESID	ID of an AESURF Bulk Data entry to which the schedule is being attached.
LALPHA	ID of an AEFACCT Bulk Data entry containing a list of angles of attack (in radians) at which schedule information is provided. (Integer > 0; Default = no angle information provided).
LMACH	ID of an AEFACCT Bulk Data entry containing a list of Mach numbers at which schedule information is provided. (Integer > 0; Default = no Mach information provided)
LSCHD	ID of an AEFACCT Bulk Data entry which contains the scheduling information. See Remarks 4. and 5. (Integer > 0; no Default)

Remarks:

- Control system schedules must be selected with the Case Control command CSSCHD = SID.
- The AESID cannot appear on an AELINK or TRIM Bulk Data entry for the same subcase.
- The control surface deflection is computed using a linear interpolation for the Mach number provided on the associated TRIM entry and the angle of attack derived as part of the trim calculation.
- The LSCHD data are provided as a list of deflections (in radians) as a function of Mach numbers and angles of attack. If there are NMACH Mach numbers and NALPHA angles of attack, the first NALPHA deflections are for the first Mach number, the next NALPHA are for the second Mach number, and so on, until the last NALPHA deflections are for the final Mach number.
- If LALPHA is blank, LSCHD contains NMACH deflections to define the Mach schedule. If LMACH is blank, LSCHD contains NALPHA deflections to define the angle of attack schedule.
- LALPHA and LMACH cannot be simultaneously blank. If LALPHA or LMACH are not blank, at least two values of angle of attack or Mach number must be defined in order to perform interpolation.
- If the Mach number or angle of attack is outside the range specified by the tabulated values, the value at the table end is used. That is, data are not extrapolated.

## CSSHL

## Solid Shell Element Connection

Defines a connection for a Solid Shell with 6 or 8 grid points in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
CSSHL	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8							

Example:

CSSHL	44	11	1	2	3	4	5	6	quad
	7	8							

CSSHL	51	22	11	12	13		21	22	tria
	23								

CSSHL	51	22	11	12	13	13	21	22	tria
	23	23							

(Note: the 2nd and 3rd examples are equivalent to each other.)

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000; Required)
PID	Property identification of a PSSHL entry. (Integer > 0; Required)
Gi	Grid point identification number of connection points. (Integer U or blank, for quad shapes all 8 values are required, for triangle shapes only G4 and G8 may be left blank in which case G4=G3 and G8=G7.)

Remarks:

1. This element can degenerate to a triangle either by leaving G4 and G8 blank or by entering G4=G3 and G8=G7 (see 2<sup>nd</sup> and 3<sup>rd</sup> examples).
2. This element is usually only used when contact on each of the shell is anticipated.
3. Mid-side nodes are not available for this element.
4. Grid point ordering is shown in the following figure.

5. The stiffness of this element is formed using one integration point in the element plane and a user defined number through the element thickness. In this way the element can capture accurate material plasticity under bending load. An additional variationally consistent stiffness term is included to eliminate the hourglass modes that are normally associated with reduced integration.
6. The number of integration points through the thickness is given by PARAM,MARCSLHT
7. This element may be collapsed to a triangular solid shell to attach to a standard shell such as CQUAD4 as follows:

8. This element is not currently available with Total Lagrange, finite strain plasticity or hyperelastic materials.

## CSSLH

## CHEXA to Solid Shell Element Connection

Defines conversion of CHEXA elements to Solid Shell elements in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
CSSLH	EID1	PID	EID2	EID3	EID4	EID5	EID6		

Example:

CSSLH	44	11	54	200	250				
-------	----	----	----	-----	-----	--	--	--	--

Describer	Meaning
EID <sub>i</sub>	CHEXA element identification numbers. See Remark 1. (0 < Integer < 100,000,000; no Default; EID1 is required)
PID	Property identification of a PSSHL entry to be used with all the elements with EID <sub>i</sub> . (Integer > 0; Required)

1. All CHEXA elements in the range EID1 to EID2 will be converted to solid shells. The original CHEXA elements will be deleted and the solid shell elements will have the same element ID's as the original CHEXA elements.
2. All CHEXA elements in the range EID3 to EID4 as well as EID5 to EID6 will be converted to solid shells if these fields are entered.
3. Mid-side nodes are not allowed.
4. Elements for this entry are mapped to Marc element type 185.
5. Please see the remarks for CSHL for additional items.
6. The PSSHL entries associated with CSSLH are not generated automatically. They must be input using a GUI or with a text editor.

## CSSHLM

## CHEXA or CPENTA to Solid Shell Material Conversion

Defines conversion of CHEXA or CPENTA elements described by material ID to Solid Shell elements in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
CSSHLM	MID1		MID2	MID3	MID4	MID5	MID6	MID7	
	MID8	MID9							

Example:

CSSHLM	100		200	700	90250				
--------	-----	--	-----	-----	-------	--	--	--	--

Describer	Meaning
MIDi	Material identification numbers. See Remark 1. (Integer > 0; no Default; MID1 is required)

Remarks:

1. All CHEXA and CPENTA elements with the MIDi specified will be converted to solid shells. The original CHEXA and CPENTA elements will be deleted and the solid shell elements will have the same element ID's as the original elements.
2. All PSOLID entries which reference all MIDi values will automatically be converted to PSSHL entries retaining the MID and CORDM values. The PSSHL property ID's will be the same as the PSOLID ID's plus IPOFF. The value of IPOFF should not be zero since the original PSOLID entries are not deleted and all property ID's should normally be unique.
3. Mid-side nodes are not allowed.
4. Elements for this entry are mapped to Marc element type 185.
5. Please see the remarks for CSSHL for additional items.
6. If this entry is used, CSSHLH and CSSHLP entries should not be used.
7. See parameters MCSSHLCK and MCSSHORR for additional options for this entry.

## CSSHLP

## CPENTA to Solid Shell Element Connection

Defines conversion of CPENTA elements to Solid Shell elements in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
CSSHLP	EID1	PID	EID2	EID3	EID4	EID5	EID6		

Example:

CSSHLP	44	11	54	200	250				
--------	----	----	----	-----	-----	--	--	--	--

Describer	Meaning
EID <sub>i</sub>	CPENTA element identification numbers. See Remark 1. (0 < Integer < 100,000,000; no Default; EID1 is required)
PID	Property identification of a PSSHL entry to be used with all the elements with EID <sub>i</sub> . (Integer > 0; Required)

Remarks:

- All CPENTA elements in the range EID1 to EID2 will be converted to solid shells. The original CPENTA elements will be deleted and the solid shell elements will have the same element ID's as the original CPENTA elements.
- All CPENTA elements in the range EID3 to EID4 as well as EID5 to EID6 will be converted to solid shells if these fields are entered.
- The solid shell elements will be collapsed Marc element 185 type elements with the 3<sup>rd</sup> and 4<sup>th</sup> grids set to G3 of the CPENTA and the 7<sup>th</sup> and 8<sup>th</sup> grids set to the 6<sup>th</sup> grid of the CPENTA.
- Mid-side nodes are not allowed.
- Please see the remarks for CSSHL for additional items.
- The PSSHL entries associated with CSSHLH are not generated automatically. They must be input using a GUI or with a text editor.

**CSUPER** Secondary Superelement Connection

Defines the grid or scalar point connections for identical or mirror image superelements or superelements from an external source. These are all known as secondary superelements.

Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
CSUPER	SSID	PSID	GP1	GP2	GP3	GP4	GP5	GP6	
	GP7	GP8	-etc.-						

Example:

CSUPER	120003	21	3	6	4	10			
--------	--------	----	---	---	---	----	--	--	--

Descriptor	Meaning
SSID	Coded identification number for secondary superelement. See Remark 1. (Integer > 0)
PSID	Identification number for referenced primary superelement. See Remark 2. (Integer > 0 or blank)
GPi	Grid or scalar point identification numbers of the exterior points of the secondary superelement. See Remark 3. (Integer > 0)

Remarks:

- The value of SSID is written in the form XXX0000 + n, where n is the referenced secondary superelement identification number and n must be less than 10000 and XXX is a displacement component sign reversal code as follows:

The sign reversal code specifies the displacement component(s) normal to the plane of the mirror through which the reflection is to be made

Blank or 0	no reversal for identical superelement. If PSID is preceded by a minus sign and there is no xxx code on SSID, then a z-reversal mirror is generated.	
1	x-reversal	} Mirror Images
2	y-reversal	
3	z-reversal	
12	x and y-reversal	} Identical Images
23	y and z-reversal	
31	z and x-reversal	
123	x, y and z-reversal	} Mirror Images

2. If  $PSID = 0$  or blank, the superelement boundary matrices are obtained from an external source (such as a database or external file). See also PARAM, [EXTDRUNT](#).

If  $PSID \neq 0$ , the secondary superelement is identical to, or is a mirror image of, a primary superelement.

3. For identical or mirror image superelements, the grid point IDs,  $GPI$ , may appear in any order. However, if they are not in the same order as the external GRIDs of the primary superelement, then the SEQSEP entry is also required. In case of external superelements, the GRID IDs must be in the order that the terms in the associated matrices occur in.
4. Image superelements and their primaries must be congruent. The identical or mirror image superelement must have the same number of exterior grid points as its primary superelement. The exterior grid points of the image superelement must have the same relative location to each other as do the corresponding points of the primary superelement. The global coordinate directions of each exterior grid point of the image superelement must have the same relative alignment as those of the corresponding grid points of the primary superelement. If congruency is not satisfied because of round-off, then the tolerance may be adjusted with PARAM,CONFAC or DIAG 37.
5. For superelements from an external source, please refer to PARAMS [EXTDR](#), [EXTDRUNT](#) and [EXTUNIT](#).

## CSUPEXT      Superelement Exterior Point Definition

Assigns exterior points to a superelement.

Format:

1	2	3	4	5	6	7	8	9	10
CSUPEXT	SEID	GP1	GP2	GP3	GP4	GP5	GP6	GP7	

Example:

CSUPEXT	2	147	562	937					
---------	---	-----	-----	-----	--	--	--	--	--

Alternate Format and Example:

CSUPEXT	SEID	GP1	“THRU”	GP2					
---------	------	-----	--------	-----	--	--	--	--	--

CSUPEXT	5	12006	THRU	12050					
---------	---	-------	------	-------	--	--	--	--	--

Describer	Meaning
SEID	Identification number of a primary superelement. (Integer > 0)
GPi	Grid or scalar point identification number in the downstream superelement or residual structure. (Integer > 0 or “THRU”; for “THRU” option, GP1 < GP2)

Remarks:

1. Grid or scalar points are connected (that is, are exterior) to a superelement only if they are connected by structural, rigid, or plot elements. MPC entries are not regarded as elements. This entry is a means of providing connectivity for this purpose.
2. Open sets are allowed with the “THRU” option.
3. Scalar points may be interior to the residual structure (SEID = 0) only.
4. This entry may be applied only to the primary superelements. The CSUPER entry is used for secondary superelements (identical image, mirror image, and external superelements).

## CTETRA Four-Sided Solid Element Connection

Defines the connections of the four-sided solid element with four to ten grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CTETRA	EID	PID	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	G10					

Example:

CTETRA	112	2	3	15	14	4	103	115	
	5	16	8	27					

Describer	Meaning	Type	Default
EID	Element identification number.	0 < Integer < 100,000,000	Required
PID	Property identification number of a PSOLID or PLSOLID entry.	Integer > 0	Required
Gi	Identification numbers of connected grid points.	Integer ≥ 0 or blank	Required

Figure 9-69 CTETRA Element Connection

Remarks:

1. Element ID numbers must be unique with respect to all other element ID numbers.
2. The topology of the diagram must be preserved, i.e., G1, G2, G3 define a triangular face; G1, G8, and G4 are on the same edge, etc.
3. The edge points, G5 to G10, are optional. For Nastran conventional elements, any or all of them may be deleted. If the ID of any edge connection point is left blank or set to zero, the equations of the element are adjusted to give correct results for the reduced number of connections. Corner grid points cannot be deleted. The element is an isoparametric element in all cases.  
Note that for advanced nonlinear elements, partial specification of mid-points is not allowed. i.e. either none of the mid-points should be specified or all of the mid points should be specified.
4. Components of stress are output in the material coordinate system, except hyperelastic elements which outputs stress in the basic coordinate system.
5. For nonhyperelastic elements, the element coordinate system is derived from the three vectors R, S, and T, which join the midpoints of opposite edges.

R vector joins midpoints of edges G1-G2 and G3-G4.

S vector joins midpoints of edges G1-G3 and G2-G4.

T vector joins midpoints of edges G1-G4 and G2-G3.

The origin of the coordinate system is located at G1. The element coordinate system is chosen as close as possible to the R, S, and T vectors and points in the same general direction. (Mathematically speaking, the coordinate system is computed in such a way that, if the R, S, and T vectors are described in the element coordinate system, a 3x3 positive definite symmetric matrix would be produced.)

Solid elements have both a material and an element coordinate system. Both systems are defined for the initial geometry, and for geometric nonlinear analysis they will rotate with the element. The material coordinate system is used to input anisotropic material properties and for stress output. The material coordinate system is defined by the CORDM field of the PSOLID entry. The element coordinate system is used for element stiffness integration (reduced shear for example) and optionally to define the material coordinate system (only if PSOLID,CORDM=-1).

Figure 9-70 CTETRA Element R, S, and T Vectors

6. It is recommended that the edge points be located within the middle third of the edge.
7. For hyperelastic elements, the plot codes are specified under the CTETRAFD element name in [Item Codes](#).
8. By default, all of the six edges of the element are considered straight unless, any of G5 through G10 are specified.
9. The internal coordinate system of the element is used internally and is based on eigenvalue techniques to insure non bias in the element formulation. For stress/strain output this internal coordinate system (CORDM=-1 on PSOLID entry) is hard to visualize. Thus a CORDM=-2 on the PSOLID is available as shown in [Figure 9-71](#).

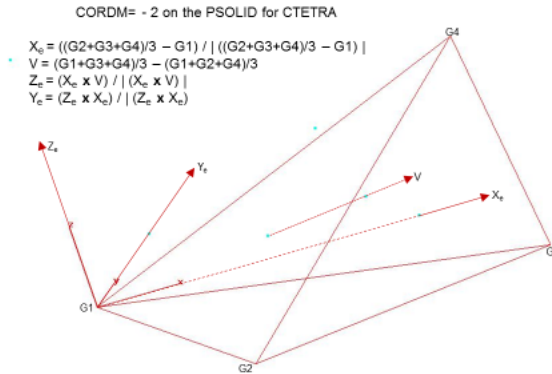

Figure 9-71 PSOLID on CTETRA

## CTRIA3      Triangular Plate Element Connection

Defines an isoparametric membrane-bending or plane strain triangular plate element.

Format:

1	2	3	4	5	6	7	8	9	10
CTRIA3	EID	PID	G1	G2	G3	THETA or MCID	ZOFFS		
		TFLAG	T1	T2	T3				

Example:

CTRIA3	111	203	31	74	75	3.0	0.98		
			1.77	2.04	2.09				

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PSHELL, PCOMP, PCOMPG or PLPLANE entry. (Integer > 0; Default = EID)
Gi	Grid point identification numbers of connection points. (Integers > 0, all unique)
THETA	Material property orientation angle in degrees. THETA is ignored for hyperelastic elements. (Real; Default = 0.0)
MCID	Material coordinate system identification number. The x-axis of the material coordinate system is determined by projecting the T1-axis of the MCID coordinate system onto the surface of the shell element as follows:  CORD1R,    x -axis of MCID the coordinate is projected onto shell surface and the CORD2R    material angle is measured from the G1-G2 line to the to the projected x-axis  CORD1C,    r-axis of MCID the coordinate is projected onto shell surface through CORD2C    the element center and the material angle is measured from the G1-G2 CORD1S,    line to the to the projected r-axis CORD2S
	Use DIAG 38 to print the computed THETA values. MCID is ignored for hyperelastic elements. For SOL 600, only CORD2R is allowed. (Integer ≥ 0; if blank, then THETA = 0.0 is assumed.)

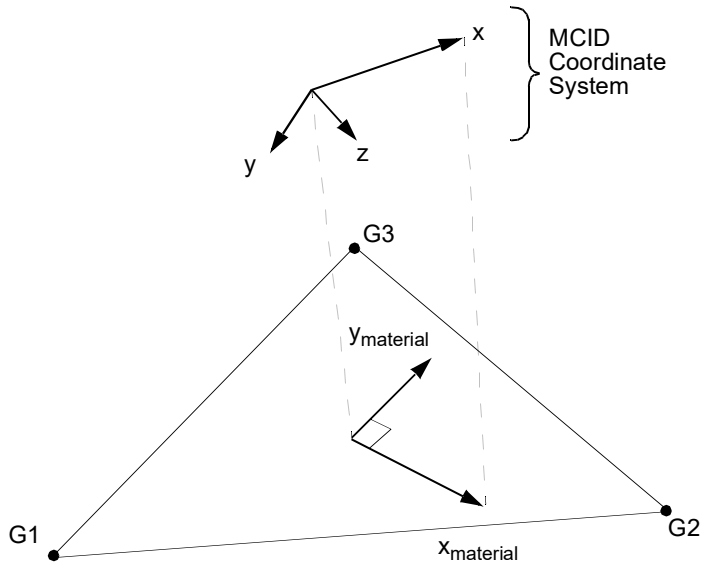

Figure 9-72 MCID Coordinate System Definition

ZOFFS	Offset from the surface of grid points to the element reference plane. See Remark 3. ZOFFS is ignored for hyperelastic elements. (Real)
TFLAG	An integer flag, signifying the meaning of the $T_i$ values. (Integer 0, 1, or blank)
$T_i$	Membrane thickness of element at grid points G1 through G3. If “TFLAG” zero or blank, then $T_i$ are actual user specified thickness. (Real $\geq 0.0$ or blank, not all zero. See Remark 4. for default.) If “TFLAG” one, then the $T_i$ are fraction relative to the T value of the PSHELL. (Real $> 0.0$ or blank; not all zero. Default = 1.0) $T_i$ are ignored for hyperelastic elements.

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. The continuation is optional. If it is not supplied, then T1 through T3 will be set equal to the value of T on the PSHELL entry.
3. Elements may be offset from the connection points by means of the ZOFFS field. Other data, such as material matrices and stress fiber locations, are given relative to the reference plane. A positive value of ZOFFS implies that the element reference plane is offset a distance of ZOFFS along the positive Z-axis of the element coordinate system. If the ZOFFS field is used, then both the MID1 and MID2 fields must be specified on the PSHELL entry referenced by PID.

Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.

For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, it is **highly recommended** to use MDLPRM, OFFDEF, LROFF. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by **MDLPRM, OFFDEF, NOMASS**.

For SOLs 106, 129, 153, and 159 the differential stiffness for offset vectors will give incorrect results with PARAM, LGDISP, 1. In addition in SOLs 106 and 129 offset vectors will produce incorrect results with thermal loading.

Figure 9-73 CTRIA3 Element Geometry and Coordinate Systems

4. The reference coordinate system for the output of stress, strain and element force depends on the element type.
  - For CTRIA3 elements, which are not hyperelastic, the reference coordinate system for output is the element coordinate system.
  - For hyperelastic elements the stress and strain are output according to CID on the PLPLANE entry.
5. For hyperelastic elements, the plot codes are specified under the CTRIAFD element name in [Item Codes](#).
6. SYSTEM(218), alias T3SKEW, allows the user to control the minimum vertex angle for TRIA3 elements at which USER WARNING MESSAGE 5491 is issued. The default value is 10. degrees.
7. By default, all of the three edges of the element are considered straight.
8. For RC network solver in thermal analysis, the ZOFFS is ignored.
9. In SOL 600, when PCOMP is used, one must define the material property with orientation, MCID>0.

## CTRIA6 Curved Triangular Shell Element Connection

Defines a curved triangular shell element or plane strain with six grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CTRIA6	EID	PID	G1	G2	G3	G4	G5	G6	
	THETA or MCID	ZOFFS	T1	T2	T3	TFLAG			

Example:

CTRIA6	302	3	31	33	71	32	51	52	
	45	.03	.020	.025	.025				

Describer	Meaning
EID	Element Identification number. (0 < Integer < 100,000,000)
PID	Property identification number of PSHELL, PCOMP, PCOMPG or PLPLANE entry. (Integer > 0)
G1, G2, G3	Identification numbers of connected corner grid points. (Unique Integers > 0)
G4, G5, G6	Identification number of connected edge grid points. Optional data for any or all three points for Nastran conventional element only. (Integer > 0 or blank) Note that for advanced nonlinear elements, partial specification of mid-points is not allowed. i.e. either none of the mid-points should be specified or all of the mid points should be specified.
THETA	Material property orientation angle in degrees. THETA is ignored for hyperelastic elements. (Real; Default = 0.0)
MCID	Material coordinate system identification number. The x-axis of the material coordinate system is determined by projecting the T1-axis of the MCID coordinate system onto the surface of the shell element as follows:  CORD1R, x -axis of MCID the coordinate is projected onto shell surface and the CORD2R material angle is measured from the G1-G2 line to the to the projected x-axis  CORD1C, r-axis of MCID the coordinate is projected onto shell surface through the CORD2C element center and the material angle is measured from the G1-G2 line CORD1S, to the to the projected r-axis CORD2S  MCID is ignored for hyperelastic elements. For SOL 600, only CORD2R is allowed. (Integer ≥ 0; if blank, then THETA = 0.0 is assumed)

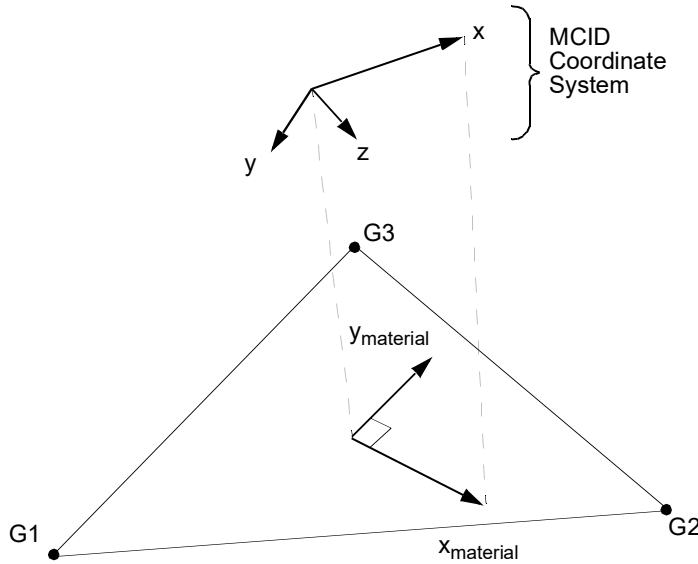

Figure 9-74 MCID Coordinate System Definition

ZOFFS	Offset from the surface of grid points to the element reference plane; see Remark 6. ZOFFS is ignored for hyperelastic elements. (Real)
Ti	Membrane thickness of element at grid points G1 through G4. If “TFLAG” zero or blank, then Ti are actual user specified thickness. (Real $\geq 0.0$ or blank, not all zero. See Remark 4. for default.) If “TFLAG” one, then the Ti are fraction relative to the T value of the PSHELL. (Real $> 0.0$ or blank, not all zero. Default = 1.0) Ti are ignored for hyperelastic elements.
TFLAG	An integer flag, signifying the meaning of the Ti values. (Integer 0, 1, or blank)

Remarks:

1. Element identification numbers should be unique with respect to all other element IDs.
2. Grid points G1 through G6 must be numbered as shown in [Figure 9-75](#).
3. The orientation of the material property coordinate system is defined locally at each interior integration point by THETA, which is the angle between  $x_{material}$  and the line of constant  $\eta$ .
4. T1, T2, and T3 are optional. If they are not supplied and no TFLAG, then T1 through T3 will be set equal to the value of T on the PSHELL entry.
5. It is recommended that the midside grid points be located within the middle third of the edge.

6. Elements may be offset from the connection points by means of the ZOFFS field. Other data, such as material matrices and stress fiber locations, are given relative to the reference plane. A positive value of ZOFFS implies that the element reference plane is offset a distance of ZOFFS along the positive z-axis of the element coordinate system. If the ZOFFS field is used, then both the MID1 and MID2 fields must be specified on the PSHELL entry referenced by PID.

Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.

For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, it is **highly recommended** to use MDLPRM, OFFDEF, LROFF. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by **MDLPRM, OFFDEF, NOMASS**.

7. If all midside grid points are deleted, then the element will be excessively stiff and the transverse shear forces will be incorrect. A User Warning Message is printed. A CTRIA3 element entry is recommended instead. If the element is hyperelastic, then the element is processed identically to the hyperelastic CTRIA3 element.
8. For a description of the element coordinate system, see [Shell Elements \(CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, CQUADR\)](#) in the *MSC Nastran Reference Guide*. Stresses and strains are output in the local coordinate system identified by  $x_l$  and  $y_l$  in [Figure 9-75](#). For hyperelastic elements, stresses and strains are output in the coordinate system defined by the CID field on the PLPLANE entry.

Figure 9-75 CTRIA6 Element Geometry and Coordinate Systems

9. For hyperelastic elements, the plot codes are specified under the CTRIAFD element name in [Item Codes, 1045](#).
10. For RC network solver in thermal analysis, the ZOFFS is ignored.
11. In SOL 600, when PCOMP is used, one must define the material property with orientation, MCID>0.

## CTRIAR Triangular Plate Element Connection

Defines an isoparametric membrane-bending triangular plate element. This element has a normal rotational (drilling) degrees-of-freedom. It is a companion to the CQUADR element.

Format:

1	2	3	4	5	6	7	8	9	10
CTRIAR	EID	PID	G1	G2	G3	THETA or MCID	ZOFFS		
		TFLAG	T1	T2	T3				

Example:

CTRIAR	111	203	31	74	75	3.0			
			1.77	2.04	2.09				

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PSHELL, PCOMP or PCOMPG entry. (Integer > 0; Default = EID)
G1, G2, G3	Grid point identification numbers of connection points. (Integers > 0; all unique)
THETA	Material property orientation angle in degrees. (Real; Default = 0.0)
MCID	Material coordinate system identification number. The x-axis of the material coordinate system is determined by projecting the T1-axis of the MCID coordinate system onto the surface of the shell element as follows:  CORD1R, x -axis of MCID the coordinate is projected onto shell surface and the CORD2R material angle is measured from the G1-G2 line to the to the projected x-axis  CORD1C, r-axis of MCID the coordinate is projected onto shell surface through the CORD2C element center and the material angle is measured from the G1-G2 line to CORD1S, the to the projected r-axis CORD2S
	Use DIAG 38 to print the computed THETA values. For SOL 600, only CORD2R is allowed. (Integer ≥ 0; if blank, then THETA = 0.0 is assumed)
ZOFFS	Offset from the surface of grid points to the element reference plane. See Remark 5.

Figure 9-76 MCID Coordinate System Definition

TFLAG	An integer flag, signifying the meaning of the $T_i$ values. (Integer 0, 1, or blank)
$T_i$	Membrane thickness of element at grid points G1 through G4. If “TFLAG” zero or blank, then $T_i$ are actual user specified thickness. (Real $\geq 0.0$ or blank, not all zero. See Remark 4. for default.) If “TFLAG” one, then the $T_i$ are fraction relative to the T value of the PSHELL. (Real $> 0.0$ or blank, not all zero. Default = 1.0) $T_i$ are ignored for hyperelastic elements.

#### Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. The continuation is optional. If it is not supplied, then T1 through T3 will be set equal to the value of T on the PSHELL entry.
3. Stresses are output in the element coordinate system at the centroid and grid points G1 through G3.
4. Inaccurate results will be obtained if interior grids have the rotation normal (drilling) to the element constrained. At the boundary of a model, the drilling degrees-of-freedom must be constrained if the user wants a fixed boundary. Also, for this element it is critical that consistent membrane (in plane) edge loads be applied. Reference the [PLOAD4](#) entry (SORL option) and the [Consistent Surface and Edge Loads](#) in the *MSC Nastran Reference Guide* for additional information.

Figure 9-77 CTRIAR Element Geometry and Coordinate Systems

5. Elements may be offset from the connection points by means of the ZOFFS field. Other data, such as material matrices and stress fiber locations, are given relative to the reference plane. A positive value of ZOFFS implies that the element reference plane is offset a distance of ZOFFS along the positive Z-axis of the element coordinate system. If the ZOFFS field is used, then both the MID1 and MID2 fields must be specified on the PSHELL entry referenced by PID.

Two methods are available for the computation of offsets: original and enhanced. The default method is the original method. The enhanced method is requested by the Bulk Data entry MDLPRM,OFFDEF,LROFF. For options of offsets, please refer to the Bulk Data entry MDLPRM,OFFDEF,option.

For solution sequences that require differential stiffness such as SOL103 (with preloading), SOL105, and SOL400, **it is highly recommended** to use MDLPRM, OFFDEF, LROFF. In SOL103, if the case control ADAMSMNF FLEXBODY=YES or AVLEXB EXBBODY=YES is present, then MDLPRM, OFFDEF, LROFF must be replaced by **MDLPRM, OFFDEF, NOMASS**.

For SOLs 106, 129, 153, and 159 the differential stiffness for offset vectors will give incorrect results with PARAM, LGDISP, 1. In addition in SOLs 106 and 129 offset vectors will produce incorrect results with thermal loading.

6. In SOL 600, when PCOMP is used, one must define the material property with orientation, MCID>0.

## CTRIAX Axisymmetric Triangular Element (Fully Nonlinear or Linear Harmonic)

Defines an axisymmetric triangular element with up to six grid points for use in fully nonlinear (i.e., large strain and large rotations) hyperelastic analysis or a linear harmonic or rotordynamic analysis. The element has between three and six grid points.

### Format:

1	2	3	4	5	6	7	8	9	10
CTRIAX	EID	PID	G1	G2	G3	G4	G5	G6	
	THETA or MCID								

### Example:

CTRIAX	111	203	31	74	75				
--------	-----	-----	----	----	----	--	--	--	--

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000) See Remark 1.
PID	Property identification number of a PLPLANE or PAXSYMH entry. (Integer > 0). See Remark 2.
G1, G2, G3	Identification numbers of connected corner grid points. Required data for all three grid points. (Unique Integers > 0). See Remark 3., 6., 7.
G4, G5, G6	Identification numbers of connected edge grid points. Optional data for any or all four grid points for Nastran conventional element only. (Integer > 0 or blank). See Remark 3., 4., 6., 7. Note that for advanced nonlinear elements, partial specification of mid-points is not allowed. i.e. either none of the mid-points should be specified or all of the mid points should be specified
THETA	Material property orientation angle in degrees. THETA is only applicable if the PLPLANE entry has an associated PSHLN2 entry which is honored only in SOL 400. For PSHLN2 BEHi=AXSOLID code, THETA is measured relative to the R axis of the element. (Real; Default = 0.0)
MCID	Material coordinate system identification number, MCID is only applicable if the PLPLANE entry has an associated PSHLN2 entry which is honored only in SOL 400. The x-axis of the material coordinate system is determined by projecting the x-axis of the MCID coordinate system onto the surface of the element. The resulting angle is measured relative to the R axis of the element. For PSHLN2 BEHi=AXSOLID code, THETA is measured relative to the R axis of the element. (Integer ≥ 0; if blank, then THETA = 0.0 is assumed.) THETA is ignored if PID refers to a PAXSYMH entry.

### Remarks:

1. Element identification numbers must be unique with respect to all other element IDs of any kind.

2. If PID refers to a PLPLANE entry, CTRIAX defines an element for use in fully nonlinear analysis. If PID refers to a PAXSYMH entry, CTRIAX defines a linear harmonic element for use in rotordynamic or harmonic analysis.
3. Gi must be numbered as shown in [Figure 9-78](#).
4. It is recommended that the edge points be located within the middle third of the edge.
5. The plot codes are specified under the CTRIAXFD element name in [Item Codes](#).
6. The grid points of the axisymmetric element must lie on the x-y plane of the basic coordinate system. Stress and strain are output in the basic coordinate system.
7. A concentrated load (e.g., FORCE entry) at Gi is divided by the radius to Gi and then applied as a force per unit circumferential length. For example, in order to apply a load of 100 N/m on the circumference at G1, which is located at a radius of 0.5 m, then the magnitude specified on the static load entry must result in:

$$(100 \text{ N/m}) \cdot (0.5 \text{ m}) = 50 \text{ N}$$

Figure 9-78 CTRIAX Element Coordinate System

## CTRIAX6

## Axisymmetric Triangular Element Connection

Defines an isoparametric and axisymmetric triangular cross section ring element with midside grid points.

Format:

1	2	3	4	5	6	7	8	9	10
CTRIAX6	EID	MID	G1	G2	G3	G4	G5	G6	
	TH								

Example:

CTRIAX6	22	999	10	11	12	21	22	32	
	9.0								

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
MID	Material identification number. (Integer > 0)
Gi	Grid point identification numbers of connected points (unique Integers > 0, or blank for deleted nodes.)
TH	Material property orientation angle in degrees. (Real; Default = 0.0)

Remarks:

1. The grid points must lie in the x-z plane of the basic coordinate system, with  $x = r \geq 0$ . The grid points must be listed consecutively beginning at a vertex and proceeding around the perimeter in either direction. Corner grid points G1, G3, and G5 must be present. Any or all edge grid points G2, G4, or G6 may be deleted for Nastran conventional element. Note that the alternate corner-edge grid point pattern is different from the convention used on the CTRIA6 element. Note that for advanced nonlinear elements, partial specification of mid-points is not allowed. i.e. either none of the mid-points should be specified or all of the mid points should be specified.
2. For structural problems, the MID may refer to a MAT1 or MAT3 entry.
3. The continuation is optional.
4. Material properties (if defined on a MAT3 entry) and stresses are given in the  $(r_m, z_m)$  coordinate system shown in [Figure 9-80](#).
5. A concentrated load (e.g., FORCE entry) at Gi is multiplied by  $2\pi$  times the radius to Gi and then applied as a force per unit circumferential length. (which is located at a radius of 0.5 m), the magnitude of the load specified on the static load entry must result in:

$$(100 \text{ N/m}) \cdot 2\pi \cdot (0.5 \text{ m}) = 314.159 \text{ N}$$

Figure 9-79 CTRIAX6 Element Idealization

Figure 9-80 CTRIAX6 Element Geometry and Coordinate Systems

6. For thermal problems, the MID may refer to a MAT4 or MAT5 entry. In order to model the convection or radiation along the edges the CHBDYG with TYPE=REV must be used.
7. To model axi-symmetric view factor computations using the CTRIAX6 elements, the normal direction for the CTRIAX6 element must point in the negative Y direction. The reason for this is to set up PATRAN for the correct nodal specification on the CHBDYG with REV option

Figure 9-81 Normal Vectors That Point in a Negative Y Direction.

Figure 9-82 View Factor Boundary Conditions.

```
$ CHBDYG Surface Elements
CHBDYG 100001          REV    1          1
        7            9          8
CHBDYG 100002          REV    2          2
        12           10         11
```

Please note that on the CHBDYG, REV option, the nodal connectivity specification is in the clockwise fashion. In this case the CHBDYG with element ID of 100001 is defined by grids 7,9,8 which means the normal vector of the edge is pointing towards right. On the other hand the edges define by grid 12,10,11 means the normal vector of the edge is pointing towards left. If you have not reverse the element direction to a negative Y direction on the CTRIAX6 element, the view factor computation will result a net view factor of zero.

## CTUBE Tube Element Connection

Defines a tension-compression-torsion tube element.

Format:

1	2	3	4	5	6	7	8	9	10
CTUBE	EID	PID	G1	G2					

Example:

CTUBE	12	13	21	23					
-------	----	----	----	----	--	--	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PTUBE entry. (Integer > 0; Default = EID)
G1, G2	Grid point identification numbers of connection points. (Integer > 0; G1 ≠ G2)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Only one tube element may be defined on a single entry.

## CVISC Viscous Damper Connection

Defines a viscous damper element.

Format:

1	2	3	4	5	6	7	8	9	10
CVISC	EID	PID	G1	G2					

Example:

CVISC	21	6327	29	31					
-------	----	------	----	----	--	--	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PVISC entry. (Integer > 0; Default = EID)
G1, G2	Grid point identification numbers of connection points. (Integer > 0; G1 ≠ G2)

Remarks:

1. Element identification numbers should be unique with respect to all other element identification numbers.
2. Only one viscous damper element may be defined on a single entry.
3. Grids G1 and G2 must not be coincident. If coincident grids are required, use either the CDAMP or CBUSH entry.

## CWELD

### Weld or Fastener Element Connection

Defines a weld or fastener connecting two surface patches or points. Large displacement and large rotational effects are supported when using SOL 600 and SOL 400 only.

Format PARTPAT:

1	2	3	4	5	6	7	8	9	10
CWELD	EWID	PWID	GS	"PARTPAT"	GA	GB		MCID	
	PIDA	PIDB							
	XS	YS	ZS						

Example:

CWELD	101	8	203	PARTPAT					
	21	33							

Alternate formats and examples:

Format ELPAT:

CWELD	EWID	PWID	GS	"ELPAT"	GA	GB		MCID	
	SHIDA	SHIDB							
	XS	YS	ZS						

Example:

CWELD	103	5	403	ELPAT					
	309	511							

Format ELEMID:

CWELD	EWID	PWID	GS	"ELEMID"	GA	GB		MCID	
	SHIDA	SHIDB							

Example:

CWELD	103	5	403	ELEMID					
	309	511							

Format GRIDID:

CWELD	EWID	PWID	GS	"GRIDID"	GA	GB	SPTYP	MCID	
	GA1	GA2	GA3	GA4	GA5	GA6	GA7	GA8	
	GB1	GB2	GB3	GB4	GB5	GB6	GB7	GB8	

Example:

CWELD	7	29	233	GRIDID			QT		
	15	28	31	35	46	51	55	60	
	3	5	8						

Format ALIGN:

CWELD	EWID	PWID		"ALIGN"	GA	GB		MCID	
-------	------	------	--	---------	----	----	--	------	--

Example:

CWELD	7	29		ALIGN	103	259			
-------	---	----	--	-------	-----	-----	--	--	--

Describer	Meaning	Type	Default
EWID	CWELD element identification number. See Remark 1.	0 < Integer < 100,000,000	Required
PWID	Property identification number of a PWELD entry.	Integer > 0	Required
GS	Identification number of a grid point which defines the location of the connector. See Remarks 2. and 3.	Integer > 0 or blank	

Describer	Meaning	Type	Default
“PARTPAT”	Character string indicating the type of connection. The format of the subsequent entries depends on the type. “PARTPAT”, for example, indicates that the connectivity of surface patch A to surface patch B is defined with two property identification numbers of PSHELL entries, PIDA and PIDB, respectively. The “PARTPAT” format connects up to 3x3 elements per patch. See Remark 4.	Character	Required
GA, GB	Grid point identification numbers of piercing points on surface A and surface B, respectively. See Remark 5.	Integer > 0 or blank	blank
MCID	Specifies the element stiffness coordinate system. See Remark 16.	Integer $\geq$ -1 or blank	Default = -1
PIDA, PIDB	Property identification numbers of PSHELL entries defining surface A and B respectively.	Integer > 0	Required for “PARTPAT”
XS, YS, ZS	Coordinates of spot weld location in basic. See Remark 2.	Real	Required if GS and GA are not defined.

For the alternate formats, the describer meaning are described below:

Describer	Meaning	Type	Default
“ELPAT”	Character string indicating that the connectivity of surface patch A to surface patch B is defined with two shell element identification numbers, SHIDA and SHIDB, respectively. The “ELPAT” format connects up to 3x3 elements per patch. See Remark 6.	Character	Required
SHIDA, SHIDB	Shell element identification numbers of elements on patch A and B, respectively.	Integer > 0	Required for “ELPAT”
“ELEMID”	Character string indicating that the connectivity of surface patch A to surface patch B is defined with two shell element identification numbers, SHIDA and SHIDB, respectively. The “ELEMID” format connects one shell element per patch. See Remark 7.	Character	Required
SHIDA, SHIDB	Shell element identification numbers of elements on patch A and B, respectively.	Integer > 0	Required for “ELEMID”

Describer	Meaning	Type	Default
“GRIDID”	Character string indicating that the connectivity of surface patch A to surface patch B is defined with two sequences of grid point identification numbers, $GA_i$ and $GB_i$ , respectively. The “GRIDID” format connects the surface of any element. See Remark 8.	Character	Required
SPTYP	Character string indicating types of surface patches A and B. SPTYP = “QQ”, “TT”, “QT”, “TQ”, “Q” or “T”. See Remark 9.	Character	Required for “GRIDID”
$GA_i$	Grid identification numbers of surface patch A. $GA_1$ to $GA_3$ are required. See Remark 10.	Integer > 0	Required for “GRIDID”
$GB_i$	Grid identification numbers of surface patch B. See Remark 10.	Integer > 0	
“ALIGN”	Character string indicating that the connectivity of surface A to surface B is defined with two shell vertex grid points $GA$ and $GB$ , respectively. See Remark 11.	Character	Required
$GA$ , $GB$	Vertex grid identification number of shell A and B, respectively.	Integer > 0	Required for “ALIGN”

#### Remarks:

1. CWELD defines a flexible connection between two surface patches, between a point and a surface patch, or between two shell vertex grid points. See Figure 9-83 through Figure 9-87.
2. Grid point  $GS$  defines the approximate location of the connector in space.  $GS$  is projected on surface patch A and on surface patch B. The resulting piercing points  $GA$  and  $GB$  define the axis of the connector.  $GS$  must have a normal projection on surface patch A and B.  $GS$  does not have to lie on the surface patches.  $GS$  is ignored for format “ALIGN”.  $GA$  is used instead of  $GS$  if  $GS$  is not specified. For the formats “ELPAT” and “PARTPAT,” if  $GS$  and  $GA$  are not specified, then  $XS$ ,  $YS$ , and  $ZS$  will be assumed.
3. The connectivity between grid points on surface patch A and grid points on surface patch B is generated depending on the location of  $GS$  and the cross sectional area of the connector. Diagnostic print outs, checkout runs and non default settings of search and projection parameters are requested on the SWLDPRM Bulk Data entry. It is recommended to start with the default settings.
4. The format “PARTPAT” defines a connection of two shell element patches A and B with PSHELL property identification numbers  $PIDA$  and  $PIDB$ , respectively. The two property identification numbers must be different, see Figure 9-83. The number of connected elements depends on the location of the piercing points  $GA$ ,  $GB$  and the size of the diameter  $D$ . The diameter  $D$  is defined on the PWELD property entry. For this option, shell element patches A and B are allowed to share a common grid.

Figure 9-83 Patch to Patch Connection Defined with the Formats PARTPAT or ELPAT

5. The definition of the piercing grid points GA and GB is optional for all formats with the exception of the format “ALIGN”. If GA and GB are given, GS is ignored. If GA and GB are not specified, they are generated from the normal projection of GS on surface patches A and B and internal identification numbers are generated for GA and GB starting with 101e+6 by default. The offset number can be changed with PARAM,OSWPPT. If GA and GB are specified, they must lie on or at least have a projection on surface patches A and B, respectively. By default, the locations of user specified GA and GB will not be changed. If the user specifies “SWLDPRM, MOVGAB, 1,” then the locations will be corrected so that they lie on surface patches A and B within machine precision accuracy. The length of the connector is the distance of grid point GA to GB, subject to being adjusted to the effective length defined in PWELD entry.
6. The format “ELPAT” defines a connection of two shell element patches A and B with shell element identification numbers SHIDA and SHIDB, see [Figure 9-83](#). The connectivity is similar to the format “PARTPAT”. The number of connected elements depends on the location of the piercing points GA, GB and the size of the diameter D. For this option, shell element patches A and B are allowed to share a common grid.
7. The format “ELEMID” defines a connection of two shell element patches A and B with shell element identification numbers SHIDA and SHIDB, see [Figure 9-84](#). The connectivity is restricted to a single element per patch regardless of the location of GA, GB and regardless of the size of the diameter of the connector. In addition, the format “ELEMID” can define a point to patch connection if SHIDB is left blank, see [Figure 9-85](#). Then grid GS is connected to shell SHIDA.

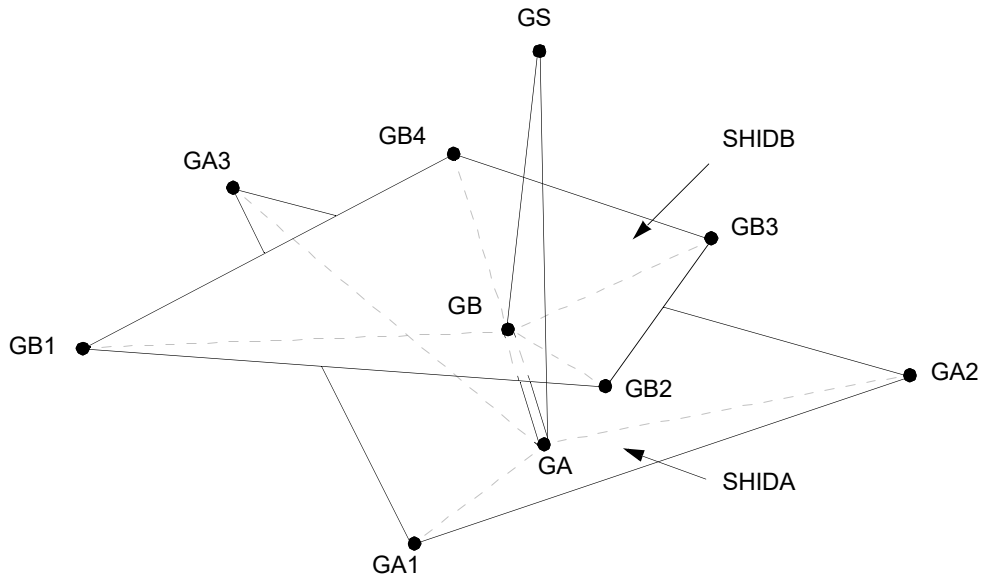

Figure 9-84 Patch to Patch Connection Defined with Format ELEMID or GRIDID

Figure 9-85 Point to Patch Connection Defined with Format ELEMID or GRID.

8. The format “GRIDID” defines a connection of two surface patches A and B with a sequence of grid points  $GA_i$  and  $GB_i$ , see [Figure 9-84](#). In addition, the format “GRIDID” can define a point to patch connection if all  $GB_i$  fields are left blank, see [Figure 9-85](#). Then grid GS is connected to grids  $GA_i$ . The grids  $GA_i$  and  $GB_i$  do not have to belong to shell elements.
9. SPTYP defines the type of surface patches to be connected. SPTYP is required for the format “GRIDID” to identify quadrilateral or triangular patches. The combinations are:

SPTYP	Description
QQ	Connects a quadrilateral surface patch A (Q4 to Q8) with a quadrilateral surface patch B (Q4 to Q8).
QT	Connects a quadrilateral surface patch A (Q4 to Q8) with a triangular surface patch B (T3 to T6).
TT	Connects a triangular surface patch A (T3 to T6) with a triangular surface patch B (T3 to T6).
TQ	Connects a triangular surface patch A (T3 to T6) with a quadrilateral surface patch B (Q4 to Q8).
Q	Connects the shell vertex grid GS with a quadrilateral surface patch A (Q4 to Q8) if surface patch B is not specified.
T	Connects the shell vertex grid GS with a triangular surface patch A (T3 to T6) if surface patch B is not specified.

10. GAI are required for the format “GRIDID”. At least 3 and at most 8 grid IDs may be specified for GAI and GBi, respectively. The rules of the triangular and quadrilateral elements apply for the order of GAI and GBi, see [Figure 9-86](#). Missing midside nodes are allowed.

Figure 9-86 Quadrilateral and Triangular Surface Patches defined with Format GRIDID

11. The format “ALIGN” defines a point to point connection, see [Figure 9-87](#). GA and GB are required, they must be existing vertex nodes of shell elements. For the other formats, GA and GB are not required. Two shell normals in the direction GA-GB are generated at GA and GB, respectively.

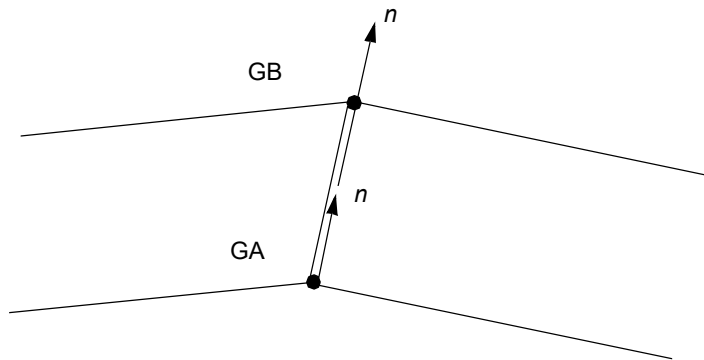

Figure 9-87 Point to Point Connection Defined with Format ALIGN

12. Forces and moments are output in the element coordinate system, see [Figure 9-88](#). The element coordinate system is constructed using the following rules:

The element x-axis points from GA to GB.

$$e_1 = \frac{x_B - x_A}{\|x_B - x_A\|} \quad \text{element x-axis}$$

In case of zero length, the normal of shell A is taken. All vector components are in basic if not noted otherwise.

Find the smallest component  $j$  of  $e_1$

$$ce_1^i = |e_1^i|$$

$$ce_1^j = \min_{i = 1, 2, 3} \left\{ ce_1^i \right\}.$$

Note that  $ce_1^i$  will be set to  $10^{-6}$  if  $ce_1^i < 10^{-6}$ .

In case of two equal components we take the one with the smaller  $i$ . The corresponding basic vector

$$b_j, \text{ e.g., for } j = 3, b_3 = \begin{Bmatrix} 0 \\ 0 \\ 1 \end{Bmatrix}$$

provides a good directional choice for  $e_2$ . In addition, the vector  $e_2$  must be orthogonal to  $e_1$ .

$$\tilde{e}_2 = b_j - \frac{e_1^T b_j}{e_1^T e_1} e_1 \quad e_2 = \frac{\tilde{e}_2}{\|\tilde{e}_2\|} \text{ element y-axis}$$

and  $e_3$  is just the cross product

$$e_3 = e_1 \times e_2 \quad \text{element z-axis}$$

The final transformation matrix is

$$T_{be} = \begin{bmatrix} e_1 & e_2 & e_3 \end{bmatrix}$$

Figure 9-88 Element Coordinate System and Sign Convention of Element Forces

13. If "PARAM, OLDWELD, YES", in a SOL 400 analysis the CWELD element using method ELEMID, GRIDID, ELPAT or PARTPAT internally gets decomposed in a CBEAM element and a number of RBE3 elements. For method ALIGN the CWELD element internally gets replaced by a CBEAM element. The CBEAM element obtains a circular cross section with its diameter and material properties taken from the PWELD input and its length is determined by the final locations of the GA and GB grids of the CWELD. The RBE3 elements connect the GA and GB grids to the plate structures. For methods ELEMID and GRIDID one RBE3 element is used on each side to establish the connection. For methods ELPAT and PARTPAT five RBE3 elements are used on each side to establish the connection.
14. The output format of the forces and moments including the sign convention is identical to the CBAR element, see [Element Force Item Codes](#).
15. This entry is not supported in SOL 700.
16. MCID = -1 or blank (Default), then the coordinate system is as defined in Remark 12.

If MCID ≥ 0, then a “beam” like coordinate system is defined. The  $x_{elem}$  axis direction of the connector defined as

$$\vec{e}_1 = \frac{\vec{x}_B - \vec{x}_A}{\|\vec{x}_B - \vec{x}_A\|}$$

The T2 direction defined by MCID will be used to define the orientation vector  $\vec{V}$  of the connector. Then the  $z_{elem}$  element axis will be defined as

$$\vec{e}_3 = \frac{\vec{e}_1 \times \vec{v}}{\|\vec{e}_1 \times \vec{v}\|}$$

The element  $y_{elem}$  axis is defined as

$$\vec{e}_2 = \vec{e}_3 \times \vec{e}_1$$

17. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
18. In SOL400, the behavior of this element in regard to large rotation is affected by the Case Control Command Rigid.
19. If partitioned superelements are present, then CWELD is supported in the main Bulk Data section only.

**CYAX**      Grid Points on Axis of Symmetry

Lists grid points that lie on the axis of symmetry in cyclic symmetry analysis.

Format:

1	2	3	4	5	6	7	8	9	10
CYAX	G1	G2	G3	G4	G5	G6	G7	G8	
	G9	G10	-etc.-						

Example:

CYAX	27	152	THRU	160	192	11			
------	----	-----	------	-----	-----	----	--	--	--

Describer	Meaning
Gi	A list of grid points on the axis of symmetry. (Integer > 0 or Character "THRU")

Remarks:

1. The displacement coordinate system (see CD field on GRID entry) for a grid point lying on the axis of symmetry must be a rectangular system with the z-component of motion aligned with the axis of symmetry. The positive axis of symmetry is defined so that the azimuthal angle from positive side 1 to side 2 of a segment is in the same direction as the angle from T1 to T2 for the axis point. This is consistent with left- or right-hand rule.
2. If the dihedral symmetry option (STYPE = "DIH" on the CYSYM entry) is selected, the y-axis must be perpendicular to side 1.
3. Grid points lying on the axis of symmetry may be constrained by SPCs but not by MPCs. If the number of segments is three or more, SPCs must be applied to both components 1 and 2 or to neither, and SPCs must be applied to both components 4 and 5 or to neither in order to satisfy symmetry. In addition, the degrees-of-freedom (not constrained by SPCs, if any) at these grid points must be in the analysis set (a-set). If all degrees-of-freedom of grid points on the axis of symmetry are constrained by SPCs (including heat transfer, where there is only one degree-of-freedom), the grid point should not be listed on the CYAX entry.
4. Grid points lying on the axis of symmetry must not be defined on side 1 or on side 2 by means of a CYJOIN entry.
5. The word "THRU" must not appear in fields 2 or 9.

## CYJOIN

## Cyclic Symmetry Boundary Points

Defines the boundary points of a segment in cyclic symmetry problems.

Format:

1	2	3	4	5	6	7	8	9	10
CYJOIN	SIDE	C	G1	G2	G3	G4	G5	G6	
	G7	G8	G9	-etc.-					

Example:

CYJOIN	1	T2	7	9	16	THRU	33	64	
	72	THRU	89						

Describer	Meaning
SIDE	Side identification. (Integer 1 or 2)
C	Type of coordinate system used on boundaries of dihedral or axisymmetry problems. See Remark 3. (Character: "T1", "T2", "T3", "R", "C", "S")
Gi	Grid or scalar point identification numbers. (Integer > 0 or Character "THRU")

Remarks:

1. CYJOIN entries are used only for cyclic symmetry problems. The CYSYM entry must be used to specify rotational, dihedral, or axisymmetry.
2. For rotational or axisymmetry problems, there must be one logical entry for SIDE = 1 and one for SIDE = 2. The two lists specify grid points to be connected; therefore, both lists must have the same length.
3. For dihedral problems, side 1 refers to the boundary between segments and side 2 refers to the middle of a segment. For dihedral and/or AXI type of symmetry, the grid point degree-of-freedom that is normal to the boundary must be specified in field 3 as "T1", "T2", or "T3" ("R", rectangular, and "C", cylindrical, are the same as "T2" while "S", spherical, is the same as "T3"). For scalar and extra points with one degree-of-freedom, these should be specified as blank, "T2", or "T3" if they are to have the same sign, and "T1", if the two connected points are to be opposite in sign.
4. All components of displacement at boundary points are connected to adjacent segments except those constrained by SPCi, MPC, or OMITi entries.
5. The points on the axis of symmetry of the model, defined in the CYAX entry must not be defined as a side 1 or side 2 point by means of this entry.
6. The word "THRU" may not appear in fields 4 or 9 of the parent entry and fields 2 or 9 on the continuation entries.
7. All grid points that are implicitly or explicitly referenced must be defined.

8. For rotational and axisymmetry problems, the displacement coordinate systems must be consistent between sides 1 and 2. This is best satisfied by the use of a spherical or cylindrical coordinate system.

**CYLINDR**

## Defines the Shape of a Cylinder

Cylindrical shape used in the initial condition definition on the TICEUL1 entry. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
CYLINDR	VID		XC1	YC1	ZC1	XC2	YC2	ZC2	
	RAD								

Example:

CYLINDR	4		0.	0.	0.	1.	1.	1.	
	.5								

Describer	Meaning
VID	Unique cylinder number. (Integer > 0; Required)
XC1, YC1, ZC1	Coordinates of point 1, See Remark 1. (Real; Required)
XC2, YC2, ZC2	Coordinates of point 2. See Remark 1. (Real; Required)
RAD	Radius of the cylinder. (Real; Required)

Remarks:

1. A cylinder is defined by the two end points of the cylinder axis and a radius.
2. Initial conditions are defined for the elements that are fully or partially inside the cylinder.
3. See also the TICEUL1 Bulk Data entry.

## CYSUP

## Fictitious Supports for Cyclic Symmetry

Defines fictitious supports for cyclic symmetry analysis.

Format:

1	2	3	4	5	6	7	8	9	10
CYSUP	GID	C							

Example:

CYSUP	16	1245							
-------	----	------	--	--	--	--	--	--	--

Describer	Meaning
GID	Grid point identification number. (Integer > 0)
C	Component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks.)

Remarks:

- Components of motion defined on this entry may not appear on SPC, SPC1, OMIT, OMIT1 entries, or in rigid elements or multipoint constraints as dependent degrees-of-freedom.
- Supports are applied at the grid point identified in field 2 to prevent rigid body motions in static analysis, or to define rigid body modes in eigenvalue analysis. All degrees-of-freedom should be at a single grid point. In other words, there can only be one such supported grid point in the model. The supports are applied only to the cyclic components of order  $k=0$  or  $k=1$ . In order to satisfy conditions of symmetry, certain restrictions are placed on the location of the grid point and the orientation of its displacement coordinate system, as shown in the following table:

Symmetry Option (STYPE on the CYSYM entry)	ROT	ROT	DIH	DIH	DIH
Number of Segments, N	2	$\geq 3$	1	2	$\geq 3$
Location of Grid Point	See Note <a href="#">c</a> .	See Note <a href="#">d</a> .	Side 1	Side 1	Side 1
Special Restrictions on Displacement Coordinate System	See Notes <a href="#">a</a> . and <a href="#">e</a> .	See Note <a href="#">b</a> .	None	See Note <a href="#">a</a> .	See Note <a href="#">b</a> .

Notes:

- T3 axis must be parallel to axis of symmetry.
- Displacement coordinate system at the referenced grid point must be cylindrical with z-axis along the axis of symmetry.

- c. Any location except on side 2.
  - d. Any location except on the axis of symmetry or on side 2.
  - e. If the grid point is on the axis of symmetry, the displacement coordinate system must be rectangular.
3. If the number of segments,  $N$ , is 1 (in the case of DIH symmetry) or 2 (in the case of ROT or AXI symmetry), it is important that the rotational components referenced in field 3 be elastically connected to the structure. If  $N \geq 2$  (in the case of DIH symmetry) or  $N \geq 3$  (in the case of ROT or AXI symmetry), it is not important, because in this case the supports for rigid body rotation are actually applied to translational motions.
  4. If  $N \geq 3$ , supports will be applied to both the 1 and 2 (inplane-translational) components, if either is referenced, and to both the 4 and 5 (out-of-plane rotational) components, if either is referenced. If component 6 is supported, component 2 should not appear on OMIT or OMIT1 entries.
  5. The restrictions noted in Remarks 2. and 4. are related to symmetry requirements. For  $N \geq 3$ , symmetry requires that the supports be symmetrical (or antisymmetrical), with respect to any plane passing through the axis of symmetry. For the DIH options,  $N = 1$  and  $N = 2$ , symmetry requires that the supports be symmetrical (or antisymmetrical) with respect to the plane(s) of symmetry. For the ROT option,  $N = 2$ , symmetry requires that a support be either parallel or perpendicular to the axis of symmetry.
  6. GID must be a grid point and not a scalar point.

**CYSYM****Cyclic Symmetry Parameters**

Defines parameters for cyclic symmetry analysis.

Format:

1	2	3	4	5	6	7	8	9	10
CYSYM	NSEG	STYPE							

Example:

CYSYM	6	ROT							
-------	---	-----	--	--	--	--	--	--	--

Describer	Meaning
NSEG	Number of segments. (Integer > 0)
STYPE	Symmetry type. (Character: "ROT", "DIH", or "AXI")

Remarks:

1. STYPE = "AXI" is a special case of STYPE = "ROT" used to model axisymmetric structures.
2. If STYPE = "AXI", then all grid points must lie on side 1, side 2, or the axis. Also, plate elements with midside grid points may not be defined.

## Entries D - E

### DAMPING

### Parameter and Hybrid Damping Specification

Specifies the values for parameter damping and/or selects optional HYBRID damping.

#### Format:

1	2	3	4	5	6	7	8	9	10
DAMPING	ID	G	ALPHA1	ALPHA2	HYBRID	GEFACT	ROTSEP		
	W3	W4	WH						

#### Example:

DAMPING	100	.02					NO		
---------	-----	-----	--	--	--	--	----	--	--

Describer	Meaning
ID	Damping entry identification number. (Integer > 0; no Default)
G	Structural damping coefficient, see Remark 1. (Real; Default = 0.0)
ALPHA1	Scale factor for mass portion of Rayleigh damping, see Remark 4. (Real; Default = 0.0)
ALPHA2	Scale factor for stiffness portion of Rayleigh damping, see Remark 4. (Real; Default = 0.0)
HYBRID	Identification number of HYBDAMP entry for hybrid damping, see Remarks 5. and 6. (Integer $\geq$ 0; Default = 0)
GEFACT	Scale factor for material damping. See Remark 1. and Remark 3. (Real; Default = 1.0)
ROTSEP	Remove rotor stiffness, mass, and structural damping from the hybrid damping calculation (Character: YES or NO; Default=YES)
W3	Average frequency for calculation of structural damping in transient response, see Remark 7. (Real $\geq$ 0.0; Default = 0.0)
W4	Average frequency for calculation of material damping in transient response, see Remark 7. (Real $\geq$ 0.0; Default = 0.0)
WH	Average frequency for calculation of hybrid ‘structural’ damping in transient response, see Remark 7. (Real $\geq$ 0.0; Default = 0.0)

#### Remarks:

1. The DAMPING entry is referenced by the RSDAMP or SEDAMP Case Control commands. If a DAMPING entry is selected in the Case Control, the DAMPING values, including defaults, will override parameter inputs.
2. All damping selections are cumulative.
3. Structural damping specified by the G and GEFACT entries will replace any structural damping by:

$$[K4]_{NEW} = G[K] + GFACT[K4]$$

The GFACT value used is  $GFACT = GE$  (default=0.0) \*  $GEFACT$  (default=1.0) where  $GE$  is the structural damping value on the material entry.

4. Rayleigh viscous damping is calculated as:

$$[B]_{Rayleigh} = \alpha_1[M] + \alpha_2[K]$$

5. Hybrid damping on the residual structure is only active for direct solution sequences. For modal solution sequences, the SDAMP Case Control request should be used.
6. Hybrid damping for superelements uses modes that are calculated using the superelement mass and stiffness matrices before upstream superelements are added and before SPC or MPC constraints are imposed. These matrices are known as the JJ-type matrices.
7. The W3 and W4 values are used in transient response only. A zero value (default) will result in no damping. The equivalent viscous damping is calculated as:

$$[B]_{equiv} = \left(\frac{G}{W3}\right)[K] + \left(\frac{GFACT}{W4}\right)[K4] + \left(\frac{1}{WH}\right)[KH]$$

8. For rotordynamic analyses (RGYRO in the Case Control Section), the DAMPING calculations for the residual structure (RSDAMP) are performed without any rotor contributions (support structure only).
9. Rayleigh damping is designed to be applied only at Superelement, Part Superelement, or External Superelement residual assembly time. It is not applied in individual Parts or External superelements.
10. If Modules are present then this entry may only be specified in the main Bulk Data section.

### Examples:

- Specify a structural damping coefficient of 0.03 for the residual structure for frequency response.  
Case Control:  
RSDAMP=100  
Bulk Data:  
DAMPING, 100, 0.03
- Specify a structural damping coefficient of 0.03 for the residual structure for transient response (use a “natural” frequency of 100 Hz)  
Case Control:  
RSDAMP=100  
Bulk Data:  
DAMPING, 100, 0.03,  
, 628.3
- Specify hybrid damping for superelement 1. Use modal damping of two percent critical for the first 6 modes.

Case Control:

```
SUBCASE 1  
  SUPER=1  
  SEDAMP=100
```

Bulk Data:

```
DAMPING, 100, , , , 101  
HYBDAMP, 101, 102, 1001  
EIGRL, 102, , , 6  
TABDMP1, 1001, CRIT,  
, 0.0, 0.02, 1000.0, 0.02, ENDT
```

**DAREA**

## Load Scale Factor

Defines scale (area) factors for static and dynamic loads. In dynamic analysis, DAREA is used in conjunction with ACSRCE, RLOADi and TLOADi entries.

**Format:**

1	2	3	4	5	6	7	8	9	10
DAREA	SID	P1	C1	A1	P2	C2	A2		

**Example:**

DAREA	3	6	2	8.2	15	1	10.1		
-------	---	---	---	-----	----	---	------	--	--

Describer	Meaning
SID	Identification number. (Integer > 0)
Pi	Grid, extra, or scalar point identification number. (Integer > 0)
Ci	Component number. (Integer 1 through 6 for grid point; blank or 0 for extra or scalar point.)
Ai	Scale (area) factor. (Real)

**Remarks:**

1. One or two scale factors may be defined on a single entry.
2. Refer to RLOAD1, RLOAD2, TLOAD1, TLOAD2, or ACSRCE entries for the formulas that define the scale factor Ai in dynamic analysis.
3. Component numbers refer to the displacement coordinate system.
4. In dynamic analysis, DAREA entries may be used with LSEQ Bulk Data entries if LOADSET is specified in Case Control. The LSEQ and static load entries will be used to internally generate DAREA entries.
5. If DAREA is referenced by a GUST entry, Pi must be defined. However, it is only used if selected through a DLOAD Case Control command. WG from the GUST entry is used instead of Ai when requested via a GUST entry.
6. All DAREA entries corresponding to all grid and scalar points are automatically converted internally by the program to equivalent FORCE/MOMENT/SLOAD entries (as appropriate) *if there are no LSEQ Bulk Data entries.*
7. In superelement analysis, DAREA may be used to specify loads not only on the interior points of the residual, but also on the interior points of upstream superelements *if there are no LSEQ Bulk Data entries.*
8. In static analysis, DAREA entries may be used *only if there are no LSEQ Bulk Data entries.* They are ignored if there are any LSEQ Bulk Data entries.

## DCONADD

## Design Constraint Set Combination

Defines the design constraints for a subcase as a union of DCONSTR entries.

### Format:

1	2	3	4	5	6	7	8	9	10
DCONADD	DCID	DC1	DC2	DC3	DC4	DC5	DC6	DC7	
	DC8	-etc.-							

### Example:

DCONADD	10	4	12						
---------	----	---	----	--	--	--	--	--	--

Describer	Meaning
DCID	Design constraint set identification number. (Integer > 0)
DCi	DCONSTR entry identification number. (Integer > 0)

### Remarks:

1. The DCONADD entry is selected by a DESSUB or DESGLB Case Control command.
2. All DCi must be unique from other DCi.
3. For PART SE, DCi from different PART SEs can be referenced on a single DCONADD and only DCONADD in the main Bulk Data Section, starts with 'BEGIN BULK' or 'BEGIN SUPER=0', will be considered as part of design constraints. Note that DCONADD entries in 'BEGIN SUPER=seid' where seid>0 will be ignored.

## DCONSTR

## Design Constraints

Defines design constraints.

### Format:

1	2	3	4	5	6	7	8	9	10
DCONSTR	DCID	RID	LALLOW/LID	UALLOW/UID	LOWFQ	HIGHFQ			

### Example:

DCONSTR	10	4	1.25						
---------	----	---	------	--	--	--	--	--	--

Describer	Meaning
DCID	Design constraint set identification number. (Integer > 0)
RID	DRESPi entry identification number. (Integer > 0)
LALLOW/LID	Lower bound on the response quantity or the set identification ID of a number of a TABLEDi entry that supplies the lower bound as a function of frequency. (Real; Default = -1.0E20)
UALLOW/UID	Upper bound on the response quantity or the set identification ID of a number of a TABLEDi entry that supplies the upper bound as a function of frequency. (Real; Default = 1.0E20)
LOWFQ	Low end of frequency range in Hertz (Real ≥ 0.0; Default = 0.0). See Remark 8.
HIGHFQ	High end of frequency range in Hertz (Real ≥ LOWFQ; Default = 1.0E+20). See Remark 8.

### Remarks:

1. The DCONSTR entry may be selected in the Case Control Section by the DESSUB or DESGLB command.
2. DCID may be referenced by the DCONADD Bulk Data entry.
3. For a given DCID, the associated RID can be referenced only once.
4. The units of LALLOW and UALLOW must be consistent with the referenced response defined on the DRESPi entry. If RID refers to an "EIGN" response, then the imposed bounds must be expressed in units of eigenvalue, (radian/time)<sup>2</sup>. If RID refers to a "FREQ" response, then the imposed bounds must be expressed in cycles/time.
5. LALLOW and UALLOW are unrelated to the stress limits specified on the MATi entry.
6. Constraints are computed as follows:

$$g = \frac{LALLOW - r}{GNORM} \text{ for lower bound constraints}$$

$$g = \frac{r - UALLOW}{GNORM} \text{ for upper bound constraints}$$

$$GNORM = \begin{cases} |LALLOW| & \text{for lower bounds if } |LALLOW| > GSCAL \\ |UALLOW| & \text{for upper bounds if } |UALLOW| > GSCAL \\ GSCAL & \text{otherwise} \end{cases}$$

GSCAL is specified on the DOPTPRM entry (Default = 0.001)

7. As Remark 6. indicates, small values of UALLOW and LALLOW require special processing and should be avoided. Bounds of exactly zero are particularly troublesome. This can be avoided by using a DRESP2 entry that offsets the constrained response from zero.
8. LOWFQ and HIGHFQ fields are functional only for frequency response RTYPE's, including DYSTIFF or those with a 'AC', 'AF', 'FR' or 'PS' prefix. (FREQ is not a frequency response). The LOWFQ and HIGHFQ fields are also functional when they are applied to a DRESP2 or DRESP3 that inherit the frequency values from these RTYPES. The bounds provided in LALLOW and UALLOW are applicable to a response only when the value of the forcing frequency of the response falls between LOWFQ and HIGHFQ. The behavior varies depending on the value of ATTB on the DRESP1 entry.
  - a. If the field is blank, the LOWFQ/HIGHFQ fields are honored. If the DCONSTR with LOWFQ/HIGHFQ refers to a DRESP2 that invokes a DRESP1 with ATTB blank, the fields are not honored.
  - b. If the field is a character, the LOWFQ/HIGHFQ fields are honored.
  - c. If the field is a real number, the LOWFQ/HIGHFQ fields are honored even when the DCONSTR refers to a DRESP2 that references the DRESP1.
9. LID and UID are optional inputs that identify tabular input to specify the lower and upper bounds as a function of frequency. They are applicable to the 'FR' and 'PSD' responses of Remark 8. and to DRESP2 and DRESP3 responses that inherit the frequency value from these RTYPES.
10. For PART SE, DCONSTR entries can reside in each individual PART SE Bulk Data Section starting with 'BEGIN SUPER=seid'. If DCID is different from a PART SE to the next, DCONADD in the residual (or main Bulk Data Section) can be utilized to group DCONSTR entries together for a single subcase.

**DDVAL** Discrete Design Variable Values

Defines real, discrete design variable values for use in discrete variable optimization, topology optimization or rotordynamics.

**Format:**

1	2	3	4	5	6	7	8	9	10
DDVAL	ID	DVAL1	DVAL2	DVAL3	DVAL4	DVAL5	DVAL6	DVAL7	

**Alternate Format:**

DDVAL	ID	DVAL1	THRU	DVAL2	BY	INC			
-------	----	-------	------	-------	----	-----	--	--	--

The Continuation Entry formats may be used more than once and in any order. They may also be used with either format above.

**Continuation Entry Format 1:**

	DVAL8	DVAL9	DVAL10	DVAL11	-etc.-				
--	-------	-------	--------	--------	--------	--	--	--	--

**Continuation Entry Format 2:**

	DVAL8	THRU	DVAL9	BY	INC				
--	-------	------	-------	----	-----	--	--	--	--

**Example:**

1	2	3	4	5	6	7	8	9	10
DDVAL	110	0.1	0.2	0.3	0.5	0.6	0.4		
	.7	THRU	1.0	BY	0.05				
	1.5	2.0							

Descriptor	Meaning
ID	Unique set identification number (Integer > 0) See Remark 1.
DVALi	Discrete values (Real, or THRU or BY) See Remarks 2. through 5.
INC	Discrete value increment (Real) See Remarks 2., 4., 5.

**Remarks:**

- DDAVAL entries may be referenced by a DESVAR entry in its DDVAL field (field 8), a TOMVAR entry in its DSVID field, a entry in its DDVALID field (field 4) or a RSPINR entry in its SPTID field (field 6).

2. Trailing fields on a DDVAL record can be left blank if the next record is of type DVAL<sub>i</sub> THRU DVAL<sub>j</sub> BY INC. Also fields 7 - 9 must be blank when the type DVAL<sub>i</sub> THRU DVAL<sub>j</sub> BY INC is used in fields 2 - 6 and fields 8 - 9 must be blank when the type DVAL<sub>i</sub> "THRU" DVAL<sub>j</sub> "BY" INC is used in fields 3 - 7 for the first record. Embedded blanks are not permitted in other cases.
3. The DVAL<sub>i</sub> values in a sequence need not be in an ascending or descending order. They can be in any order.
4. If the format DVAL<sub>i</sub> THRU DVAL<sub>j</sub> BY INC is employed, INC must be a positive real value if DVAL<sub>i</sub> < DVAL<sub>j</sub> and INC must be a negative real value if DVAL<sub>i</sub> > DVAL<sub>j</sub>. The program terminates the execution with an appropriate fatal error if this requirement is not satisfied.
5. The format DVAL<sub>i</sub> THRU DVAL<sub>j</sub> BY INC defines a list of discrete values given by DVAL<sub>i</sub>, DVAL<sub>i</sub>+INC, DVAL<sub>i</sub>+2.0\*INC, ..., DVAL<sub>j</sub>. The last discrete value of DVAL<sub>j</sub> is always included, even if the range is not evenly divisible by INC.
6. If Modules are present then this entry may only be specified in the main Bulk Data section.

## DEACTEL

## Elements To Be Deactivated for SOL 400 Analysis

This entry identifies the elements that do not participate in the analysis or do not participate in a particular physics pass of a coupled analysis. SOL 400 for NLSTATIC, and NLTRAN, as well Perturbation analyses only.

### Format:

1	2	3	4	5	6	7	8	9	10
DEACTEL	ID				ISET				

### Example:

DEACTEL	2				200				
---------	---	--	--	--	-----	--	--	--	--

Describer	Meaning
ID	ID of the DEACTEL entry. This is referenced by a DEACTEL=ID Case Control command. (Integer; no Default)
ISET	SID of a list of elements defined by a SET3 entry. (Integer; no Default)

### Remarks:

1. DEACTEL can only be referenced before the first subcase and/or inside the first subcase and/or inside the first step of the first subcase and/or inside each substep of the first step of the first subcase. References that are made anywhere else are currently ignored. It is referenced by the Case Control command DEACTEL=ID.
2. The description field (DES) of the SET3 entry referenced by ISET can only be of type ELEM.
3. Element IDs in the list originating from some set that do not exist are ignored.

## DEACTEL Define Elements that Should be Deactivated for a Particular Subcase in SOL 600

This entry allows the user to deactivate elements that have failed or are no longer necessary in a particular subcase. Some or all of these elements can be re-activated in a subsequent subcase using the ACTIVAT entry.

### Format:

1	2	3	4	5	6	7	8	9	10
DEACTEL	ID	STRESS	STRAIN	IGEOM	ISET				

### Example:

DEACTEL	2	1	1	0	200				
---------	---	---	---	---	-----	--	--	--	--

Describer	Meaning
ID	Identification number of a matching DEACTEL Case Control command defining the subcase to which these elements should be deactivated. (Integer; no Default)
STRESS	Flag to control output stresses after the elements have been deactivated. (Integer; Default = 0) 0 Stresses have the same value as just prior to deactivation 1 Stresses are set to zero
STRAIN	Flag to control output strains after the elements have been deactivated. (Integer; Default = 0) 0 Strains have the same value as just prior to deactivation 1 Strains are set to zero
IGEOM	Flag to control whether to update the geometry on the post file. (Integer; Default = 0) 0 Update the geometry. 1 Do not update the geometry.
ISET	ID of a list of elements described by SET3 is ID=ISET to be deactivated. (Integer; no Default)

### Remarks:

1. This entry maps to Marc's DEACTIVATE (option A) History definition (option B is not supported in SOL 600).

**DEFORM**

## Static Element Deformation

Defines enforced axial deformation for one-dimensional elements for use in statics problems.

**Format:**

1	2	3	4	5	6	7	8	9	10
DEFORM	SID	EID1	D1	EID2	D2	EID3	D3		

**Example:**

DEFORM	1	535	.05	536	-.10				
--------	---	-----	-----	-----	------	--	--	--	--

Describer	Meaning
SID	Deformation set identification number. (Integer > 0)
EIDi	Element number. (Integer > 0)
Di	Deformation. (Real; positive value represents elongation.)

**Remarks:**

1. The referenced element must be one-dimensional (CROD, CONROD, CTUBE, CBAR, CBEAM).
2. Deformation sets must be selected in the Case Control Section with DEFORM = SID.
3. One to three enforced element deformations may be defined on a single entry.
4. The DEFORM entry, when called by the DEFORM Case Control command, is applicable to linear static, inertia relief, differential stiffness, and buckling (Solutions 101, 105, 114, and 200) and will produce fatal messages in other solution sequences. Use SPCD to apply enforced displacements in solution sequences for which DEFORM does not apply.

## DEFUSET

## Degree-of-Freedom Set Name Definition

Defines new names for degree-of-freedom sets.

### Format:

1	2	3	4	5	6	7	8	9	10
DEFUSET	OLD1	NEW1	OLD2	NEW2	OLD3	NEW3	OLD4	NEW4	

### Example:

DEFUSET	U2	X	U4	Y	U3	Z			
---------	----	---	----	---	----	---	--	--	--

Describer	Meaning
OLDi	Default set name. (One to four characters)
NEWi	New set name. (One to four characters)

### Remarks:

1. From one to four set names may be specified on a single entry.
2. OLDi must refer to any of the set names given in [Degree-of-Freedom Sets](#). It is recommended that OLDi refer only to the set names U1 through U6. If sets PA or PS are referenced, a user fatal message is issued.
3. All NEWi names must be unique with respect to all other set names.
4. The DEFUSET entry is optional since default set names exist for all displacement sets.
5. The DEFUSET entry must be present in the Bulk Data Section in all restarts.

## DELAY Dynamic Load Time Delay

Defines the time delay term  $\tau$  in the equations of the dynamic loading function.

### Format:

1	2	3	4	5	6	7	8	9	10
DELAY	SID	P1	C1	T1	P2	C2	T2		

### Example:

DELAY	5	21	6	4.25	7	6	8.1		
-------	---	----	---	------	---	---	-----	--	--

Describer	Meaning
SID	Identification number of the DELAY entry. (Integer > 0)
Pi	Grid, extra, or scalar point identification number. (Integer > 0)
Ci	Component number. (Integer 1 through 6 for grid point, blank or 0 for extra point or scalar point.)
Ti	Time delay $\tau$ for designated point Pi and component Ci. (Real)

### Remarks:

1. One or two dynamic load time delays may be defined on a single entry.
2. SID must also be specified on a RLOAD1, RLOAD2, TLOAD1, TLOAD2, or ACSRCE entry. See those entry descriptions for the formulas that define the manner in which the time delay  $\tau$  is used.
3. A DAREA, LSEQ or static load entry should be used to define a load at Pi and Ci.
4. In superelement analysis, DELAY entries may only be applied to loads on points in the residual structure.

## DEQATN Equation Definition

Defines one or more equations for use in analysis.

### Format:

1	2	3	4	5	6	7	8	9	10	
DEQATN	EQID	EQUATION								
		EQUATION (Cont.)								

### Example:

DEQATN	14	F1(A, B, C, D, R) = A + B · C – (D ** 3 + 10.0) + sin(PI(1) · R) + A**2/(B – C) ; F = A + B – F1 · D							
--------	----	---	--	--	--	--	--	--	--

Describer	Meaning
EQID	Unique equation identification number. (Integer > 0)
EQUATION	Equation(s). See Remarks. (Character)

### Remarks:

1. EQUATION is a single equation or a set of nested equations and is specified in fields 3 through 9 on the first entry and may be continued on fields 2 through 9 on the continuation entries. On the continuation entries, no commas can appear in columns 1 through 8. All data in fields 2 through 9 must be specified in columns 9 through 72. The large-field format is not allowed.

A single equation has the following format:

$$\text{variable-1 (x1, x2, ..., xn)=expression-1}$$

A set of nested equations is separated by semicolons and has the format:

$$\begin{aligned} &\text{variable-1 (x1, x2, ..., xn)=expression-1;} \\ &\text{variable-2=expression-2;variable-3=expression-3;} \end{aligned}$$

etc.

$$\text{variable-m=expression-m}$$

Expression-i is a collection of constants, real variables, and real functions, separated by operators, and must produce a single real value. (x1, x2, ..., xn) is the list of all the variable names (except variable-i) that appear in all expressions. Variable-i may be used in subsequent expressions. The last equation, variable-m=expression-m, provides the value that is returned to the Bulk Data entry that references EQID; e.g., DRESP2. The example above represents the following mathematical equations:

$$F1 = A + B \cdot C - (D^3 + 10) + \sin(\pi \cdot R) + \frac{A^2}{B - C}$$

$$F = A + B + F1 \cdot D$$

where SIN and PI are intrinsic functions. See Remark 4.

2. EQUATION may contain embedded blanks. EQUATION must contain less than 32,000 nonblank characters. If more characters are required for use with a DRESP2 entry, the DRESP2 can be divided into two or more DRESP2 entries with a master DRESP2 referencing subsequent DRESP2s.
3. The syntax of the expressions follows FORTRAN language standards. The allowable arithmetic operations are shown in Table 8 in the order of execution precedence. Parenthesis are used to change the order of precedence. Operations within parentheses are performed first with the usual order of precedence being maintained within the parentheses.

Table 8 DEQATN Entry Operators

Operator	Operation	Sample Expressions	Interpreted As
-, +	Negative or Positive immediately preceded by exponentiation	$X^{**}(-Y)$	$X^{**}(-Y)$
**	Exponentiation	$-X^{**}Y$	$(-X^{**}Y)$
-, +	Negative or Positive	$-X-Y$	$(-X)-Y$
*, /	Multiplication or Division	$X*Y-Z$	$(X*Y)-Z$
+, -	Addition or Subtraction	$X+Y$	$X+Y$

4. The expressions may contain intrinsic functions. Table 9 contains the format and descriptions of functions that may appear in the expressions. The use of functions that may be discontinuous must be used with caution because they can cause discontinuous derivatives. These are ABS, DIM, MAX, MIN, and MOD. For examples and further details see the [MSC Nastran DMAP Programmer's Guide](#).

Table 9 DEQATN Entry Functions

Format	Description	Mathematical Expressions
ABS(x)	absolute value	$ x $
ACOS(x)	arccosine	$\cos^{-1} x$
ACOSH(x)	hyperbolic arccosine	$\cosh^{-1} x$
ASIN(x)	arcsine	$\sin^{-1} x$
ASINH(x)	hyperbolic arcsine	$\sinh^{-1} x$
ATAN(x)	arctangent	$\tan^{-1} x$
ATAN2(x,y)	arctangent of quotient	$\tan^{-1} (x/y)$
ATANH(x)	hyperbolic arctangent	$\tanh^{-1} x$
ATANH2(x,y)	hyperbolic arctangent of quotient	$\tanh^{-1} (x/y)$

Table 9 DEQATN Entry Functions (continued)

Format	Description	Mathematical Expressions
AVG( $X_1, X_2, \dots, X_n$ )	average	$\frac{1}{n} \sum_{i=1}^n X_i$
COS(x)	cosine	cos x
COSH(x)	hyperbolic cosine	cosh x
DB(P, PREF)	sound pressure in decibel	$20.0 \cdot \log\left(\frac{P}{PREF}\right)$
DBA(P, PREF, F)	sound pressure in decibel (perceived)	$20.0 \cdot \log\left(\frac{P}{PREF}\right) + 10.0 \cdot \log(Ta1) + 10.0 \cdot \log(Ta2)$
DIM(x,y)	positive difference	x-MIN(x,y)
EXP(x)	exponential	$e^x$
INVDB(DB, PREF)	inverse Db	$10^{\left(\frac{DB}{20.0} + \log PREF\right)}$
INVDBA(DBA, PREF, F)	inverse Dba	$10^{\left(\frac{DBA - 10.0 \cdot \log(Ta1) - 10.0 \cdot \log(Ta2)}{20.0}\right)}$
LOG(x)	natural logarithm	$\log_e x$
LOG10(x)	common logarithm	$\log_{10} x$
LOGX(x,y)	base x logarithm	$\log_x y$
MAX( $x_1, x_2, \dots$ )	maximum	maximum of $x_1$ , etc.
MIN( $x_1, x_2, \dots$ )	minimum	minimum of $x_1$ , etc.
MOD(x,y)	remainder (modulo)	$x - y \cdot (\text{INT}(x/y))$
PI(x)	multiples of pi ( $\pi$ )	$x \cdot \pi$
RSS( $X_1, X_2, \dots, X_n$ )	square root of sum of squares	$\sqrt{\sum_{i=1}^n X_i^2}$
SIN(x)	sine	sin x
SINH(x)	hyperbolic sine	sinh x
SQRT(x)	square root	$\sqrt{x}$

Table 9 DEQATN Entry Functions (continued)

Format	Description	Mathematical Expressions
SSQ( $X_1, X_2, \dots, X_n$ )	sum of squares	$\sum_{i=1}^n X_i^2$
SUM( $X_1, X_2, \dots, X_n$ )	summation	$\sum_{i=1}^n X_i$
TAN(x)	tangent	tan x
TANH(x)	hyperbolic tangent	tanh x

where

- $X_1, X_2, \dots, X_n, P$  = structure responses or acoustic pressure
- PREF = reference pressure
- F = forcing frequency
- DB = acoustic pressure in decibel
- DBA = perceived acoustic pressure in decibel

$$Ta1 = \frac{K3 \cdot F^4}{(F^2 + P2^2)(F^2 + P3^2)}$$

$$Ta2 = \frac{K1 \cdot F^4}{(F^2 + P1^2)^2 (F^2 + P4^2)^2}$$

$$K1 = 2.242882e+16$$

$$K3 = 1.562339$$

$$P1 = 20.598997$$

$$P2 = 107.65265$$

$$P3 = 737.86223$$

$$P4 = 12194.22$$

5. If the DEQATN entry is referenced by the:

- DVCREL2, DVMREL2, or DVPREL2 entry, then  $X_j$  represents the DVIDj and LABELk fields.

- DRESP2 entry, then  $X_i$  represents the DVIDj, LABELk, NRm, Gp, DPIPq, DCICr, DMIMs, DPI2Pt, DCI2Cu, DMI2Mv, and NRRw fields in that order.
6. If the DEQATN entry is referenced by DRESP2, DVCREL2, DVMREL2 or DVPREL2 entries, constants must be specified in single precision regardless of your machine's word length.
  7. The DMAP logical operators NOT, AND, OR, XOR, and XQV cannot be used as  $X_i$  names.
  8. Input errors on the DEQATN entry often result in poor messages. Substituting a “[” for a parenthesis or violating the restriction against large field format are examples. Known messages are UFM 215, SFM 233 and UFM 5199. If any of these messages are encountered then review the DEQATN entry input.
  9. Intrinsic functions AVG, MAX, MIN, RSS, SSQ and SUM are limited to <97 arguments. If more arguments are desired, the functions may be divided up. For example, to perform a sum of squares on 170 items, use:

$$SSQ(X1,X2,...X95) + SSQ(X96,X97,...X170).$$

For MAX/MIN, the following concatenation can be used:

$$MAX1 = MAX(X1,X2,..X95), MAX2=MAX(X96,X97...X170); MAXT=MAX(MAX1,MAX2).$$

For AVG, an example to average 170 terms is:

$$AVG1=AVG(X1,X2,...X95);AVG2=AVG(X96,X97..X170); AVGT = (95. * AVG1 + 75. * AVG2) / 170.$$

10. Arithmetic is carried out using the type of the input data. For example, in the expression:

$$X = A^{**}(1/2)$$

both values in the exponent are integers so that the value returned for the exponent is calculated using integer arithmetic or  $1/2 = 0$ . In this case  $1/2$  should be replaced by (.5).

**DESVAR**

## Design Variable

Defines a design variable for design optimization.

**Format:**

1	2	3	4	5	6	7	8	9	10
DESVAR	ID	LABEL	XINIT	XLB	XUB	DELXV	DDVAL		

**Example:**

DESVAR	2	BARA1	35.0	10.	100.	0.2			
--------	---	-------	------	-----	------	-----	--	--	--

Describer	Meaning
ID	Unique design variable identification number. (Integer > 0)
LABEL	User-supplied name for printing purposes. (Character)
XINIT	Initial value. (Real; $XLB \leq XINIT \leq XUB$ )
XLB	Lower bound. (Real; Default = $-1.0E+20$ )
XUB	Upper bound. (Real; Default = $+1.0E+20$ )
DELXV	Fractional change allowed for the design variable during approximate optimization. (Real > 0.0; for Default see Remark 2.)
DDVAL	ID of a DDVAL entry that provides a set of allowable discrete values. (Blank or Integer > 0; Default=blank for continuous design variables. See Remark 3.)

**Remarks:**

1. DELXV can be used to control the change in the design variable during one optimization cycle.
2. If DELXV is blank, the default is taken from the specification of the DELX parameter on the DOPTPRM entry. If DELX is not specified, then the default is 0.5.
3. If the design variable is to be discrete (Integer > 0 in DDVAL field), and if either of the XLB and/or XUB bounds are wider than those given by the discrete list of values on the corresponding DDVAL entry, XLB and/or XUB will be replaced by the minimum and maximum discrete values.

## DETSPH

## Spherical Detonation Wave

Defines the ignition point from which a spherical detonation wave travels, causing the reaction of high explosive materials. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
DETSPH	DID	MID	X	Y	Z	VEL	TIME		

### Example:

DETSPH	100	10	96.5	177.6	37.4	2379.	1.7E-6		
--------	-----	----	------	-------	------	-------	--------	--	--

Describer	Meaning
DID	Unique detonation number. (Integer > 0; Required)
MID	References MATDEUL id of the exploding material. (Integer > 0; Required)
X, Y, Z	Coordinates of the ignition point. (Real, 0.0)
VEL	Velocity of the detonation wave. (Real ≥ 0.0, 0.0)
TIME	Detonation time. (Real ≥ 0.0, 0.0)

### Remark:

1. An element detonates when a spherical detonation wave originating from the detonation point at the specified time reaches the element.

**DIVERG**

## Divergence Analysis Data

Defines Mach numbers (m) for a static aeroelastic divergence analysis.

**Format:**

1	2	3	4	5	6	7	8	9	10
DIVERG	SID	NROOT	M1	M2	M3	M4	M5	M6	
	M7	M8	-etc.-						

**Example:**

DIVERG	70	2	.5	.8	.9				
--------	----	---	----	----	----	--	--	--	--

Describer	Meaning
SID	Unique set identifier. (Integer > 0)
NROOT	Number of divergence roots that are to be output and their eigenvectors printed. (Integer; Default = 1)
Mi	Mach number. (Real $\geq$ 0.0)

**Remarks:**

1. The DIVERG entry is referenced in Case Control by “DIVERG = SID”.
2. The NROOT lowest divergence dynamic pressures are printed. If there are fewer than NROOT pressures, all available dynamic pressures are printed.
3. Mi values must be distinct.
4. A blank Mach number field terminates the input.

## DLINK Multiple Design Variable Linking

Relates one design variable to one or more other design variables.

### Format:

1	2	3	4	5	6	7	8	9	10
DLINK	ID	DDVID	C0	CMULT	IDV1	C1	IDV2	C2	
	IDV3	C3	-etc.-						

### Example:

DLINK	10	2	0.1	0.33	4	2.0	6	-1.0	
	8	7.0							

Describer	Meaning
ID	Unique identification number. (Integer > 0)
DDVID	Dependent design variable identification number. (Integer > 0)
C0	Constant term. (Real; Default = 0.0)
CMULT	Constant multiplier. (Real; Default = 1.0)
IDVi	Independent design variable identification number. (Integer > 0)
Ci	Coefficient i corresponding to IDVi. (Real)

### Remarks:

- DLINK defines the relationship

$$DDVID = C0 + CMULT * \sum_i C_i * IDV_i$$

- This capability provides a means of linking physical design variables such as element thicknesses to nonphysical design variables such as the coefficients of interpolating functions.
- CMULT provides a simple means of scaling the Ci. For example if Ci = 1/7, 2/7, 4/7, etc. is desired, then CMULT = 1/7 and Ci = 1, 2, 4, etc., may be input.
- An independent IDVi must not occur on the same DLINK entry more than once.
- ID is for user reference only.
- If a design variable is specified as dependent on a DLINK entry, then it cannot be specified as independent on another DLINK entry.

## DLOAD

### Dynamic Load Combination or Superposition

Defines a dynamic loading condition for frequency response or transient response problems as a linear combination of load sets defined via RLOAD1, RLOAD2, TLOAD1, TLOAD2 and ACSRCE entries for frequency response or TLOAD1 or TLOAD2 entries for transient response.

#### Format:

1	2	3	4	5	6	7	8	9	10
DLOAD	SID	S	S1	L1	S2	L2	S3	L3	
	S4	L4	-etc.-	*					

#### Examples:

DLOAD	17	1.0	2.0	6	-2.0	7	2.0	8	
	-2.0	9							

Describer	Meaning
SID	Load set identification number. See Remarks 1. and 4. (Integer > 0)
S	Scale factor. See Remarks 2. and 8. (Real)
Si	Scale factors. See Remarks 2., 7. and 8. (Real)
Li	Load set identification numbers of RLOAD1, RLOAD2, TLOAD1, TLOAD2, and ACSRCE entries. See Remarks 3. and 7. (Integer > 0)

#### Remarks:

- Dynamic load sets must be selected in the Case Control Section with DLOAD = SID.
- The load vector being defined by this entry is given by

$$\{P\} = S \sum_i S_i \{P_i\}$$

- Each Li must be unique from any other Li on the same entry.
- SID must be unique from all ACSRCE, RLOAD1, RLOAD2, TLOAD1 and TLOAD2 dynamic load entries.
- Nonlinear transient load sets (NOLINi entries) may not be specified on DLOAD entries. NOLINi entries are selected separately in the Case Control Section by the NONLINEAR command.
- A DLOAD entry may not reference a set identification number defined by another DLOAD entry.
- The scale factor Si will apply to all dynamic load entries with load set identification number of Li.
- For RC network solver in thermal analysis, the S and Si factors are always taken as 1.
- If Modules are present then this entry may only be specified in the main Bulk Data section.

## DMI Direct Matrix Input

Defines matrix data blocks. Generates a matrix of the following form:

$$[\text{NAME}] = \begin{bmatrix} X_{11} & X_{12} & \dots & X_{1n} \\ X_{21} & X_{22} & \dots & X_{2n} \\ \cdot & \cdot & \cdot & \cdot \\ X_{m1} & \dots & \dots & X_{mn} \end{bmatrix}$$

where the elements  $X_{ij}$  may be real ( $X_{ij} = A_{ij}$ ) or complex ( $X_{ij} = A_{ij} + iB_{ij}$ ). The matrix is defined by a single header entry and one or more column entries. Only one header entry is required. A column entry is required for each column with nonzero elements.

### Header Entry Format:

1	2	3	4	5	6	7	8	9	10
DMI	NAME	"0"	FORM	TIN	TOUT		M	N	

### Column Entry Format for Real Matrices:

DMI	NAME	J	I1	A(I1,J)	A(I1+1,J)		-etc.-	I2	
	A(I2,J)		-etc.-						

### Column Entry Format for Complex Matrices:

DMI	NAME	J	I1	A(I1,J)	B(I1,J)	A(I1+1,J)	B(I1+1,J)	-etc.-	
	I2	A(I2,J)	B(I2,J)	-etc.-					

### Example of a Real Matrix:

DMI	BBB	0	2	1	1		4	2	
DMI	BBB	1	1	1.	3.	5.			
DMI	BBB	2	2	6.	4	8.			

$$\text{BBB} = \begin{bmatrix} 1.0 & 0.0 \\ 3.0 & 6.0 \\ 5.0 & 0.0 \\ 0.0 & 8.0 \end{bmatrix}$$

**Example of a Complex Matrix:**

DMI	QQQ	0	2	3	3		4	2	
DMI	QQQ	1	1	1.0	2.0	3.0	0.0	3	
		5.0	6.0						
DMI	QQQ	2	2	6.0	7.0	4	8.0	9.0	

$$[QQQ] = \begin{bmatrix} 1.0 + 2.0i & , & 0.0 + 0.0i \\ 3.0 + 0.0i & , & 6.0 + 7.0i \\ 5.0 + 6.0i & , & 0.0 + 0.0i \\ 0.0 + 0.0i & , & 8.0 + 9.0i \end{bmatrix}$$

Describer	Meaning
NAME	Name of the matrix. See Remark 1. Name is used to reference the data block in the DMAP sequence. (One to eight alphanumeric characters, the first of which must be alphabetic.)
FORM	Form of matrix, as follows: (Integer) <ul style="list-style-type: none"> <li>1 Square matrix (not symmetric)</li> <li>2 General rectangular matrix</li> <li>3 Diagonal matrix (M=number of rows, N = 1)</li> <li>4 Lower triangular factor</li> <li>5 Upper triangular factor</li> <li>6 Symmetric matrix</li> <li>8 Identity matrix (M=number of rows, N = M)</li> </ul>
TIN	Type of matrix being input, as follows: (Integer) <ul style="list-style-type: none"> <li>1 Real, single precision (one field used/element)</li> <li>2 Real, double precision (one field used/element)</li> <li>3 Complex, single precision (two fields used/element)</li> <li>4 Complex, double precision (two fields used/element)</li> </ul>

Describer	Meaning
TOUT	Type of matrix being output, as follows: (Integer) 0 Set by precision cell 1 Real, single precision 2 Real, double precision 3 Complex, single precision 4 Complex, double precision
M	Number of rows in NAME. (Integer > 0)
N	Number of columns in NAME. Except for FORM 3 and 8. (Integer > 0)
"0"	Indicates the header entry.
J	Column number of NAME. (Integer > 0)
I1, I2, etc.	Row number of NAME, which indicates the beginning of a group of nonzero elements in the column. See Remark 13. (Integer > 0)
A(Ix,J)	Real part of element (see TIN). (Real)
B(Ix,J)	Imaginary part of element (see TIN). (Real)

**Remarks:**

1. In order to use the DMI feature, the user must write a DMAP, or make alterations to a solution sequence that includes the DMIIN module. See the [MSC Nastran DMAP Programmer's Guide](#). All of the rules governing the use of data blocks in DMAP sequences apply.
2. The total number of DMIs and DTIs may not exceed 1000.
3. Field 3 of the header entry must contain an integer of zero (0).
4. For symmetric matrices, the entire matrix must be input.
5. Only nonzero terms need be entered.
6. Leading and trailing zeros in a column do not have to be entered. However, a blank field between nonzero fields on this entry is not equivalent to a zero. If a zero input is required, the appropriate type zero must be entered (i.e., 0.0 or 0.0D0).
7. Complex input must have both the real and imaginary parts entered if either part is nonzero; i.e., the zero component must be input explicitly.
8. If A(Ix,J) is followed by "THRU" in the next field and an integer row number "IX" after the THRU, then A(Ix,J) will be repeated in each row through IX. The "THRU" must follow an element value. For example, the entries for a real matrix RRR would appear as follows:

1	2	3	4	5	6	7	8	9	10
DMI	NAME	J	I1	A(I1,J)			I1	A(I2,J)	
DMI	RRR	1	2	1.0	THRU	10	12	2.0	

These entries will cause the first column of the matrix RRR to have a zero in row 1, the values 1.0 in rows 2 through 10, a zero in row 11, and 2.0 in row 12.

9. Each column must be a single logical entry. The terms in each column must be specified in increasing row number order.
10. The “FORM” options 4, 5, and 8 are nonstandard forms and may be used only in conjunction with the modules indicated in [Table 10](#).

**Table 10**      **DMI FORM Options**

FORM	Matrix Description	Modules			
		ADD	FBS	MATPRN	MPYAD
4	Lower Triangular Factor		X	X	
5	Upper Triangular Factor		X	X	
8	Identity	X	X	X	X

11. Form 3 matrices are converted to Form 6 matrices, which may be used by any module.
12. Form 7 matrices may not be defined on this entry.
13. I1 must be specified. I2, etc. are not required if their matrix elements follow the preceding element in the next row of the matrix. For example, in the column entry for column 1 of QQQ, neither I2 nor I3 is specified.
14. The DMIG entry is more convenient for matrices with rows and columns that are referenced by grid or scalar point degrees-of-freedom.
15. If Modules are present then this entry may only be specified in the main Bulk Data section.

## DMIAX

### Direct Matrix Input for Axisymmetric Analysis

Defines axisymmetric (fluid or structure) related direct input matrix terms.

The matrix is defined by a single header entry and one or more column entries. Only one header entry is required. A column entry is required for each column with nonzero elements.

#### Header Entry Format:

1	2	3	4	5	6	7	8	9	10
DMIAX	NAME	"0"	IFO	TIN	TOUT				

#### Column Entry Format:

DMIAX	NAME	GJ	CJ	NJ					
	G1	C1	N1	A1	B1				
	G2	C2		-etc.-					

#### Example:

DMIAX	B2PP	0	1	3	4				
DMIAX	B2PP	32							
	1027	3		4.25+6	2.27+3				

Describer	Meaning
NAME	Name of the matrix. See Remark 2. (One to eight alphanumeric characters, the first of which is alphabetic.)
IFO	Form of matrix: (Integer) <ul style="list-style-type: none"> <li>1            Square matrix</li> <li>2            General rectangular matrix</li> <li>6            Symmetric matrix</li> </ul>
TIN	Type of matrix being input: (Integer) <ul style="list-style-type: none"> <li>1            Real, single precision (One field is used per element.)</li> <li>3            Complex, single precision (Two fields are used per element.)</li> </ul>

Describer	Meaning
TOUT	Type of matrix that will be created: (Integer) 1           Real, single precision 2           Real, double precision 3           Complex, single precision 4           Complex, double precision
GJ, Gi	Grid, scalar, RINGFL fluid point, PRESPT pressure point, FREEPT free surface displacement, or extra point identification number. (Integer > 0)
CJ, Ci	Component number for GJ or Gi grid point (0 ≤ Integer ≤ 6; Blank or zero if GJ or Gi is a scalar, fluid, or extra point.)
NJ, Ni	Harmonic number of RINGFL point. Must be blank if a point type other than RINGFL is used. A negative number implies the “sine” series; a positive number implies the “cosine” series. (Integer)
Ai, Bi	Real and imaginary parts of matrix element; row (Gi, Ci, Ni) column (GJ, CJ, NJ). If the matrix is real (TIN = 1), then Bi must be blank.

1. This entry is allowed only if an AXIF entry is also present.
2. Matrices defined on this entry may be used in dynamics by selection with the Case Control commands K2PP = NAME, B2PP = NAME, or M2PP = NAME for  $[K_{pp}^2]$ ,  $[B_{pp}^2]$ , or  $[M_{pp}^2]$ , respectively. See [Superelement Analysis](#) in the *MSC Nastran Reference Guide*.
3. Field 3 or the header entry must contain an integer 0.
4. For symmetric matrices, either the upper or the lower triangle terms may be specified, but not both.
5. Only nonzero terms need be entered.
6. If any DMIAX entry is changed or added on restart then a complete re-analysis may be performed. Therefore, DMIAX entry changes or additions are not recommended on restart.

## DMIG Direct Matrix Input at Points

Defines direct input matrices related to grid, extra, and/or scalar points. The matrix is defined by a single header entry and one or more column entries. A column entry is required for each column with nonzero elements.

### Header Entry Format:

1	2	3	4	5	6	7	8	9	10
DMIG	NAME	"0"	IFO	TIN	TOUT	POLAR		NCOL	

### Column Entry Format:

DMIG	NAME	GJ	CJ		G1	C1	A1	B1	
	G2	C2	A2	B2	-etc.-				

### Example:

DMIG	STIF	0	1	3	4				
DMIG	STIF	27	1		2	3	3.+5	3.+3	
	2	4	2.5+10	0.	50		1.0	0.	

Describer	Meaning
NAME	Name of the matrix. See Remark 1. (One to eight alphanumeric characters, the first of which is alphabetic.)
IFO	Form of matrix input. IFO = 6 must be specified for matrices selected by the K2GG, M2GG, and B2GG Case Control commands. (Integer) 1 Square 2 or 9 Rectangular 6 Symmetric
TIN	Type of matrix being input: (Integer) 1 Real, single precision (One field is used per element.) 2 Real, double precision (One field is used per element.) 3 Complex, single precision (Two fields are used per element.) 4 Complex, double precision (Two fields are used per element.)
TOUT	Type of matrix that will be created: (Integer) 0 Set by precision system cell (Default) 1 Real, single precision 2 Real, double precision 3 Complex, single precision

Describer	Meaning
	4            Complex, double precision
POLAR	Input format of Ai, Bi. (Integer=blank or 0 indicates real, imaginary format; Integer > 0 indicates amplitude, phase format.)
NCOL	Number of columns in a rectangular matrix. Used only for IFO = 9. See Remarks 5. and 6. (Integer > 0)
GJ	Grid, scalar or extra point identification number for column index. (Integer > 0)
CJ	Component number for grid point GJ. (0 < Integer ≤ 6; blank or zero if GJ is a scalar or extra point.)
Gi	Grid, scalar, or extra point identification number for row index. (Integer > 0)
Ci	Component number for Gi for a grid point. (0 < CJ ≤ 6; blank or zero if Gi is a scalar or extra point.)
Ai, Bi	Real and imaginary (or amplitude and phase) parts of a matrix element. If the matrix is real (TIN = 1 or 2), then Bi must be blank. (Real)

### Remarks:

- Matrices defined on this entry may be used in dynamics by selection in the Case Control with K2PP = NAME, B2PP = NAME, M2PP = NAME for  $[K_{\rho\rho}]$ ,  $[B_{\rho\rho}]$ , or  $[M_{\rho\rho}]$ , respectively. Matrices may also be selected for all solution sequences by K2GG = NAME, B2GG = NAME, and M2GG = NAME. The g-set matrices are added to the structural matrices before constraints are applied, while p-set matrices are added in dynamics after constraints are applied. Load matrices may be selected by P2G = NAME for dynamic and superelement analyses.
- The header entry containing IFO, TIN and TOUT is required. Each nonnull column is started with a GJ, CJ pair. The entries for each row of that column follows. Only nonzero terms need be entered. The terms may be input in arbitrary order. A GJ, CJ pair may be entered more than once, but input of an element of the matrix more than once will produce a fatal message.
- Field 3 of the header entry must contain an integer 0.
- For symmetric matrices (IFO = 6), a given off-diagonal element may be input either below or above the diagonal. While upper and lower triangle terms may be mixed, a fatal message will be issued if an element is input both below and above the diagonal.
- The recommended format for rectangular matrices requires the use of NCOL and IFO = 9. The number of columns in the matrix is NCOL. (The number of rows in all DMIG matrices is always either p-set or g-set size, depending on the context.) The GJ term is used for the column index. The CJ term is ignored.
- If NCOL is not used for rectangular matrices, two different conventions are available:
  - If IFO = 9, GJ and CJ will determine the sorted sequence, but will otherwise be ignored; a rectangular matrix will be generated with the columns submitted being in the 1 to N positions, where N is the number of logical entries submitted (not counting the header entry).

- If  $IFO = 2$ , the number of columns of the rectangular matrix will be equal to the index of the highest numbered non-null column (in internal sort). Trailing null columns of the g- or p-size matrix will be truncated.
7. The matrix names must be unique among all DMIGs.
  8. TIN should be set consistent with the number of decimal digits required to read the input data adequately. For a single-precision specification on a short-word machine, the input will be truncated after about eight decimal digits, even when more digits are present in a double-field format. If more digits are needed, a double precision specification should be used instead. However, note that a double precision specification requires a “D” type exponent even for terms that do not need an exponent. For example, unity may be input as 1.0 in single precision, but the longer form 1.0D0 is required for double precision.
  9. On long-word machines, almost all matrix calculations are performed in single precision and on short-word machines, in double precision. It is recommended that DMIG matrices also follow these conventions for a balance of efficiency and reliability. The recommended value for TOUT is 0, which instructs the program to inspect the system cell that measures the machine precision at run time and sets the precision of the matrix to the same value. TOUT = 0 allows the same DMIG input to be used on any machine. If TOUT is contrary to the machine type specified (for example, a TOUT of 1 on a short-word machine), unreliable results may occur.
  10. If any DMIG entry is changed or added on restart then a complete re-analysis is performed. Therefore, DMIG entry changes or additions are not recommended on restart.

**DMIG,UACCEL**

## Direct Matrix Input of Enforced Static Acceleration

Defines rigid body accelerations in the basic coordinate system.

**Format:**

1	2	3	4	5	6	7	8	9	10
DMIG	UACCEL	"0"	"9"	TIN				NCOL	
DMIG	UACCEL	L			G1	C1	X1		
	G2	C2	X2		G3	C3	X3		

**Example:**

DMIG	UACCEL	0	9	1				4	
DMIG	UACCEL	2			2	3	386.4		
DMIG	UACCEL	3			2	4	3.0		
DMIG	UACCEL	4			2	6	1.0		

Descriptor	Meaning
TIN	Type of matrix being input. (Integer 1 or 2) 1        Real, single precision (One field is used per element.) 2        Real, double precision (One field is used per element.)
NCOL	Number of columns, see Remark 2. Default is the number of columns specified. (Integer > 0)
L	Load sequence number. (Integer > 0)
Gi	Grid point identification number of a single reference point. (Integer > 0)
Ci	Component number for Gi in the basic coordinate system. See Remark 4. (0 < Integer ≤ 6)
Xi	Value of enforced acceleration term in the basic coordinate system. (Real)

**Remarks:**

1. DMIG,UACCEL is an optional entry when PARAM,INREL,-1 is specified in SOLs 101 or 200. If DMIG,UACCEL is present, the loads applied to the structure are the sum of the conventional applied loads plus the inertia loads resulting from the rigid body accelerations defined on this entry. If it is not present, conventional inertia relief calculations are performed.
2. The load sequence number interpretation depends on the value of the NCOL field. The recommended method is to set it equal to the number of loading conditions. The load sequence number L is then the sequence number of the subcase to which the applied acceleration will be applied.

3. The grid point identification number listed on Gi defines a single grid point on the model where loads will be applied to cause the enforced acceleration state. Gi must also appear on a SUPORT Bulk Data entry. It must also appear on a PARAM,GRDPNT entry. In superelement analysis, it must be a residual structure point exterior to all superelements.
4. The Xi value is the enforced acceleration at grid point Gi. The translation and rotation components are in consistent units and will be applied in the basic coordinate system regardless of the displacement coordinate system specified for Gi (CD field on GRID entry).
5. Only nonzero terms need be entered.
6. See [Superelement Analysis](#) in *the MSC Nastran Reference Guide* for the theoretical basis of inertia relief with superelements.
7. If any DMIG entry is changed or added on restart then a complete re-analysis is performed. Therefore, DMIG entry changes or additions are not recommended on restart.

**DMIGOUT****DMIG Matrices to be Output from the Marc Portion of SOL 600**

Defines DMIG matrices to be output from the Marc Portion of SOL 600.

**Header Entry Format:**

1	2	3	4	5	6	7	8	9	10
DMIGOUT	ID	ISTIFF	IDIFF	IMASS	IDAMP	ICOND	ISPECIF	ISOL	
		ICTRL	IFREQ	ICORD	KIND	AMIN	IUSEK	IUSEM	
		IE1	THRU	IE2		IE3	THRU	IE4	

**Example:**

DMIGOUT	100	1	1	0	0	0	0	103	
		2	-1	2	2	1.0E-16			

Describer	Meaning
ID	Subcase for which the reduced matrices will be output. ID must correlate to a SUBCASE Case Control ID, for example if the Case Control contains SUBCASE 20, ID would be 20. To output matrices in Marc's phase zero, etc ID=0. (Integer; Default = 1, see Remark 11.)
ISTIFF	Flag to output stiffness matrices. (Normally contains the differential stiffness and all other stiffness terms.) (Integer; Default = 0) 0 Do not output the matrix 1 Output the matrix
IDIFF	Flag to output differential stiffness matrices. (Only available for buckling analysis or subcases.) (Integer; Default = 0) 0 Do not output the matrix 1 Output the matrix
IMASS	Flag to output mass matrices. (Integer; Default = 0) 0 Do not output the matrix 1 Output the matrix (must be a dynamic analysis)
IDAMP	Flag to output damping matrices. (Integer; Default = 0) 0 Do not output the matrix 1 Output the matrix (must be a dynamic analysis)
ICOND	Flag to output conductivity matrices. (Integer; Default = 0) 0 Do not output the matrix 1 Output the matrix
ISPECIF	Flag to output specific heat matrices. (Integer; Default = 0)

Describer	Meaning
	0 Do not output the matrix
	1 Output the matrix
ISOL	Solution sequence to run using the DMIG matrices. (Integer absolute value > 100; Default = 0, which means do not run any solution sequence using the DMIG's created by Marc in this execution). To speed up the solution, use DOMAINSOLVER ACMS (PARTOPT=DOF) for eigenvalues and set ISOL to the negative value of the solution sequence desired (-103, -111 or -112).
ICTRL	Controls type of matrix. (Integer; Default = 2)
	1 Element matrices
	2 Global matrices
	3 Element and global matrices
IFREQ	Controls how often the matrices are output (Integer; no Default)
	1 Output at every increment
	2 Output every other increment, etc.
	3 Output every 3rd increment, etc.
	-1 Output only at start of the subcase. (See Remark 12.)
ICORD	Controls matrix output coordinate system (Integer; no Default)
	1 Nastran basic coordinate system
	2 Current transformed coordinate system (at the start of the run, this is the Nastran global coordinate system)
KIND	Controls which elements are written (Integer; Default = 2)
	1 A list of elements starting with the 3 <sup>rd</sup> entry will be specified
	2 All elements will be written
AMIN	Values below AMIN will not be written (Real; Default = 1.0E-15). Values below AMIN will be skipped.
IUSEK	Increment to use in SOL 600 CONTINUE option for the stiffness matrix (if CONTINUE is specified on the SOL 600 entry). (Integer; Default = -1) Increments 0 to 9999 may be specified. If -1 is specified, the last increment output by Marc will be used. As an example, the Marc DMIG file for the global stiffness matrix for increment 10 will have the name jid.marc_cglsti_0020.
IUSEM	Increment to use in SOL 600 CONTINUE option for the mass matrix (If CONTINUE is specified on the SOL 600 entry). (Integer, Default = -1) Increments 0 to 9999 may be specified. If -1 is specified, the last increment output by Marc will be used. As an example, the Marc DMIG file for the global mass matrix for increment 20 will have the name jid.marc_cglmas_0020.

Describer	Meaning
IE1, IE3	Starting element number of a range of elements (Integer; no Default) Only enter IE1 is KIND=1
IE2, IE4	Ending element number of a range of elements (Integer; no Default) Only enter IE2 is KIND=1 (IE2 is required if IE1 is entered).

**Remarks:**

1. The first continuation line is required.
2. The second continuation line should only be entered if KIND=1 and may be repeated as many times as necessary to define all applicable elements.
3. ICTRL, IFREQ, ICORD, KIND and AMIN apply to all types of matrices to be written for the subcase.
4. Only one DMIGOUT entry can be entered per subcase. If more than one is entered, only the first encountered will be used.
5. DMIGOUT entries may be made for each subcase desired.
6. Marc DMIG element output will be in files named jid.marc\_dmigXX\_inc where XX is shown below and inc is the increment number.

ST	Stiffness Matrices
DF	Differential stiffness matrices
MS	Mass matrices
DM	Damping
CO	Conductivity matrices
SP	Specific heat matrices

Global matrices are named jid\_marc\_cglsti\_inc.

7. If the SOL 600 CONTINUE options is invoked, Case Control commands and a Bulk Data include statement to receive the matrices will be automatically added to the original input data file. A second Nastran execution will be spawned from the original Nastran execution after completion of the Marc execution.
8. ID may not be 600 or 700 in the Executive Control statement, SOL 600,ID.
9. The following Bulk Data parameters are usually required in addition to the DMIGOUT entry:  

```
$2345678x234567890123456x34567890123456
param* mrspawn2      nastcmd
pram,mrmtxnam,KAAX
param,marcfile,nastb.rc
```

 where

- a. `nastcmd` is the name of the command to run the primary and continuation jobs (examples are `nastran`, `nast2006t1`, `nast2006t2`, etc.)
  - b. `nastb.rc` should be changed to the name of the rc file to be used for the continuation run. It usually will specify `mem=` with a larger value than that of the primary run and also include a line `bat=no` (except for windows systems).
  - c. `PARAM,MARCFILi` should not be used.
10. For standard nonlinear static or dynamic analyses the stiffness matrix contains all contributions including the differential stiffness matrix and it is not possible to obtain the differential stiffness matrix separately. For a buckling analysis, the differential stiffness matrix may be obtained separately.
  11. To obtain stiffness and mass matrices for SOL 600,103, ID in field 2 of this entry must be must be zero.
  12. If IFREQ is 1 or a small number, the number of matrices output for dynamic analyses (SOL 600,109 or SOL 600,120) can be extremely large.
  13. If ID=0, IFREQ should be 1.
  14. Setting IFREQ to a value larger than the actual number of increments in a subcase will produce no matrices.

## DMIGROT

## DMIG Matrices for which large rotation in SOL 600

Defines large rotation and other characteristics of a matrix entered using DMIG in SOL 600.

### Format for K2GG and K2PP Stiffness DMIG Matrices:

1	2	3	4	5	6	7	8	9	10
DMIGROT	Name	G1	G2	G3	SCALE	ITRAN	IACT	IDEACT	

### Format for M2GG and M2PP Mass DMIG Matrices:

DMIGROT	Name				SCALE		IACT		
---------	------	--	--	--	-------	--	------	--	--

### Example:

DMIGROT	KAAX	375							
DMIGROT	KAAY	401	402	403					
DMIGROT	KAAX				1.25	1	2	5	
DMIGROT	MAAX				0.001		7	8	

Describer	Meaning
Name	Name of the DMIG matrix for which large rotation is specified. See Remark 1. (Character; Required field; no Default)
G1	Grid ID specifying the rotation of the matrix. See Remark 2. (Integer; Required field; no Default)
G2	Grid ID which combined with G1 and G3 specifies a plane whose rotation provides the rigid body rotation of the matrix. See Remark 2. (Integer; Default = 0; )
G3	Grid ID which combined with G1 and G2 specifies a plane whose rotation provides the rigid body rotation of the matrix. See Remark 2. (Integer; Default = 0)
SCALE	Scale factor. Each term in the DMIG matrix will be scaled by this value. (Real; Default = 1.0)
ITRAN	Flag indicating whether to transform the DMIG's or not. (Integer, Default = 0) 0 Do not transform the DMIG matrix. 1 Transform the DMIG using G1, G2, G3 to form the transformation matrix.
IACT	Subcase ID for which this DMIG matrix will be activated. See Remark 5. (Integer; Default = 0). 0 The matrix is active for all subcases. N The matrix is activated starting with subcase N
IDEACT	Subcase ID for which this DMIG matrix will be deactivated. See Remark 5. (Integer; no Default; leave blank if the matrix should be active fro the entire analysis or starting with subcase IACT)

**Remarks:**

1. All DMIG matrices with the name specified in field 2 will rotate with grids  $G_i$ .
2. If  $G_1$  has 6 dof it is not necessary to specify  $G_2$  or  $G_3$  and the DMIG matrix will rotate with the same rotation as  $G_1$ . If  $G_1$  has fewer than 6 dof, or if it is desired that the DMIG matrix rotate with a plane defined by  $G_1$ ,  $G_2$  and  $G_3$ ,  $G_2$  and  $G_3$  must be entered and may not all be collinear.
3. If a transformation is to be applied to the stiffness matrix, the DMIG **must** contain all of the degrees of freedom associated with the node to which the transformation is applied.
4. This bulk data entry maps to Marc's K2GG (and K2PP) model definition entry.
5. IACT and IDEACT are ID's of the Case Control SUBCASE entry.
6.  $G_1$ ,  $G_2$ ,  $G_3$  and ITRAN may not be entered for mass matrices.

## DMIJ

### Direct Matrix Input at js-Set of the Aerodynamic Mesh

Defines direct input matrices related to collation degrees-of-freedom (js-set) of aerodynamic mesh points for CAERO1, CAERO3, CAERO4 and CAERO5 and for the slender body elements of CAERO2. These include W2GJ, FA2J and input pressures and downwashes associated with AEPRESS and AEDW entries. The matrix is described by a single header entry and one or more column entries. A column entry is required for each column with nonzero elements. For entering data for the interference elements of a CAERO2, use DMIJI or DMI.

#### Header Entry Format:

1	2	3	4	5	6	7	8	9	10
DMIJ	NAME	"0"	IFO	TIN	TOUT	POLAR		NCOL	

#### Column Entry Format:

DMIJ	NAME	GJ	CJ		G1	C1	A1	B1	
	G2	C2	A2	B2	-etc.-				

#### Example:

DMIJ	ALPH1	0	9	2	0			1	
DMIJ	ALPH1	1	1		1	1	.1		
	2	1	.1						

Descriptor	Meaning
NAME	Name of the matrix. See Remark 1. (One to eight alphanumeric characters, the first of which is alphabetic.)
IFO	Form of matrix being input. (Integer) 1            Square 9 or 2      Rectangular 6            Symmetric
TIN	Type of matrix being input: (Integer) 1            Real, single precision (One field is used per element) 2            Real, double precision (One field is used per element) 3            Complex, single precision (Two fields are used per element) 4            Complex, double precision (Two fields are used per element)
TOUT	Type of matrix being created: (Integer) 0            Set by precision system cell (Default) 1            Real, single precision

Describer	Meaning
	2      Real, double precision
	3      Complex, single precision
	4      Complex, double precision
POLAR	Input format of Ai, Bi. (Integer = blank or 0 indicates real, imaginary format. Integer > 0 indicated magnitude, phase format.)
NCOL	Number of columns in a rectangular matrix. Used only for IFO = 9. (Integer > 0)
GJ	Grid, scalar or extra point identification number for column index. (Integer > 0)
CJ	Component number for grid point GJ. (0 < Integer ≤ 6; blank or zero if GJ is a scalar or extra point.)
Gi	Grid, scalar, or extra point identification number for row index. (Integer > 0)
Ci	Component number for Gi for a grid point. (0 < CJ ≤ 6; blank or zero if Gi is a scalar or extra point.)
Ai, Bi	Real and imaginary (or amplitude and phase) parts of a matrix element. If the matrix is real (TIN = 1 or 2), then Bi must be blank. (Real)

**Remarks:**

1. Matrices defined on this entry are referenced in static aeroelastic analysis by reference on AEDW and/or AEPRESS entries. In that paradigm, a single column is required. Also, DMIJ may also be used for the W2GJ and FA2J entries. Again, a single column is required. If both DMI and DMIJ are specified for W2GJ or FA2J, the DMI entry will be used. DMI may NOT be used for AEDW and AEPRESS.
2. The js-set DOF's for each aerodynamic theory are limited to the six-DOF paradigm (3 translations and 3 rotations). However, particular DOF's are permanently SPC'd based on the theory's ability to support those degrees-of-freedom. Unlike the DMIG entry, DMIJ data will be partitioned to the j-set, not reduced. No warnings are issued about truncated data. The j-set DOF's for each aerodynamic element/grid are highly method dependent. The following data define the known set, but the j-set definition is somewhat arbitrary in the general (external aerodynamics) paradigm.

Entry Type	COMP				
	1	2	3	5	6
CAERO1			X		
CAERO2-Y		X			
CAERO2-Z			X		
CAERO2-ZY		X	X		

3. The header entry containing IFO, TIN and TOUT is required. Each nonnull column is started with a GJ, CJ pair. The entries for each row of that column then follow. Only nonzero terms need be entered. The terms may be input in arbitrary order. A GJ, CJ pair may be entered more than once, but the input of an element of the matrix more than once results in a fatal message.
4. Field 3 of the header entry must contain an integer 0.
5. For symmetric matrices (very rare in the j-set!) (IFO=6), a given off-diagonal element may be input either below or above the diagonal. While upper and lower triangle terms may be mixed, a fatal message will be issued if an element is input both above and below the diagonal.
6. The recommended format for rectangular matrices requires the use of NCOL and IFO = 9, the number of columns in the matrix is NCOL. (The number of rows in all DMIJ matrices is always the js-set size--the union of the j-set and the permanently SPC'd partition). The GJ term is used for the column index. the CJ term is ignored.
7. If NCOL is not used for rectangular matrices, two different conventions are available:
  - If IFO = 9, GJ and CJ will determine the sorted sequence, but will otherwise be ignored; a rectangular matrix will be generated with the columns submitted being in the 1 to N positions, where N is the number of logical entries submitted (not counting the header entry).
  - If IFO = 2, the number of columns of the rectangular matrix will be equal to the index of the highest numbered non-null column (in internal sort). Trailing null columns of the js-size matrix will be truncated.
8. The matrix names must be unique among all DMIJ.
9. TIN should be consistent with the number of decimal digits required to read the input data adequately. For a single precision specification on a short word machine, the input will be truncated after about eight decimal digits, even when more digits are present in a double field format. If more digits are needed, a double precision specification should be used instead. However, not that a double precision specification requires a "D" type exponent even for terms that do not need an exponent. For example, unity may be input as 1.0 in single precision, but the longer form 1.0D0 is required for double precision.
10. On long word machines, almost all matrix calculations are performed in single precision and, on short word machines, in double precision. It is recommended that DMIJ matrices also follow these conventions for a balance of efficiency and reliability. The recommended value for TOUT is 0, which instructs the program to inspect the system cell that measures the machine precision at run time and sets the precision of the matrix to the same value. TOUT = 0 allows the same DMIJ input to be used on any machine. If TOUT is contrary to the machine type specified, unreliable results may occur.
11. If any DMIJ entry is changed or added on restart then a complete reanalysis is performed. Therefore, DMIJ entry changes or additions are not recommended on restart.

**DMIJ**

**Direct Matrix Input at js-Set of the Interference Body**

Defines direct input matrices related to collation degrees-of-freedom (js-set) of aerodynamic mesh points for the interference elements of CAERO2. These include W2GJ, FA2J and input pressures and downwashes associated with AEPRESS and AEDW entries. The matrix is described by a single header entry and one or more column entries. A column entry is required for each column with nonzero elements. For entering data for the slender elements of a CAERO2, or a CAERO1, 3, 4 or 5 use DMIJ or DMI.

**Header Entry Format:**

1	2	3	4	5	6	7	8	9	10
DMIJ	NAME	"0"	IFO	TIN	TOUT	POLAR		NCOL	

**Column Entry Format:**

DMIJ	NAME	GJ	CJ		G1	C1	A1	B1	
	G2	C2	A2	B2	-etc.-				

**Example:**

DMIJ	ALPH1	0	9	2	0			1	
DMIJ	ALPH1	1	1		1	1	.1		
	2	1	.1						

Describer	Meaning
NAME	Name of the matrix. See Remark 1. (One to eight alphanumeric characters, the first of which is alphabetic.)
IFO	Form of matrix being input. (Integer) 1 Square 9 or 2 Rectangular 6 Symmetric
TIN	Type of matrix being input: (Integer) 1 Real, single precision (One field is used per element) 2 Real, double precision (One field is used per element) 3 Complex, single precision (Two fields are used per element) 4 Complex, double precision (Two fields are used per element)
TOUT	Type of matrix being created: (Integer) 0 Set by precision system cell (Default) 1 Real, single precision 2 Real, double precision

Describer	Meaning
	3          Complex, single precision
	4          Complex, double precision
POLAR	Input format of Ai, Bi. (Integer = blank or 0 indicates real, imaginary format. Integer > 0 indicated magnitude, phase format.)
NCOL	Number of columns in a rectangular matrix. Used only for IFO = 9. (Integer > 0)
GJ	Grid, scalar or extra point identification number for column index. (Integer > 0)
CJ	Component number for grid point GJ. (0 < Integer ≤ 6; blank or zero if GJ is a scalar or extra point.)
Gi	Grid, scalar, or extra point identification number for row index. (Integer > 0)
Ci	Component number for Gi for a grid point. (0 < CJ ≤ 6; blank or zero if Gi is a scalar or extra point.)
Ai, Bi	Real and imaginary (or amplitude and phase) parts of a matrix element. If the matrix is real (TIN = 1 or 2), then Bi must be blank. (Real)

**Remarks:**

1. Matrices defined on this entry are referenced in static aeroelastic analysis by reference on AEDW and/or AEPRESS entries. In that paradigm, a single column is required. DMI may NOT be used for AEDW and AEPRESS.
2. The js-set DOF's for each aerodynamic theory are limited to the six-DOF paradigm (3 translations and 3 rotations). However, particular DOF's are permanently SPC'd based on the theory's ability to support those degrees-of-freedom. Unlike the DMIG entry, DMIJI data will be partitioned to the j-set, not reduced. No warnings are issued about truncated data. The j-set DOF's for each aerodynamic element/grid are highly method dependent. The following data define the known set, but the j-set definition is somewhat arbitrary in the general (external aerodynamics) paradigm.

Entry Type	COMP				
	1	2	3	5	6
CAERO2-Y		X			
CAERO2-Z			X		
CAERO2-ZY		X	X		

3. The header entry containing IFO, TIN and TOUT is required. Each nonnull column is started with a GJ, CJ pair. The entries for each row of that column then follow. Only nonzero terms need be entered. The terms may be input in arbitrary order. A GJ, CJ pair may be entered more than once, but the input of an element of the matrix more than once results in a fatal message.
4. Field 3 of the header entry must contain an integer 0.

5. For symmetric matrices (very rare in the j-set!) (IFO=6), a given off-diagonal element may be input either below or above the diagonal. While upper and lower triangle terms may be mixed, a fatal message will be issued if an element is input both above and below the diagonal.
6. The recommended format for rectangular matrices requires the use of NCOL and IFO = 9. the number of columns in the matrix is NCOL. (The number of rows in all **DMJI** matrices is always the js-set size--the union of the j-set and the permanently SPC'd partition). The GJ term is used for the column index. the CJ term is ignored.
7. If NCOL is not used for rectangular matrices, two different conventions are available:
  - If IFO = 9, GJ and CJ will determine the sorted sequence, but will otherwise be ignored; a rectangular matrix will be generated with the columns submitted being in the 1 to N positions, where N is the number of logical entries submitted (not counting the header entry).
  - If IFO = 2, the number of columns of the rectangular matrix will be equal to the index of the highest numbered nonnull column (in internal sort). Trailing null columns of the js-size matrix will be truncated.
8. The matrix names must be unique among all **DMJI**.
9. TIN should be consistent with the number of decimal digits required to read the input data adequately. For a single precision specification on a short word machine, the input will be truncated after about eight decimal digits, even when more digits are present in a double field format. If more digits are needed, a double precision specification should be used instead. However, not that a double precision specification requires a "D" type exponent even for terms that do not need an exponent. For example, unity may be input as 1.0 in single precision, but the longer form 1.0D0 is required for double precision.
10. On long word machines, almost all matrix calculations are performed in single precision and, on short word machines, in double precision. It is recommended that **DMIJ** matrices also follow these conventions for a balance of efficiency and reliability. The recommended value for TOUT is 0, which instructs the program to inspect the system cell that measures the machine precision at run time and sets the precision of the matrix to the same value. TOUT = 0 allows the same **DMJI** input to be used on any machine. If TOUT is contrary to the machine type specified, unreliable results may occur.
11. If any **DMIJ** entry is changed or added on restart then a complete reanalysis is performed. Therefore, **DMIJ** entry changes or additions are not recommended on restart.

## DMIK

### Direct Matrix Input at ks-Set of the Aerodynamic Mesh

Defines direct input matrices related to physical (displacement) degrees-of-freedom (ks-set) of aerodynamic grid points. These include WKK, WTFAC and input forces associated with AEFORCE entries. The matrix is described by a single header entry and one or more column entries. A column entry is required for each column with nonzero elements.

#### Header Entry Format:

1	2	3	4	5	6	7	8	9	10
DMIK	NAME	"0"	I FO	TIN	TOU T	POLAR		NCOL	

#### Column Entry Format:

DMIK	NAME	GJ	CJ		G1	C1	A1	B1	
	G2	C2	A2	B2	-etc.-				

#### Example:

DMIK	ALPH1	0	9	2	0			1	
DMIK	ALPH1	1	1		1	1	1.0		
	2	1	1.0						

Descriptor	Meaning
------------	---------

NAME	Name of the matrix. See Remark 1. (One to eight alphanumeric characters, the first of which is alphabetic.)
I FO	Form of matrix being input. (Integer) 1 Square 9 or 2 Rectangular 6 Symmetric
TIN	Type of matrix being input: (Integer) 1 Real, single precision (One field is used per element) 2 Real, double precision (One field is used per element) 3 Complex, single precision (Two fields are used per element) 4 Complex, double precision (Two fields are used per element)
TOU T	Type of matrix being created: (Integer) 0 Set by precision system cell (Default) 1 Real, single precision 2 Real, double precision 3 Complex, single precision

Describer	Meaning
	4          Complex, double precision
POLAR	Input format of Ai, Bi. (Integer = blank or 0 indicates real, imaginary format. Integer > 0 indicated magnitude, phase format.)
NCOL	Number of columns in a rectangular matrix. Used only for IFO = 9. (Integer > 0)
GJ	Grid, scalar or extra point identification number for column index. (Integer > 0)
CJ	Component number for grid point GJ. (0 < Integer ≤ 6; blank or zero if GJ is a scalar or extra point.)
Gi	Grid, scalar, or extra point identification number for row index. (Integer > 0)
Ci	Component number for Gi for a grid point. (0 < CJ < 6; blank or zero if Gi is a scalar or extra point.)
Ai, Bi	Real and imaginary (or amplitude and phase) parts of a matrix element. If the matrix is real (TIN = 1 or 2), then Bi must be blank. (Real)

**Remarks:**

1. Matrices defined on this entry are referenced in static aeroelastic analysis by reference on AEFORCE entries. In that paradigm, a single column is required. Also, DMIK may also be used for the WKK and WTFAC T entries. Matrices defined on this entry are referenced in static aeroelastic analysis by reference on AEFORCE entries. In that paradigm, a single column is required. Also, DMIK may also be used for the WKK and WTFAC T entries. If both DMI and DMIK are specified for WKK or WTFAC T, the DMI entry will be used. DMI may NOT be used for AEFORCE.
2. The ks-set DOF's for each aerodynamic theory are limited to the six-DOF paradigm (3 translations and 3 rotations). However, particular DOF's are permanently SPC'd based on the theory's ability to support those degrees-of-freedom. Unlike the DMIG entry, DMIK data will be partitioned to the k-set, not reduced. No warnings are issued about truncated data. The k-set DOF's for each aerodynamic element/grid are highly method dependent. The following data define the known set, but the j-set definition is somewhat arbitrary in the general (external aerodynamics) paradigm.

Entry Type	COMP				
	1	2	3	5	6
CAERO1			X	X	
CAERO2-Y		X		X	
CAERO2-Z			X		X
CAERO2-ZY		X	X	X	X

3. The header entry containing IFO, TIN and TOUT is required. Each nonnull column is started with a GJ, CJ pair. The entries for each row of that column then follow. Only nonzero terms need be entered. The terms may be input in arbitrary order. A GJ, CJ pair may be entered more than once, but the input of an element of the matrix more than once results in a fatal message.

4. Field 3 of the header entry must contain an integer 0.
5. For symmetric matrices (IFO=6), a given off-diagonal element may be input either below or above the diagonal. While upper and lower triangle terms may be mixed, a fatal message will be issued if an element is input both above and below the diagonal.
6. The recommended format for rectangular matrices requires the use of NCOL and IFO = 9. The number of columns in the matrix is NCOL. (The number of rows in all DMIK matrices is always the ks-set size--the union of the k-set and the permanently SPC'd partition). The GJ term is used for the column index. The CJ term is ignored.
7. If NCOL is not used for rectangular matrices, two different conventions are available:
  - If IFO = 9, GJ and CJ will determine the sorted sequence, but will otherwise be ignored; a rectangular matrix will be generated with the columns submitted being in the 1 to N positions, where N is the number of logical entries submitted (not counting the header entry).
  - If IFO = 2, the number of columns of the rectangular matrix will be equal to the index of the highest numbered non-null column (in internal sort). Trailing null columns of the js-size matrix will be truncated.
8. The matrix names must be unique among all DMIK.
9. TIN should be consistent with the number of decimal digits required to read the input data adequately. For a single precision specification on a short word machine, the input will be truncated after about eight decimal digits, even when more digits are present in a double field format. If more digits are needed, a double precision specification should be used instead. However, not that a double precision specification requires a "D" type exponent even for terms that do not need an exponent. For example, unity may be input as 1.0 in single precision, but the longer form 1.0D0 is required for double precision.
10. On long word machines, almost all matrix calculations are performed in single precision and, on short word machines, in double precision. It is recommended that DMIK matrices also follow these conventions for a balance of efficiency and reliability. The recommended value for TOUT is 0, which instructs the program to inspect the system cell that measures the machine precision at run time and sets the precision of the matrix to the same value. TOUT = 0 allows the same DMIK input to be used on any machine. If TOUT is contrary to the machine type specified, unreliable results may occur.
11. If any DMIK entry is changed or added on restart then a complete reanalysis is performed. Therefore, DMIK entry changes or additions are not recommended on restart.

## DOPTPRM

## Design Optimization Parameters

Overrides default values of parameters used in design optimization.

### Format:

1	2	3	4	5	6	7	8	9	10
DOPTPRM	PARAM1	VAL1	PARAM2	VAL2	PARAM3	VAL3	PARAM4	VAL4	
	PARAM5	VAL5	-etc.-						

### Example:

DOPTPRM	IPRINT	5	DESMAX	10					
---------	--------	---	--------	----	--	--	--	--	--

Describer	Meaning
PARAMi	Name of the design optimization parameter. Allowable names are given in <a href="#">Table 11</a> . (Character)
VALi	Value of the parameter. (Real or Integer, see <a href="#">Table 11</a> .)

Table 11 PARAMi Names and Descriptions

Name	Description, Type, and Default Value
APRCOD	Approximation method to be used. (Integer 1, 2, or 3; Default = 2)
	1 Direct Linearization. APRCOD = 1 is recommended for shape, topology and topography optimization problems.
	2 Mixed Method based on response type
	3 Convex Linearization
AUTOSE	Flag to request an AESO job. AUTOSE = 1 activates an AESO creation run. (Integer $\geq 0$ ; Default = 0)
CONV1	Relative criterion to detect convergence. If the relative change in objective between two optimization cycles is less than CONV1, then optimization is terminated. Topology optimization can be terminated with $CONV1 < 5.00E-3$ (Real $> 0.0$ ; Default = 0.001).
CONV2	Absolute criterion to detect convergence. If the absolute change in objective between two optimization cycles is less than CONV2, then optimization is terminated. (Real $> 0.0$ ; Default = $1.0E-20$ )
CONVDV	Relative convergence criterion on design variables. (Real $> 0.0$ ; Default = 0.001 for non-topology; Default = 0.0001 for topology optimization)
CONVPR	Relative convergence criterion on properties. (Real $> 0.0$ ; Default = 0.001)

Table 11 PARAMi Names and Descriptions (continued)

Name	Description, Type, and Default Value	
CT	Constraint tolerance. Constraint is considered active if current value is greater than CT. (Real < 0.0; Default = -0.03)	
CTMIN	Constraint is considered violated if current value is greater than CTMIN. (Real > 0.0; Default = 0.003)	
DABOBJ	Maximum absolute change in objective between two consecutive iterations to indicate convergence at optimizer level. F0 is the initial objective function value. (Real > 0.0; Default = MAX[0.001*ABS(F0), 0.0001])	
DELB	Relative finite difference move parameter. (Real > 0.0; Default = 0.0001; 0.001 for fatigue responses)	
DELOBJ	Maximum relative change in objective between two consecutive iterations to indicate convergence at optimizer level. (Real > 0.0; Default = 0.001)	
DELP	Fractional change allowed in each property during any optimization design cycle. This provides constraints on property moves. (Real, 0.0<DELP<1.0, default=0.2)	
DELX	Fractional change allowed in each design variable during any optimization cycle. (Real > 0.0; Default = .5 for sizing/shape/topometry optimization; Default = 0.2 for topology and topography optimization)	
DELXESL	Fractional change allowed in each design variable during the ESLNRO loop. (Real > 0.0, Default = 0.5)	
DESMAX	Maximum number of design cycles (not including FSD cycle) to be performed. (Integer ≥ 0; Default = 5 for sizing/shape optimization; Default = 30 for topology, topography, and topometry optimization)	
DISCOD	Discrete Processing Method: (Integer 0, 1, 2, 3 or 4; Default = 1)	
	0	No Discrete Optimization
	1	Design of Experiments
	2	Conservative Discrete Design
	3	Round up to the nearest design variable
4	Round off to the nearest design variable	
DISBEG	Design cycle ID for discrete variable processing initiation. Discrete variable processing analysis is carried out for every design cycle after DISBEG. (Integer ≥ 0; Default = 0=the last design cycle)	
DPMAX	Maximum fraction of change on designed property (Default = 0.5), used by Trust Region Method.	
DPMIN	Minimum move limit imposed. (Real > 0.0; Default = 0.01)	
DRATIO	Theshold value that can be used to turn off an active AESO job. An AESO job is terminated if the ratio of the size of a design model to that of an analysis model is greater than DRATIO. (Real > 0.; Default = 0.1)	

Table 11 PARAMi Names and Descriptions (continued)

Name	Description, Type, and Default Value	
DSMXESL	Maximum number of design cycles applied to the ESLNRO loop. (Integer $\geq 0$ ; Default = 20)	
DXMAX	Maximum fraction of change on design variable (Default = 1.0), used by Trust Region Method.	
DXMIN	Minimum design variable move limit. (Real $> 0.0$ ; Default = 0.05 for sizing/shape/topometry optimization; Default = 1.0E-5 for topology and topography optimization)	
ETA1 ( $\eta_1$ )	the cutting ratio 1 (Default = 0.01), used by Trust Region Method.	
ETA2 ( $\eta_2$ )	the cutting ratio 2 (Default = 0.25), used by Trust Region Method.	
ETA3 ( $\eta_3$ )	the cutting ratio 3 (Default = 0.7), used by Trust Region Method.	
FSDALP	Relaxation parameter applied in Fully Stressed Design. (Real, $0.0 < \text{FSDALP} \leq 1.0$ ; Default = 0.9)	
FSDMAX	Specifies the number of Fully Stressed Design Cycles that are to be performed. (Integer; Default = 0)	
GMAX	Maximum constraint violation allowed at the converged optimum. (Real $> 0.0$ ; Default = 0.005)	
GSCAL	Constraint normalization factor. See Remarks under the DSCREEN and DCONSTR entries. (Real $> 0.0$ ; Default = 0.001)	
IGMAX	If IGMAX = 0, only gradients of active and violated constraints are calculated. If IGMAX $> 0$ , up to IGMAX gradients are calculated including active, violated, and near active constraints. For many constraint problems, a reasonable value of IGMAX = 2*NDV (number of design variables). A smaller IGMAX has a faster performance of MSCADS. (Integer $> 0$ ; Default = 0)	
IPRINT	Print control during approximate optimization phase. Increasing values represent increasing levels of optimizer information. ( $0 \leq \text{Integer} \leq 7$ ; Default = 0)	
	0	No output (Default)
	1	Internal optimization parameters, initial information, and results
	2	Same, plus objective function and design variables at each iterations
	3	Same, plus constraint values and identification of critical constraints
	4	Same, plus gradients
	5	Same, plus search direction
	6	Same, plus scaling factors and miscellaneous search information
7	Same, plus one dimensional search information	
ISCAL	Design variables scaling. (Integer $\geq -1$ ; Default = 0) = -1 no scaling; $\geq 0$ scaling	

Table 11 PARAMi Names and Descriptions (continued)

Name	Description, Type, and Default Value	
METHOD	Optimization Method: (Integer $\geq 0$ ; Default = 0)	
	0	Automatic selection for a better performance based on number of design variables, number of constraints, number of active/violated constraints and computer memory.
	1	Modified Method of Feasible Directions for MSCADS.
	2	Sequential Linear Programming for MSCADS
	3	Sequential Quadratic Programming for MSCADS
	4	SUMT method for MSCADS
	IJK	See Remark 3.
NASPRO	First cycle analysis output control. (Integer 0 or 1)	
	0	Print analysis output of first cycle. (Default)
	1	Do NOT print analysis output of first cycle.
OBJMOD	Objective function modification. (Integer; Default = 0)	
	0	Objective function will not be modified.
	1	Objective function will be reset to 0.0. Subsequently, printed objective function value represents the change of objective function.
OPTCOD	OPTCOD. See Remark 2. (Character; Default = Blank)	
	Blank	Taken from system cell number 413
	"MSCADS"	MSCADS is used
	"IPOPT"	IPOPT is used
	"External Optimizer SCA Service Identifier"	
	Must be defined in the CONNECT Service statement (see <i>MSC Nastran User Defined Services User's Guide</i> )	
P1	Print control items specified for P2. (Integer $\geq 0$ ; Default = 0) Initial results are always printed prior to the first approximate optimization. If an optimization task is performed, final results are always printed for the final analysis unless PARAM,SOFTEXIT,YES is specified. These two sets of print are not controllable.	
	n	Print at every n-th design cycle.

Table 11 PARAMi Names and Descriptions (continued)

Name	Description, Type, and Default Value	
P2	Items to be printed according to P1: (Integer; Default = 1)	
	0	No print.
	1	Print objective and design variables. (Default for sizing/shape optimization) Print objective. (Default for topology optimization) P2 ≥ 13 Print design variables for topology, topography, and topometry optimization
	2	Print properties.
	4	Print constraints.
	8	Print responses.
	16	Print weight as a function of a material ID (note that this is not a design quantity so that only inputs to the approximate design are available).
	n	Sum of desired items. For example, P2 = 10 means print properties and responses.
P2CALL	Maximum number of retained constraints of all categories to be printed per category. This single parameter can be used in place of the individual parameters P2CBL, P2CC, P2CDDV, P2CM, P2CP and P2CR. If any of these six parameters are non-zero, the P2CALL value is overridden for that constraint type. (Integer > 0; default is to print all retained constraints.)	
P2CBL	Maximum number of constraints on beam library dimensions to be printed. (Integer ≥ 0; default is to print all beam library constraints.)	
P2CC	Maximum number of constraints on connectivity properties to be printed. (Integer ≥ 0; default is to print all connectivity property constraints.)	
P2CDDV	Maximum number of constraints on dependent design variables to be printed. (Integer ≥ 0; default is to print all dependent design variable constraints.)	
P2CM	Maximum number of constraints on material properties to be printed. (Integer ≥ 0; default is to print all material property constraints.)	
P2CP	Maximum number of constraints on element properties to be printed. (Integer ≥ 0; default is to print all element property constraints.)	
P2CR	Maximum number of constraints on design responses to be printed. (Integer ≥ 0; default is to print all retained design response constraints.)	
P2RSET	ID of a SET1 Bulk Data entry to identify the set of retained responses (DRESP1, DRESP2 and/or DRESP3) to be printed. (Integer; Default is to print all responses associated with printed constraints. If P2CR is > 0, the set associated P2RSET > 0 will be printed independent of the responses associated with the printed constraint. If P2CR > 0 and PR2SET = -1, all retained responses will be printed.	

Table 11 PARAMi Names and Descriptions (continued)

Name	Description, Type, and Default Value	
PENAL	Penalty parameter used to transform an infeasible approximate optimization task to a feasible one. Setting this parameter to to; e.g., 2.0 may improve optimizer performance when the starting design is infeasible. (Real; Default = 0.0)	
PLVIOL	Flag for handling of property limit violation. By default, the job will terminate with a user fatal message if the property derived from design model (DVPRELi, DVMRELi, DVCRELi) exceeds the property limits. Setting PLVIOL to a non-zero number will cause the program to issue a user warning message by ignoring the property limits violation and proceed with the analysis. (Integer; Default = 0)	
PTOL	Maximum tolerance on differences allowed between the property values on property entries and the property values calculated from the design variable values on the DESVAR entry (through DVPRELi relations). PTOL is provided to trap ill-posed design models. (The minimum tolerance may be specified on user parameter DPEPS. See <a href="#">Parameters</a> ) (Real > 0.0; Default = 1.0E+35)	
STPSCL	Scaling factor for shape finite difference step sizes, to be applied to all shape design variables. (Real > 0.0; Default = 1.0)	
TCHECK	Topology Checkerboarding/minimum member size control option. (Integer $\geq$ -1)	
	1	Filtering algorithm
	2	Density constraint
	0	No control
-1	Automatic selection of filtering or density constraint algorithm for a better performance. (Default)	
TDMIN	Minimum diameter of members in topology optimization. This option is applied on 2 and 3D elements only. (Real > 0.0)	
TREGION	Flag to invoke Trust Region method.	
	0	Don't employ trust regions (Default)
	1	Turn Trust Region on
UPDFAC1	Updating factor 1 (Default = 2.0), used by Trust Region Method.	
UPDFAC2	Updating factor 2 (Default = 0.5), used by Trust Region Method.	

**Remarks:**

1. Only one DOPTPRM entry is allowed in the Bulk Data Section. All defaults recommended.
2. OPTCOD specifies which optimization code to be used in SOL 200 and METHOD specifies which optimization method to be used. The default is recommended.
3. METHOD = IJK enables a user selectable optimization strategy as documented in Vanderplaats, G. N., ADS -- A Fortran Program for Automated Design Synthesis -- Version 1.10, NASA CR 177985, 1985. The default is recommended.

The I selects one of ten available strategy options:

0	None -- Go directly to the optimizer
1	Sequential unconstrained minimization using the exterior penalty function method
2	Sequential unconstrained minimization using the linear extended interior penalty function method
3	Sequential unconstrained minimization using the quadratic extended interior penalty function method
4	Sequential unconstrained minimization using the cubic extended interior penalty function method
5	Augmented Lagrange multiplier method
6	Sequential linear programming
7	Method of centers
8	Sequential quadratic programming
9	Sequential convex programming

The J selects one of five available optimizer options:

1	Fletcher-Reeves algorithm for unconstrained minimization
2	Davidon-Fletcher-Powell (DFP) variable metric method for unconstrained minimization
3	Broydon-Fletcher-Goldfarb-Shanno (BFGS) variable metric method for unconstrained minimization
4	Method of feasible directions for constrained minimization
5	Modified method of feasible directions for constrained minimization

And K selects one of eight available one-dimensional search strategies:

1	Find the minimum of an unconstrained function using the Golden Section method
2	Find the minimum of an unconstrained function using the Golden Section method followed by polynomial interpolation
3	Find the minimum of an unconstrained function by first finding bounds and then using the Golden Section method followed by polynomial interpolation
4	Find the minimum of an unconstrained function by polynomial interpolation/extrapolation without first finding bounds on the solution

5	Find the minimum of a constrained function using the Golden Section method
6	Find the minimum of a constrained function using the Golden Section method followed by polynomial interpolation
7	Find the minimum of a constrained function by first finding bounds and then using polynomial interpolation
8	Find the minimum of a constrained function by polynomial interpolation/extrapolation without first finding bounds on the solution

## DPHASE      Dynamic Load Phase Lead

Defines the phase lead term  $\theta$  in the equation of the dynamic loading function.

### Format:

1	2	3	4	5	6	7	8	9	10
DPHASE	SID	P1	C1	TH1	P2	C2	TH2		

### Example:

DPHASE	4	21	6	2.1	8	6	7.2		
--------	---	----	---	-----	---	---	-----	--	--

Describer	Meaning
SID	Identification number of DPHASE entry. (Integer > 0)
Pi	Grid, extra, or scalar point identification number. (Integer > 0)
Ci	Component number. (Integers 1 through 6 for grid points; zero or blank for extra or scalar points)
THi	Phase lead $\theta$ in degrees. (Real)

### Remarks:

1. One or two dynamic load phase lead terms may be defined on a single entry.
2. SID must be referenced on a RLOADi entry. Refer to the RLOAD1 or RLOAD2 entry for the formulas that define how the phase lead  $\theta$  is used.
3. A DAREA, LSEQ or static load entry should be used to define a load at Pi and Ci.
4. In superelement analysis, DPHASE entries may only be applied to loads on points in the residual structure.
5. RC network solver does not support DPHASE for thermal analysis.

## DRESP1

## Design Sensitivity Response Quantities

Defines a set of structural responses that is used in the design either as constraints or as an objective.

### Format:

1	2	3	4	5	6	7	8	9	10
DRESP1	ID	LABEL	RTYPE	PTYPE	REGION	ATTA	ATTB	ATT1	
	ATT2	-etc.-							

### Example:

DRESP1	1	DX1	STRESS	PROD	2	3		102	
	103								

DRESP1	10	BMWV	WMPID	PSHELL		10		10	
	20	30							

Describer	Meaning
ID	Unique entry identifier. (Integer > 0)
LABEL	User-defined label. (Character, no default)
RTYPE	Response type. See <a href="#">Table 12</a> . (Character)
PTYPE	Element flag (PTYPE = "ELEM") or property entry name. Used with element type responses (stress, strain, force, etc.) to identify the property type, since property entry IDs are not unique across property types. (Character: "ELEM", "PBAR", "PSHELL", etc.)
REGION	Region identifier for constraint screening. See <a href="#">Remark 10</a> for defaults. (Integer > 0)
ATTA, ATTB, ATTi	Response attributes. See <a href="#">Table 12</a> . (Integer > 0 or Real or blank)

Table 12      Design Sensitivity Response Attributes

Response Type (RTYPE)	Response Attributes		
	ATTA (Integer > 0)	ATTB (Integer > 0 or Real > 0.0)	ATTI (Integer > 0)
WEIGHT	Row Number ( $1 \leq \text{ROW} \leq 6$ ) See Remark 23.	Column Number ( $1 \leq \text{COL} \leq 6$ )	SEID <sub>i</sub> or All or blank. See Remark 12.
VOLUME	Blank	Blank	SEID <sub>i</sub> or ALL or blank. See Remark 12.
FRMASS See Remarks 27. & 28.	Blank	Blank	Blank or Property ID (PID). See Remark 36.
COMP See Remark 27.	Blank	Blank	Blank
EIGN	Normal Modes Mode Number. See Remark 32.	Approximation Code. See Remark 19.	Blank
CEIG	Complex Eigenvalue Mode Number. (Integer > 0)	ALPHA or OMEGA (Default = ALPHA)	Blank
FREQ	Normal Modes Mode Number. See Remarks 18. and 32.	Approximation Code. See Remark 19.	Blank
LAMA	Buckling Mode Number	Approximation Code. See Remark 19.	Blank
DISP	Displacement Component	Blank or Mode Number	Grid ID
STRAIN	Strain Item Code	Blank or Mode Number	Property ID (PID) or Element ID (EID)
ESE	Strain Energy Item Code See Remark 20.	Blank or Mode Number	Property ID (PID) or Element ID (EID)
STRESS	Stress Item Code	Blank or Mode Number	Property ID (PID) or Element ID (EID)
FORCE	Force Item Code	Blank or Mode Number	Property ID (PID) or Element ID (EID)
FATIGUE (pseudo-static) See Remark 38.	Fatigue Item Code. See Remark 42.	ID of a FATIGUE case control. See Remark 39.	Property ID (PID) or Element ID (EID)

Table 12 Design Sensitivity Response Attributes

Response Type (RTYPE)	Response Attributes		
	ATTA (Integer > 0)	ATTB (Integer > 0 or Real > 0.0)	ATTI (Integer > 0)
FRFTG (frequency response - random vibration fatigue) See Remark 38.	Fatigue Item Code. See Remark 42.	ID of a FATIGUE case control. See Remark 39.	Property ID (PID) or Element ID (EID)
SPCFORCE	SPC Force Component	Blank	Grid ID
CSTRAIN See Remark 2.	Strain Item Code	LAMINA Number or GPLYIDi (Integer; Default = 1)	Property ID (PID) or Element ID (EID)
CSTRESS See Remark 2.	Stress Item Code	LAMINA Number or GPLYIDi (Integer; Default = 1)	Property ID (PID) or Element ID (EID)
CFailure See Remark 2.	Failure Indices Item Code	LAMINA Number or GPLYIDi (Integer; Default = 1)	Property ID (PID) or Element ID (EID)
CSTRAT See Remark 2.	Composite Strength Ratio Item Code	LAMINA Number or GPLYIDi (Integer; Default = 1)	Property ID (PID) or Element ID (EID)
TOTSE (Total Strain Energy)	Blank	Blank or Mode Number	SEIDi or All or blank. See Remark 12.
GPFORCE	GPFORCE Component Code (1-6; see Remark 24.)	Blank	Element ID
GPFORCP	Grid Point (see Remark 25.)	Blank	Grid ID connected to ATTA grid to specify orientation.
ABSTRESS	Arbitrary Beam Stress Item Code (see Remark 29.)	Blank	Property ID (PID) or Element ID (EID)
FRDISP	Displacement Component	Frequency Value. (Blank; Real $\geq 0.0$ or Character) See Remarks 15. and 20.	Grid ID
PRES	Acoustic Pressure Component (= 1 or 7)	Frequency Value. (Blank; Real $\geq 0.0$ or Character) See Remarks 15. and 20.	Grid ID

Table 12 Design Sensitivity Response Attributes

Response Type (RTYPE)	Response Attributes		
	ATTA (Integer > 0)	ATTB (Integer > 0 or Real > 0.0)	ATTI (Integer > 0)
FRVELO	Velocity Component	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Grid ID
FRACCL	Acceleration Component	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Grid ID
FRSPCF	SPC Force Component	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Grid ID
FRSTRE	Stress Item Code	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Property ID (PID) or Element ID (EID)
FRFORC	Force Item Code	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Property ID (PID) or Element ID (EID)
PSDDISP	Displacement Component (see Remarks 26. and 30.)	Frequency Value. (Blank; Real $\geq$ 0.0 or Character). See Remarks 15. and 20.	Grid ID
PSDVELO	Velocity Component (see Remarks 26. and 30.)	Frequency Value (Blank; Real $\geq$ 0.0 or Character). See Remarks 15. and 20.	Grid ID
PSDACCL	Acceleration Component (see Remarks 26. and 30.)	Frequency Value. (Blank; Real $\geq$ 0.0 or Character). See Remarks 15. and 20.	Grid ID

Table 12 Design Sensitivity Response Attributes

Response Type (RTYPE)	Response Attributes		
	ATTA (Integer > 0)	ATTB (Integer > 0 or Real > 0.0)	ATTI (Integer > 0)
RMSDISP	Displacement Component (see Remark 30.)	RANDPS ID	Grid ID
RMSVELO	Velocity Component (see Remark 30.)	RANDPS ID	Grid ID
RMSACCL	Acceleration Component (see Remark 30.)	RANDPS ID	Grid ID
ACPWR (Acoustic Power radiated through a panel) See Remark 33.	Blank	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Blank
ACINTS (Acoustic Intensity)	Blank	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Grid ID of wetted surface.
AFPRES (Acoustic Pressure for AFPM) See Remark 34.	Acoustic Pressure Component (Integer = 1 or 7)	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Grid ID of AFPMID.
AFINTS (Acoustic Intensity for AFPM) See Remark 34.	Component Code - 0 - normal to AFPM, 1 - x-dir 2 - y-dir 3 - z-dir	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Grid ID of AFPMID.
AFVELO (Velocity for AFPM) See Remark 34.	Component Code - 11 - Real/Mag in x-dir 12 - Real/Mag in y-dir 13 - Real/Mag in z-dir 71 - Img/Ph in x-dir 72 - Img/Ph in y-dir 73 - Img/Ph in z-dir	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Grid ID of AFPMID.
AFPWR (Acoustic Power for AFPM) See Remark 34.	Blank	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Blank

Table 12 Design Sensitivity Response Attributes

Response Type (RTYPE)	Response Attributes		
	ATTA (Integer > 0)	ATTB (Integer > 0 or Real > 0.0)	ATTI (Integer > 0)
DYSTIFF	Dynamic Stiffness Component	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Grid ID
ERP See Remarks 40. and 41.	ERP Item Code	Frequency Value. (Blank; Real $\geq$ 0.0 or Character) See Remarks 15. and 20.	Set3 ID or Blank
TDISP	Displacement Component	Time Value. (Blank; Real; or Character) See Remarks 16. and	Grid ID
TVELO	Velocity Component	Time Value. (Blank; Real, or Character) See Remarks 16. and	Grid ID
TACCL	Acceleration Component	Time Value. (Blank; Real, or Character) See Remarks 16. and	Grid ID
TSPCF	SPC Force Component	Time Value. (Blank; Real, or Character) See Remarks 16. and	Grid ID
TSTRE	Stress Item Code	Time Value. (Blank; Real, or Character) See Remarks 16. and	Property ID (PID) or Element ID (EID)
TFORC	Force Item Code	Time Value. (Blank; Real, or Character) See Remarks 16. and	Property ID (PID) or Element ID (EID)
STMONP1 Structural MONPNT1	Component See Remark 35.	Blank	Blank
STMOND1 Structural MONDSP1	Component See Remark 35.	Blank	Blank
MONPNT3	Component See Remark 35.	Blank	Blank

Table 12 Design Sensitivity Response Attributes

Response Type (RTYPE)	Response Attributes		
	ATTA (Integer > 0)	ATTB (Integer > 0 or Real > 0.0)	ATTI (Integer > 0)
AEMONP1 Aerodynamic MONPNT1	Component See Remark 35.	Blank	Blank
AEMOND1 Aerodynamic MONDSP1	Component See Remark 35.	Blank	Blank
TRIM	AESTAT or AESURF entry ID	Blank	Blank
STABDER	AESTAT or AESURF entry ID	Restraint Flag. (Integer 0 or 1) See Remark 13.	Component
FLUTTER	Blank	Blank	See Remark 14.
DIVERG	Divergence Root Number See remark 37.	Blank	Mach No.
WMPID See Remarks 43. and 44.	MID	SEID	PID

**Remarks:**

1. Stress, strain, force, fatigue and ERP item codes can be found in [Item Codes](#). For stress or strain item codes that have dual meanings, such as von Mises or maximum shear, the option specified in the Case Control Section will be used; i.e., STRESS(VONM) or STRESS(MAXS).
2. RTYPE = “CSTRESS”, “CSTRAIN”, “CFAILURE”, and “CSTRAT” are used only with the PCOMP/PCOMPG entry. “CSTRESS” and “CSTRAIN” item codes are described under Table 1 (Element Stress/Strain Item Codes) in [Item Codes](#). “CFAILURE” and “CSTRAT” item codes are described under Table 2 (Element Force Item Codes) in [Item Codes](#). Only force item codes that refer to failure indices of direct stress and interlaminar shear stress are valid.

The CFAILURE and CSTRAT response types requires the following specifications on the applicable entries:

- Failure theory in the FT field on PCOMP/PCOMPG entry.
  - Allowable bonding shear stress in the SB field on PCOMP/PCOMPG entry.
  - Stress limits in the ST, SC, and SS fields on all MATi entries.
  - When the PCOMPG is invoked, there is no default for the ATTB field.
3. ATTB can be used for responses of weight, composite laminae, dynamics, real and complex eigenvalues, WMPID and stability derivatives. For eigenvector responses, such as DISP, the ATTB identifies the mode of interest. For other responses, this field must be blank.

4. All grids associated with a DRESP1 entry are considered to be in the same region for screening purposes. Only up to NSTR displacement constraints (see DSCREEN entry) per group per load case will be retained in the design optimization phase.
5. DRESP1 identification numbers must be unique with respect to DRESP2 identification numbers.
6. If PTYPE = "ELEM", the ATT<sub>i</sub> correspond to element identification numbers.
7. If RTYPE = "DISP", "SPCFORCE", "GPFORCE", "TDISP", "TVELO", "TACCL" or "TSPCF", multiple component numbers (any unique combination of the digits 1 through 6 with no embedded blanks) may be specified on a single entry. Multiple response components may not be used on any other response types.
8. If RTYPE = "FRDISP", "FRVELO", "FRACCL", or "FRSPCF" only one component number may be specified in the ATTA field. Numbers 1 through 6 correspond to real (or magnitude) components and 7 through 12 imaginary (or phase) components. If more than one component for the same grid is desired, then a separate entry is required.
9. Real/imaginary representation is the default for complex response types. Magnitude/phase representation must be requested by the corresponding Case Control command; e.g., DISP(PHASE) = ALL for FRDISP type responses.
10. REGION is used for constraint screening. The NSTR field on DSCREEN entries gives the maximum number of constraints retained for each region per load case.  
If RTYPE = "WEIGHT", "VOLUME", "LAMA", "EIGN", "FREQ", "CEIG", "TOTSE", "RMSDISP", "RMSVELO", "RMSACCL", no REGION identification number should be specified. If the region field is left blank for a grid response, one region is created for each DRESP1 ID. If the region field is left blank for an element response, one region is created for each property ID invoked. Usually, the default value is appropriate.  
If the REGION field is not blank, all the responses on this entry as well as all responses on other DRESP1 entries that have the same RTYPE and REGION identification number will be grouped into the same region.
11. REGION is valid only among the same type of responses. Responses of different types will never be grouped into the same region, even if they are assigned the same REGION identification number by the user.
12. If RTYPE = "WEIGHT", "VOLUME", or "TOTSE" field ATT<sub>i</sub> = "ALL" implies total weight/volume/total strain energy of all superelements except external superelements, 0 implies residual only and i implies SEID=i. Default="ALL". RTYPE="TOTSE" is not supported for shape optimization.
13. RTYPE = "STABDER" identifies a stability derivative response. ATTB is the restraint flag for the stability derivative. ATTB = 0 means unrestrained, and ATTB = 1 means restrained. For example, ATTA = 4000, ATTB = 0, and ATT1 = 3 reference the unrestrained C<sub>z</sub> derivative for the AESTAT (or AESURF) entry ID = 4000.
14. RTYPE = "FLUTTER" identifies a set of damping responses. The set is specified by ATT<sub>i</sub>:  
ATT1 = Identification number of a SET1 entry that specifies a set of modes.  
ATT2 = Identification number of an FLFACT entry that specifies a list of densities.

ATT3 = Identification number of an FLFACT entry that specifies a list of Mach numbers.

ATT4 = Identification number of an FLFACT entry that specifies a list of velocities.

If the flutter analysis is type PKNL, it is necessary to put PKNL in the PTYPE field of this entry.

15. For RTYPE = “FRXXXX”, “PSDXXXX”, “PRES” and “ERP” a real value for ATTB specifies a frequency value in cycles per unit time. If a real ATTB value is specified, then the responses are evaluated at the closest excitation frequency. The default for ATTB is all excitation frequencies. See Remark for additional ATTB options. The OFREQ Case Control command has no effect on the selection of the frequencies.
16. For RTYPE = “TDISP”, “TVELO”, “TACCL”, “TSPCF”, “TFORC”, and “TSTRE”, ATTB specifies a time value. If ATTB is specified, then the responses are evaluated at the closest time selected by the OTIME command. The default for ATTB is all time steps selected by the OTIME command.
17. Intermediate station responses on CBAR elements due to PLOAD1 and/or CBARAO entries may not be defined on the DRESP1 entry.
18. RTYPE = “EIGN” refers to normal modes response in terms of eigenvalue (radian/time)\*\*2 while RTYPE = “FREQ” refers to normal modes response in terms of natural frequency or units of cycles per unit time.
19. For RTYPE = LAMA, EIGN or FREQ, the response approximation used for optimization can be individually selected using the ATTB field when APRCOD = 1 is being used.

For RTYPE = LAMA, ATTB = blank or 1 selects direct linearization, ATTB = 2 = inverse linearization.

For RTYPE = EIGEN or FREQ, ATTB = blank = Rayleigh Quotient Approximation, = 1 = direct linearization, = 2 = inverse approximation.

The default Rayleigh Quotient Approximation should be preferred in most cases.

Character input for ATTB is available for RTYPE of “FRXXXX”, “PSDXXXX”, “TXXXX”, “PRES”, “ERP”, “ACPWR”, “ACINTS”, “AFPRES”, “AFINTS”, “AFVELO”, “AFPWR” and “DYSTIFF”. The character input represents a mathematical function and the options for character input are SUM, AVG, SSQ, RSS, MAX and MIN. The expression of mathematical function is shown as follows:

$$\text{SUM}(X_1, X_2, \dots, X_n) = \sum_{i=1}^n X_i$$

$$\text{AVG}(X_1, X_2, \dots, X_n) = \sum_{i=1}^n X_i/n$$

$$\text{SSQ}(X_1, X_2, \dots, X_n) = \sum_{i=1}^n X_i^2$$

$$RSS(X_1, X_2, \dots, X_n) = \sqrt{\sum_{i=1}^n X_i^2}$$

MAX( $X_1, X_2, \dots, X_n$ ) = Maximum value among  $X_i$ ( $i=1$  to  $n$ )

MIN( $X_1, X_2, \dots, X_n$ ) = Minimum value among  $X_i$ ( $i=1$  to  $n$ )

where  $X_i$  is the response for a forcing frequency or time step. For example

DRESP1,10,DX1,FRSTRE,ELEM,,3,AVG,10

yields a response which is equal to the average stress for element 10 across all forcing frequencies.

**CAUTION!**

1. If the ID of a DRESP1 with ATTB character input is referenced by a DRESP2 using the "DRESP2" flag, the results of the mathematical function are used to evaluate the DRESP2.
2. If the ID of a DRESP1 with ATTB character input is referenced by a DRESP2 using the "DRESP1" flag, the individual values of the DRESP1 are used to compute individual DRESP2 values and the mathematical function is not used by the DRESP2.

20. Element strain energy item codes can be found under [Table 7-12](#) in [Item Codes](#). Only element strain energy and element strain energy density can be referenced on a DRESP1 entry. RTYPE="ESE" is not supported for shape optimization.
21. For RTYPE=RMSDISP, RMSVELO, or RMSACCL the ATTB specifies the appropriate RANDPS ID.
22. Input other than 1 or 7 of ATTA field, acoustic pressure component, for PRES response type will be reset to 1 (if less than 7) or 7 (if greater than 6 and less than 13).
23. Design response weight is obtained from Grid Point Weight Generator for a reference point GRDPNT (see parameter GRDPNT). If GRDPNT is either not defined, equal to zero, or not a defined grid point, the reference point is taken as the origin of the basic coordinate system. Fields ATTA and ATTB refer to the row and column numbers of the rigid body weight matrix, which is partitioned as follows:

$$[W] = \begin{bmatrix} W_x & W_{12} & W_{13} & W_{14} & W_{15} & W_{16} \\ W_{21} & W_y & W_{23} & W_{24} & W_{25} & W_{26} \\ W_{31} & W_{32} & W_z & W_{34} & W_{35} & W_{36} \\ W_{41} & W_{42} & W_{43} & I_x & W_{45} & W_{46} \\ W_{51} & W_{52} & W_{53} & W_{54} & I_y & W_{56} \\ W_{61} & W_{62} & W_{63} & W_{64} & W_{65} & I_z \end{bmatrix}_{6 \times 6}$$

The default values of ATTA and ATTB are 3, which specifies weight in the Z direction. Field ATT1 = "ALL" implies total weight of all superelements except external superelements. SEIDi refers to a superelement identification number. SEIDi = "0" refers to the residual superelement. The default of ATT1 is blank which is equivalent to "ALL".

24. For RTYPE = GPFORCE, the PTYPE field is used to designate the GRID ID at which the force is defined. Output that is produced using PARAM NOELOF > 0 is not supported for the DRESP1 entry.
25. For RTYPE = GPFORCP, the PTYPE field is blank. The grid point force is for the sum of all elements from the GRID ID listed in ATTA to the GRID (orient ID) listed in ATTi. This response corresponds to that produced with PARAM NOELP > 0. It is not necessary to set PARAM NOELP > 0 to compute the GPFORCP response.
26. For RTYPE = PSDXXXX, the PTYPE field specifies the RANDPS ID.
27. RTYPE=COMP (compliance of structures =  $\mathbf{P}^T \mathbf{u}$ ) and FRMASS (mass fraction of topology designed elements) entries are used for topology optimization or combined topology, sizing/shape optimization.
28. RTYPE=FRMASS can be used for topology and topometry optimization. For topology, FRMASS, is the mass divided by the mass calculated if all topology design variables are 1.0. FRMASS is calculated for designed elements only. FRMASS = 1.0 if all design variables are 1.0. For topometry, the initial FRMASS is defined as 1.0 for the initial design specified on the TOMVAR entries. For non-volume elements like CELAS, an artificial mass = 1.0 is assumed for each element.
29. Response type ABSTRESS is for element type code of 238 (CBAR) and 239 (CBEAM) only.
30. If a PSDxxxx or RMSxxxx response is being applied with RANDPS Bulk Data entries that include multiple subcases, the DESSUB or DESOBJ Case Control command that invokes the PSDxxxx or RMSxxxx response must be in the first subcase used by the RANDPS entry.
31. Response types, ESE, TOTSE, GPFORCE and GPFORCP are not supported for shape optimization.
32. For RTYPE=EIGN or FREQ, PTYPE field can be utilized to identify the source of the mode. Valid options are 'STRUC' or 'FLUID'. The default is 'STRUC'.
33. For RTYPE=ACPWR, PTYPE field can be utilized to identify the panel name. The default is 'total' which covers the whole interface between structural and fluid field.

34. For RTYPE=AFxxxx, PTYPE field can be utilized to specified the ID of Acoustic Field Point Mesh, AFPM.
35. For monitor point responses (RTYPE = STMONP1, STMOND1, MONPNT3 AEMONP1 or AEMOND1) the ATTA field specifies the components to be extracted. These can be any subset of the integers 1 through 6 that appear on the monitor quantity with the NAME provided in the PTYPE field. All of these responses can be invoked in a static aeroelastic (ANALYSIS=SAERO) subcase. STMOND1 and MONPNT3 can be invoked from a static (ANALYSIS=STAT) subcase. The responses are not available in a dynamic response or normal modes subcase. The response types have the following meaning:
  - a. STMONP1 – A structural MONPNT1
  - b. STMOND1 – A structural MONDSP1
  - c. MONPNT3 – A MONPNT3
  - d. AEMONP1 – An aerodynamic MONPNT1
  - e. AEMOND1 – An aerodynamic MONDSP1For all but the STMONP1, the response is the elastic monitor point value. For the STMONP1, it is the elastic “minus” inertial “plus” elastic applied load value.
36. For RTYPE=FRMASS, if the PID in the ATTi field is not blank, the PTYPE field must specify the type of property the PID references.
37. RTYPE=DIVERG is for subcases with ANALYSIS=DIVERG (aeroelastic static divergence). Only a single Mach number can be specified for this RTYPE.
38. For RTYPE = FATIGUE (pseudo-static fatigue), PTYPE must be set to ELEM or PSOLID, PSHELL, PBAR, PBEAM, or PWELD. For RTYPE = FRFTG (frequency response fatigue), PTYPE must be set to ELEM or PSOLID or PSHELL. ATTB is the FID of a FATIGUE case control and must be the same FID for all RTYPEs of type FATIGUE or FRFTG. RTYPEs of type FATIGUE and FRFTG cannot be mixed; either all are RTYPE=FATIGUE or all are RTYPE=FRFTG.
39. If a FATIGUE case control references a SET ID, then ATTB must reference one of the IDs referenced by the SET. Design optimization using fatigue responses is currently limited to one fatigue analysis, that is, one loading sequence. Multiple fatigue responses referencing different loading sequences, i.e., FATIGUE case control IDs, will result in an error.
40. For the ERP response, the PTYPE field must be ERPPNL.
41. If the ATT1 field is blank for the ERP response, all panels are invoked.
42. Fatigue Item Codes can be found in [Fatigue Item Codes](#). Item codes that are available as design responses are 4-9 and 12 for the element centroid or first node/layer/location and the comparable items for ensuing nodes/layers/locations. The use of NODA on the FTGPARM entry is not supported.
43. For the WMPID (weight as a function of material and property ID), the following conventions apply:
  - a. ATTA is required, ATTB and ATTi are optional.
  - b. ATTB specifies the superelement with ATTB=0 indicating the residual, >0, indicates superelement ATTB and ATTB = ALL or blank means all superelements)

- c. The ATTi fields designate the property ID's of interest. If ATTi is specified, the associated property type (e.g., PSHELL) must be specified by the PTYPE input of field 5 on the DRESP1 entry.
  - d. If there is no ATTi, all material with MID=ATTA will be used to generate the response.
  - e. If there are multiple ATTi, a single scalar weight is calculated that is the sum of the all the properties
  - f. Materials that are supported with this entry are: MAT1, MAT2, MAT3, MAT8, MAT9 and MAT10
  - g. Properties that are supported are: PSHELL, PROD, PBEAM, PTUBE, PSHEAR, PBAR, PSOLID, PBEND, PCOMP, PCOMPG, PBARL, PBEAML, PBRSECT and PBMSECT.
44. Certain restrictions apply for RTYPE=WMPID
- a. The density of the material referenced on the ATTA field cannot also be designed using a DVMRELx entry
  - b. The property referenced on the ATTI field cannot also be invoked by a TOMVAR entry.
  - c. The WMPID response is supported for topology optimization or for shape sizing optimization, but not for both topology and shape sizing optimization.

**DRESP2****Design Sensitivity Equation Response Quantities**

Defines equation responses that are used in the design, either as constraints or as an objective.

**Format:**

1	2	3	4	5	6	7	8	9	10
DRESP2	ID	LABEL	EQID or FUNC	REGION	METHOD	C1	C2	C3	
	“DESVAR”	DVID1	DVID2	DVID3	DVID4	DVID5	DVID6	DVID7

		DLIL8	-etc.-						

**Example:**

DRESP2	1	LBUCK	5	3					
	DESVAR	101	3	4	5	1	205	209	
		201							
	DTABLE	PI	YM	L					
	DRESP1	14	1	4	22	6	33	2	

	DNODE	14	1	4	1	22	3		
		2	1	43	1				
	DVPREL1	101	102						
	DVCREL1	201	202						
	DVMREL1	301							
	DVPREL2	401	402						
	DVCREL2	501							
	DVMREL2	601	602	603					
	DRESP2	50	51						

Describer	Meaning
ID	Unique identification number. (Integer > 0)
LABEL	User-defined label. (Character, no default)
EQID	DEQATN entry identification number. (Integer > 0)
FUNC	Function to be applied to the arguments. See Remark 8. (Character)
REGION	Region identifier for constraint screening. See Remark 5. (Integer > 0)
METHOD	When used with FUNC = BETA, METHOD = MIN indicates a minimization task while MAX indicates a maximization task. (Default = MIN)  When used with FUNCT = MATCH, METHOD = LS indicated a least squares while METHOD = BETA indicated minimization of the maximum difference. (Default = LS)
Ci	Constants used when FUNC = BETA or FUNC = MATCH in combination with METHOD = BETA. See Remark 8. (Real; Defaults: C1 = 1.0., C2 = .005, and C3=10.0)
“DESVAR”	Flag indicating DESVAR entry identification numbers. (Character)
DVIDi	DESVAR entry identification number. (Integer > 0)
“DTABLE”	DTABLE flag. Indicates that the LABELs for the constants in a DTABLE or DTABLE2 entry follow. This field may be omitted if there are no constants involved in this relation. (Character)
LABLi	Label for a constant on the DTABLE or DTABLE2 entry. (Character)
“DRESP1”	Flag indicating DRESP1 entry identification numbers. (Character). See Remark 13.
NRk	DRESP1 entry identification number. (Integer > 0)
“DNODE”	Flag indicating grid point and component identification numbers. (Character)
Gm	Identification number for any grid point in the model. (Integer > 0)
Cm	Component number of grid point Gm. (1 ≤ Integer ≤ 3)
“DVPREL1”	Flag indicating DVPREL1 entry identification number. (Character)
DPIPi	DVPREL1 entry identification number. (Integer > 0)

Describer	Meaning
“DVCREL1”	Flag indicating DVCREL1 entry identification number. (Character)
DCICi	DVCREL1 entry identification number. (Integer > 0)
“DVMREL1”	Flag indicating DVREL1 entry identification number. (Character)
DMIMi	DVMREL1 entry identification number. (Integer > 0)
“DVPREL2”	Flag indicating DVPREL2 entry identification number. (Character)
DPI2Pi	DVPREL2 entry identification number. (Integer > 0)
“DVCREL2”	Flag indicating DVCREL2 entry identification number. (Character)
DCI2Ci	DVCREL2 entry identification number. (Integer > 0)
“DVMREL2”	Flag indicating DVMREL2 entry identification number. (Character)
DMI2Mi	DVMREL2 entry identification number. (Integer > 0)
“DRESP2”	Flag indicating other DRESP2 entry identification number. (Character). See Remark 13.
NRRk	DRESP2 entry identification number. (Integer > 0)
“DVLREL”	Flag indicating DVLREL1 identification numbers. (Character)
DLILi	DVLREL1 entry identification number. (Integer > 0)

**Remarks:**

1. DRESP2 entries may only reference DESVAR, DTABLE, DRESP1, DNODE, DVPREL1, DVCREL1, DVMREL1, DVPREL2, DVCREL2, DVMREL2 and DVLREL1 entries. They may also reference other DRESP2 entries. However, a DRESP2 entry cannot reference itself directly or recursively.
2. a) If the referenced DRESP1 entries span subcases, the DRSPAN Case Control command is required to identify DRESP1 IDs for each subcase. DRESP2 entries that span subcases must be invoked above the subcase level by DESGLB on DESOBJ commands.  
 b) Referenced DRESP entries that span superelements are supported automatically.  
 c) Referenced DRESP2 entries cannot span subcases or superelements.
3. DRESP2 entries must have unique identification numbers with respect to DRESP1 entries.
4. The “DESVAR”, “DTABLE”, “DRESP1”, “DNODE”, “DVPREL1”, “DVCREL1” and “DVMREL1”, “DVPREL2”, “DVCREL2”, “DVMREL2”, “DRESP2” and DVLREL1 flags in field 2 must appear in the order given above. Any of these words, along with the identification numbers associated with them, may be omitted if they are not involved in this DRESP2 relationship. However, at least one of these ten types of arguments must exist.
5. The REGION field follows the same rules as for the DRESP1 entries. DRESP1 and DRESP2 responses will never be contained in the same region, even if they are assigned the same REGION identification number. The default is to put all responses referenced by one DRESP2 entry in the same region.

6. The variables identified by DVIDi, LABLj, NRk, the Gm, CMPM pairs, DPIPi, DCICm, DMIMn, DPI2Po, DCI2Cp, DMI2Mq, and NRRu are assigned (in that order) to the variable names (x1, x2, x3, etc.) specified in the left-hand side of the first equation on the DEQATN entry referenced by EQID. In the example below,

DESVARs 101 and 3 are assigned to arguments A and B.

DTABLEs PI and YM are assigned to arguments C and D.

Grid 14, Component 1 is assigned to argument R.

DRESP2	1	LBUCK	5	3						
	DESVAR	101	3							
	DTABLE	PI	YM							
	DNODE	14	1							
DEQATN	5	F1(A, B, C, D, R)=A+B*C-(D**3+10.0)+sin(C*R)								

7. (Gm, Cm) can refer to any grid component and is no longer limited to a designed grid component.
8. The FUNC attributes can be used in place of the EQID and supports the functions shown in the following table:

Function	Description
SUM	Sum of the arguments
SFMAX	Minimization of compliance and maximization of frequency. See remark 14.
AVG	Average of the arguments
SSQ	Sum of the squares of the arguments
RSS	Square root of the sum of the squares of the arguments
MAX	The maximum value of the argument list
MIN	The minimum value of the argument list
BETA	Minimize the maximum response. See Remark 10.
MATCH	Match analysis results with user specified values. See Remark 11.

When EQID has character input, the DEQATN entry is no longer needed. The functions are applied to all arguments on the DRESP2 regardless of the type. See Remark of the DRESP1 entry for the explanations of SUM, AVG, SSQ, RSS, MAX and MIN.

9. The number of arguments of a DEQATN can be more than the number of values defined on the DRESP2 if the DRESP1s referenced have RTYPE with 'FR' or 'PSD' prefix. Arguments are still positional. The extra arguments in the DEQATN must appear at the end of the argument list. The discrepancy is resolved internally with the forcing frequency(ies) associated with DRESP1s. An example is shown as follows:

DRESP1	10	FDISP1	FRDISP			1	10.	1001	
DRESP1	20	FDISP2	FRDISP			1	20.	1001	

DRESP2	30	AVGFD	100							
	DRESP1	10	20							
DEQATN	100	AVG(D1,D2,F1,F2) = (D1/F1+D2/F2)*0.5								

In the above example, the DEQATN has two more additional terms than have been defined on the DRESP2. The first additional term is the forcing frequency (in hertz) of the first DRESP1 ID on the DRESP2. The second additional term is the forcing frequency of second DRESP1 ID in the list. When all DRESP1s involved have the same frequency, the user is not required to name all the additional terms in the argument list of DEQATN.

10. FUNC = BETA facilitates a design task where the objective is to minimize the maximum response. Only DRESP1 entries can be invoked by DRESP2 and the DRESP's cannot span subcases. The BETA function creates the following design task:

$$\text{Minimize } \phi = C_1 X_\beta$$

$$\text{Subject to } g = \frac{r_j - \gamma X_\beta}{C_3} \leq 0$$

where  $\gamma$  is determined from

$$C_2 = (r_{jmax} - \gamma X_\beta) / C_3$$

User input parameters  $C_1$ ,  $C_2$ ,  $C_3$  therefore have the following meaning:

$C_1$  (Default = 1.0) weights the spawned design variable,  $X_\beta$ , to create the objective. Since  $X_\beta$  starts at 1.0,  $C_1$  is the initial objective.

$C_2$  sets the initial value of the maximum constraint created by this process. The default values of 0.005 is equal to DOPTPRM parameter GMAX.

$C_3$  (Default = 10.0) is an offset value to avoid dividing by zero when creating constraints.

11. FUNC = MATCH creates a response from the difference between analysis results,  $r_j$ , that are associated with DRESP1s and target values,  $r_j^T$ , that are input using DTABLE data. Only DRESP1 entries and DTABLE entries can be invoked by the DRESP2 entry.

When METHOD = LS, a least square minimization is performed where the response is

$$r_2 = \sum_{j=1}^m \left( \frac{r_j - r_j^T}{r_j^T} \right)^2$$

When METHOD = BETA, the design task becomes one of minimizing an objective that is the maximum normalized difference between the analysis and target values

$$\frac{r_j - r_j^T}{|r_j^T|}$$

in the same manner as outlined in Remark 10.

12. With FUNC=MATCH, if the DTABLE LABELj invokes an integer VALUi on the DTABLE entry, the integer points to a TABLEDi entry that provides tabular input as a function of frequency or time. This is used in conjunction with a single DRESP1 NRk that provides a response across a range of frequencies or times (i.e., RTYPE=FRxxxx, PSDxxxx, ACxxxx or Txxxx). When the TABLEDi option is invoked, the response can only be constrained, it cannot be the objective. This further implies that FUNC=MATCH, METHOD=BETA is not supported with TABLEDi.
13. If the mathematical function from a DRESP1 that has character input in the ATTB field (see remark 20 of the DRESP1) is to be used in the DRESP2 evaluation, the DRESP1 must be referenced under the “DRESP2” flag, not the “DRESP1” flag. If the “DRESP1” flag is used in this situation, it will result in a DRESP2 being evaluated for each of the individual values that contribute to the mathematical function.
14. The function SFMAX requires n+1 DRESP1 IDs. The first ‘n’ IDs correspond to compliance constraints for the first ‘n’ static subcases. The final ID refers to a DRESP1 with RTYPE=FREQ and mode=1. The function minimizes the sum of the compliance constraints while maximizing the fundamental frequency.

**DRESP3****Design Sensitivity Response using user-supplied routine(s)**

Defines an external response using user-supplied routine(s).

**Format:**

1	2	3	4	5	6	7	8	9	10	
DRESP3	ID	LABEL	GROUP	TYPE	REGION					
	“DESVAR”	DVID1	DVID2	DVID3	DVID4	DVID5	DVID6	DVID7		
		DVID8	etc.							
	“DTABLE”	LABL1	LABL2	LABL3	LABL4	LABL5	LABL6	LABL7		
		LABL8	etc.							
	“DRESP1”	NR1	NR2	NR3	NR4	NR5	NR6	NR7		
		NR8	etc.

	DVLRREL1	DLIL1	DLIL2	DLIL3	DLIL4	DLIL5	DLIL6	DLIL7		
		DLIL8	DLIL9	-etc.-						
	“USRDATA”	String								
		-etc.-								

**Example:**

DRESP3	1	LBUCK	TAILWNG	BUCK					
	DESVAR	101	3	4	5	1	205	209	

		201								
	DTABLE	PI	YM	L						
	DRESP1	14	1	4	22	6	33	2		
	DNODE	14	1	4	1	22	3			
		2	1	43	1					
	DVPREL1	101	102							
	DVCREL1	201	202							
	DVMREL1	301								
	DVPREL2	401	402							
	DVCREL2	501								
	DVMREL2	601	602	603						
	DRESP2	50	51							
	USRDATA	Constants: 12345.6 789.0 99.								

Descriptor	Meaning
ID	Unique identification number. (Integer > 0)
LABEL	User-defined label. (Character, no default)
GROUP	Group name the external response type belongs to (Character). See Remark 2.
TYPE	External response type (Character). See Remark 3.
“DESVAR”	Flag indicating DESVAR entry identification numbers. (Character)
DVIDi	DESVAR entry identification number. (Integer > 0)
“DTABLE”	DTABLE flag. Indicates that the LABELs for the constants in a DTABLE or DTABLE2 entry follow. This field may be omitted if there are no constants involved in this relation. (Character)
LABELi	Label for a constant on the DTABLE or DTABLE2 entry. (Character)
“DRESP1”	Flag indicating DRESP1 entry identification numbers. (Character)
NRk	DRESP1 entry identification number. (Integer > 0)
“DNODE”	Flag signifying that the following fields are grid points.
Gm	Grid point identification number. (Integer > 0)
Cm	Degree-of-freedom number of grid point Gm. ( $1 \leq \text{Integer} \leq 3$ )
“DVPREL1”	Flag indicating DVPREL1 entry identification number. (Character)
DPIPi	DVPREL1 entry identification number. (Integer > 0)
“DVCREL1”	Flag indicating DVCREL1 entry identification number. (Character)
DCiCi	DVCREL1 entry identification number. (Integer > 0)
“DVMREL1”	Flag indicating DVMREL1 entry identification number. (Character)
DMiMi	DVMREL1 entry identification number. (Integer > 0)

Describer	Meaning
“DVPREL2”	Flag indicating DVPREL2 entry identification number. (Character)
DPI2Pi	DVPREL2 entry identification number. (Integer > 0)
“DVCREL2”	Flag indicating DVCREL2 entry identification number. (Character)
DCI2Ci	DVCREL2 entry identification number. (Integer > 0)
“DVMREL2”	Flag indicating DVMREL2 entry identification number. (Character)
DMI2Mi	DVMREL2 entry identification number (Integer > 0)
“DRESP2”	Flag indicating other DRESP2 entry identification number. (Character)
NRRk	DRESP2 entry identification number. (Integer > 0)
“DVLREL1”	Flag indicating DVLREL1 identification number (character)
DLILi	DVLREL1 entry identification number (integer)
“USRDATA”	Flag indicating user input data (Character). See Remark 8.

### Remarks:

- DRESP3 entries may reference DESVAR, DTABLE, DRESP1, DNODE, DVPREL1, DVCREL1, DVMREL1, DVPREL2, DVCREL2, DVMREL2, DRESP2 and DVLREL1 entries. However, a DRESP3 entry cannot reference another DRESP3 entry.
- The group name must be referenced by an FMS CONNECT entry.
- Multiple types of external responses can be defined in one group. Each type name identifies a specific external response evaluated in the user-supplied routines. See [Building and Using the Sample Programs MSC Nastran Utilities Guide](#) for a discussion of how to incorporate external responses.
- Referenced DRESP2 entries cannot span subcases or superelements.
  - If referenced DRESP1 entries span subcases, the DRSPAN Case Control command is required to identify the DRESP1 IDs for each subcase. DRESP3 entries that span subcases must be invoked above the subcase level by DESGLB or DESOBJ commands.
  - Referenced DRESP1 entries that span superelements are supported automatically.
- DRESP3 entries must have unique identification numbers with respect to DRESP2 and DRESP1 entries.
- The “DESVAR”, “DTABLE”, “DNODE”, “DVPREL1”, “DVCREL1” and “DVMREL1”, “DVPREL2”, “DVCREL2”, “DVMREL2”, “DRESP2”, “DVLREL1” and “USRDATA” keywords on the continuation entries must appear in the order given above. Any of these words, along with the subsequent data associated with them, may be omitted if they are not involved in this DRESP3 relationship. However, at least one of these types of arguments must exist.
- The REGION field follows the same rules as for the DRESP1 entries. DRESP1 and DRESP3 responses will never be contained in the same region, even if they are assigned the same REGION identification number. The default is to put all responses referenced by one DRESP3 entry in the same region.

8. The data in the USRDATA field is character string based. It provides a convenient way to pass constants to the external response server routines. The maximum number of characters allowed is 32000.

## DSCREEN

## Design Constraint Screening Data

Defines screening data for constraint deletion.

### Format:

1	2	3	4	5	6	7	8	9	10
DSCREEN	RTYPE	TRS	NSTR						

### Example:

DSCREEN	STRESS	-0.7	2						
---------	--------	------	---	--	--	--	--	--	--

Describer	Meaning
RTYPE	Response type (or ALL, See Remark 9.) for which the screening criteria apply. (Character)
TRS	Truncation threshold. (Real; Default = -0.5)
NSTR	Maximum number of constraints to be retained per region per load case. See Remark 3. (Integer > 0; Default = 20)

### Remarks:

1. Grid responses associated with one particular load case are grouped by the specification of DRESP1 entries. From each group, a maximum of NSTR constraints are retained per load case.
2. Element responses are grouped by the property; i.e., all element responses for one particular load case belonging to the set of PIDs specified under ATTi on a DRESPi entry are regarded as belonging to the same region. In superelement sensitivity analysis, if the property (PID) is defined in more than one superelement, then separate regions are defined. A particular stress constraint specification may be applied to many elements in a region generating many stress constraints, but only up to NSTR constraints per load case will be retained.
3. For aeroelastic responses, that is RTYPE = "TRIM", "STABDER", and "FLUTTER", the NSTR limit is applied to all DRESP1 IDs that are the same RTYPE and have the same REGION specified.
4. For responses that are not related to grids or elements, that is RTYPE = "WEIGHT", "VOLUME", "EIGN", "FREQ", "LAMA", "CEIG", "FRMASS", "COMP", and "TOTSE", NSTR is not used. TRS is still applicable.
5. The RTYPE field is set to EQUA if constraints that are associated with DRESP2 entries are to be screened. The RTYPE field is set to DRESP3 if constraints that are associated with DRESP3 entries are to be screened. If the REGION field on the DRESP2 or DRESP3 is blank, one region is established for each DRESP2/DRESP3 entry.
6. If a certain type of constraint exists but no corresponding DSCREEN entry is specified, all the screening criteria used for this type of constraint will be furnished by the default values.
7. Constraints can be retained only if they are greater than TRS. See the Remarks under the [DCONSTR](#) entry for a definition of constraint value.

8. Constraint screening is applied to each superelement.
9. RTYPE=ALL specifies that the specified TRS and NSTR applies to all response types and other DSCREEN entries are ignored.

**DTABLE** Table Constants

Defines a table of real constants that are used in equations (see DEQATN entry).

**Format:**

1	2	3	4	5	6	7	8	9	10
DTABLE	LABL1	VALU1	LABL2	VALU2	LABL3	VALU3	LABL4	VALU4	
	LABL5	VALU5	LABL6	VALU6	LABL7	VALU7	LABL8	VALU8	
		-etc.-							

**Example:**

DTABLE	PI	3.142	H	10.1	E	1.0E6			
	G	5.5E5	B	100.					

Describer	Meaning
LABLi	Label for the constant. (Character)
VALUi	Value of the constant or TABLEDx ID. (Real or Integer, respectively)

**Remarks:**

- Multiple DTABLE entries may be specified in the Bulk Data Section.
- LABLi are referenced by the LABj on the DRESP2, DRESP3, DVCREL2, DVMREL2, or DVPREL2 entries.
- Trailing blank fields are permitted at the end of each line of LABLi/VALUi pairs, but intermediate blanks are not. (See the example above for permitted trailing blanks.)
- For PART SE, if LABLi is referenced on SEDRSP2 and/or SEDRSP3, DTABLE entries must be placed in a PART SE where companion design model entries, such as DESVAR, DRESP1 and etc, are available.
- If the VALUi is an integer, this points to the ID of a TABLEDx Bulk Data entry that lists the constants as a function of frequency or time. See Remark 12. on the DRESP2 entry.
- LABLi must be unique across all DTABLE and DTABLE2 entries.

**DTABLE2** Table Constants

Defines real constants from a field of property, material or connections bulk data entries which then can be invoked by a DV<sub>x</sub>REL2, DRESP2, or DRESP3 entry.

**Format:**

1	2	3	4	5	6	7	8	9	10
DTABLE2	LABL1	PNAME1	PID1	FNAME1	LABL2	PNAME2	PID2	FNAME2	
	LABL3	PNAME3	PID3	FNAME3					

**Example:**

DTABLE2	PTHK10	PSHELL	10	T	MATIE	MAT1	38	E	
	CBARX1	CBAR	3888	X1					

Describer	Meaning
LABLi	Label for the constant. (Character)
PNAMEi	Property, material or connection bulk data entry name. (Character)
PIDi	ID of PNAMEi entry. (Integer > 0)
FNAMEi	Field name of PNAMEi. (Character)

**Remarks:**

1. LABLi on DTABLE2 and DTABLE must be unique.
2. LABLi on DTABLE2 can be referenced under DTABLE flag of DV<sub>x</sub>REL2 (where x=P, M or C)/DRESP2/DRESP3.
3. Values for the FNAMEi field of the PNAMEi Bulk Data entry with the ID of PIDi are taken from analysis model before updating of analysis values with the designed value. If the updated value is desired, use the DV<sub>x</sub>REL2 flag on DRESP2 or DRESP3 entries instead.
4. FNAMEi must be the same as the character string that appears on the PNAMEi Bulk Data entry.
5. DTABLE2 must be utilized along with 'NASTRAN SYSTEM(444)=1' in input file or 'sys444=1' during job submittal.

**DTI** Direct Table Input

Defines table data blocks.

**Format:**

1	2	3	4	5	6	7	8	9	10
DTI	NAME	"0"	T1	T2	T3	T4	T5	T6	
	V01	V02	-etc.-						
DTI	NAME	IREC	V1	V2	V3	V4	V5	V6	
	V7	V8	V9	V10	-etc.-	"ENDREC"			

**Example: (The first logical entry is the header entry.)**

DTI	XXX	0	3	4	4096		1	0	
	1.2	2.3							
DTI	XXX	1	2.0	-6	ABC	6.000	-1	2	
	4	-6.2	2.9	1	DEF	-1	ENDREC		

Describer	Meaning
NAME	Any character string that will be used in the DMAP sequence to reference the data block. See Remark 1. (Character; the first character must be alphabetic.)
Ti	Trailer values. (Integer $\geq 0$ ; Default = 32767)
IREC	Record number. (Integer $> 1$ )
V0i, Vi	Value. (Integer, Real, Character or blank)
"ENDREC"	Flags the end of the string of values (V0i or Vi) that constitute record IREC. (Character)

**Remarks:**

1. The user defines the data block and therefore must write a DMAP (or ALTER a solution sequence), which includes the DTIIN modules, in order to use the DTI feature. See the [MSC Nastran DMAP Programmer's Guide](#). All of the rules governing the use of data blocks in DMAP sequences apply.
2. All fields following ENDREC must be blank.
3. The entry using IREC = 0 is called the header entry and is an optional entry. The values T1 through T6 go to a special record called the trailer. Other values on the optional continuation go to the header record. If the header entry or the trailer is not specified, T1 through T6 = 32767. On this entry, "ENDREC" may be used only if there is at least one continuation.
4. In addition to the optional header entry, there must be one logical entry for each record in the table. Null records require no entries.

5. “ENDREC” is used to input blank values at the end of a record. If “ENDREC” is not specified, the string for a record ends with the last nonblank field.
6. The maximum number of DMI and DTI data blocks is 1000.
7. If Ti is not an integer, a machine-dependent error will be issued that may be difficult to interpret.
8. If Modules are present then this entry may only be specified in the main Bulk Data section.

## DTI,ESTDATA

## Superelement Estimation Data Overrides

Provides override data for time and space estimation for superelement processing operations.

### Format:

1	2	3	4	5	6	7	8	9	10
DTI	ESTDATA	"0"							
	kd1	vd1	kd2	vd2	-etc.-				

The next entries are repeated for any superelement for which estimate data overrides are desired. IREC must be incremented by 1.

DTI	ESTDATA	IREC	SEFLAG	SEID	k1	v1	k2	v2	
	k3	v3	-etc.-						

### Example:

DTI	ESTDATA	0							
	NOMASS	-1							
DTI	ESTDATA	1	SE	10	C1	5.5	C3	4.5	
	C7	7.3							

Describer	Meaning
kdi	Keyword for estimation parameter. (Character from <a href="#">Table 9-9</a> .)
vdi	Value assigned to the estimation parameter kdi. (The type given in <a href="#">Table 9-9</a> .)
IREC	Record number beginning with 1. (Integer > 0)
SEFLAG	SEFLAG = "SE" or "SEID" indicates the next field containing a superelement identification number. (Character)
SEID	Superelement identification number. (Integer > 0)
ki	Keyword for override of estimation parameter for indicated superelement. (Character from <a href="#">Table 9-9</a> .)
vi	Value for keyword ki. (Type depends on ki as shown in the <a href="#">Table 9-9</a> .)

Table 9-9 DTI,ESTDATA Input Parameter Descriptions

Input Parameters				Meaning and Comments
Keyword	Type	Default Value	Math Symbol	
CRMS*	Real	-1.0	C	Number of active columns in $[K_{oo}]$ .
FCRMS*	Real	0.10		If $FCRMS \leq 0.0$ , FCRMS is used (c/o).
C1	Real	6.0	$c_1$	Average number of degrees-of-freedom per grid point in o-set.
C3	Real	8.0	$c_3$	Average number of connections per grid point.
C4	Real	0.15	$c_4$	I/O time (seconds) per block transferred.
C5	Real	6.0	$c_5$	Average number of effective degrees-of-freedom per grid point in a-set.
C6	Real	1.2	$c_6$	Total CPU factor.
C7	Real	6.0	$c_7$	Number of equivalent KGG data blocks for space estimation.
WF	Real	-1.0	W	If $WF \leq 0.0$ then use available working storage in units of single-precision words.
NOMASS	Integer	1		If $NOMASS \neq 1$ then exclude mass terms from estimates.
TSEX	Real	0.5 (min)		Threshold limit for CPU.
SSEX	Real	50.0 (blocks)		Threshold limit for space.
TWALLX	Real	5.0 (min)		Threshold limit for wall time.
BUFSIZ	Integer	Machine Buffsize	B	Buffsize. See <a href="#">The NASTRAN Statement (Optional)</a> in the <i>MSC Nastran Reference Guide</i> .
ML	Real	Machine Loop Time	M	Arithmetic time for the multiply/add loop. See the <i>SOL 700 Explicit Nonlinear User's Guide</i> .
CONIO	Integer	Machine I/O ratio		I/O count/CPU equivalence
PREC	Integer	1 or 2		Machine Word Length (1 = long, 2 = short). See <a href="#">The NASTRAN Statement (Optional)</a> in the <i>MSC Nastran Reference Guide</i> .
NLOADS	Integer	1	$N_L$	Number of loading conditions
SETYPE	Character	"T"		Superelement type (T = Tip)
CMAX	Real	-1.0	$C_{max}$	Maximum bandwidth

### Parameters Obtained from SEMAP

NGI	Number of interior grid points.
NPE	Number of exterior grid points.
NS	Number of scalar points
NE	Number of elements.

### Derived Parameters

$O = C1 + NGI$	Size of o-set.
$A = C5(NPE - NS) + NS$	Size of a-set.
$T = \text{BUFFSIZE}/\text{PREC}$	Number of matrix terms in a buffer.

### Estimation Equations

For each superelement, estimates of CPU time and disk space are made using the following equations.

Table 9-10      Equations Used for CPU Time and Disk Space Estimate

Printout Symbol	Math Symbol	Equations
TD	$T_1$	$T_1 = 1/2 \cdot M \cdot O \cdot C^2$
TFBS	$T_2$	$T_2 = 2 \cdot M \cdot C \cdot O \cdot a$
TMAA	$T_3$	$T_3 = M \cdot O \cdot a^2$ (set to 0.0 if NOMASS $\neq$ +1)
TSE	$T_{SE}$	$T_{SE} = C_6(T_1 + T_2 + T_3)$
SLOO	$S_1$	$S_1 = O \cdot C \cdot \frac{\text{PREC}}{b}$
SGO	$S_2$	$S_2 = O \cdot a \cdot \frac{\text{PREC}}{B}$
SKGG	$S_3$	$S_3 = 36(NG_i + NG_e - NS)(c_3 + 1.0) \left( \frac{\text{PREC}}{B} \right)$

Table 9-10 Equations Used for CPU Time and Disk Space Estimate

Printout Symbol	Math Symbol	Equations
SSE	$S_{SE}$	$S_{SE} = S_1 + S_2 + c_7 \cdot S_3$
PASSES	$p$	$FBS \text{ passes} = p = a \cdot O \cdot \frac{PREC}{WF}$
BKSTRN	$BT$	Blocks Transferred = $BT = 2 \cdot p \cdot S_1 + S_2 + p \cdot S_2$ . (Last term omitted if $NOMASS \neq +1$ )
TWALL	$T_W$	Wall Time = $T_W = T_{SE} + c_4 \cdot BT$

**Remarks:**

- In the superelement solution sequences, this data is stored automatically.
- The header record continuation entries are optional if no global override data is to be specified. In this case, the complete header entry is optional.
  - Active column data can come from one of several places. The value for CRMS is determined as follows:
    - RMS from the entry when  $IREC > 0$  and field 4 is "SE".
    - RMS from entries with  $IREC = 0$ .
    - Computed bandwidth when  $PARAM, OLDSEQ$  is specified.
    - If  $FCRMS$  is specified when  $IREC > 0$  and field 4 is "SE", then  $CRMS = FCRMS \cdot O$ .
    - If  $FCRMS$  is specified when  $IREC = 0$ , then  $CRMS = FCRMS \cdot O$ .
    - $CRMS = 0.1 \cdot O$ .
- If  $C_{MAX}$  is not specified, then it is defaulted to  $CRMS$ .
- In the example above, mass terms are excluded for all superelements and new values are given for parameters  $C_1$ ,  $C_3$ , and  $C_7$  for Superelement 10 only.
- The estimates for  $TSEX$ ,  $SSEX$ , and  $TWALLX$  are not printed unless at least one estimate exceeds the threshold.

## DTI,INDTA Stress, Strain and/or Force Sort/Filter Item Code Override

Specifies or overrides default item codes for the sorting and filtering of element stresses, strains, and forces.

### Format:

1	2	3	4	5	6	7	8	9	10
DTI	INDTA	"0"							

To specify/override items for a sort of stress quantities:

DTI	INDTA	"1"	B1	C1	B2	C2	"ENDREC"		
-----	-------	-----	----	----	----	----	----------	--	--

To specify/override items for a sort of force quantities:

DTI	INDTA	"2"	B1	C1	B2	C2	"ENDREC"		
-----	-------	-----	----	----	----	----	----------	--	--

### Examples:

DTI	INDTA	0							
-----	-------	---	--	--	--	--	--	--	--

To specify/override items for a sort of stress quantities:

DTI	INDTA	1	64	18	75	18	ENDREC		
-----	-------	---	----	----	----	----	--------	--	--

To specify/override items for a sort of force quantities:

DTI	INDTA	2	34	2	2	4	ENDREC		
-----	-------	---	----	---	---	---	--------	--	--

Describer	Meaning
Bi	Element type identification number. See the table in <a href="#">Item Codes</a> for allowable values. (Integer > 0)
Ci	Item code identification number for the stress, strain, or force quantity on which the sort or filter is to be performed. See the table in the <a href="#">Item Codes</a> for allowable values. (Integer)

### Remarks:

- This table is recognized only in SOLs 101, 103, 105, 106, 108, 109, 111, 112, 114, 115, 144, 153, and for stress, strain or force quantities only. One or more of the user parameters S1, S1G, or S1M must be specified with a value greater than or equal to zero in order to request sorting and/or filtering. See user parameter S1 in [Parameters](#). In order to sort force or strain quantities, a DMAP Alter is required.

2. If the Ci value is -1, the element type will be suppressed on the output file. An example of this feature could be as follows: If an element type is to be sorted on two different values and output twice, this can be accomplished by two calls to the STRSORT module with two unique DTI tables. However, other element types will be printed twice. This additional print can be suppressed by setting their sort codes to -1.
3. [Table 13](#) lists the elements currently that are sortable. In addition, the element type identification number, the default stress output quantity, and the associated stress code identification numbers are provided. If this entry is not specified, then the stresses are sorted based on the default quantity given in [Table 13](#).

The following should be noted:

- a. The element type identification number is used internally by the program to differentiate element types.
- b. The stress code identification number is merely the word number in the standard printed output for the stress quantity of interest. For example, the thirteenth word of stress output for the CHEXA element is the octahedral shear stress. For this element type, the element identification number and the grid point ID each count as a separate word. Stress codes for the elements are tabulated in [Item Codes](#).
- c. By default, stress sorting for the membrane and plate elements will be performed on the Hencky-von Mises stress. For maximum shear stress, the STRESS (MAXS) Case Control command should be specified.

Table 13 Sortable Elements

Element	Element Type ID Number	Default Stress Output Quantity and Identification Number	
		Quantity	Stress Code ID Number
CBAR	34	Maximum stress at end B	14
CBEAM	2	Maximum stress at end B	108

CTRIAX6	53	No default	---
CTUBE	3	Axial stress	2

\*CORNER output

## DTI,SETREE

### Superelement Tree Definition

Defines a superelement tree that determines the superelement processing order.

#### Format:

1	2	3	4	5	6	7	8	9	10
DTI	SETREE	"1"	SEUP1	SEDOWN1	SEUP2	SEDOWN2	SEUP3	SEDOWN3	
	SEUP4	SEDOWN4	SEUP5	SEDOWN5	-etc.-				

#### Example:

DTI	SETREE	1	1	14	2	14	3	14	
	4	14	14	0					

Describer	Meaning
SEUP <sub>i</sub>	Identification number of the superelement upstream from SEDOWN <sub>i</sub> . (Integer > 0)
SEDOWN <sub>i</sub>	Identification number of the superelement into which SEUP <sub>i</sub> is assembled. (Integer ≥ 0)

#### Remarks:

1. SETREE entries or the DTI,SETREE entry are required for multi-level superelement configurations.
2. If an DTI,SETREE entry is provided, then SETREE entries are not required.
3. If both SETREE entries and a DTI,SETREE entry exist, then the DTI,SETREE entry will be ignored.
4. If a superelement is not referenced on the DTI,SETREE or SETREE entry, then the manner in which it is handled depends on the type of that superelement. If it is a PART superelement, then the residual will be regarded as its downstream superelement and the undefined superelement will therefore be placed immediately above the residual in the tree. If it is a Main Bulk Data superelement, then it will also be handled like an undefined PART superelement as above *if all of its exterior points belong to the residual*. However, if one or more of its exterior points do not belong to the residual, then the program will terminate with a user fatal error complaining that one of more of the superelements are not in the same path.
5. If this entry is not present, the superelement tree and the processing order are determined automatically.
6. A superelement identification may appear only once in a SEUP<sub>i</sub> field.
7. On restart, if a superelement identification does not appear in a SEUP<sub>i</sub> field, its matrices will not be assembled, even though they may be present in the database.
8. See the *MSC Nastran Superelements and Modules User's Guide* for a description of user-designated trees.

9. This entry is stored in the database automatically. Once stored, the Bulk Data entry may be removed from the input file.
10. In the example above, the following superelement tree is defined:

Figure 9-89 Sample Superelement Tree

## DTI,SPECSEL

## Response Spectra Input Correlation Table

Correlates spectra lines specified on TABLED1 entries with damping values.

### Format:

1	2	3	4	5	6	7	8	9	10
DTI	SPECSEL	RECNO		TYPE	TID1	DAMP1	TID2	DAMP2	
	TID3	DAMP3	TID4	DAMP4	TID5	DAMP5	-etc.-		

### Example:

DTI	SPECSEL	1		A	1	.02	2	.04	
	3	.06							
DTI	SPECSEL	3		V	4	.01			

Describer	Meaning
RECNO	Spectrum number. (Integer > 0)
TYPE	Type of spectrum. (Character: "A" for acceleration, "V" for velocity, or "D" for displacement.)
TID <sub>i</sub>	TABLED1 entry identification number. (Integer > 0)
DAMP <sub>i</sub>	Damping value assigned to TID <sub>i</sub> . (Real)

### Remarks:

1. The RECNO is the number of the spectrum defined by this entry. It is referenced on DLOAD Bulk Data entries.
2. The TID<sub>i</sub>, DAMP<sub>i</sub> pairs list the TABLED1 entry, which defines a line of the spectrum and the damping value assigned to it. The damping value is in the units of fraction of critical damping.
3. This entry is placed in the database automatically. Once stored, the Bulk Data entry may be removed from the input file.

## DTI,SPSEL

### Response Spectra Generation Correlation Table

Correlates output requests with frequency and damping ranges.

#### Format:

1	2	3	4	5	6	7	8	9	10
DTI	SPSEL	RECNO	DAMPL	FREQ1	G1	G2	G3	G4	
	G5	G6	G7	-etc.-					

#### Example:

DTI	SPSEL	1	2	1	11	12			
DTI	SPSEL	2	4	3	1	7	11	12	
	13	14							

Describer	Meaning
DAMPL	Identification number of the FREQ, FREQ1, or FREQ2 Bulk Data entry that specifies the list of damping values. (Integer > 0)
FREQ1	Identification number of the FREQi Bulk Data entry that specifies the list of frequencies. (Integer > 0)
Gi	Grid point number where response spectra will be calculated. (Integer > 0)
RECNO	Record number of spectra to be generated. (Sequential integer beginning with 1.)

#### Remarks:

1. This table is used in SOLs 109 and 112.
2. Damping values are in the units of fraction of critical damping.
3. Output of response spectra requires the use of the XYPLOT...SPECTRA(RECNO)/Gi... command, where Gi is restricted to the grid points listed on the (RECNO) record of this entry.
4. The SPSEL table is stored in the database automatically in SOLs 109 and 112. Once stored, the Bulk Data entry may be removed from the input file.
5. There must be case control output request for displacements and velocities of the points to be output. For example you could use case control commands:

DISP(PLOT) = ALL

VELO(PLOT) = ALL

**DTI,UNITS**

## Unit Definitions

Defines units necessary for conversion during the analysis for the Nastran/ADAMS interface or a Nastran fatigue analysis.

**Format:**

1	2	3	4	5	6	7	8	9	10
DTI	UNITS	1	MASS	FORCE	LENGTH	TIME	STRESS		

**Example:**

DTI	UNITS	1	KG	N	M	S	MPA		
-----	-------	---	----	---	---	---	-----	--	--

**Remarks:**

1. The DTI,UNITS Bulk Data entry is required for a ADAMSMNF FLEXBODY=YES run. See the [ADAMSMNF\\* \(Case\)](#) case control entry. ADAMS is not a unitless code (as is Nastran). Units must be specified. A DTI Bulk Data entry provides 'UNITS' (a unique identifier) input as the above example illustrates. Once identified, the units will apply to all superelements in the model. Acceptable character input strings are listed in the table below. MASS, FORCE, LENGTH, and TIME are required for ADAMS interface.
2. MSC Nastran is a unitless code and it is the user's responsibility to ensure compatible units. During a fatigue analysis, stress is converted to SI units of MPa because the fatigue material property stress parameters as defined on the MATFTG entry are internally converted to standard SI units of MPa. The stresses from the analysis must match. Thus it is necessary for the user to use DTI,UNITS to define the stress units to ensure proper conversion. The default units are MPa and this entry is only necessary if stresses are not in MPa.

Mass	Force	Length	Time	Stress*
KG - kilogram	N - newton	KM - kilometer	H - hour	MPA - megapascal
LBM - pound-mass	LBF - pounds-force	M - meter	MIN - minute	PA - pascal
SLUG - slug	KGF - kilograms-force	CM - centimeter	S - second	PSI - pound per square inch
GRAM - gram	OZF - ounce-force	MM - millimeter	MS - millisecond	KSI - kilo pound per square inch
OZM - ounce-mass	DYNE - dyne	MI - mile	US - microsecond	PSF - pound per square foot

Mass	Force	Length	Time	Stress*
KLBM - kilo pound-mass (1000 lbm)	KN - kilonewton	FT - foot	NANOSEC - nanosecond	KSF - kilo pound per square foot
MGG - megagram	KLBF - kilo pound-force (1000 lbf)	IN- inch	D - day	DYNECM2 - dyne per square centimeter
SLINCH - 12 slugs	MN - millinewton	UM - micrometer		BAR - bar
UG - microgram	UN - micronewton	NM - nanometer		ATM - physical atmosphere
NG - nanogram	NN - nanonewton	ANG - angstrom		
USTON - US ton		YD - yard		
		MIL - milli-inch		
		UIN - micro-inch		

\* For fatigue analysis of spot welds, only MPA, PA, PSI, KSI, PSF, and KSF are supported. For random vibration fatigue analysis using SOL 108 or 111, only MPA, PA, PSI, and KSI are supported.

**DVBSHAP**

## Design Variable to Boundary Shapes

Associates a design variable identification number to a linear combination of boundary shape vectors from a particular auxiliary model.

**Format:**

1	2	3	4	5	6	7	8	9	10
DVBSHAP	DVID	AUXMOD	COL1	SF1	COL2	SF2	COL3	SF3	

**Example:**

DVBSHAP	4	1	1	1.6					
---------	---	---	---	-----	--	--	--	--	--

Describer	Meaning
DVID	Design variable identification number of a DESVAR entry. (Integer > 0)
AUXMOD	Auxiliary model identification number. (Integer > 0)
COLi	Load sequence identification number from AUXMODEL Case Control command. (Integer > 0)
SFi	Scaling factor for load sequence identification number. (Real; Default = 1.0)

**Remarks:**

1. Design variable DVID must be defined on a DESVAR entry.
2. Multiple references to the same DVID and/or COLi will result in the vector addition of the referenced boundary shape vectors.
3. Multiple DVBSHAP entries may be specified.

**DVCREL1****Design Variable to Connectivity Property Relation**

Defines the relation between a connectivity property and design variables.

**Format:**

1	2	3	4	5	6	7	8	9	10
DVCREL1	ID	TYPE	EID	CPNAME	CPMIN	CPMAX	C0		
	DVID1	COEF1	DVID2	COEF2	DVID3	COEF3	-etc.-		

**Example:**

DVCREL1	5	CQUAD4	1	ZOFFS		1.0			
	1	1.0							

Describer	Meaning
ID	Unique identification number. (Integer > 0)
TYPE	Name of an element connectivity entry, such as “CBAR”, “CQUAD4”, etc. (Character)
EID	Element Identification number. (Integer > 0)
CPNAME	Name of connectivity property, such as “X1”, “X2”, “X3”, “ZOFFS”, etc. (Character)
CPMIN	Minimum value allowed for this property. If CPNAME references a connectivity property that can only be positive, then the default value of CPMIN is 1.0E-15. Otherwise, it is -1.0E35. See Remark 4. (Real)
CPMAX	Maximum value allowed for this property. See Remark 4. (Real; Default =1.0E+20)
C0	Constant term of relation. (Real; Default = 0.0)
DVIDi	DESVAR entry identification number. (Integer > 0)
COEFi	Coefficient of linear relation or keyword = “PVAL”. (If i = 1, Real or Character; if i > 1, Real)

**Remarks:**

1. The relationship between the connectivity property and design variables is given by:

$$CP_j = C_0 + \sum_i COEF_i \cdot X_{DVID_i}$$

2. The continuation entry is required.
3. The fifth field of the entry, CPNAME, only accepts string characters. These string values must be the same as those given in the connectivity entry descriptions in this Guide. For example, if the plate offset is to be designed (CQUAD4, CTRIA3, etc), ZOFFS (case insensitive) must be specified on the CPNAME field.

4. The default values for CPMIN and CPMAX are not applied when the linear property is a function of a single design variable and  $C0=0$ . It is expected that the limits applied on the associated DESVAR entry will keep the designed property within meaningful bounds.
5. When "PVAL" is used for the COEF1 field, this is a flag to indicate that the COEF1 value is to be obtained from the connectivity bulk data entry. If a DVCREL1 entry references more than one design variable with the PVAL option, a User Fatal Message will be issued.
6. If the user inputs CQUAD4/CTRIA3 entries and then uses QRMETH = 5 to convert them to CQUADR/CTRIAR entries, the design of items on these entries using the DVCREL1 entry should refer to the converted type (i.e., CQUADR/CTRIAR). Similarly, if QRMETH=2 or 3 is used, the DVCREL1 entry should refer to CQUAD4/CTRIA3 types.

**DVCREL2****Design Variable to Connectivity Property Relation**

Defines the relation between a connectivity property and design variables with a user-supplied equation.

**Format:**

1	2	3	4	5	6	7	8	9	10
DVCREL2	ID	TYPE	EID	CPNAME	CPMIN	CPMAX	EQID		
	“DESVAR”	DVID1	DVID2	DVID3	DVID4	DVID5	DVID6	DVID7	
		DVID8	-etc.-						
	“DTABLE”	LABL1	LABL2	LABL3	LABL4	LABL5	LABL6	LABL7	
		LABL8	-etc.-						

**Example:**

DVCREL2	1	CBAR	100	X1	0.05	1.0	100		
	DESVAR	1001							
	DTABLE	X10							

Describer	Meaning
ID	Unique identification number. (Integer > 0)
TYPE	Name of an element connectivity entry, such as “CBAR”, “CQUAD4”, etc. (Character)
EID	Element Identification number. (Integer > 0)
CPNAME	Name of connectivity property, such as “X1”, “X2”, “X3”, “ZOFFS”, etc. (Character)
CPMIN	Minimum value allowed for this property. If CPNAME references a connectivity property that can only be positive, then the default value of CPMIN is 1.0E-15. Otherwise, it is -1.0E35. (Real)
CPMAX	Maximum value allowed for this property. (Real; Default =1.0E+20)
EQID	DEQATN entry identification number. (Integer > 0)
“DESVAR”	DESVAR flag. Indicates that the IDs of DESVAR entries follow. (Character)
DVIDi	DESVAR entry identification number. (Integer > 0)
“DTABLE”	DTABLE flag. Indicates that the LABLs for the constants in a DTABLE or DTABLE2 entry follow. This field may be omitted if there are no constants involved in this relation. (Character)
LABLi	Label for a constant on the DTABLE or DTABLE2 entry. (Character)

**Remarks:**

1. The variable identified by  $DVID_i$  and  $LABL_i$  correspond to variable names ( $x_1, x_2$ , etc.) listed in the left-hand side of the first equation on the DEQATN entry identified by EQID. The variable names  $x_1$  through  $x_N$  (where  $N = m + n$ ) are assigned in the order  $DVID_1, DVID_2, \dots, DVID_m, LABL_1, LABL_2, \dots, LABL_n$ .
2. If both “DESVAR” and “DTABLE” are specified in field 2, “DESVAR” must appear first.
3. The fifth field of the entry, CPNAME, only accepts string characters. These string values must be the same as those given in the connectivity entry descriptions in this Guide. For example, if the plate offset is to be designed (CQUAD4, CTRIA3, etc.), ZOFFS (case insensitive) must be specified on the CPNAME field.
4. If the user inputs CQUAD4/CTRIA3 entries and then uses QRMETH = 5 to convert them to CQUADR/CTRIAR entries, the design of items on these entries using the DVCREL2 entry should refer to the converted type (i.e., CQUADR/CTRIAR). Similarly, if QRMETH=2 or 3 is used, the DVCREL2 entry should refer to CQUAD4/CTRIA3 types.

**DVGRID**

## Design Variable to Grid Point Relation

Defines the relationship between design variables and grid point locations.

**Format:**

1	2	3	4	5	6	7	8	9	10
DVGRID	DVID	GID	CID	COEFF	N1	N2	N3		

**Example:**

DVGRID	3	108	5	0.2	0.5	0.3	1.0		
--------	---	-----	---	-----	-----	-----	-----	--	--

Describer	Meaning
DVID	DESVAR entry identification number. (Integer > 0)
GID	Grid point (GRID) or geometric point (POINT) identification number. (Integer > 0)
CID	Coordinate system identification number. (Integer ≥ 0; Default = 0)
COEFF	Multiplier of the vector defined by Ni. (Real; Default = 0.0)
Ni	Components of the vector measured in the coordinate system defined by CID. (Real; at least one Ni ≠ 0.0)

**Remarks:**

1. A CID of zero or blank (the default) references the basic coordinate system.
2. Multiple references to the same grid ID and design variable result in vectorial addition of the participation vectors defined by CID, COEFF, and Ni. There is no restriction on the number of DVGRID entries that may reference a given grid (GID) or design variable (DVID).
3. The coordinate update equation is given as

$$\{g\}_i - \{g\}_i^0 = \sum_j \text{COEFF}_j (X_{\text{DVID}j} - X_{\text{DVID}j}^0) \{N\}_j$$

where  $\{g\}_i$  is the location of the  $i$ -th grid,  $[g_x g_y g_z]^T$ .

The vector  $\{N\} = [N_x N_y N_z]^T$  is determined from CID and Ni. Note that it is a change in a design variable from its initial value  $X^0$ , and not the absolute value of the design variable itself, that represents a change in a grid point location,  $\{g\}_i - \{g\}_i^0$ .

4. The DVGRID entry defines the participation coefficients (basis vectors) of each design variable for each of the coordinates affected by the design process in the relationship

$$\{\Delta g\}_i = \sum_j \{T\}_{ij} \cdot \Delta X_j$$

5. DVGRID entries that reference grid points on MPCs or RSSCON entries produce incorrect sensitivities. Often the sensitivities are 0.0 which may result in a warning message indicating zero gradients which may be followed by UFM 6499. Other rigid elements produce correct results.

**DVLREL1**

Defines the linear relation between analysis model loading and design variables in SOL 200 with Analysis = STATICS

**Format:**

1	2	3	4	5	6	7	8	9	10
DVLREL1	ID	TYPE	SID	LNAME	LMIN	LMAX	C0		
	ATT1	ATT2	ATT3	ATT4	ATT5				
	DVID	COEF	DVID2	COEF2	DVID3	Etc			

**Example: Design the N1 FORCE at GRID 100 to be equal to DESVAR=10**

DVLREL1	10	FORCE	300	N1					
	100								
	10	1.0							

Describer	Meaning
ID	Unique identification number (Integer>0)
TYPE	Name of Load, such as FORCE, see Remark 2. for supported types (Character)
SID	Load set ID (Integer>0)
LNAME	Load Name, such as F or N1 on the FORCE entry. See Remark 2. (Character)
LMIN	Minimum value for the load. See Remark 5. (Real, default=-1.0e35)
LMAX	Maximum value for the load (Real, Default=1.0e20)
C 0	Constant term of relation (Real, Default=0.0)
ATTi	Attributes of the designed load, see Remark 2. (Integer>0 or blank)
DVIDi	DESVAR entry identification number. (Integer>0)
COEFi	Coefficient of linear relation or keyword="PVAL", See Remark 3. (If i=1, Real or Character; if i>1, Real )

**Remarks:**

1. The relationship between the analysis model load and the design variables is given by:

$$L_i = C_0 + \sum COEFF_i X_{DVID_i}$$

2. Supported TYPEs and their ATTi meaning are given in the following table:

Load Type	LNAME (character)	ATT1 (integer)	ATT2 (integer)	ATT3 (integer)	ATT4 (integer)	ATT5 (integer)
FORCE	F, N1, N2 or N3	G	CID (see remark 6)			
LOAD	S or Si	0 if LNAME is S, Li otherwise				
MOMENT	M, N1, N2 or N3	G	CID (see remark 6)			

- When "PVAL" is used for the COEF1 field, this is a flag to indicate that the COEF1 value is to be obtained from the load bulk data entry. If a DVLREL1 entry references more than one design variable with the PVAL option, a User Fatal Message will be issued.
- If there are multiple loads that satisfy the designation of the request (for example two FORCE entries with identical SID, GRID and CID values), it is a user input error.
- The default values of LMIN and LMAX are not applied when the linear property is a function of a single design variable and C0=0. It is expected that the limits applied on the DESVAR entry will keep the designed property within reasonable bounds
- Input of these data is optional. In most cases, leaving it off will result in a single load that qualifies with the remaining attributes. If there are multiple instances that qualify, it is a user input error.
- The use of this entry is limited to statics and buckling analyses in SOL 200.

## DVMREL1      Design Variable to Material Relation

Defines the relation between a material property and design variables.

### Format:

1	2	3	4	5	6	7	8	9	10
DVMREL1	ID	TYPE	MID	MPNAME	MPMIN	MPMAX	C0		
	DVID1	COEF1	DVID2	COEF2	DVID3	COEF3	-etc.-		

### Example:

DVMREL1	5	MAT1	1	RHO	0.05	1.0			
	1	1.0							

Describer	Meaning
ID	Unique identification number. (Integer > 0)
TYPE	Name of a material property entry, such as “MAT1”, “MAT2”, etc. (Character)
MID	Material Identification number. (Integer > 0)
MPNAME	Name of material property, such as “E” or “RHO”. (Character)
MPMIN	Minimum value allowed for this property. If MPNAME references a material property that can only be positive, then the default value for MPMIN is 1.0E-15. Otherwise, it is -1.0E35. See Remark 4. (Real)
MPMAX	Maximum value allowed for this property. See Remark 4. (Real; Default = 1.0E+20)
C0	Constant term of relation. (Real; Default = 0.0)
DVIDi	DESVAR entry identification number. (Integer > 0)
COEFi	Coefficient of linear relation or keyword = “PVAL”. (If i = 1, Real or Character; if i > 1, Real)

### Remarks:

1. The relationship between the material property and design variables is given by:

$$MP_i = C_0 + \sum_i COEF_i \cdot X_{DVID_i}$$

2. The continuation entry is required.
3. The fifth field of the entry, MPNAME, only accepts string characters. It must be the same as the name that appears in the [Bulk Data Entries](#) for various material properties. For example, if the isotropic material density is to be designed, RHO (case insensitive) must be specified on the MPNAME field.

4. The default value for MPMIN and MPMAX are not applied when the linear property is a function of a single design variable and  $C0=0.0$ . It is expected that the limits applied to the DESVAR entry will keep the designed property within reasonable bounds.
5. When "PVAL" is used for the COEF1 field, this is a flag to indicate that the COEF1 value is to be obtained from the material bulk data entry. If a DVMREL1 entry references more than one design variable with the PVAL option, a User Fatal Message will be issued.

**DVMREL2****Design Variable to Material Relation**

Defines the relation between a material property and design variables with a user-supplied equation.

**Format:**

1	2	3	4	5	6	7	8	9	10
DVMREL2	ID	TYPE	MID	MPNAME	MPMIN	MPMAX	EQID		
	DESVAR	DVID1	DVID2	DVID3	DVID4	DVID5	DVID6	DVID7	
		DVID8	-etc.-						
	DTABLE	LABL1	LABL2	LABL3	LABL4	LABL5	LABL6	LABL7	
		LABL8	-etc.-						

**Example:**

DVMREL2	5	MAT1	1	E	0.05	1.0	100		
	DESVAR	1	2						
	DTABLE	E0							

Describer	Meaning
ID	Unique identification number. (Integer > 0)
TYPE	Name of a material property entry, such as “MAT1”, “MAT2”, etc. (Character)
MID	Material Identification number. (Integer > 0)
MPNAME	Name of material property, such as “E” or “RHO”. (Character)
MPMIN	Minimum value allowed for this property. If MPNAME references a material property that can only be positive, then the default value for MPMIN is 1.0E-15. Otherwise, it is -1.0E35. (Real)
MPMAX	Maximum value allowed for this property. (Real; Default = 1.0E+20)
EQID	DEQATN entry identification number. (Integer > 0)
DESVAR	DESVAR flag. Indicates that the IDs of DESVAR entries follow. (Character)
DVIDi	DESVAR entry identification number. (Integer > 0)
DTABLE	DTABLE flag. Indicates that the LABLs for the constants in a DTABLE or DTABLE2 entry follow. This field may be omitted if there are no constants involved in this relation. (Character)
LABLi	Label for a constant on the DTABLE or DTABLE2 entry. (Character)

**Remarks:**

1. The variables identified by  $DVID_i$  and  $LABL_i$  correspond to variable names ( $x_1, x_2$ , etc.) listed in the left-hand side of the first equation on the DEQATN entry identified by EQID. The variable names  $x_1$  through  $x_N$  (where  $N = m + n$ ) are assigned in the order  $DVID_1, DVID_2, \dots, DVID_m, LABL_1, LABL_2, \dots, LABL_n$ .
2. If both “DESVAR” and “DTABLE” are specified in field 2, “DESVAR” must appear first.
3. The fifth field of the entry, MPNAME, only accepts string characters. It must be the same as the name that appears in the [Bulk Data Entries](#) for various material properties. For example, if the isotropic material density is to be designed, RHO (case insensitive) must be specified on the MPNAME field.

**DVPREL1****Design Variable to Property Relation**

Defines the relation between an analysis model property and design variables.

**Format:**

1	2	3	4	5	6	7	8	9	10
DVPREL1	ID	TYPE	PID	PNAME/ FID	PMIN	PMAX	C0		
	DVID1	COEF1	DVID2	COEF2	DVID3	-etc.-			

**Example:**

DVPREL1	12	PBAR	612	6	0.2	3.0			
	4	0.25	20	20.0	5	0.3			

Describer	Meaning
ID	Unique identification number. (Integer > 0)
TYPE	Name of a property entry, such as “PBAR”, “PBEAM”, etc. (Character)
PID	Property entry identification number. (Integer > 0)
PNAME/FID	Property name, such as “T”, “A”, or field position of the property entry, or word position in the element property table of the analysis model. Property names that begin with an integer such as 12I/T**3 may only be referred to by field position. (Character or Integer ≠ 0)
PMIN	Minimum value allowed for this property. If PMIN references a property that can only be positive, then the default value for PMIN is 1.0E-15. Otherwise, it is -1.0E35. See Remark 6. (Real)
PMAX	Maximum value allowed for this property. (Real; Default = 1.0E+20)
C0	Constant term of relation. (Real; Default = 0.0)
DVIDi	DESVAR entry identification number. (Integer > 0)
COEFi	Coefficient of linear relation or keyword = “PVAL”. See Remark 7. (If i = 1, Real or Character; if i > 1, Real)

**Remarks:**

1. The relationship between the analysis model property and design variables is given by:

$$P_j = C_0 + \sum_i COEF_i \cdot X_{DVID_i}$$

2. The continuation entry is required.
3. TYPE=“PBEND” is not supported. TYPE=“PBEAML” supports only PNAME and not FID.

4. FID may be either a positive or a negative number. If FID > 0, it identifies the field position on a property entry. If FID < 0, it identifies the word position of an entry in the element property table. For example, to specify the area of a PBAR, either PNAME=A, FID=+4 or FID=-3 can be used. In general, use of PNAME is recommended. For Type "PBUSH", PNAME is recommended, if FID is used it must be < 0.
5. Designing PBEAML or PBEAM requires specification of both property name and station. [Table 14](#) shows several examples.

Table 14

PTYPE	Property Name	END A	END B	i-th Station
PBEAML	DIM1	DIM1 or DIM1(A)	DIM1(B)	DIM1(i)
PBEAM	A	A or A(A)	A(B)	A(i)

Only stations that are input on a PBEAM or PBEAML entry can be referenced by a DVPREL1. For example, referencing an END B property name on a DVPREL1 entry when the referenced PBEAM does not explicitly specify the END B station, is not allowed.

6. The default values of PMIN and PMAX are not applied when the linear property is a function of a single design variable and C0=0. It is expected that the limits applied on the DESVAR entry will keep the designed property within reasonable bounds.
7. When "PVAL" is used for the COEF1 field, this is a flag to indicate that the COEF1 value is to be obtained from the property bulk data entry. If a DVPREL1 entry references more than one design variable with the PVAL option, a User Fatal Message will be issued.
8. With GPLY for TYPE field and GPLYID for PID field, a ply identified with GPLYID across all PCOMPG entries in the model can be designed. Internally, a DVPREL1 will be spawned for each PCOMPG has a ply ID of GPLYID. For TYPE=GPLY, the relationship between the analysis model property and design variables is given by.

$$P_i = C0 + (T0_i \text{ or } THETA0_i) \cdot \sum_j (COEF_j \cdot X_{DVID_j}) \text{ for PNAME=T or THETA}$$

Where T0 and THETA0 are value of thickness and theta angle on the original PCOMPG. Note that non-zero C0 is not recommended for TYPE=GPLY or PCOMPG. For THETA0 with original value equal to 0.0, THETA0 is taken as 1.0 and it is recommended to have XINIT of DVID set to 0.0.

**DVPREL2****Design Variable to Property Relation**

Defines the relation between an analysis model property and design variables with a user-supplied equation.

**Format:**

1	2	3	4	5	6	7	8	9	10
DVPREL2	ID	TYPE	PID	PNAME/ FID	PMIN	PMAX	EQID		
	“DESVAR”	DVID1	DVID2	DVID3	DVID4	DVID5	DVID6	DVID7	
		DVID8	-etc.-						
	“DTABLE”	LABL1	LABL2	LABL3	LABL4	LABL5	LABL6	LABL7	
		LABL8	-etc.-						

**Example:**

DVPREL2	13	PBAR	712	5	0.2	0.4	50		
	DESVAR	4	11	13	5				
	DTABLE	PI	YM						

Descriptor	Meaning
ID	Unique identification number. (Integer > 0)
TYPE	Name of a property entry, such as PBAR, PBEAM, etc. (Character)
PID	Property entry identification number. (Integer > 0)
PNAME/FID	Property name, such as “T”, “A”, or field position of the property entry, or word position in the element property table of the analysis model. Property names that begin with an integer such as 12I/T**3 may only be referred to by field position. (Character or Integer ≠ 0)
PMIN	Minimum value allowed for this property. If FID references a stress recovery location field, then the default value for PMIN is -1.0+35. PMIN must be explicitly set to a negative number for properties that may be less than zero (for example, field ZO on the PCOMP entry). (Real; Default = 1.E-15)
PMAX	Maximum value allowed for this property. (Real; Default = 1.0E20)
EQID	DEQATN entry identification number. (Integer > 0)
“DESVAR”	DESVAR flag. Indicates that the IDs of DESVAR entries follow. (Character)
DVIDi	DESVAR entry identification number. (Integer > 0)
“DTABLE”	DTABLE flag. Indicates that the LABLs for the constants in a DTABLE or DTABLE2 entry follow. This field may be omitted if there are no constants involved in this relation. (Character)
LABLi	Label for a constant on the DTABLE or DTABLE2 entry. (Character)

**Remarks:**

1. The variables identified by DVID<sub>i</sub> and LABL<sub>i</sub> correspond to variable names (x<sub>1</sub>, x<sub>2</sub>, etc.) listed in the left-hand side of the first equation on the DEQATN entry identified by EQID. The variable names x<sub>1</sub> through x<sub>N</sub> (where N = m+n) are assigned in the order DVID<sub>1</sub>, DVID<sub>2</sub>, ..., DVID<sub>n</sub>, LABL<sub>1</sub>, LABL<sub>2</sub>, ..., LABL<sub>m</sub>.
2. If both “DESVAR” and “DTABLE” are specified in field 2, “DESVAR” must appear first.
3. FID may be either a positive or a negative number. If FID > 0, it identifies the field position on a property entry. If FID < 0, it identifies the word position of an entry in EPT. For example, to specify the area of a PBAR, either PNAME=A, FID = +4 or FID = -3 may be used. In general, use of PNAME is recommended. For Type "PBUSH", PNAME is recommended, if FID is used it must be < 0.
4. Types “PBEND”, “PBARL” and “PBEAML” are not supported for the DVPREL2.
5. Designing PBEAM requires specification of both property name and station. [Table 15](#) shows one example.

Table 15

PTYPE	Property Name	END A	END B	i-th Station
PBEAM	A	A or A(A)	A(B)	A(i)

Only stations that are input on a PBEAM entry can be referenced by a DVPREL2. For example, referencing an END B property name on a DVPREL2 entry when the referenced PBEAM does not explicitly specify the END B station, is not allowed.

**DVSHAP****Design Variable to Basis Vector(s)**

Defines a shape basis vector by relating a design variable identification number (DVID) to columns of a displacement matrix.

**Format:**

1	2	3	4	5	6	7	8	9	10
DVSHAP	DVID	COL1	SF1	COL2	SF2	COL3	SF3		

**Example:**

DVSHAP	2	1	2.0	4	1.0				
--------	---	---	-----	---	-----	--	--	--	--

Describer	Meaning
DVID	Design variable identification number on the DESVAR entry. (Integer > 0)
COLi	Column number of the displacement matrix. See Remark 2. ( $1 \leq \text{Integer} \leq \text{maximum column number in the displacement matrix.}$ )
SFi	Scaling factor applied to the COLi-th column of the displacement matrix. (Real; Default = 1.0)

**Remarks:**

1. DVID must be defined on a DESVAR entry.
2. COLi must be a valid column number in the displacement matrix.
3. Multiple references to the same DVID and/or COLi will result in a linear combination of displacement vectors. In the example above, the shape basis vector is a linear combination of the fourth column and twice the second column.
4. The displacement matrix must have been created by SOL 101 or 200 with analysis = statics and be available on a database, which is attached via the DBLOCATE FMS statement shown below:

```
ASSIGN    DISPMAT=' physical filename of MASTER DBset '
DBLOCATE DATABLK=(UG/UGD,GEOM1/GEOM1D,GEOM2/GEOM2D) ,
LOGICAL=DISPMAT
```

## DVPSURF Design Variable to Control Surface Setting Relation

Defines the relationship between a control surface setting in a particular subcase and a design variable.

### Format:

1	2	3	4	5	6	7	8	9	10
DVPSURF	ID	AELABEL	TRIMID	DVID	COEF				

### Example:

DVPSURF	10	OBDFLAP	1	100	0.01746				
---------	----	---------	---	-----	---------	--	--	--	--

Describer	Meaning
ID	Unique identification number (Integer>0)
AELABEL	LABEL of the AESURF entry that is being designed (Character ,no default)
TRIMID	Associated trim set identification number (Integer>0)
DVID	DESVAR entry identification number (Integer>0)
COEF	Coefficient of linear relation (Real)

### Remarks:

1. The relationship between the control surface setting and the design variable is given by  $\delta_{SURF} = COEF * X_{DVID}$
2. The surface called out by AELABEL must also appear on the trim entry specified by TRIMID. The value specified on the trim entry will be overwritten by the value obtained from the relationship of Remark 1.
3. Limits on the control deflection are not provided on this entry but can be specified on the underlying DESVAR
4. The DVID called out on this entry cannot be associated with any other designed property.
5. Note that since the DVPSURF calls out a TRIM ID, it is associated only with a single subcase.

## DYFSISW

## Fluid Structure Interaction Activation Switch

Allows activating or deactivating Fluid Structure Interaction and Eulerian solver. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
DYFSISW	SWID	TID	INITV						

### Example:

DYFSISW	14	10							
---------	----	----	--	--	--	--	--	--	--

### Describer

### Meaning

SWID	Unique number of a DYFSISW entry. (Integer > 0; Required)
TID	TABLED1 ID. Fluid Structure Interface and Euler solver are switched on and off, depending on the y-value of the table. The x-value of the table represents the time; the y-value denotes: ON        y > 0.0 OFF       y < 0.0
INITV	Euler element initialization flag. See remark 3. (Character, Default=NO) NO        Element initialization at cycle 0 YES       Element initialization when the elements becomes active

### Remarks:

1. The default is that COUPLE, AIRBAG and Euler solver is active at all times.
2. When Euler solver is deactivated, no output will be generated for the Eulerian elements.
3. For simulations involving a prestress phase the Euler elements can be initially deactivated. When the Euler elements are activated the Eulerian masses still originate from the Euler initiation at cycle 0. If during prestressing the structure did not move much, then these Eulerian masses of cycle 0 can give a stable run. But if there has been substantial movement of the structure then Eulerian masses can be erroneously compressed. This shows up by large pressures and velocities in the Euler elements and a time step too small. To avoid this instability the Euler initialization can be postponed until the Euler elements become active.

**DYPARAM, ATBAOUT**      Output Frequency to Main Output File of ATB - SOL 700

Defines the frequency at which output is written to the main output file of ATB. Used in SOL700 only.

**Format:**

DYPARAM, ATBAOUT, value

**Example:**

DYPARAM, ATBAOUT, 5.0E-3

Option	Content
Value	Every multiple of ATBAOUT seconds, the main output file of ATB is updated. (Real > 0.0; default=10.0E-3)

**Remarks:**

1. Only active when field 3 on the A5 card of the ATB input file is set to a value of -1.
2. Controls the frequency of the output of segment acceleration, velocity and displacement, joint forces and moments.

## DYPARAM, ATBHOUT

### Write ATB Output to Time history files - SOL 700

A time-history file is created containing the output as requested in the ATB input file on cards H.1 to H.11. Used in SOL700 only.

#### Format:

DYPARAM, ATBHOUT, option

#### Example:

DYPARAM, ATBHOUT, NO

Option	Content
Option	Flag of ATBHOUT. (Character; default=YES)
	YES: The time history files are created.
	NO: The time history files are not created.

## **DYPARAM, ATBTOUT**

### Output Frequency to Time-History Files of ATB - SOL 700

Defines the frequency at which output is written to the time-history files of ATB. Used in SOL700 only.

#### **Format:**

DYPARAM, ATBTOUT, value

#### **Example:**

DYPARAM, ATBTOUT, 1.0E-4

Option	Content
Value	Every multiple of ATBTOUT seconds, the time-history files of ATB are updated. (Real > 0.0; default=1.0E-3)

#### **Remarks:**

1. Only active when field 26 on the A5 card of the ATB input file is set to a value of -1.
2. Controls the frequency of all output requested on the H-cards, and of the tabular time-histories that are controlled by field 18 on the A5 card of the ATB input file.

## DYPARAM,AUTOCOUP

## Automatic Coupling

Defines the automatic coupling algorithm. Used in Sol700 only.

### Format:

DYPARAM,AUTOCOUP,ACTIVE,CLEAN,DUMMY,TOL\_AREA, OUTPUT, FAIL

### Example:

DYPARAM, AUTOCOUP, ON

Describer	Meaning
ACTIVE	Flag of activation of the sub element approach. (Character; default=OFF)
	ON                    Turn on the sub element approach.
	OFF                   Turn off the sub element approach.
CLEAN	Flag of cleaning obsolete sub elements. (Character; default=OFF)
	ON                    Cleans obsolete sub elements
	OFF                   Obsolete elements will not be removed from memory.
DUMMY	Flag of putting dummy segments on coupling surface archives. (Character; default=OFF)
	ON                    Puts dummy segments on the coupling surface archive
	OFF                   Does not put dummy segments on the coupling surface archive.
TOL_AREA	If the area of a hole is smaller than TOL_AREA a 1D flow computation method is used. (Real $\geq$ 0.0; default=0.0).
OUTPUT	Determines how results of Euler elements that are intersected by the structure are written to the Euler archive. (Character, Default = ZERO).
	ZERO                   Write zero for the results of these intersected elements.
	AVERAGE            Average across sub elements. Each sub element has the same weight.
	AVEREAGEU          Average across sub element using the uncover fraction as weights.
	MAXUNC              The results are taken from the sub element with the largest volume uncover fraction.
	COVER                Uses the cover field of COUPLE to select the proper sub element. Only supported for COVER=OUTSIDE or COVER=INSIDE. Not supported for COVER =NONE.
FAIL	Activates fluid flow through failed shell segments in the coupling surface. (Character; there is no default, if failure is not used, then FAIL should be left blank)
	POROUS              Makes failed segment porous. This is the fast coupling approach.
	REMOVE              Removes the failed segments from the coupling surface.

**Remarks:**

1. Features that are not supported are:
  - Multiple Euler domain
  - Adaptive Euler meshes
  - Fluid flow through failed segments in the coupling surface failure can only be defined by option FAIL of DYPARAM, AUTOCOUP. Defining this failure by use of COUP1FL and COUPINT is not supported.
  - COUPLE with option AIRBAG
  - Graded meshes
  - Euler import
  - Viscosity
  - Porosity
  - Option FAIL=POROUS and REMOVE are not supported by DMP.
  - Markers
2. With automatic coupling fluid can be defined on both sides of the coupling surface. To do this option COVER of the COUPLE entry has to be set to NONE. When using COVER = OUTSIDE fluid is only initialized in the inside region of the coupling surface. For COVER = INSIDE the opposite applies. When the coupling surface is not closed, only COVER=NONE is allowed.
3. In the auto coupling approach holes in the coupling surface are meshed with dummy segments. For holes with large deformations PARAM DUMSEGS, ON can be used to maintain good dummy segments.
4. For adding FAIL = POROUS failed segments have to be made fully porous. This is straightforward.
5. FAIL = REMOVE. When the structure fails, holes in the coupling surface are formed. For a closed coupling surface each side of a segment is connected to another segment. Therefore, the segments have no free edges. But a segment adjacent to a hole has a free edge. At this edge it is not connected to any other segment. A list of free edges of the coupling surface specifies the holes. By maintaining a list of free edges auto coupling handles these holes automatically. If a segment fails, this list of free edges has to be updated. Also the failed segment has to be removed from the coupling surface.

**Note:**

This entry also supports DMP. While using for DMP, no changes to input is needed. In the auto coupling method Euler elements that are intersected by the structure are split into sub elements. For details refer to [1]. To enable dmp for auto coupling some of the properties of sub elements have to be communicated across CPU's. If holes in the coupling surface extend across multiple CPUs, also communication across CPU's is needed.

## DYPARAM,AXIALSYM

## Axial Symmetric Analyses - SOL 700

Enables an efficient and accurate 2-D axial symmetry for Eulerian materials. A much larger time step becomes possible by not taking into account the mesh-size in circumferential direction. Used in SOL 700 only.

### Format:

DYPARAM,AXIALSYM,MESHTYPE,AXIALAXIS,SYMPLAN,PHI,ALIGN,PHI2

### Example:

DYPARAM,AXIALSYM,RECT,X,XY,2.5,YES,0.0

Describer	Meaning
MESHTYPE	Two types of Euler meshes are supported: (Character; Required) AXIAL      Axial symmetric meshes. RECT        Rectangular meshes
AXIAL AXIS	X            X-Axis (Character; Required) Y            Y-Axis Z            Z-Axis
SYMPLAN	The approximate symmetry plan of the Euler mesh. On for MESHTYPE=AXIAL. See Remark 7. (Character; Required) XY          XY-Plane YZ          YZ-Plane ZX          ZX-Plane
PHI	Only used for MESHTYPE = RECT. Used to create a 2D axial symmetric mesh with angles +PHI/2 and -PHI/2. (Real; Default = 0.0)
ALIGN	Only used for MESHTYPE = AXIAL. (Character; Default = YES) YES         Align normals of oblique Euler element faces. This prevents errors in strains that can arise from small errors in Euler face normals. NO          Do not align normals.
PHI2	As a final operation rotate the mesh around the axial axis by the angle PHI2. See Remark 6. (Real; Default = 0.0)

### Remarks:

1. Only available for Eulerian elements and does not support Lagrange elements. The effect of this parameter is not limited to the solvers. Also Euler archives will reflect the modified Euler mesh geometry.

2. The Euler mesh can already be symmetric but also a rectangular mesh comprising of one layer can be used. Using the angle specified by PHI this Euler mesh is mapped into a 2d axial symmetric mesh.
3. The Euler mesh has to consist of one layer.
4. Rectangular meshes that can be made 2d symmetric using the angle PHI should satisfy:
  - All boundary Euler faces are aligned with a coordinate direction
  - Only one layer thick.
  - The axial symmetry axis is either on the boundary of the Euler mesh or outside the Euler mesh. It is not allowed that the axial axis is inside the Euler mesh.Initialization of Euler element using geometric regions as defined by the TICEUL entry is carried out onto the transformed 2d axial mesh.
5. In the time step computation the circumferential mesh-size will not be taken into account.
6. Use option PHI2 with caution. Euler initialization is done using the mesh rotated by the angle PHI2. So after including the angle PHI2 or modifying its value the Euler initialization should be revised.
7. It is assumed that one of the coordinate planes is an approximate symmetry plane of the Euler mesh. Although approximate symmetry is sufficient, the coordinate plane can always be made an exact symmetry plane by the use of PHI2. If for example the Euler mesh has angles 0 and 2.5, PHI2 has to be set to -1.25 to get exact symmetry.

## DYPARAM,AXREMAP

## 2D Axial symmetric Euler archive remap - SOL 700

Allows import of a 2D axial symmetric Euler archive into a 3D simulation.

### Format:

1	2	3	4	5	6	7	8	9	10
DYPARAM	AXREMAP	x0	y0	z0	xn	yn	zn	range	

### Example:

DYPARAM	AXREMAP	0.0	0.5	0.5	1.	0.	0.		
---------	---------	-----	-----	-----	----	----	----	--	--

Describer	Meaning
x0,y0,z0	x,y,z-coordinate of the point at which the 2D axial symmetric mesh is remapped. (Real; Default = 0.0)
xn,yn,zn	Unit vector that specifies the direction of the axial axis of the 2D axial symmetric mesh as viewed in the 3D mesh. (Real; Default = (1.0, 0.0, 0.0) )
range	Only material whose distance from the axial axis is smaller than "range" will be initialized with the 2D axi-symmetric Euler archive. (Real, Default = 1e+20)

### Remarks:

1. Since 2D axial symmetric simulations run much faster than 3D simulation it can save much cpu time to do the first part of the simulation with a 2D axial symmetric mesh. Afterwards the 2D-axial symmetric Euler archive is imported into the 3D simulation. By default the 2D axial symmetric archive will not be expanded in 3D. To enable this expansion DYPARAM, AXREMAP has to be used. It is useful for blast wave simulations. The 2D axial symmetric simulation has to be terminated before the blast wave approaches any 3D structure.
2. This import of Euler archives is done by means of the eid option in the pth file.
3. To generate axial symmetric meshes DYPARAM,AXIALSYM can be used.

## **DYPARAM,BULKL**

## Linear Bulk Viscosity Coefficient- SOL700

Defines the default value of the linear bulk viscosity coefficient.

### **Format:**

DYPARAM, BULKL, VALUE

### **Example:**

DYPARAM, BULKL, 0 . 1

<b>Describer</b>	<b>Meaning</b>
value	Value of the linear coefficient in the bulk viscosity equation. (Real $\geq$ 0.0; default=0.0)

### **Remarks:**

1. The default value works well for the majority of problems.
2. The value defined on this entry is used as the default whenever BULKL is blank on the MATBV material entry.
3. When BULKL is specified on a material definition entry, the default value is overridden for that specific material.

## DYPARAM,BULKQ

## Quadratic Bulk Viscosity Coefficient - SOL700

Defines the default value of the quadratic bulk viscosity coefficient.

### Format:

DYPARAM, BULKQ, VALUE

### Example:

DYPARAM, BULKQ, 1.6

Describer	Meaning
value	Value of the quadratic coefficient in the bulk viscosity equation. (Real $\geq$ 0.0; default=0.0)

### Remarks:

1. The default value works well in the majority of situations.
2. The value defined on this entry is used as the default whenever BULKQ is blank on the MATBV material entry.
3. When BULKQ is specified on a material definition entry, the default value is overridden for that specific material.

## **DYPARAM,BULKTYP**

Bulk Viscosity Type - SOL700

Defines the default type of bulk viscosity.

### **Format:**

DYPARAM, BULKTYP, option

### **Example:**

DYPARAM, BULKTYP, DYNA

<b>Describer</b>	<b>Meaning</b>
Option	bulk viscosity type. (Character; Default=DYNA)
DYNA	Standard DYNA3D model
DYTRAN	Enhanced DYNA model

### **Remarks:**

## DYPARAM,CFULLRIG

Converts 123456 Constraints to FULLRIG on RBE2 - SOL700

Converts all 123456 constraints to the FULLRIG option on all entries. Used in SOL 700 only.

### Format:

DYPARAM,CFULLRIG,value

### Example:

DYPARAM,CFULLRIG,NO

Describer	Meaning
value	Activation flag. (Character; Default=YES)
YES	123456 constraints are converted to FULLRIG.
NO	123456 constraints are not converted to FULLRIG.

## DYPARAM,CLUFLIM

## Limiter of Volume Stain Rate for Clumps - SOL700

In some cases, airbag runs become instable. Often, this is caused by a much too large volume strain rate in a clump that consists of too many elements. These clumps typically have a small average volume uncovered fraction. The large volume strain rate causes a huge compression work and this blows up the specific internal energy. When this happens it is clearly visible in the OUT file and in the results. This DYPARAM activates a limiter that scales down the volume strain rate for clumps with a small average uncovered fraction. It can keep an instable airbag run stable, just like PARAM, VELMAX can keep runs stable. Used in SOL 700 only.

### Format:

DYPARAM, CLUFLIM, value

### Example:

DYPARAM, CLUFLIM, 0.22

Describer	Meaning
value	The volume strain rate in a clump will be reduced when the average Uncovered Fraction of elements in a CLump falls below CLUFLIM. CLUFLIM has to be smaller than FBLEND. The default value of FBLEND is 0.66 giving a value of 0.22 for CLUFLIM. For more details on FBLEND refer to PARAM,FBLEND. (0<Real<FBLEND; default=FBLEND/3)

### Remarks:

- The Volume strain rate  $\frac{DIV}{\Delta t}$  in clumps will be limited by

$$\left(\frac{DIV}{\Delta t}\right)_{Lim} = MIN\left(1, \frac{U}{CLUFLIM}\right)\left(\frac{DIV}{\Delta t}\right)$$

Here, U is the average uncovered fraction of elements in the clump as given by

$$U = \frac{\sum_{eleclump} Uncf_{el} \cdot Vol_{el}}{\sum_{eleclump}}$$

Here Uncf and Vol denote the uncovered fraction and volume of an element inside the clump.

Therefore, only when the average uncover fraction falls below CLUFLIM, the volume strain rate is limited.

**DYPARAM,CLUMPENR**

Switch for Kinetic Energy Calculation Scheme of Blended Clumps - SOL700

Sets the definition of the kinetic energy calculation method for Eulerian blended clumps. Used in SOL 700 only.

**Format:**

DYPARAM, CLUMPENR, value

**Example:**

DYPARAM, CLUMPENR, SUM

Describer	Meaning
value	Flag for CLUMPENR.(Character; default=AVERAGE)
	<p><b>AVERAGE</b>     The kinetic energy of a Eulerian blended clump is calculated from the average velocity of the clump. The average velocity of the blended clump is computed as the sum of the momentum of each member of the clump divided by the total clump mass.</p>
	<p><b>SUM</b>             The kinetic energy of a Eulerian blended clump is calculated as the sum of the kinetic energy of each member of the clump.</p>

**DYPARAM,CONM2OUT**

CONM2 Summary Output - SOL700

Determines if a summary of concentrated masses and their energy and momentum is written to the output file. Used in SOL 700 only.

**Format:**

DYPARAM, CONM2OUT, value

**Example:**

DYPARAM, CONM2OUT, NO

Describer	Meaning
value	Flag for CONM2OUT. (Character; default=NO)
NO	No information about concentrated masses is written to the cycle and material summaries on the output file.
YES	A complete summary of concentrated masses including the associated mass, momentum, and energy is written to the output file.

**Remarks:**

1. When DYPARAM,CONM2OUT is set to NO, there is no summary of the concentrated mass. This means that the mass, momentum, and energy of the concentrated masses, is not added to the material and cycle summaries. Setting DYPARAM,CONM2OUT,NO saves memory and CPU time.

## DYPARAM,CONTACT

## Sets Defaults for CONTACT - SOL700

Defines certain defaults for the contact definitions. Used in SOL 700 only.

### Format:

DYPARAM, CONTACT, option, value1, value2, value3, value4, value5, value6

### Example:

DYPARAM, CONTACT, VERSION, V4

Describer	Meaning
VERSION	Defined the default version of contact. Only support value1. (Character; required) V4 General Contact algorithm of SOL700
BELT	Suited for modeling contact between a belt element and a rigid structure. Primary secondary contact only. The contact logic doesn't apply a contact force, but applies an enforced displacement and velocity that keeps the secondary nodes exactly on top of the primary face. The secondary node does not slide relative to the primary face when the friction coefficient (FS) is set to 1E20.
BELT1	Identical to BELT algorithm, except that the secondly nodes are initially repositioned on top of the closest primary face.
DRAWBEAD	Suited for modeling a drawbead.
THICK	Defines the default value for THICK. Only support vaule1. (Real>0.0; required.)
GAP	Defines the default value for GAP. Only support vaule1. (Real>0.0; required.)
LIMITS	Definition of a three dimensional contact region where contact in the analysis model takes place. Significant CPU time savings can be achieved when used in adaptive contact. 6 values are used to define area.  The format of this option is DYPARAM,CONTACT,LIMITS,xmin,xmax,ymin,ymax,zmin.zmax. (Real; default=1.0E20 for xmax, ymax and zmax and -1.0E20 for xmin, ymin and zmin) XMIN(value1) Lower limit in x-direction where main contact occurs XMAX(value2) Upper limit in x-direction where main contact occurs YMIN(value3) Lower limit in y-direction where main contact occurs YMAX(value4) Upper limit in y-direction where main contact occurs ZMIN(value5) Lower limit in z-direction where main contact occurs ZMAX(value6) Upper limit in z-direction where main contact occurs
DAMPING	Defines the default for usage of damping. Only support value1. (Character; required) YES Use damping in CONTACT

Describer	Meaning
	NO Not use damping in CONTACT
COPOR	Activates contact based porosity. Only support value1. (Character; default=NO)
	YES Use porosity in CONTACT
	NO Not use porosity in CONTACT
DAMPFOR	Defines whether the noncontact forces acting on the grid points need to be taken into account in the contact damping. This option is only used if DAMPING is set to YES. This option prevents large penetrations that might occur when the forces acting on the grid points tend to push them into the contact surface. This happens, for example, in airbag analyses, where a large pressure exists inside the bag. Only support value1. (Character; required)
	YES Damping is considered in noncontact forces
	NO Damping is not considered in noncontact forces
DYNA	The following parameters of the contact definition get the default values consistent with Dyna. (Character ; required)
	THICK 1.0
	THICKOF 0.0
INFO	Information on the contact state of grid points G1,G2,... is printed to ASCII files, named CNT. This information can be useful in debugging models with contacts. Supports many values as you want. (Integer > 0; required.)
EVIEW	Defines the default value of the view angle of Edge to Edge contacts. The value of the angle must be in degrees. Only support value1. (Real > 0.0; required)
FORCE	Controls the contact forces on the grid points. Supports value1, value2, value3. See Remark 1. (value1: Integer > 0; default=10, value2: Real > 0; default=10.0; value3: Character; default=ZERO)
	NMCYC Frequency check of contact force; applied on each grid point. (Integer > 0; (value1) default = 100).
	SCALE Scale factor for maximum allowable contact force. (value2) $F_{max} = SCALE \cdot F_{last\ check}$ (Integer > 0; default = 10)
	TYPE Contact force limitation. (Character; default=ZERO) (value3)
	ZERO 0.0
	FMAXF Update contact limit forces using new contact forces (where non allowable forces are not taken into account)

**Remarks:**

1. The DYPARAM, FORCE check takes up some CPU time and, therefore, do not make this value too small. Furthermore, when the check is performed at each cycle, the force will be too limited and the bag will not unfold. Recommended values are between 5 and 200. The same problems can occur for SCALE (value2). In case this value is too small, the bag will not unfold either. The minimum value for air bags that should be used is about 5. The maximum is about 20. When this value is too big a difference will not be noticed. TYPE (value3)=ZERO is a bigger restriction. In some cases, TYPE=FMAXF might yield better results.

## **DYPARAM,COSUBMXT**

Time-dependent Subcycle Limit in Euler/Lagrange Coupling - SOL700

Defines the maximum number of subcycles that can occur in Euler/Lagrange coupling. During a subcycle, the geometry of the coupling surface is not updated. This number can vary in time and is given by a table. Used in SOL 700 only.

### **Format:**

DYPARAM, COSUBMXT, value

### **Example:**

DYPARAM, COSUBMAT, 10

<b>Describer</b>	<b>Meaning</b>
value	TABLED1 ID that specifies for each time the maximum number of time steps between updating the coupling surface geometry in the coupling calculations. (Integer > 0; required)

### **Remarks:**

1. Updating the coupling geometry takes a lot of CPU time. Subcycling gives substantial savings in CPU time for coupled calculations.
2. The smaller the value of this parameter, the greater the accuracy of the analysis and the greater the cost. Conversely, larger values offer significant CPU savings, but very large values give incorrect results.
3. If the geometry of the coupling surface is changing rapidly, smaller values on the table should be used.

## DYPARAM,COUFRIC

### Coupling Surface Friction for Nonmetallic Eulerian Solids - SOL700

Defines the Coulomb friction scheme. Please check DYPARAM,COHESION too. Used in SOL 700 only.

#### Format:

DYPARAM, COUFRIC, value

#### Example:

DYPARAM, COUFRIC, NO-METAL

Describer	Meaning
value	Flag for COUFRIC usage. (Character; default=METAL)
METAL	A tensile condition will result in zero load on the structure part on cohesive coupling.
NO-METAL	a tensile load was applied in tensile condition on cohesive coupling.

#### Remarks:

1. Only used when Coulomb friction coefficients have been specified for a COUPLE entry.

**DYPARAM,COHESION**

Cohesion for Coulomb Friction - SOL 700

Allows friction and sticking during tensile conditions at the coupling surface.

**Format:**

DYPARAM,COHESION,MAXSTRS,FRIC,REFVEL

**Example:**

DYPARAM,COHESION,8.0e+10,8.0e+5,20.0

Describer	Meaning
MAXSTRS	Maximal normal stress. Allows tensile stresses at the coupling surface as long as the normal stress does not exceed MAXSTRS. (Real > 0)
FRIC	Friction stress under tensile conditions. (Real > 0)
REFVEL	Reference value for velocity. (Real > 0)

**Remarks:**

1. Only used when coulomb friction coefficients have been specified for a COUPLE entry.
2. During tension any relative tangential velocity between coupling surface and Eulerian material will yield a shear stress whose magnitude equals:

$$FRIC \cdot \min\left(1, \frac{V_{rel,tangential}}{REFVEL}\right)$$

This is a viscous-like friction law.

3. This shear force opposes the relative tangential movement along the coupling surface.

## DYPARAM,DMPOPT

Sets DMP option - SOL700

Sets DMP option. Used in SOL 700 only.

### Format:

PARAM,DMPOPT,value1,value2,value3,value4

### Example:

PARAM,DMPOPT,2,1

Describer	Meaning
Value1	Set dmp option. (Integer>0, default=1) 1 Only Euler dmp is activated, 2 Only Lagrangian dmp is activated. 3 Both, Euler and Lagrangian dmp are activated.
Value2	Set contact dmp type. (Integer>0, default=1). 1 Serial mode in contact 2 Parallel mode in contact (check value4)
Value3	Set number of printing summary for each item. (Integer>0, default=0). 0 Print all summaries (see Remark 2.)
Value4	Set parallel mode type in contact. (Integer>0, default=not used). -1 Use the same contact domain partitioning as the element domain partitioning and all primary surfaces must be made by MATRIG definition (see Remark 3.)

### Remarks:

1. To set partitioning manually, check DYPARAM,EULERPR for Euler partitioning and DYPARAM,LAGPR for Lagrangian partitioning.
2. Printing out too large summaries of each item can cause unexpected failure of job under certain conditions. This option can limit to certain number of summary information to avoid such failure.
3. When the same contact domain partitioning as the element domain partitioning is used, the dmp performance of contact may not be enhanced. However, when all deformable grid points are assigned in secondary body and they are involved to contact at the similar time, the dmp performance of contact will be enhanced as expected. For example, stamping of sheet metal may show a good performance.

## **DYPARAM, DUMSEGS**      Creating dummy segments for the auto coupling approach - SOL700

Specifies how holes in the coupling surface are meshed. It is only used for the auto coupling approach. This approach is activated by DYPARAM, AUTOCOUP.

### **Format and Example:**

DYPARAM,DUMSEGS,INTERNAL

Describer	Meaning
INTERNAL	Meshes internal holes with a triangular dummy segment mesh [YES,NO] Default NO

### **Remarks:**

1. With the auto coupling method, holes are partially or completely meshed with dummy segments. With option NO the standard method of creating dummy segment is used. For details see chapter 8 of the SOL700 User's Guide. In this standard method holes are partially meshed with dummy segments. For an example refer to Figure 20 of Chapter 8. For holes that rotate, have arbitrary form or show large deformations, the standard method of creating dummy segments can cause the simulation to terminate with messages like

```
%E-P4307807-P4_SUBELM_MESH_CURVED_HOLES, ,(13), DUMMY SURFACE
CANNOT BE TRIANGULATED THIS IS PROGRAM ERROR. PLEASE CONTACT
MSC. USING PARAM,DUMSEGS,ON CAN SOLVE THIS TRIANGULATION
PROBLEM.
```

```
%E-P4309907-V4_SUBELEM_CONNECT_EXTENDED_GPS, , DUMMY SURFACE
CANNOT BE TRIANGULATED THIS IS PROGRAM ERROR. PLEASE CONTACT
MSC. USING PARAM,DUMSEGS,ON CAN SOLVE THIS TRIANGULATION
PROBLEM.
```

In that case PARAM,DUMSEGS,ON can maintain a good dummy surface. The quality of the dummy surface can be checked by requesting a coupling surface archive. This is done by using the CPLSURFS command and by putting option DUMMY of DYPARAM, AUTOCOUP to ON. For all holes that are not internal holes, the standard method is used.

**DYPARAM,ELDLTH**

- SOL700

Print initial time step sizes for elements in the first cycle in SOL 700.

**Format:**

DYPARAM,ELDLTH,<value>

**Example:**

DYPARAM,ELDLTH,1

Describer	Meaning
value	Number of elements to be output. (Integer)
0	First 100 elements with the smallest time step sizes are printed.
1	The governing time step sized for all elements are printed. (Default)

**DYPARAM,EULERCB**

Euler Domain Decomposition Control - SOL700

Divides a Euler domain into several cubes. For SOL 700 only

**Format:**

DYPARAM,EULERCB,NELCUBE,NBX,NBY,NBZ

**Example:**

DYPARAM,EULERCB,2000,2,2,2

Describer	Meaning
NELCUBE	The number of elements per cube. (Integer; Default = 0)
NBX	The number of cubes in the x-direction. See Remark 2. (Integer; Default = 0)
NBY	The number of cubes in the y-direction. (Integer; Default = NBX)
NBZ	The number of cubes in the z-direction. (Integer; Default = NBX)

**Remarks:**

1. By setting NELCUBE equal to 2000 optimal use is made of memory caching during Euler computation. This may give a speedup of 1.5. When using adaptive meshing with dmp additional Euler cubes are created during the simulation. To keep the total number of cubes that are created within bounds the initial number of cubes should be limited to 100.
2. Defining NBX overrules the definition of NELCUBE.
3. Only supports Euler domains created by MESH,BOX. Limitations are:
  - No PEULERx/CHEXA's
  - No FLOW or BARRIER that use the BCID option are allowed. All FLOW and BARRIER entries must use either the DIR option or the XMIN,YMIN,ZMIN, XMAX,YMAX,ZMAX option to define the Euler MESH boundaries.

## DYPARAM,EULERPR

## Euler Cube Partition Control - SOL700

Divides a Euler domain into several cubes. For SOL 700 only

### Format:

DYPARAM,EULERPR,PROCDIR,NPX,NPY,NPZ

### Example:

DYPARAM,EULERPR,USER,2,2,2

Describer	Meaning
PROCDIR	This directive controls the way cubes are distributed across processors. The effect can be checked by checking the Eulerian output variable PARTITION. (Character; Default = X) X            Partition in global X direction first. Y            Partition in global Y direction first. Z            Partition in global Z direction first. USER        Define user defined partitioning SIMPLE      Partition Euler cubes in a simple pattern. ORB         Partitions using orthogonal recursive bisection
NPX	The number of cubes in the x-direction. Required for PROCDIR=USER. (Integer; Default = 0)
NPY	The number of cubes in the y-direction. (Integer; Default = NPX)
NPZ	The number of cubes in the z-direction. (Integer; Default = NPX)

### Remarks:

1. There are several ways to distribute cubes across processors. Some ways may lead to bad load balancing. To avoid this it is possible to control the way Euler cubes are distributed across processors by defining PROCDIR.
2. When option PROCDIR=USER, the values for NBX, NBY and NBZ must be such that NBX is equal or a multiple of NPX, NBY is equal or a multiple of NPY and NBZ is equal or a multiple of NPZ. Also for this option, NPX\*NPY\*NPZ must be equal to the number of processors used in the cluster.
3. For option PROCDIR=SIMPLE, the values NBX, NBY and NBZ on DYPARAM,EULERCUB must be such that NBX\*NBY\*NBZ is equal or a multiple of the number of processors used. For instance, if the number of processors in the cluster is 4, NBX\*NBY\*NBZ must be equal to either 4 or 8 or 12, etc. Otherwise the calculation will terminate prematurely with an error message.
4. Only supports Euler domains created by MESH,BOX. Limitations are:
  - No MESH,ADAPT and no PEULERx/CHEXA's

- No FLOW or BARRIER that use the BCID option are allowed. All FLOW and BARRIER entries must use either the DIR option or the XMIN,YMIN,ZMIN, XMAX,YMAX,ZMAX option to define the Euler MESH boundaries.
5. With the orthogonal recursive bisection method the mesh is repeatedly cut in half. Each cut is along a coordinate direction and the direction of the cut is chosen to minimize the communication cost. To illustrate this method consider for example a mesh with 200,150 and 50 elements in respectively the x,y and z-direction. When split in x-direction the number of Euler faces at the split will be  $150 \cdot 50 = 7500$ . When splitting across the y-direction it will be  $200 \cdot 50 = 10000$  and for the z-direction it will be  $200 \cdot 150 = 30000$ . Since the x-split has the smallest number of faces at the split, the x-split has the smallest communication cost. Therefore the ORB scheme will select the x-split. At the x-split there are two mesh parts. Both have  $100 \cdot 150 \cdot 50$  elements. Now a split in y-direction will give the minimal communication costs. This process of bisecting is continued until the number of sub meshes equals the number of CPU's.

## DYPARAM,EULTRAN      Switch for Euler Transport Scheme of the Multi-Material Solver and the Single Material Strength Solver - SOL700

Sets the definition of the face velocity used in the transport scheme of the Multi-material solver and the single material strength solver. Used in SOL 700 only.

### Format:

DYPARAM,EULTRAN,option1,option2

### Example:

DYPARAM,EULTRAN,AVERAGE,FAIL

Describer	Meaning	
Option1	IMPULSE	The face velocity is impulse weighted. (Character; Default = IMPULSE)
	AVERAGE	The face velocity is a simple average.
Option2	NOFAIL	Failure is transported. See Remark 5. and 6. (Character; Default = NOFAIL)
	FAIL	Failure is transported. See Remark 5. and 6.

### Remarks:

1. The default value of IMPULSE is sufficient for most Euler problems. Especially problems where the reference density of the different materials varies widely (e.g., orders of magnitude) are required to use the default option.
2. In case the IMPULSE option (default) is used, the Euler transport scheme computes that the face velocity uses an impulse weighted average of the material velocity in the left and the right element adjacent to the face.
3. In case the AVERAGE option is used, the Euler transport scheme computes the face velocity as one-half times the sum of the material velocity in the left and the right element adjacent to the face.
4. Does not apply to the single material hydrodynamic solver and the Roe solver.
5. The option FAIL requires a failure model for at least one Eulerian material. In case of the default NOFAIL then failed Euler material can support shear stress again as soon as new material enters the Euler element. Thus the information that part of the material inside the Euler element has failed is lost. The option FAIL activates transport of fail fraction and thereby keeps track of material that has failed. In this way only the failed part of the element can no longer supports shear stresses. In more detail, the yield stress in the material is scaled by  $(1 - \text{failfrac})$ , where failfrac denotes the fail fraction of the material. The fail fraction of the first material in an element can be retrieved from Euler archive or time-history results files in the variable DAMAGE. The value of fail fraction DAMAGE is between zero and one.
6. Option FAIL cannot be combined with the Johnson-Cook failure model (FAILJC).

## DYPARAM,EUSUBMAX

- SOL700

Defines the maximum number of subcycles that can occur in the Euler solver. During a subcycle, the Euler computations are skipped. Used in SOL 700 only.

If coupling surface computations are more expensive than Euler computations than use of PARAM,COSUBMAX should be considered first. In that case the optimal setting of EUSUBMAX is LINKCS=BOTH and DFVUMAX is blank.

As with PARAM,COSUBMAX use of EUSUBMAX can lead to loss of accuracy for certain simulations. It is recommended to validate the use of EUSUBMAX by comparing the difference in results between using EUSUBMAX and not using EUSUBMAX for some typical target simulations.

### Format

DYPARAM,EUSUBMAX,NSUBMAX,DFVUMAX,LINKCS

### Example:

DYPARAM,EUSUBMAX,5

Describer	Meaning
NSUBMAX	NSUBMAX, The maximum number of time steps between updating Euler variables. (Integer $\geq 0$ ; Default = 0)
DFVUMAX	Maximum allowed increase in uncovered volume fraction between to subsequent Eulerian computations. (Real $> 0$ ; Required when COSUBMAX is present. Leave blank when COSUBMAX is not present.)
LINKCS	Specifies interactions between Euler subcycling and coupling surface subcycling. EUSUBMAX can be used with COSUBMAX. LINKCS specifies how the two subcycling processes influence each other. (Character; Default = BOTH)
BOTH	The Euler computations will not be skipped when the coupling surface computations has been done. On the other hand if an Euler computation is to be done, also a coupling surface computation is done. The number of time that the Euler computation I skipped equals the number of times that the coupling surface computation has been done.
COUPLE	If an Euler computation is to be done, also a coupling surface computation is done.
EULER	If a coupling surface computation is to be done, also a Euler computation is done.
NONE	The Euler subcycling and coupling surface subcycling are independent. DFVUMAX has to be defined.

**Remarks:**

1. Updating the coupling geometry takes a lot of CPU time. Subcycling gives substantial savings in CPU time for coupled calculations.
2. The smaller the value of DFBVUMAX, the greater the accuracy of the analysis and the greater the cost. Conversely, larger values offer significant CPU savings, but very large values give incorrect results.
3. When the Euler time step is considerably larger than the Lagrange time step it can be worthwhile to skip the Euler computation for several cycles. This can reduce computational costs considerable.
4. Skipping the Euler computation for several cycles, leads to postponed time steps. When the Euler computations are done these have to be taken into account by fluxing with an accumulated time step. Skipping the Euler computation is stopped as soon as the accumulated time step will become larger than the stable Euler time step. The total number of skipped cycles is limited by NSUBMAX. NSUBMAX is required input.
5. In skipping the Euler computation also the movement of the coupling surface has to be monitored. To estimate this movement the change in uncovered fraction of the elements is used. If the change in uncovered volume fraction from one cycle to the other is larger than DFBVUMAX than the Euler computation is not skipped that cycle. DFBVUMAX has to be left blank if coupling surface subcycling is used. Coupling surface subcycling already monitors the movement of the coupling surface. Choosing too large values for DFBVUMAX can make results inaccurate.
6. EUSUBMAX is only supported by the multi-material Euler solver and the standard single material Euler solver. It is not supported by the Roe solver.

## **DYPARAM,EUSUBCYC**

## Growth or Subcycling Interval in Euler Computations - SOL700

Controls the growth of the subcycling interval in Euler computations. Used in SOL 700 only.

### **Format:**

DYPARAM,EUSUBCYC,value

### **Example:**

DYPARAM,EUSUBCYC,100

<b>Describer</b>	<b>Meaning</b>
value	Maximum growth of the subcycling interval. (Integer > 0; default=1)

### **Remarks:**

1. The subcycling algorithm automatically estimates the number of subcycles to be used. This is updated throughout the calculation. This parameter controls how much the number of subcycles can grow. For example, EUSUBCYC is set to 1, and the current number of time steps between updates of the Euler variables. If Dytran estimates that the subcycling interval should be 7, the subcycling interval is increased by 1 until a value of 7 is reached.
2. There is no control on the amount by which the subcycling interval can decrease.

## DYPARAM,FAILDT

## Element Time-step Based Failure Model - SOL700

Defines the property of a failure model where element failure occurs when the element's time step falls below the specified limit. Used in SOL 700 only

### Format:

DYPARAM, FAILDT, value

### Example:

DYPARAM, FAILDT, 1.0E-3

Describer	Meaning
value	Minimum time-step. (Real > 0.0; default=1.0E-20)

### Remarks:

1. This failure model is valid for all Lagrangian solid (CHEXA) and shell (CQUAD4) elements.
2. All elements for which the time step falls below the specified value are removed from the computation.
3. Although it is not usually necessary to limit the element time-step for Lagrangian elements, there are occasions where specifying a minimum time-step can be advantageous for computational performance, for example, when adaptive contact is used.
4. Note that this parameter should be used with care as you may influence the results of the analysis when you set the time-step criterion to a too high value. You then run the risk that elements are removed from the analysis while they may still be relevant.

## **DYPARAM,FAILOUT**

Failed Element Output Parameter - SOL700

Defines whether failed elements are written to the output file (ARCHIVES). Used in SOL700 only.

### **Format:**

DYPARAM, FAILOUT, value

### **Example:**

DYPARAM, FAILOUT, NO

<b>Describer</b>	<b>Meaning</b>
value	Flag for FAILOUT. (Character; default=YES)
	NO            Failed elements are not written to the archive files.
	YES          Failed elements are written to the archive files.

### **Remarks:**

1. When the NO option is chosen, the archives are written out as one file per requested time step regardless of the number set in the SAVE command for the archive files that appear in the Case Control Section. Please check \$\$700.

**DYPARAM, FLOWMETH****Flow-Method Between Two Euler Domains Across Open Areas in Coupling Surfaces - SOL700**

Defines the method for simulating material flow between two Euler domains across open areas in coupling surfaces. Used in SOL 700 only.

**Format:**

DYPARAM, FLOWMETH, value

**Example:**

DYPARAM, FLOWMETH, POLPACK

Describer	Meaning
value	Flag for FLOWMETH. (Character; default=NO)
POLPACK	The facets in the coupling surfaces that represent an open area are subdivided into smaller facets, with each connecting exactly to one Euler element in the first Euler domain and to exactly one Euler element in the second Euler domain. Material flow takes place across these smaller, subdivided facets (POLPACKs). This is the most accurate method.
FACET	The facets in the coupling surfaces that represent an open area are not subdivided. Material flow takes place across the original facets. If these facets are too large in relation with the Euler elements, the method becomes inaccurate. Material flow across one facet can involve several Euler elements on both sides of the hole and averaging occurs.

**Remarks:**

- This parameter applies to simulations where:
  - Two coupling surfaces share a common set of facets.
  - Each coupling surface has own Euler domain.
  - Material flows from one Euler domain into the other through the open area represented by the common set of facets.

Flow only occurs if:

- The common facets are defined as 'open', using PORFCPL.
- The common facets open up due to failure of a shell structure, using COUP1INT.

Examples simulations are:

- Holes between air bag compartments.
- Holes between containers filled with gas or liquid.
- Open area between the top of a fuel-tank baffle and the fuel-tank skin.

- Open area in-between wide straps inside an air bag.
  - Failure of walls in between aircraft wing compartments.
  - Failure of tank armor by a blast wave.
  - Etc.
2. The following table summarizes what input cards support the simulation of material flow between two Euler domains across open areas in coupling surfaces:

Euler Solver	Material flow through a coupling surface	FLOW-METHOD=POLPACK	FLOW-METHOD=FACE	PORFLCPL (velocity based)	PORFLCPL (Pressure based)	COUP1INT/ COUP1FL (Failure of shell elements creates the opening)
HYDRO	YES	YES	NO	YES	YES	Only for flow method = polpack
HYDRO-Roe solver-1 <sup>st</sup> Order	YES	YES	YES	YES	YES	YES
HYDRO-Roe solver- 2 <sup>nd</sup> Order	YES	YES	YES	YES	YES	YES
MMHYDRO	YES	YES	NO	YES	NO	Only for flow method = polpack
STRENGTH	NO	-	-	-	-	-
MMSTREN	YES	YES	NO	YES	NO	Only for flow method = polpack

3. The Euler domains are shown below with the support types for each:

	FLOW-METHOD=POLACK	FLOW METHOD = FACET
<i>MESH</i> → <i>TYPE= ADAPT</i>	YES	No
<i>MESH</i> → <i>TYPE= BOX</i>	YES	YES
Modeling of CHEXA elements	No	YES

4. A Euler domain is associated with a coupling surface by specifying the MESHID or SET1ID on the COUPLE option.
5. FLOWMETH = POLPACK has the following limitations:

The entries NSTGP and NSTEL on all MESH entries should be left blank. It is not allowed to specify for any MESH entry the starting element number or starting grid point number.

- There are restrictions on output requests.

- Flow faces and wallets are not supported while FLOWDEF is supported.
- Viscosity is not supported

A case where these limitations require the use of FLOWMETH = FACET is when the Euler elements are generated in Patran, not using the MESH option, and one or more of the following options is used:

- FLOW boundaries are defined on some Euler faces.
- WALLET boundaries are defined on some Euler faces.
- Viscosity is defined.

**DYPARAM,GEOCHECK**

## Define Geometry Consistency Check - SOL700

This parameter forces a check of the geometry for consistent connectivity of the defined hexagonal elements and correction if needed. Used in SOL 700 only.

**Format:**

DYPARAM, GEOCHECK, value

**Example:**

DYPARAM, GEOCHECK, ON

Describer	Meaning
value	Flag for activating GEOCHECK. (Character; default=OFF)
ON	Geometry consistency check is performed.
OFF	No geometry consistency check is performed.

**Remarks:**

1. The defined geometry is checked for consistent connectivity of the hexagonal elements. If an inconsistency is detected, the connectivity is corrected. CFACE entries with references to elements that have been corrected are corrected as well.
2. If a hexagonal mesh is generated with other commercial preprocessors, this parameter can correct the connectivity of the hexagonal elements in case problems are encountered with face generation or volume computation.

## DYPARAM,FASTCOUP

## Fast Coupling Algorithm - SOL700

Defines the fast coupling algorithm. Used in SOL 700 only.

### Format:

DYPARAM,FASTCOUP,option1,option2,option3,option4,option5,option6,option7

### Example:

DYPARAM,FASTCOUP,INPLANE,FAIL

Describer	Meaning
Option1	NO Fast coupling interaction is turned off. (Character; Default = INPLANE)
	INPLANE Small offset for inplane coupling surface segments.
	NOFFSET No offset for inplane coupling surface segments
Option2	NOFAIL No failure of the coupling surface. (Character; Default = NOFAIL)
	FAIL Failure of the coupling surface will be taken into account.
Option3	Euler check algorithm. (Character; Default = NOCHKEUL)
	CHKEUL Checking whether all segments of the coupling surface are fully inside Euler elements.
	NOCHKEUL No checking
Option4	Euler update algorithm. (Character; Default = ALL)
	NEARONLY Do the full coupling surface only in the first cycle. In subsequent cycles only update elements and faces that are near the coupling surface.
	ALL Do the full coupling surface computation each cycle.
Option5	Controls coupling surface computations when there are multiple cubes defined with DYPARAM,EULERCB. (Character; Default = NONE)
	NONE All coupling surface computations are done for each cube.
	FACES The face cover fraction computation is done in one go for all cubes. The other coupling computations are still done per cube.
	POLPK The polpack computation efficiently handles multiple cubes. The other coupling computations are still done per cube.
	ALL All coupling surface computations efficiently handle cubes.

Describer	Meaning
Option6	<p>In the coupling surface computations it is determined which structural segments intersect the Euler mesh. This is done by looping across all structural segments. For dmp each cpu has only part of the Euler mesh. Therefore for many segments it is known beforehand that they will not intersect the Euler mesh of the cpu and can be skipped at an early stage of the computation. Option 6 activates this skipping. (Character; Default = ON)</p> <p>OFF            For dmp each CPU goes over all segments.</p> <p>ON             Each CPU skips all segments that do not intersect the Euler mesh of the CPU.</p>
Option7	<p>Each coupling surface segment has to be intersected with the Euler elements and Euler faces. For large Euler meshes a substantial amount of checking has to be done to find the intersecting elements and faces. By dividing the Euler mesh in search boxes the costs of this checking is kept to a minimum. Especially for large Euler meshes combined with large coupling surface this checking can become expensive and then the use of search boxes can significantly reduce the costs. For Euler meshes of less than 100000 elements the use of search boxes will have little effect. (Character; Default = ON)</p> <p>OFF            Search boxes are not used.</p> <p>ON             Search boxes are used.</p>

### Remarks:

1. The fast coupling algorithm is always turned on by default. In order to use general coupling, option1=NO should be used.
2. When option1 is set to INPLANE or when option 1 is blank, a small offset is given to coupling surface segments that are on top of a face of an Eulerian element. This is done because coupling surfaces segments on Eulerfaces make the Euler element volume computation invalid. Also boundary conditions on these segments are not correctly imposed. The net effect of these problems is unpredictable. The problem can either run correctly, or remain stable but give false results or become instable.
3. Option2 can only be used in combination with either PARAM,LIMITER,ROE or MMHYDRO or MMSTREN. The coupling surface must consist of CQUADs and/or CTRIAs and a failure model for the material of the surface must be defined.
4. This parameter can only be used when the Eulerian mesh is aligned with the basic coordinate system axes.

**DYPARAM, HYDROBOD**

## Hydro Body Force - SOL700

Defines a body force for single hydro material in Euler. Used in MSC Nasran SOL 700 only.

**Format:**

DYPARAM, HYDROBOD, XACC, YACC, ZACC

**Example:**

DYPARAM, HYDROBOD, -300., 0., 150.

Describer	Meaning
XACC	X-acceleration (Real; Default = 0.0)
YACC	Y-acceleration. (Real; Default = 0.0)
ZACC	Z-acceleration. (Real; Default = 0.0)

**Remark:**

1. This parameter defines a constant body force load in Euler for single hydro material only.

## **DYPARAM,HGCMEM**

## Shell Membrane Hourglass Damping Coefficient Parameters - SOL700

Defines the default membrane damping coefficient for shell elements. Used in SOL 700 only.

### **Format:**

DYPARAM, HGCMEM, value

### **Example:**

DYPARAM, HGCMEM,0.07

<b>Describer</b>	<b>Meaning</b>
value	Hourglass damping coefficient. ( $0.0 \leq \text{Real} \leq 0.15$ ; default=See remark <a href="#">3.</a> )

### **Remarks:**

1. The default value applies to all types of hourglass suppression methods and should be used unless there is a good reason to define the hourglass damping coefficient by another means.
2. The value specified on this entry is used whenever the coefficient is not explicitly defined on the HGSUPPR entry.
3. If this entry is omitted, the default value of the coefficient used in the hourglass suppression method for shell elements is either equal to the default value of 0.1 or is equal to the default value defined on a DYPARAM,HGCOEFF entry.

## DYPARAM,HGCOEFF

## Hourglass Damping Coefficient - SOL700

Defines the global default hourglass damping coefficient. Used in SOL 700 only.

### Format:

DYPARAM, HGCOEFF, value

### Example:

DYPARAM, HGCOEFF, 0.14

Describer	Meaning
value	Hourglass damping coefficient. (0.0 ≤ Real ≤ 0.15; default=See remark 3.)

### Remarks:

1. The default applies to all types of hourglass suppression methods and should be used unless there is good reason to define the hourglass damping coefficient by another means.
2. The value specified on this entry is used whenever the coefficients are not explicitly defined on HGSUPPR entries or on a HGCMEM HGCWRP, HGCTWS, or HGCSOL entry.
3. If this entry is omitted, the default value of the hourglass damping coefficients is either equal to the default value of 0.1 or is equal to the value specified on a HGCMEM, HGCTWS, HGCWRP, or HGCSOL DYPARAM entry.
4. The value of the coefficients can be explicitly defined for each property by using an HGSUPPR entry.

**DYPARAM,HGCSOL**

## Solid Hourglass Damping Coefficient - SOL700

Define the default damping coefficient for solid elements. Used in SOL 700 only.

**Format:**

DYPARAM, HGCSOL, value

**Example:**

DYPARAM, HGCSOL, 0.11

Describer	Meaning
value	Hourglass damping coefficient. ( $0.0 \leq \text{Real} \leq 0.15$ ; default=See remark 3.)

**Remarks:**

1. The default value applies to all types of hourglass suppression methods and should be used unless there is a good reason to define the hourglass damping coefficient by another means.
2. The value specified on this entry is used whenever the coefficient is not explicitly defined on the HGSUPPR entry.
3. If this entry is omitted, the default value of the coefficient used in the hourglass suppression method for solid elements is either equal to the default value of 0.1 or is equal to the default value defined on a DYPARAM,HGCOEFF entry.

## DYPARAM,HGCTWS

## Shell Twisting Hourglass Damping Coefficient - SOL700

Defines the default twisting damping coefficient for shell elements. Used in SOL 700 only.

### Format:

DYPARAM, HGCTWS, value

### Example:

DYPARAM, HGCTWS, 0.02

Describer	Meaning
value	Hourglass damping coefficient. (0.0 ≤ Real ≤ 0.15; default=See remark 3.)

### Remarks:

1. The default value applies to all types of hourglass suppression methods and should be used unless there is a good reason to define the hourglass damping coefficient by another means.
2. The value specified on this entry is used whenever the coefficient is not explicitly defined on the HGSUPPR entry.
3. If this entry is omitted, the default value of the coefficient used in the hourglass suppression method for shell elements is either equal to the default value of 0.1 or is equal to the default value defined on a DYPARAM,HGCOEFF entry.

## **DYPARAM,HGCWRP**

## Shell Warping Hourglass Damping Coefficient - SOL700

Defines the default warping damping coefficient for shell elements. Used in SOL 700 only.

### **Format:**

DYPARAM, HGCWRP, value

### **Example:**

DYPARAM, HGCWRP, 0.0

<b>Describer</b>	<b>Meaning</b>
value	Hourglass damping coefficient. ( $0.0 \leq \text{Real} \leq 0.15$ ; default=See remark 3.)

### **Remarks:**

1. The default value applies to all types of hourglass suppression methods and should be used unless there is a good reason to define the hourglass damping coefficient by another means.
2. The value specified on this entry is used whenever the coefficient is not explicitly defined on the HGSUPPR entry.
3. If this entry is omitted, the default value of the coefficient used in the hourglass suppression method for shell elements is either equal to the default value of 0.1 or is equal to the default value defined on a DYPARAM,HGCOEFF entry.

## DYPARAM,HGSHELL

## Shell Hourglass Suppression Method - SOL700

Defines the default hourglass suppression method for shell elements. Used in SOL 700 only.

### Format:

DYPARAM, HGSHELL, value

### Example:

DYPARAM, HGSHELL, DYNA

Describer	Meaning
value	Type of HGSHELL. (Character; default=See remark 2.)
FBV	Flanagan-Belytschko viscous hourglass damping
DYNA	Viscous hourglass damping

### Remarks:

1. The type of hourglass suppression method defined on this entry is used as the default whenever the type fields on the HGSUPPR for shell properties are left blank.
2. If this entry is omitted, the default suppression method used for shell elements is either FBV or the default method defined on the DYPARAM,HGTYPE entry.

## DYPARAM,HGSOLID

## Solid Hourglass Suppression Method - SOL700

Defines the default hourglass suppression method for solid elements. Used in SOL 700 only.

### Format:

DYPARAM, HGSOLID, value

### Example:

DYPARAM, HGSOLID, FBS

Describer	Meaning
value	Type of HGSOLID. (Character; default=See remark 2.)
FBS	Flanagan-Belytschko stiffness hourglass damping
DYNA	Viscous hourglass damping

### Remarks:

1. The type of hourglass suppression method defined on this entry is used as the default whenever the type fields on the HGSUPPR for solid properties are left blank.
2. If this entry is omitted, the default suppression method used for solid elements is either FBS or the default method defined on the DYPARAM,HGTYPE entry.

## DYPARAM,HGTYPE

## Hourglass Suppression Method - SOL700

Defines the default type of hourglass suppression method. Used in SOL 700 only.

### Format:

DYPARAM, HGTYPE, value

### Example:

DYPARAM, HGTYPE, FBS

Describer	Meaning
value	Type of HGTYPE. (Character; default=See remark 2.)
FBS	Flanagan-Belytschko stiffness hourglass damping.
FBV	Flanagan-Belytschko viscous hourglass damping.
DYNA	Viscous hourglass damping.

### Remarks:

1. The type of the hourglass suppression method defined on this entry is used as the default whenever the type fields in the HGSUPPR entries are left blank.
2. If this entry is omitted, the type can be defined on a DYPARAM,HGSHELL entry for shell elements, a DYPARAM,HGSOLID entry for solid elements, or on the HGSUPPR entries; otherwise the defaults apply. For shell elements the default is FBV; for solid elements, the default is FBS.

## **DYPARAM,HICGRAV**

Gravity Used by HIC Calculations - SOL700

Defines the value of the gravity to be used by the HIC calculations. Used in SOL 700 only.

### **Format:**

DYPARAM, HICGRAV, value

### **Example:**

DYPARAM, HICGRAV, 980.7

<b>Describer</b>	<b>Meaning</b>
value	Gravity used by HIC Calculations. (Real > 0.0; default=9.80665)

### **Remarks:**

1. The value set by this parameter will be used by all HIC output requests.
2. This parameter can only be set once in the input deck.

## DYPARAM,HVLFAIL

## Failure at Hydrodynamic Volume Limit - SOL700

Defines element failure on the hydrodynamic volume limit. Used in SOL 700 only.

### Format:

DYPARAM, HVLFAIL, value

### Example:

DYPARAM, HVLFAIL, YES

Descriptor	Meaning
value	Flag of HVLFAIL. (Character; default=NO)
YES	Element failure on hydrodynamic volume limit
NO	No element failure on hydrodynamic volume limit

### Remarks:

1. Lagrangian elements (CHEXA) that have a material model with a failure model fail when the hydrodynamic volume limit is reached and the parameter is set to YES.  
 The elements can fail only when the following items are presented in the input:
  - a. The material model has a hydrodynamic volume limit (HVL).
  - b. A failure model is defined.
  - c. DYPARAM, HVLFAIL, YES
2. The hydrodynamic volume limit by default allows for 10% expansion.

**DYPARAM,IMM**

## Initial Metric Method Formulation - SOL700

The option allows to specify the IMM method to be used. Used in SOL 700 only.

**Format:**

DYPARAM, IMM, OPTION1, OPTION2, VALUE1, VALUE2

**Example:**

DYPARAM, IMM, ZERO, YES, 1.0E-3, 1.0E-3

Describer	Meaning
OPTION1	Flag for element condition under compression. (Character; default=FULL)
	FULL While elements are under IMM condition, they will carry stresses when under compression.
	REDUCED While elements are under IMM condition they will carry a reduced stress when under compression. The relative area factor SMDFER is used to reduce the Young's modulus.
	ZERO While elements are under IMM condition they do not carry any compressive stresses. Use material damping to avoid excessive nodal velocities.
OPTION2	Flag for recalculation of IMM strain. (Character; default=See remark 2.)
	NO or OFF Do not recalculate IMM strains during the calculation.
	YES or ON Recalculate IMM strains during the calculation.
VALUE1	Start time of recalculation of IMM strains. See remark 3.(Real > 0.0; Default is 1.0E-3)
VALUE2	Times between recalculation of IMM strains. See remark 3.(Real > 0.0; Default is 1.0E-3)

**Remarks:**

- Method ZERO is best suitable when initially more than a couple of elements with zero or near zero area are present in the model.
- The default for Option2 depends on Option1.

Option1	Default for Option2
FULL	OFF
REDUCED	OFF
ZERO	ON

- When Option2 is OFF or NO, STREC and DTREC are neglected.

## DYPARAM,INFOBJ

## List the Generated BJOINS and Spotwelds - SOL700

Additional information about the BJOIN and spotweld connectivity will be listed in the output file. Used in SOL 700 only.

### Format:

DYPARAM, INFOBJ, value

### Example:

DYPARAM, INFOBJ, 0.14

Describer	Meaning
value	Flag of activation of writing BJOIN information. (Character; default=NO)
YES	Information is issued.
NO	Information is not issued.

### Remarks:

1. The information listed is:
  - Grid point pairs forming a BJOIN or a spotweld.
  - BJOINS and spotwelds initially connected.

## **DYPARAM,INISTEP**

Initial Time Step - SOL700

Defines the time step used at the start of the analysis. Used in SOL 700 only.

### **Format:**

DYPARAM, INISTEP, value

### **Example:**

DYPARAM, INISTEP, 1.0E-6

<b>Describer</b>	<b>Meaning</b>
value	Time step (in analysis time units) used for the first iteration. (Real > 0.0; required)

### **Remarks:**

1. This parameter is required to start an analysis.

## DYPARAM,LAGPR

## Lagrangian Partitioning Control - SOL700

Controls the partitions of the Lagrangian elements on the processors. Used in SOL 700 only.

### Format:

PARAM, LAGPR, IOPT, xvec, yvec, zvec, xcen, ycen, zcen

### Example:

PARAM, LAGPR, 6, 1.0, 0.0, 0.0, 0.0, -100.0, 0.0

Describer	Meaning
IOPT	Set partitioning type. See remark 1. (Integer > 0, default=1).
	1 Metis best partitioning
	2 Metis Decomposition on element based
	3 Metis Decomposition on node based
	4 Vector Decomposition with Specified User Direction. xvec, yvec and zvec are required.
	5 Radial Decomposition with User Direction. xvec, yvec, zvec, xcen, ycen and zcen are required.
	6 Angular Decomposition with User Direction. xvec, yvec, zvec, xcen, ycen and zcen are required.
	7 Recursive Coordinate Bisection Decomposition
xvec	X-component of directional vector. (Real, default=0.0)
yvec	Y-component of directional vector. (Real, default=0.0)
zvec	Z-component of directional vector. (Real, default=0.0)
xcen	X-coordinate of the origin of axis. (Real, default=0.0)
ycen	Y-coordinate of the origin of axis. (Real, default=0.0)
zcen	Z-coordinate of the origin of axis. (Real, default=0.0)

### Remark:

1. To use the option, check [DYPARAM,DMPOPT](#).

## **DYPARAM,LIMCUB**

## Contact Cube Sort Algorithm - SOL700

Defines the maximum number of cubes used to sort the grid points in a contact definition. Used in SOL 700 only.

### **Format:**

DYPARAM, LIMCUB, value

### **Example:**

DYPARAM, LIMCUB, 2300

<b>Describer</b>	<b>Meaning</b>
value	Maximum number of cubes. (Integer > 0; default=200)

### **Remarks:**

1. Each secondary node has to search for primary nodes that are close enough to have potential contact. It is too expensive to have each secondary node check each primary node. To limit the number of checks, the space in which the nodes reside is subdivided into cubes. This subdivision is done so that the secondary nodes have to check only the primary nodes in their own cube and those in the neighboring cubes. The maximum number of cubes used to subdivide the space is equal to the value of LIMCUB.

## DYPARAM,MATRMERG

## Merges MATRIG and RBE2-FULLRIG Assemblies - SOL700

Merges MATRIG and/or RBE2-FULLRIG rigid bodies into a new FULLRIG assembly. Used in SOL 700 only.

### Format:

DYPARAM, MATRMERG, FR<id1>, MR<id2>, MR<id3>, FR<id4>, ...  
DYPARAM, MATRMERG, AUTO

### Example:

DYPARAM, MATRMERG, FR1, MR2, MR6, MR7, FR4, MR8

Describer	Meaning
FR<id1>	Name of the new FULLRIG assembly. (Character; required.)
MR<idi> or FR<idi>	Names of MATRIG and/or RBE2-FULLRIG rigid bodies merged into a new FULLRIG assembly with name FR<id1>. No names can be supplied for the AUTO option.
AUTO	Automatic merge. See remark 2. (Character; required.)

### Remarks:

1. FR<id1> must be a nonexisting RBE2-FULLRIG. The properties of FR<id1> (as mass, center of gravity, and moments of inertia) are computed by solver from the properties of each rigid body mentioned on the entry. Rigid body output can be asked for FR<id1>, and loads or rigid body constraints can be applied to FR<id1>. The other MATRIGs and RBE2-FULLRIGs mentioned on the MATRMERG entry disappear after they have been merged.
2. Instead of supplying rigid body names, the AUTO option can be used. After all the normal DYPARAM,MATRMERG and DYPARAM,MATRMERG1 entries have been applied, a DYPARAM,MATRMERG,AUTO merges all the resulting MATRIGs and RBE2-FULLRIGs which have common grid points into a new rigid assembly called FM<id>, where the id is a new FM number starting from 1. As it is not known at the start of an analysis how many FM assemblies will be created, no rigid body output can be asked for FM<id>, and no constraints or loads can be applied to FM<id>. The MATRIGs and RBE2-FULLRIGs, which have been merged by the AUTO option into a new FM<id> assembly, disappear.
3. To supply predefined properties for the merged assembly, DYPARAM,MATRMERG1 can be used, where the first rigid body mentioned on the entry must be an existing RBE2-FULLRIG or MATRIG.

**DYPARAM, MATRMRG1**

## Merges MATRIG and RBE2-FULLRIG Assemblies - SOL700

Merges MATRIG and/or RBE2-FULLRIG rigid bodies into one existing MATRIG or RBE2-FULLRIG assembly with predefined properties. Used in SOL 700 only.

**Format:**

DYPARAM, MATRMRG1, MR<id1>, MR<id2>, MR<id3>, FR<id4>, ...  
DYPARAM, MATRMRG1, FR<id1>, MR<id2>, MR<id3>, FR<id4>, ...

**Example:**

DYPARAM, MATRMRG1, MR1, MR2, MR6, MR7, FR4, MR8

Describer	Meaning
MR<id1> or FR<id1>	Name of the existing MATRIG or FULLRIG assembly (must be an existing one). (Character; required.)
MR<idi> or FR<idi>	Names of MATRIG and/or RBE2-FULLRIG rigid bodies, which are merged with the existing MR<id1> or FR<id1> into a new MATRIG assembly, with name MR<id1> or FR<id1>. (Character; required.)

**Remarks:**

1. MR<id1> or FR<id1> must be an existing MATRIG or RBE2-FULLRIG, respectively. For a FULLRIG, the properties of FR<id1> (as mass, center of gravity and moments of inertia) are computed by solver from the properties of each rigid body mentioned on the entry. For a MATRIG, the mass of MR<id1> is either the predefined mass on the MATRIG (id1) entry or the predefined density on the MATRIG (id1) entry times the total volume of all MATRIG members in the MATRMRG1 entry. The center of gravity and moments of inertia of MR<id1> are either predefined on the MATRIG (id1) entry, or are otherwise computed from the properties of each rigid body on the entry. The other MATRIGs and RBE2 FULLRIGs mentioned on the MATRMRG1 entry disappear after they have been merged.

## DYPARAM,MAXSTEP

## Maximum Time Step - SOL700

Defines the maximum allowable time step. Used in SOL 700 only.

### Format:

DYPARAM, MAXSTEP, value

### Example:

DYPARAM, MAXSTEP, 1 . E-3

Describer	Meaning
value	The maximum time step. (Real > 0.0; default=1.0E20)

### Remarks:

1. If the time step calculated by solver is greater than MAXSTEP, the time step is set to MAXSTEP.

## **DYPARAM,MESHPLN**

## Mesh Density for Covering Rigid Planes - SOL700

Defines Mesh density for covering rigid planes. Used in SOL 700 only.

### **Format:**

DYPARAM, MESHPLN, value

### **Example:**

DYPARAM, MESHPLN, 4

<b>Describer</b>	<b>Meaning</b>
value	Rigid planes will be meshed with MESHPLN times MESHPLN dummy quad elements. (Integer > 0; default=3)

### **Remarks:**

1. The default is sufficient in most cases.

**DYPARAM,MINSTEP****Minimum Time Step - SOL700**

Defines the minimum time step that causes the analysis to terminate. Used in SOL 700 only.

**Format:**

DYPARAM,MINSTEP,value

**Example:**

DYPARAM,MINSTEP,1.E-6

Describer	Meaning
value	When the time step is less than the MINSTEP value, the analysis terminates. (Real > 0.0; default=10% of DYPARAM,INISTEP)

**Remarks:**

1. When the elements become very distorted, in a poorly designed mesh for example, or when they have endured a very large distortion, the time step may drop dramatically. The analysis continues, however, and a lot of computer resources may be wasted. This option allows you to specify a minimum time step that causes the analysis to terminate.

## DYPARAM,MIXGAS

Controls Updating of Gas Fractions - SOL700

Specifies whether the gas constants of the Euler material or of gas bags are updated based on the gas composition and temperature. Used in SOL 700 only.

### Format:

DYPARAM, MIXGAS, value

### Example:

DYPARAM, MIXGAS, YES

Describer	Meaning
value	Flag of MIXGAS. (Character; default=NO)
YES	The gas constants for the Euler material and any gas bags are recalculated based on temperature and gas composition.
NO	Euler and gas bag gas constants are not recalculated.

### Remarks:

1. This parameter is only defined for use with GBAG gas bag definitions and/or the single-material Euler solver.
2. This parameter can be used in conjunction with INFLTR and INFLHB inflator definitions and with PORHOLE, PERMEAB, PORFGBG, and PERMGBG porosity definitions.
3. By default, DYPARAM,MIXGAS is set to YES if any INFLHB or INFLGAS entries are present.

## DYPARAM,NZEROVEL

## Auto Constrain Failed Nodes - SOL700

Set the velocity of a node to zero in case all attached elements have failed. Used in SOL 700 only.

### Format:

DYPARAM, NZEROVEL, value

### Example:

DYPARAM, NZEROVEL, YES

Describer	Meaning
value	Flag of NZEROVEL. (Character; default=NO)
	YES            Perform check and set the velocity to zero if all attached elements have failed.
	NO             Do not perform check.

### Remarks:

1. This parameter applies only to nodes of Lagrangian elements.
2. Specifying NO reduces the CPU overhead time.
3. When the velocity of a node is set to zero, effectively the node is constraint, like an SPC or SPC1.
4. Special attention is necessary for the contact definition. If the failed node is not taken out of the contact, it behaves as a rigid boundary constraint.

## **DYPARAM,OLDLAGT**

Use Collapsed Hexahedron Scheme for CTETRA - SOL700

Activate the collapsed hexahedron scheme as default for lagrangian CTETRA elements. Used in SOL 700 only.

### **Format:**

DYPARAM, OLDLAGT, value

### **Example:**

DYPARAM, OLDLAGT, 1

<b>Describer</b>	<b>Meaning</b>
value	Flag of OLDLAGT. (Integer $\geq 0$ ; default=See remark 1.)
	0     Deactivate collapsed hexahedron scheme
	1     Activate

### **Remarks:**

1. The current default integration scheme for Lagrangian CTETRA elements use linear tetrahedron FE one. It is more consistent (in terms of accuracy) and efficient (both in memory and CPU time) compared with the collapsed hexahedron scheme. The old scheme based on collapsed hexahedron with reduced integration is deactivated. If the old scheme is activated, it is used as default. But, it is still possible to use the new scheme for CTETRA by using separate PSOLID with IN = 1 and ISOP = 1 combination.

## DYPARAM,JWLDET

## Hydro Body Force - SOL700

Specifies whether the blast wave of one explosive can ignite another explosive. Here it assumed that the explosives are modeled by a combination of EOSJWL and DETSPH entries.

### Format:

PARAMJWLDET,OPTION

### Example:

PARAM,JWLDET,NOLINK

Describer	Meaning
LINK	Multiple denotations with EOSJWL are LINKED. The detonation wave of one explosive can ignite another explosive.
NOLINK	Multiple denotations with EOSJWL are NOT LINKED. The detonation wave of one explosive cannot ignite another explosive.
Default	NOLINK

### Remark:

1. Option NOLINK: TDET is set to -1 for elements that have no JWL material. The "NOLINK" option is only valid with true JWL materials - not valid for the "Static Detonation/Ideal Gas" model.
2. Setting this parameter as "NOLINK" will prevent "sympathetic ignition". Each charge will ignite at the specified "TDET" in its own DETSPH card.

**DYPARAM,LIMITER**

## Original Roe-Type Euler Solver Scheme - SOL700

Defines the type and the spatial accuracy of scheme used in the Euler solver based on the ideas of Prof. Philip Roe. Used in SOL 700 only.

**Format:**

DYPARAM,LIMITER,TYPE,OPTION

**Example:**

DYPARAM,LIMITER,ROE

Describer	Meaning
TYPE	Type of scheme. (Character; Default = ROE)
	ROE           Roe solver for single hydrodynamic materials.
OPTION	blank        Second order in space. (Character; Default = blank)
	NONE        First order in space.

**Remarks:**

1. By default, when the parameter is not set, the solver is used that is defined on the PEULER or the PEULER1 entry. In case “2ndOrder” or “1stOrder” was defined on the PEULER or PEULER1 entry, the parameter setting has no effect.
2. By default, second order spatial accuracy is used. The temporal accuracy is automatically defined according to the spatial accuracy that you select.
3. Note that 2<sup>nd</sup> order spatial accuracy in the Roe solver involves the internal flow field only. We recommend that you use the full 2<sup>nd</sup> order improved fluid-and gas Euler solver. You can activate the improved solver by putting the “2ndOrder” field on the PEULER or PEULER1 entry.
4. When type ROE is defined, no void elements are allowed and it cannot be used in combination with EOSJWL. Also options concerning air-bag analyses are not supported.
5. For more details on fluid- and gas Euler solvers, refer to the Getting Started and the Theory Manuals.

## DYPARAM,PARALLEL

## Parallel Execution Information - SOL700

The option allows you to gather information on the parallel section. Used in SOL 700 only.

### Format:

DYPARAM, PARALLEL, INFPAR, value

### Example:

DYPARAM, PARALLEL, INFPAR, ON

Describer	Meaning
INFPAR	A report is written on the actual amount of work done at the reported parallel levels. (Character; required)
Value	Flag for INFPAR. (Character; default=OFF)
	ON            Activate writing information.
	OFF           Deactivate writing information.

### Remarks:

1. A summary on the parallel operation when using the shared-memory mode can be requested by including a DYPARAM,PARALLEL,INFPAR,ON entry in the input file.
2. Currently, the information on the parallel sections is available for the shell solver only.

**DYPARAM,PLCOVCUT**

Pressure Cut Off Time - SOL700

Defines time when PLCOVER is cut off. Used in SOL 700 only.

**Format:**

DYPARAM, PLCOVCUT, value

**Example:**

DYPARAM, PLCOVCUT, 3.E-3

Describer	Meaning
value	<p>If there are one or more COUPLE definitions with a PLCOVER specified on the COUOPT entry, a cut off is applied to the PLCOVER until time = PLCOVCUT. From time = 0 to time = PLCOVCUT, the PLCOVER is cut off to the pressure in the intersected Eulerian element.</p> <p>For times greater than PLCOVCUT, the full PLCOVER is applied to the coupling surface.</p> <p>This parameter is useful in air-bag analyses, where PLCOVER is used to model the environment pressure. During the early stages of the deployment of the air bag, the pressure inside the bag may drop. Applying the full PLCOVER may lead to an unstable deployment of the air bag. (Real <math>\geq 0.0</math>; default=0).</p>

**Remarks:**

1. See also the COUPLE and COUOPT Bulk Data entries.

## DYPARAM,PMINFAIL

## Switches Failure at Spall Limit - SOL700

Defines Lagrangian solid element failure on reaching the spall limit. Used in SOL 700 only.

### Format:

DYPARAM, PMINFAIL, value

### Example:

DYPARAM, PMINFAIL, YES

Describer	Meaning
VALUE	Flag of PMINFAIL. (Character; default=NO)
YES	Element failure on spall limit
NO	No element failure on spall limit

### Remarks:

1. Lagrangian elements (CHEXA) that have a material definition with a failure model will fail when the parameter is set to YES and the spall limit (minimum pressure) is reached, even when the other failure criterion is not yet reached.
2. The spall limit is set on the PMINC entry.

## **DYPARAM,RBE2INFO**

Lists MATRIG and RBE2 Grid Points - SOL700

The grid points attached to MATRIG and RBE2assemblies are listed to the output file. Used in SOL 700 only.

### **Format:**

DYPARAM, RBE2INFO, value

### **Example:**

DYPARAM, RBE2INFO, GRIDON

<b>Describer</b>	<b>Meaning</b>
VALUE	Flag of PBE2INFO. (Character; default=GRIDOFF)
GRIDON	Information is issued C
GRIDOFF	No information is issued

## DYPARAM,RHOCUT

## Global Density Cutoff Value - SOL700

Defines the minimum density for all Eulerian elements. Used in SOL 700 only.

### Format:

DYPARAM, RHOCUT, value

### Example:

DYPARAM, RHOCUT, 1.E-10

Describer	Meaning
value	Density cutoff. (Real > 0.0; default=See remark 4.)

### Remarks:

1. Any Eulerian element with a density less than RHOCUT is considered to be empty. All of its variables are set to zero, and the equation of state is bypassed.
2. In the Eulerian transport calculation, if the material is flowing from element A to element B, and
  - a. If the density of element B after transport is less than RHOCUT, then no transport is done.
  - b. If the density of element A after transport is less than RHOCUT, then all of the mass is transported to element B.
3. A reasonable value of RHOCUT is 1.E-5 times the initial density.
4. If only RHOCUT is defined, all Eulerian elements use the RHOCUT value as cutoff density. If RHOCUT is omitted, all Eulerian elements use a cutoff density automatically set to 1.E-5 times a characteristic density. For single-material Eulerian elements, this characteristic density is the reference density.

**DYPARAM,RJSTIFF**

## Rigid-joint Stiffness - SOL700

Defines the stiffness of a rigid joint. Used in SOL 700 only.

**Format:**

DYPARAM, RJSTIFF, value

**Example:**

DYPARAM, RJSTIFF, 100 .

Describer	Meaning
value	Multiplication factor for the stiffness of all rigid joints. (Real > 0.0; default=1.0)

**Remarks:**

1. The absolute stiffness of rigid joints is calculated automatically by solver. The stiffness of joints is taken so that a stable solution is guaranteed. The stiffness calculation takes into account the fact that a rigid body can be constrained by more than one joint.
2. This parameter can be used to increase or decrease the stiffness of the joints. Care must be taken because too high a value may lead to an unstable calculation.

## DYPARAM,SCALEMAS

## Mass Scaling Definition - SOL 700

Defines the activation of mass scaling.

### Format:

DYPARAM, SCALEMAS, DTMIN, MXPERC, STEPS.

### Example:

DYPARAM, SCALEMAS, 1.0E-6, 100.0, 1

Descriptor	Meaning
DTMIN	Minimum allowable time step. (Real > 0.0; required)
MXPERC	Maximum percentage of added numerical mass with respect to original mass. (Real > 0.0; required)
STEPS	Number of steps. (Integer > 0; required)

### Remarks:

1. Numerical mass is added to all Lagrangian solid, triangular, quadrilateral, rod, bar and beam elements such that its time step never becomes less than:

$$dt = STEPFACT * DTMIN.$$

Where,

dt = time step of calculation

STEPFACT = time step safety factor (see PARAM, STEPFACT)

DTMIN = value specified on the PARAM, SCALEMAS entry

If the added mass of a certain element exceeds the maximum percentage (MXPERC) of its original mass, no more mass will be added, and subsequently, the time step may decrease again.

2. The value of STEPS determines the checking frequency against the mass scaling criterion; the check is done for every defined number of STEPS. STEPS = 1 is recommended.
3. By requesting MSMASS in an ELOUT output request, the ratio of scaled mass to original mass of the elements can be retrieved. By making fringe plots of this parameter, a check can be made if mass has not been added in a critical area.
4. See *MSC Nastran Explicit Nonlinear (SOL 700) User's Guide*, Chapter 4: Special Modeling Techniques, [Mass Scaling](#) Definition for instructions on how to use this entry

**DYPARAM,SHELLFRM**

Sets the Default of the Shell Formulation - SOL700

Sets the default for the shell formulation for quadrilateral elements. Used in SOL 700 only.

**Format:**

DYPARAM, SHELLFORM, value

**Example:**

DYPARAM, SHELLFORM, BLT

Describer	Meaning
value	Flag for default of shell formulation. (Character; default=KEYHOFF)
BLT	The shell-formulation default is BLT.
KEYHOFF	The shell-formulation default if KEYHOFF.

**Remarks:**

1. The DYPARAM,SHELLFORM changes the default formulation for quadrilateral shell elements. All shell properties entries that do not explicitly define the formulation, use the default as specified on the DYPARAM entry.
2. Triangular shell elements have only one formulation (C0-TRIA). Therefore, the DYPARAM is ignored for triangular elements.

## DYPARAM,SHELMSYS

## Shell Element System Definition - SOL700

Defines the shell element system for the BLT shells. Used in SOL 700 only.

### Format:

DYPARAM, SHELMSYS, value

### Example:

DYPARAM, SHELMSYS, SIDE21

Describer	Meaning
value	Type of shell element system. (Character; default=MIDSIDES)
	SIDE21      x-axis along side21.
	MIDSIDES    x-axis connecting midpoints.

### Remarks:

1. SIDE21 puts the x-axis along side21 of the element, whereas MIDSIDES puts the x-axis along the vector connecting the midpoints of the side14 and side32.
2. Using the SIDE21 option for the BLT shell will result in the same Belytschko-Lin-Tsay implementation as BELY.

**DYPARAM,SHPLAST**

## Type of Plane-Stress Plasticity for Shells - SOL700

Specifies the type of calculation used to determine the plane-stress plasticity method for shells. Used in SOL 700 only.

**Format:**

DYPARAM, SHPLAST, value

**Example:**

DYPARAM, SHPLAST, VECT

Describer	Meaning
value	Type of Plain-stress plasticity for shells. (Character; default=ITER)
RADIAL	Noniterative, approximate radial return.
VECT	Iterative, vectorized with three iterations.
ITER	Nonvectorized iterations.

**Remarks:**

1. The RADIAL approach does not require iterations and, therefore, is the most efficient. It is, however, an approximation.
2. The other two approaches iterate to find the solution. ITER is the best since it takes as many iterations as are necessary. On vector machines, such as CRAY, this is inefficient since it cannot be vectorized. VECT always performs three vectorized iterations, which is more efficient. However, three iterations may not be enough, and inaccuracies could occur.

## DYPARAM,SHSTRDEF

## Composite Shell Stress and Strain Output Definition - SOL700

Specifies the default coordinate system for the stress and strain output of composite shells. Used in SOL 700 only.

### Format:

DYPARAM, SHSTRDEF, value

### Example:

DYPARAM, SHSTRDEF, ELEM

Describer	Meaning
value	Type of output. (Character; default=FIBER)
FIBER	Stresses and strains are output in the fiber and matrix directions.
ELEM	Stresses and strains are output in the element coordinate system.

### Remarks:

1. The default setting can be overruled per property on a PCOMPA entry on the STRDEF field.

**DYPARAM,SHTHICK**

## Shell-Thickness Modification Option - SOL700

Specifies whether or not the thickness of the shell changes with membrane straining. Used in SOL 700 only.

**Format:**

DYPARAM, SHTHICK, value

**Example:**

DYPARAM, SHTHICK, YES

Describer	Meaning
value	Flag of shell thickness modification. (Character; default=YES)
	YES Shell thickness is modified according to the membrane strain.
	NO Shell thickness is constant.

**Remarks:**

1. The YES option gives a true large-strain shell but requires some extra computation.
2. The NO option should give adequate results as long as the membrane strains are not very large (i.e., not more than 5–10%).
3. This option applies to all the formulations of the shell elements, except for the PCOMP. The thickness of PCOMP shell elements will always remain constant.

## DYPARAM,SLELM

## Store Shell Sublayer Variables - SOL700

Defines whether shell sublayer variables are to be stored in the element arrays. Used in SOL 700 only.

### Format:

DYPARAM, SLELM, value

### Example:

DYPARAM, SLELM, NO

Describer	Meaning
value	Flag of storing shell sublayer variables. (Character; default=YES)
	YES      Store as an element variable.
	NO      Do not store as an element variable.

### Remarks:

1. This parameter applies only to shell elements.
2. The shell sublayer variables are primarily stored in sublayer arrays. They can be copied into the element arrays only for specific output purposes.
3. Specifying NO reduces the CPU overhead time.
4. Irrespective of the entry on this parameter, sublayer variables are accessible in the sublayer arrays. For example, requesting TXX1 retrieves the stress from the element array, whereas TXX01 retrieves it from the sublayer arrays.

## DYPARAM,SMP,BATCHSIZ

## SMP Batchsize and CPULOOOP Definition - SOL700

Define batch size and number of CPU loops, per entity type. Used in SOL 700 only.

### Format:

DYPARAM, SMP, <entity>, BATCHSIZ, <value1>, CPULOOPS, <value2>

### Example:

DYPARAM, SMP, BEAMS, BATCHSIZ, AUTOMAT  
 DYPARAM, SMP, BEAMS, BATCHSIZ, 256

Describer	Meaning
ENTITY	Define the batchsize for the following entities. (Character; required) BEAMS      Beam elements SHELLS     Shell elements SOLIDS      Solid elements CONTACT    Contacts
VALUE1	The batchsize for this entity (Integer number) or AUTOMAT (character). See Remarks 1.and 3. (Character or Integer >0; default = 63)
VALUE2	If value1 is defined as AUTOMATIC, the user may define the number of loops per CPU See Remark 2.(Integer > 0; default=2)

### Remarks:

- The batchsize may be defined per entity type. The SMP parts uses the batchsize to assign a certain number of batches to each CPU. Example:
  - Batchsize = 63 (default)
  - Number of Beam elements = 580
  - Number of CPUs = 4

As a results,

- Needs to process 10 batches (9x63 + 1x13)
- To spread this evenly over four CPUs, a solver increases this to 12 batches because then each CPU can process 3 batches.
- As a result, the batch size is recalculated for 12 batches to: batchsize = 49
- This means that:

CPU# 1,2,3 process three batches of 49 elements each (3x3x49 = 441 elements)

CPU# 4 processes two batches of 49 elements and one batch of 41

It is clear that the user-defined batchsize may not be used ultimately. The reason for this is that each CPU is allocated the same number of batches in order to optimize the work done by each processor.

2. When the batchsize is set to AUTOMAT, a solver computes an initial batchsize based on the number of batches processed by each CPU. By default, processes two batches per CPU.

In the example above, this means that based on:

- Batchsize = AUTOMAT
- Number of batches per CPU = 2 (default)
- Number of Beam elements = 580
- Number of CPUs = 4

As a result,

- Computes an initial batchsize of 72 ( $=580/(4*2)$ )
- Increases this batchsize to a higher number to make sure the number of batches fits in the fixed number of CPU's:  $\text{batchsize} = 72 + (580 - 4*2*72) = 72 + 4 = 76$  elements
- Based on this initial batchsize, the number of batches would be:  $1 + (580-1)/76 = 8$  batches
- This fits nicely on four CPU's as expected
- The CPUs process:

CPU# 1,2,3 processes two batches of 76 elements each ( $3*2*76 = 456$  elements)

CPU# 4 processes one batch of 76 elements and 1 batch of 48 elements.

3. By default, a solver does not use the AUTOMAT batchsize algorithm. Testing has shown that an initial batchsize of 63 yields the fastest results. This may vary depending on the problem simulated and the number of elements and may be worth adjusting.

The reason for this may be found in the fact, that with many elements in the model, the number of elements per batch increases significantly when the AUTOMAT batchsize algorithm is used. Each CPU will have to process two batches (by default) with many elements. Based on the cache memory, this is usually not optimal for a CPU processor. Shorter batchsizes ( $< 128$ ) will do a better job.

**DYPARAM,SMP,CPUINFO**

## SMP CPU Information - SOL700

Define the CPU information per entity type. Used in SOL 700 only.

**Format:**

DYPARAM, SMP, <entity>, CPUINFO, <value1>

**Example:**

DYPARAM, SMP, CONTACT, CPUINFO, ON

Describer	Meaning
ENTITY	Define the CPUINFO for the following entities. (Character; required)
BEAMS	Beam elements
SHELLS	Shell elements
SOLIDS	Solid elements
CONTACT	Contacts
MEMBR	Membrane elements
EULT9	Eulerian Roe Solver
FSCOUP	Fast coupling algorithm
ALL	Output for all of the above
VALUE1	Flag for writing CPU information. (Character; required)
ON	Ask for parallel CPU time information C
OFF	No CPU time information (default)

**Remarks:**

1. By default, a solver does not give any SMP CPU timings per entity. In order to judge the efficiency of the different algorithms, this parameter may be used to judge the speedup acquired by processing on multiple CPUs.

## DYPARAM,SNDLIM

## Sound Speed Minimum Value - SOL700

Defines the minimum value for the speed of sound. Used in SOL 700 only.

### Format:

DYPARAM, SNDLIM, value

### Example:

DYPARAM, SNDLIM, 1 . E-6

Describer	Meaning
value	Minimum value of speed of sound. (Real > 0.0; default=1.0E-3)

### Remarks:

1. This parameter is used to avoid the possibility of division by zero in the time step calculation.
2. SNDLIM has the units of velocity.

**DYPARAM,SPREMAP**

## 1-D Spherical Symmetric Euler Archive Remap - SOL700

Allows a 1-D spherical symmetric Euler archive importation to a 3-D simulation. Used in SOL 700 only.

**Format:**

DYPARAM,SPREMAP,X0,Y0,Z0,range

**Example:**

DYPARAM,SPREMAP,0.0,0.5,0.5

Descriptor	Meaning
X0,Y0,Z0	X, Y, Z coordinate of the point at which the 1-D spherical symmetric mesh is remapped. (Real; default=0.0)
RANGE	Only material whose distance to (X0,Y0,Z0) is smaller than "range" will be initialized with the 1-D spherical symmetric Euler archive. (Real > 0.0; default = 1.0E20)

**Remarks:**

1. Since 1-D spherical symmetric simulations run much faster than 3-D simulation, it can save much CPU time to do the first part of the simulation with a 1-D axial symmetric mesh. Afterwards, the 1-D spherical symmetric Euler archive is imported into the 3-D simulation. By default, the 1-D spherical symmetric archive will not be expanded in 3-D. To enable this expansion, DYPARAM,SPREMAP has to be used. It is useful for blast wave simulations. The 1-D spherical symmetric simulation has to be terminated before the blast wave approaches any 3-D structure.
2. This import of Euler archives is done by means of the EID option in the pth file.
3. To generate axial symmetric meshes DYPARAM,SPHERSYM can be used.
4. The remap of 1-D spherical symmetric to axial symmetric Euler meshes is supported.

## DYPARAM,SPHERSYM

## Spherical Symmetric Analyses - SOL700

Enables an efficient and accurate 1D spherical symmetric solution for Eulerian materials. A much larger time step becomes possible by basing the time step only on the mesh-size in radial direction. Used in SOL 700 only.

### Format:

DYPARAM, SPHERSYM, MESHTYPE, RADAXIS, PHI

### Example:

PARAM, SPHERSYM, RECT, X, 2.0

Descriptor	Meaning
MESHTYPE	Two types of Euler meshes are supported. (Character; required) SPHERIC     Axial symmetric meshes RECT         Rectangular meshes
RADAXIS	Radial Axis. (Character; required.) X             Global x direction Y             Global y direction Z             Global z direction
PHI	Only used for MESHTYPE = RECT. Used to creates a 1d Spherical mesh with angles +PHI/2 and -PHI/2. (Real ≥ 0; default=0.0)

### Remarks:

1. Only available for Eulerian elements and does not support Lagrange elements. The effect of this parameter is not limited to the solvers. Also Euler archives will reflect the modified Euler mesh geometry.
2. The Euler mesh can already be symmetric but also a rectangular mesh comprising of one row of elements can be used. Using the angle specified by PHI this Euler mesh is mapped into a 1D spherical symmetric mesh.
3. The Euler mesh has to consist of one row of elements.
4. In the time step computation only the mesh-size in radial direction will be taken into account.

## **DYPARAM,STRNOUT**

## Shell Sublayer Strain Output - SOL700

Saves the total strains and equivalent effective stress (von Mises stress) at shell sublayers for output. Used in SOL 700 only.

### **Format:**

DYPARAM, STRNOUT, value

### **Example:**

DYPARAM, STRNOUT, YES

<b>Describer</b>	<b>Meaning</b>
value	Flag for writing strain results. (Character; default=YES)
	YES      Save
	NO      Do not save.

### **Remarks:**

1. A limited output set saves memory.
2. Perfectly elastic materials only have the limited output set.
3. Total strain output for shell composite materials can be requested from the PCOMPA Bulk Data entry.

## DYPARAM,TOLCHK

## Tolerance for Fast Coupling - SOL700

Fast coupling requires that Euler elements are orthogonal. This means that normals of Euler element faces have to be in a coordinate direction. In practice there can be small errors in the geometry of the Euler element and Euler face normals do not always exactly point into a coordinate direction. Small deviations from the coordinate direction do not give problems and are allowed by fast coupling.

To check the direction of an Euler face, the face normal vector is projected onto the closest coordinate direction. If this projection is 1, the normal is exactly in the coordinate direction. When this projection is within a sufficient small tolerance of 1, the face can be handled by fast coupling. The tolerance used is TOLCHK. If the projection is smaller than 1-TOLCHK, the face cannot be handled by fast coupling and the analysis terminates. Options are then to slightly increase TOLCHK, write out double precision format in PATRAN, use general coupling, or use the MESH entry. Increasing TOLCHK too much can make the coupling surface computation less accurate. To keep the computation accurate, the maximal allowed value of TOLCHK is 1e-6. If DYPARAM,TOLCHK is not used, the tolerance used is 1e-14. Used in SOL 700 only.

### Format:

DYPARAM, TOLCHK, value

### Example:

DYPARAM, TOLCHK, 1e-10

Describer	Meaning
value	Tolerance in accepting faces by fast coupling. (Real > 0.0; required.)

## DYPARAM,VDAMP

## Dynamic Relaxation Parameter - SOL700

Controls the global damping in the dynamic relaxation. Used in SOL 700 only.

### Format:

DYPARAM, VDAMP, value

### Example:

DYPARAM, VDAMP, 0.001

Describer	Meaning
value	Dynamic relaxation parameter. (Real $\geq 0.0$ ; default=0.0)
0.0	No dynamic relaxation.

### Remarks:

- The dynamic relaxation parameter is connected to the system natural frequency,  $\omega$ , as  $\omega = s\omega_0 t$ , where  $s$  denotes a percentage of critical damping. The damping occurs by factoring the velocities every time step as follows:

$$F_1 = (1 - \gamma) / (1 + \gamma)$$

$$F_2 = 1 / (1 + \gamma)$$

$$v^{n+1/2} = F_1 v^{n-1/2} + F_2 a^n \Delta t^n$$

where  $v$  is the velocity,  $a$  is the acceleration, and  $\gamma$  is the dynamic relaxation parameter.

## DYPARAM,VELMAX

## Maximum Velocity - SOL700

Defines the maximum velocity in Eulerian and Lagrangian meshes. Used in SOL 700 only.

### Format:

DYPARAM, VELMAX, value, option

### Example:

DYPARAM, VELMAX, 1 . E 6

Describer	Meaning				
VALUE	Maximum velocity. (Real > 0.0; default=1.0E10)				
OPTION	Flag for removing Euler elements. (Character; default=YES)				
	<table border="0"> <tr> <td>YES</td> <td>Remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.</td> </tr> <tr> <td>NO</td> <td>Do not remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.</td> </tr> </table>	YES	Remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.	NO	Do not remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.
YES	Remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.				
NO	Do not remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.				

### Remarks:

1. For Eulerian elements, VELMAX is applied to the velocity components separately. Therefore, the magnitude of the velocity vector is limited to VELMAX. For Lagrangian elements, all components are scaled down by the same factor to ensure that the maximal magnitude of the velocity vector does not exceed VELMAX.
2. Although it is not usually necessary to limit the velocity in Eulerian meshes, there are occasions in regions of near-vacuous flow for example, where specifying a maximum velocity can be advantageous. The same applies to Lagrangian meshes in contact regions for example. This parameter should be used with care.
3. Because very high velocities occur mostly in Eulerian elements with very small mass, the mass in these elements can be removed to keep the analysis stable. This option is not available for Lagrangian solid elements.
4. VELMAX must be greater than the minimum velocity specified by PARAM,VELCUT.

**DYPARAM,VELMAX1**

## Maximum Translational and Angular Velocity - SOL700

Defines the maximum translational and angular velocity in Eulerian and Lagrangian meshes. Used in SOL 700 only.

**Format:**

DYPARAM, VELMAX1, VELMAXT, option, VELMAXA

**Example:**

DYPARAM, VELMAX1, 1.E6

Describer	Meaning				
VELMAXT	Maximum translational velocity. (Real > 0.0; default=1.0E20)				
OPTION	Flag for removing Euler elements. (Character; default=YES)				
	<table border="0"> <tr> <td>YES</td> <td>Remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.</td> </tr> <tr> <td>NO</td> <td>Do not remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.</td> </tr> </table>	YES	Remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.	NO	Do not remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.
YES	Remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.				
NO	Do not remove the mass in Eulerian elements in which the velocity exceeds the maximum specified velocity.				
VELMAXA	Maximum angular velocity. (Real > 0.0; default=1.0E20)				

**Remarks:**

1. For Eulerian elements, VELMAXT is applied to the velocity components separately. Therefore, the magnitude of the velocity vector is limited to VELMAXT. For Lagrangian elements, all components are scaled down by the same factor to ensure that the maximal magnitude of the velocity vector does not exceed VELMAXT.
2. VELMAXA is used to limit the angular velocity of grid points. By default, the angular velocities are not limited. In general, there is no need to limit angular grid point velocities.
3. Although it is not usually necessary to limit the velocity in Eulerian meshes, there are occasions in regions of near-vacuous flow for example, where specifying a maximum velocity can be advantageous. The same applies to Lagrangian meshes in contact regions for example. This parameter should be used with care.
4. Because very high velocities occur mostly in Eulerian elements with very small mass, the mass in these elements can be removed to keep the analysis stable. This option is not available for Lagrangian solid elements.
5. VELMAXT must be greater than the minimum velocity specified by PARAM, VELCUT.
6. DYPARAM, VELMAX, and DYPARAM, VELMAX1 can be used in the same input deck. The values set by DYPARAM, VELMAX1 will overrule the values set by DYPARAM, VELMAX.

For example, when using

DYPARAM, VELMAX, 1000, YES

```
DYPARAM,VELMAX1,,YES,1e+10
```

In the OUT file shows:

```
%I-INIT 02-p3_set_velmaxat, , , (13),  
SUMMARY VELMAX SETTINGS:  
MAXIMAL VALUE TRANSLATIONAL VELOCITY = 0.100000E+04  
MAXIMAL VALUE ANGULAR VELOCITY = 0.100000E+11  
REMOVE EULERIAN MASS WHEN VELOCUIITY EXCEEDS LIMIT: YES
```

## DYPARAM,VISCPPLAS

## Use Overstress Formula to Update Strain-rate Dependent Plasticity - SOL700

Activate the overstress formula to update strain-rate dependent plasticity. This formula is normally used for viscous-plastic material. Used in SOL 700 only.

### Format:

DYPARAM,VISCOPLAS,value

### Example:

DYPARAM,VISCOPLAS,1

Describer	Meaning
VALUE	Flag of updating overstress formula. (Integer $\geq 0$ ; default=0)
	0 Use scaling-up scheme
	1 Use overstress formula

### Remarks:

1. The strain rate dependent plasticity is normally calculated by scaling up the basic yield stress without strain rate effect. Then the trial stresses are mapped back to the scaled-up yield surface. This algorithm may lead to premature instability. Another technique is to calculate the so-called viscous-plastic strain rate using “overstress” formula. And then the stresses are updated based on this viscous-plastic strain. This technique seems to be more stable than the previous one. For shell elements, this option works when combined with DYPARAM,SHPLAST,RADIAL. Only MATEP and Johnson-Cook models are supported. For solid elements, this option works only for MATEP.
2. For shell elements, DYPARAM,VISCOPLAS,1, in combination with DYPARAM,SHPLAST,RADIAL, will use consistent plane stress plasticity algorithm both for strain rate dependent and independent plasticity. This new algorithm is more accurate than 3-D approach.

## ECHOOFF Deactivate Printed Echo

Marks the point or points in the input file to deactivate printed echo of the input file.

### Format:

1	2	3	4	5	6	7	8	9	10
ECHOOFF									

### Example:

ECHOOFF									
---------	--	--	--	--	--	--	--	--	--

### Remarks:

1. This entry may also be used in the Executive Control and Case Control Sections. It is described in the Case Control command, [ECHO \(Case\)](#).
2. The companion to this entry is the ECHOON entry.
3. The ECHOOFF command is BEGIN BULK or BEGIN SUPER = n dependent. Its last time used does carry over between changes in BEGIN BULK or BEGIN SUPER = n commands. Also, the Case Control ECHO command should be above subcase level and the following is recommended:  
ECHO=UNSORT.

## ECHOON

### Activate Printed Echo

Marks the point or points in the input file to activate printed echo of the input file.

#### Format:

1	2	3	4	5	6	7	8	9	10
ECHOON									

#### Example:

ECHOON									
--------	--	--	--	--	--	--	--	--	--

#### Remarks:

1. This entry may also be used in the Executive Control and Case Control Sections. It is described in the Case Control command, [ECHO \(Case\)](#).
2. The companion to this entry is the ECHOOFF entry.
3. The ECHOON command is BEGIN BULK or BEGIN SUPER = n dependent. Its last time used does carry over between changes in BEGIN BULK or BEGIN SUPER = n commands. Also, the Case Control ECHO command should be above subcase level and the following is recommended:  
ECHO=UNSORT.

## EIGB Buckling Analysis Set

Defines data needed to perform buckling analysis.

### Format:

1	2	3	4	5	6	7	8	9	10
EIGB	SID	METHOD	L1	L2	NEP	NDP	NDN		
	NORM	G	C						

### Example:

EIGB	13	INV	0.1	2.5	2	1	1		
	MAX								

Describer	Meaning
SID	Set identification number. (Unique Integer > 0)
METHOD	Method of eigenvalue extraction. (Character: "INV" for inverse power method or "SINV" for enhanced inverse power method.)
L1, L2	Eigenvalue range of interest. (Real, L1 < L2)
NEP	Estimate of number of roots in positive range not used for METHOD = "SINV". (Integer > 0)
NDP, NDN	Desired number of positive and negative roots. (Integer>0; Default = 3*NEP)
NORM	Method for normalizing eigenvectors. (Character: "MAX" or "POINT"; Default = "MAX")
	MAX            Normalize eigenvectors to the unit value of the largest component in the analysis set. (Default).
	POINT        Normalize eigenvectors to the unit value of the component defined in G and C fields. The value for NORM defaults to MAX if the defined component is zero.
G	Grid or scalar point identification number. Required only if NORM="POINT". (Integer > 0)
C	Component number. Required only if NORM="POINT" and G is a geometric grid point. (1 ≤ Integer ≤ 6)

### Remarks:

1. The EIGB entry must be selected with the Case Control command METHOD = SID.
2. Each eigenvalue is the factor by which the pre-buckling state of stress is multiplied to produce buckling in the shape defined by the corresponding eigenvector.

3. The continuation entry is optional. If the continuation is not specified, than NORM = “MAX” normalization is performed.
4. If NORM = “MAX”, components that are not in the analysis set may have values larger than unity.
5. The SINV method is an enhanced version of the INV method. It uses Sturm sequence techniques to ensure that all roots in the range have been found. It is generally more reliable and more efficient than the INV method.
6. Convergence is achieved at  $10^{-6}$ .
7. For buckling solutions, the Lanczos algorithm is most reliable if it is allowed to compute the lowest mode first, then the remainder in increasing order of magnitude. The lowest mode is usually the mode of most interest. If the L1 and L2 fields are left blank, an estimate of the first mode eigenvalue is found by a robust, efficient inverse iteration. If NDP and NDN are set to 1, there is a high probability that the first mode will be computed reliably. If more modes are needed it is easier to fill out the other fields correctly once the location of the lowest mode is known.
8. If Modules are present then this entry may only be specified in the main Bulk Data section.

## EIGC Complex Eigenvalue Extraction Data

Defines data needed to perform complex eigenvalue analysis.

### Format:

1	2	3	4	5	6	7	8	9	10
EIGC	SID	METHOD	NORM	G	C	E	ND0		

The following continuation is repeated for each desired search region. (J = 1 to n, where n is the number of search regions.

	ALPHAAJ	OMEGA AJ	ALPHABJ	OMEGABJ	LJ	NEJ	NDJ		
--	---------	----------	---------	---------	----	-----	-----	--	--

### Alternate Format for Continuation Entry for Block Complex Lanczos:

	ALPHAAJ	OMEGA AJ	MBLKSZ	IBLKSZ	KSTEPS		NJi		
--	---------	----------	--------	--------	--------	--	-----	--	--

### Examples:

EIGC	14	CLAN							
		+5.6					4		
EIGC	15	HESS					6		

Describer	Meaning
SID	Set identification number. (Unique Integer > 0)
METHOD	Method of complex eigenvalue extraction. (Character: "INV", "HESS", or "CLAN")
INV	Inverse power.
HESS	Upper Hessenberg. For linear perturbation of ANALYSIS= DCEIG with large displacement, please don't use HESS. See Remarks 2. and 3.
CLAN	Complex Lanczos. For linear perturbation of ANALYSIS= DCEIG with large displacement, CLAN is recommended. See Remark 8.
IRAM	Implicitly Restarted Arnoldi Method. See Remark 13.
NORM	Method for normalizing eigenvectors. See Remark 7. (Character: "MAX" or "POINT"; Default = "MAX")
MAX	Normalize the component having the largest magnitude to a unit value for the real part and a zero value for the imaginary part.
POINT	Normalize the component defined in fields 5 and 6 to a unit value for the real part and a zero value for the imaginary part. The value for NORM defaults to "MAX" if the magnitude of the defined component is zero.
G	Grid or scalar point identification number. Required if and only if NORM = "POINT". (Integer > 0)

Descriptor	Meaning
C	Component number. Required if and only if NORM = "POINT" and G is a geometric grid point. ( $0 \leq \text{Integer} \leq 6$ )
E	Convergence criterion. (Real $\geq 0.0$ . Default values are: $10^{-4}$ for METHOD = "INV", $10^{-15}$ for METHOD = "HESS", E is machine dependent for METHOD = "CLAN".)
MBLKSZ	Maximum block size. See Remark 11. (Default = 7; Real $\geq 0.0$ )
IBLKSZ	Initial block size. See Remark 11. (Default = 2; Real $\geq 0.0$ )
KSTEPS	Frequency of solve. (Default = 5; Integer $> 0$ )

Table 9-11 Relationship Between METHOD Field and Other Fields

Field	METHOD Field		
	HESS	INV	CLAN
NDj (Integer $> 0$ )	Desired number of eigenvalues and eigenvectors. (No Default)	Desired number of roots and eigenvectors in j-th search region. (Default = $3 \cdot \text{NE}_j$ )	Desired number of roots and eigenvectors to be extracted at j-th shift point. (No Default)
ALPHAAj OMEGAAj Real and imaginary parts of $A_j$ in radians per unit time. (Real).	Not used	End point $A_j$ of j-th search region in complex plane. (Default = 0.0)	j-th shift point. (Default = 0.0)
ALPHABj OMEGABj Real and imaginary parts of $B_j$ in radians per unit time. (Real).	Not used	End point $B_j$ of j-th search region in complex plane. (Default = 0.0)	See alternate definitions in fields MBLKSZ and IBLKSZ below; see also Remark 11.
Lj (Real $> 0.0$ )	Not used	Width of j-th search region. (Default = 1.0)	See alternate definitions in fields MBLKSZ and IBLKSZ below; see also Remark 11.
NEj (Integer $> 0$ )	Not used	Estimated number of roots in j-th search region.	Not used
MBLKSZ For block CLAN only			Maximum Block Size Default = 7
IBLKSZ For block CLAN only			Initial Block Size Default = 2

Figure 9-90 Sample Search Regions

**Remarks:**

1. The EIGC entry must be selected in the Case Control Section with the command CMETHOD = SID. Methods of solution are also controlled by SYSTEM(108) on the NASTRAN statements.

SYSTEM(108)	Specification
0 (Default)	QZ HESS method or CLAN block Lanczos, as selected by EIGC entry or equivalent PARAM input. Default value.
1	Force Householder QR (Hessenberg with spill, mass matrix must be nonsingular)
2	Force old single vector complex Lanczos
4	Force new block complex Lanczos
8	Debugging output for Lanczos methods
16	Turn off block reduction in block complex Lanczos
32	Turn off block augmentation in block complex Lanczos
64	Turn of full orthogonality in block complex Lanczos

SYSTEM(108)	Specification
128	Turn off preprocessing of initial vectors in block complex Lanczos
256	Force LR method (Hessenberg, no spill, mass matrix must be invertible)
512	Force QZ method
65536	Use semi-algebraic sort on imaginary part of roots (pre-V70.6 sort)

The word “force” above implies that the method selected by the system cell will be used even when another method has been selected on an EIGC entry. Sums of these values will produce two or more actions at once, when feasible. As the numbers get larger, the function is more developer-oriented than user-oriented.

- When using METHOD = “HESS”, the following should be noted:  
The “HESS” method is generally more reliable and economical for small and moderate-size problems. It computes ND eigenvalues and eigenvectors.  
For linear perturbation of ANALYSIS= DCEIG with large displacement (param, lgdisp, 1) in SOL 400, HESS may yield incorrect results. Therefore, please avoid to use HESS in linear perturbation analysis with large displacement.
- The EIGC entry may or may not require continuations as noted below.
  - For the “HESS” method, continuations are not required; and their contents are ignored when present, except for ND1. However, it is recommended that continuations are not used.
  - For the “CLAN” method when the continuation entry is not used a shift is calculated automatically. When a shift is input on the first continuation entry it is used as the initial shift. Only one shift is used. Data on other continuation entries is ignored.
  - For METHOD = “INV”, each continuation defines a rectangular search region. Any number of regions may be used and they may overlap. Roots in overlapping regions will not be extracted more than once.
  - For all methods, if no continuation is present, then ND0 must be specified on the first entry. If a continuation is present, then NDj must be specified on the continuation and not on the first entry.
- The units of ALPHA AJ, OMEGA AJ, ALPHA BJ, and OMEGA BJ are radians per unit time.
- DIAG 12 prints diagnostics for the inverse power method, the complex Lanczos method and the QZ HESS method.
- If METHOD = “HESS” and the LR or QR methods (non-default methods) are selected by system cell 108 the mass matrix must be nonsingular. The default QZ method does not require a nonsingular mass matrix.
- The normalized eigenvectors may be output with the SDISPLACEMENT and/or DISPLACEMENT Case Control commands.

8. When using METHOD = CLAN, the following should be noted. The modern CLAN method (default for METHOD entry of CLAN) has been enhanced to include a block complex Lanczos approach. This method is more reliable and will not accept inaccurate roots which the old method had a tendency to do. Thus, given the same input, the new method may often accept fewer roots. For continuity the old method has been maintained and may be selected by setting SYSTEM(108). For linear perturbation of ANALYSIS= DCEIG with large displacement (param, lgdisp, 1) in SOL 400, CLAN is recommended.
9. The SVD method is provided for DMAP applications. If used in solution 107 or 110, and mass or damping terms are present, a user fatal exit is taken. See the MSC Web site for the Flight Loads Product examples on the use of the SVD method. The SVD operation decomposes the input stiffness matrix K into the factors U, S, and V. U and V are collections of vectors of orthogonal functions. S is a rectangular matrix with terms on the diagonal of its left partition. The factors satisfy the equation  $K = U*S*V'$ , where " ' " implies complex conjugate transpose. The ND1 value has a meaning for the SVD functions which differs from eigensolution.

ND1	OUTPUT
>0	All vectors of U and V are output.
=0	U and V are returned in a purged state.
<0	S is returned as a square matrix whose number of columns is equal to the minimum number of rows or columns of the input matrix. U and V are truncated to be commensurate with S. This is a method to reduce the costs of solving very rectangular input matrices by providing a partial solution for the most interesting vectors.

10. For DMAP applications there are input parameters, not present in the solution sequences, that may be used to replace the function of the EIGC and CMETHOD entries. See the MSC website for details.
11. The MBLKSZ and IBKLSZ parameters are integers in concept, but must be input at real numbers (that is, with a decimal point.) They represent maximum sizes, and may be reduced internally for small size problems.
12. The IRAM method is an out-of-core implementation of the public domain ARPACK complex eigenvalue solver. To use IRAM, the mass matrix has to be symmetric or Hermitian, and the number of modes desired can be at most the order of the generalized eigenproblem minus one. IRAM does not compute the left eigenvectors and thus is not suitable for SOL200 design optimization analysis.
13. For the "IRAM" method, only the fields that contain EIGC, SID, METHOD, NORM, ND0, NDJ are meaningful. The user selects the method by specifying IRAM in the METHOD field, the eigenvector normalization scheme in the NORM field, and the number of desired modes in the ND0 or the NDj field. The other fields are irrelevant.
14. If Modules are present then this entry may only be specified in the main Bulk Data section.

**EIGP** Poles in Complex Plane

Defines poles that are used in complex eigenvalue extraction by the Determinant method.

**Format:**

1	2	3	4	5	6	7	8	9	10
EIGP	SID	ALPHA1	OMEGA1	M1	ALPHA2	OMEGA2	M2		

**Example:**

EIGP	15	-5.2	0.0	2	6.3	5.5	3		
------	----	------	-----	---	-----	-----	---	--	--

Describer	Meaning
SID	Set identification number. (Integer > 0)
ALPHA <sub>i</sub> ,OMEGA <sub>i</sub>	Coordinates of point in complex plane. (Real)
M <sub>i</sub>	Multiplicity of complex root at pole defined by point at ALPHA <sub>i</sub> and OMEGA <sub>i</sub> . (Integer > 0)

**Remarks:**

1. The EIGP entry defines poles in the complex plane that are used with an associated EIGC entry having the same set number.
2. The units of ALPHA<sub>i</sub> and OMEGA<sub>i</sub> are radians per unit time.
3. Poles are used only in the determinant method. (METHOD = "DET" on the EIGC entry).
4. One or two poles may be defined on a single entry.
5. See *The NASTRAN Theoretical Manual*, Section 10.3.4, for details.
6. If Modules are present then this entry may only be specified in the main Bulk Data section.

## EIGR Real Eigenvalue Extraction Data

Defines data needed to perform real eigenvalue analysis.

### Format:

1	2	3	4	5	6	7	8	9	10
EIGR	SID	METHOD	F1	F2	NE	ND			
	NORM	G	C						

### Example:

EIGR	13	LAN				12			
------	----	-----	--	--	--	----	--	--	--

Describer	Meaning
SID	Set identification number. (Unique Integer > 0)
METHOD	Method of eigenvalue extraction. (Character) Modern Methods: LAN        Lanczos Method AHOU      Automatic selection of HOU or MHOu method. See Remark 13. Obsolete Methods: INV        Inverse Power method. SINV      Inverse Power method with enhancements. GIV        Givens method of tridiagonalization. MGIV      Modified Givens method. HOU        Householder method of tridiagonalization. MHOu      Modified Householder method. AGIV      Automatic selection of METHOD = "GIV" or "MGIV". See Remark 13.
NORM	Method for normalizing eigenvectors. (Character: "MASS," "MAX," or "POINT"; Default = "MASS") MASS      Normalize to unit value of the generalized mass. (Default) MAX        Normalize to unit value of the largest component in the analysis set. POINT     Normalize to a positive or negative unit value of the component defined in fields 3 and 4. The POINT option is not supported for METHOD=LAN. (Defaults to "MASS" if defined component is zero.)

Describer	Meaning
G	Grid or scalar point identification number. Required only if NORM = "POINT". (Integer > 0)
C	Component number. Required only if NORM = "POINT" and G is a geometric grid point. (1 ≤ Integer ≤ 6)

Table 9-12 Relationship Between METHOD Field and Other Fields for Obsolete Methods

Field	METHOD Field	
	INV or SINV	GIV, MGIV, HOU, or MHO
F1, F2	Frequency range of interest. F1 must be input. If METHOD = "SINV" and ND, is blank, then F2 must be input. See also Remark 21. (Real ≥ 0.0)	Frequency range of interest. If ND is not blank, F1 and F2 are ignored. If ND is blank, eigenvectors are found with natural frequencies that lie in the range between F1 and F2. (Real ≥ 0.0; F1 < F2)
NE	Estimate of number of roots in range (Required for METHOD = "INV"). Not used by "SINV" method. (Integer > 0)	Not used.
ND	Desired number of roots. If this field is blank and METHOD = "SINV", then all roots between F1 and F2 are searched and the limit is 600 roots. (Integer > 0, Default is 3 · NE for METHOD = "INV" only.)	Desired number of eigenvectors. If ND is zero, the number of eigenvectors is determined from F1 and F2. If all three are blank, then ND is automatically set to one more than the number of degrees-of-freedom listed on SUPORTi entries. (Integer ≥ 0; Default = 0)

**Remarks:**

1. The EIGR entry must be selected with the Case Control command METHOD = SID.
2. See [Real Eigenvalue Analysis](#) in the *MSC Nastran Dynamic Analysis Guide* for a discussion of method selection.
3. The units of F1 and F2 are cycles per unit time.
4. The continuation entry is optional. If the continuation entry is not specified, then mass normalization is performed.
5. The contemporary methods are LAN and AHOU. The other methods are in a maintenance-only status, with no enhancements planned for them. They may be eliminated in a future release of Nastran.

6. The LAN method is the most general-purpose method, and may be used on both small- and large-size problems. It takes advantage of sparsity of input matrices, leading to greater efficiency on large-size problems. Because Lanczos performance is tuned for medium to large problems, this has caused difficulties with very small problems. Thus, by default, on problems with fewer than 20 degrees-of-freedom when the LAN method is selected, the method is switched to AHOU. The criteria for automatic switching is controlled by SYSTEM(359) on the NASTRAN entry. The NE, G, and C fields are ignored for the LAN method. The NORM field may be set to MASS (the default value) or MAX. The conventions used when both the Fi and ND fields are specified are described in [Table 9-13](#) of the EIGRL entry description. The EIGRL entry is an alternate method to select the LAN method. It has several other input options for special cases. When both and EIGRL and EIGR have the same SID and that SID is selected by a METHOD command the EIGRL entry takes precedence.
7. The AHOU method is competitive with the LAN method when there are small, dense matrices and many eigenvectors are required. This most commonly occurs when static or dynamic reduction is performed. The AHOU method does not take advantage of matrix sparsity, so that computation cost rises with the cube of the number of DOFs. The AHOU method responds to all permitted values for all the other fields except NE, which is ignored.
8. All methods require a positive semi-definite (psd) mass matrix for stable solutions. The mass matrix may be tested for this condition for all methods of solution by setting SYSTEM(303). A value of “-4” should be sufficient to identify problem matrices. A fatal error exit is taken when it is not met. All Nastran metric elements are designed to produce psd mass matrices. CMASSi elements, DMIG matrices selected by the M2GG command, and matrices input via INPUTT4 are special methods that allow addition of non-psd terms by use of non-metric element input. If none of this type of special input is present and the fatal error exit is taken you may have encountered an error in a metric element. Contact your local MSC technical representative for corrective action in this case.
9. The LAN and AHOU methods allow singular but positive semi-definite mass matrices.
10. The tridiagonal methods include the xGIV and xHOU methods, where “x” is described in the following comments. All tridiagonal methods compute all eigenvalues, and the number of eigenvectors specified by the Fi and Nd fields, as described in [Table 9-12](#).
11. If “x” is blank (for example, the HOU method is selected) the mass matrix must be non-singular.
12. If “x” is M (for example, the MHOU method is selected) the mass matrix may be singular. A modified, shifted problem is solved in an inverse basis with this method. Some precision in the solution and longer computation time is exchanged for a more stable solution.
13. If “x” is A (for example, the AHOU method is selected) an attempt is made to solve the problem without shifting, in the interest of cost reduction and maximum precision. If the mass matrix is determined to be poorly conditioned for inversion the basis is automatically shifted with the modified method.
14. If NORM = “MAX”, components that are not in the analysis set may have values larger than unity.
15. If NORM = “POINT”, the selected component should be in the analysis set (a-set). (The program uses NORM = “MAX” when it is not in the analysis set.) The displacement value at the selected component will be positive or negative unity.

16. The “SINV” method is an enhanced version of the “INV” method. It uses Sturm sequence number techniques to make it more likely that all roots in the range have been found. It is generally more reliable and more efficient than the “INV” method.
17. For the “INV” and “SINV” methods, convergence is achieved at  $10^{-6}$ . Convergence is tested by other criteria for the other methods.
18. For the “SINV” method only, if F2 is blank, the first shift will be made at F1, and only one eigensolution above F1 will be calculated. If there are no modes below F1, it is likely that the first mode will be calculated. If there are modes below F1 (including rigid body modes defined by SUPORT entries), a mode higher than the first mode above F1 may be calculated.
19. When F1, F2, and ND are all zero or blank, ND is reset to 1. A User Warning Message is produced for this condition, which is interpreted as likely to be due to an inadvertent omission by the user.
20. For buckling solutions, the Lanczos algorithm is most reliable if it is allowed to compute the lowest mode first, then the remainder in increasing order of magnitude. The lowest mode is usually the mode of most interest. If the F1 and F2 fields are left blank, an estimate of the first mode eigenvalue is found by a robust, efficient inverse iteration. If ND is set to 1, there is a high probability that the first mode will be computed reliably. If more modes are needed it is easier to fill out the other fields correctly once the location of the lowest mode is known.
21. F2 must be specified if DOMAINSOLVER ACMS or DOMAINSOLVER MODES is also specified in the Executive Control Section.
22. For large sized problems, Lanczos is the most efficient and is the recommended method for large problems.
23. It is not recommended to use AHOU, HOU, MHOU if RIGID=LAGRAN case control.
24. If Modules are present then this entry may only be specified in the main Bulk Data section.

## EIGRL Real Eigenvalue Extraction Data, Lanczos Method

Defines data needed to perform real eigenvalue (vibration or buckling) analysis with the Lanczos method.

### Format:

1	2	3	4	5	6	7	8	9	10
EIGRL	SID	V1	V2	ND	MSGLVL	MAXSET	SHFSCL	NORM	
option_1 = value_1    option_2 = value_2,    etc.									

### Example:

EIGRL	1	0.1	3.2	10					
NORM=MAX    NUMS=2									

Describer	Meaning
SID	Set identification number. (Unique Integer > 0)
V1, V2	For vibration analysis: frequency range of interest. For buckling analysis: eigenvalue range of interest. See Remark 4. (Real or blank, $-5 \times 10^{16} \leq V1 < V2 \leq 5. \times 10^{16}$ )
ND	Number of roots desired. See Remark 4. (Integer > 0 or blank)
MSGLVL	Diagnostic level. ( $0 \leq$ Integer $\leq 4$ ; Default = 0)
MAXSET	Number of vectors in block or set. See Remark 13.
SHFSCL	Estimate of the first flexible mode natural frequency. See Remark 9. (Real or blank)
NORM	Method for normalizing eigenvectors (Character: "MASS" or "MAX")
	<div style="display: flex; align-items: flex-start;"> <div style="width: 100px; padding-right: 10px;">MASS</div> <div>Normalize to unit value of the generalized mass. Not available for buckling analysis. (Default for normal modes analysis.)</div> </div>
	<div style="display: flex; align-items: flex-start;"> <div style="width: 100px; padding-right: 10px;">MAX</div> <div>Normalize to unit value of the largest displacement in the analysis set. Displacements not in the analysis set may be larger than unity. (Default for buckling analysis.)</div> </div>
ALPH	Specifies a constant for the calculation of frequencies (Fi) at the upper boundary segments for the parallel method based on the following formula. See Remark 12. (Real > 0.0; Default = 1.0):
	$\text{ALPH} < 1.0, \quad Fi = V1 + (V2 - V1) \frac{1 - \text{ALPH}^i}{1 - \text{ALPH}^{\text{NUMS}}}$
	$\text{ALPH} = 1.0, \quad Fi = V1 + (V2 - V1) \frac{i}{\text{NUMS}}$
NUMS	Number of frequency segments for the parallel method. (Integer > 0; Default = 1)

Descriptor	Meaning
Fi	Frequency at the upper boundary of the i-th segment. See Remark 12. (Real or blank; $V1 < F1 < F2 < \dots < F15 < V2$ )
option_i= value_i	Assigns a value to the fields above except for SID. ALPH, NUMS, and Fi must be specified in this format. V1, V2, ND, MSGVLV, MAXSET, SHFSCL, and NORM may be specified in this format as long as their corresponding field is blank in the parent entry.

**Remarks:**

1. Real eigenvalue extraction data sets must be selected with the Case Control command METHOD = SID.
2. The units of V1 and V2 are cycles per unit time in vibration analysis, and are eigenvalues in buckling analysis. Each eigenvalue is the factor by which the prebuckling state of stress is multiplied to produce buckling in the shape defined by the corresponding eigenvector.
3. NORM = "MASS" is ignored in buckling analysis and NORM = "MAX" will be applied.
4. The roots are found in order of increasing magnitude; that is, those closest to zero are found first. The number and type of roots to be found can be determined from Table 9-13.

Table 9-13 Number and Type of Roots Found with EIGRL Entry

V1	V2	ND	Number and Type of Roots Found
V1	V2	ND	Lowest ND or all in range, whichever is smaller.
V1	V2	blank	All in range
V1	blank	ND	Lowest ND in range $[V1, +\infty]$
V1	blank	blank	Lowest root in range $[V1, +\infty]$
blank	blank	ND	Lowest ND roots in $[-\infty, +\infty]$
blank	blank	blank	Lowest root. See Remark 10.
blank	V2	ND	Lowest ND roots below V2
blank	V2	blank	All below V2

5. In vibration analysis, if  $V1 < 0.0$ , the negative eigenvalue range will be searched. (Eigenvalues are proportional to  $V_i$  squared; therefore, the negative sign would be lost.) This is a means for diagnosing improbable models. In buckling analysis, negative V1 and/or V2 require no special logic.
6. Eigenvalues are sorted on order of magnitude for output. An eigenvector is found for each eigenvalue.
7. MSGVLV controls the amount of diagnostic output during the eigenvalue extraction process. The default value of zero suppresses all diagnostic output. A value of one prints eigenvalues accepted at each shift. Higher values result in increasing levels of diagnostic output.

8. In vibration analysis, if V1 is blank, all roots less than zero are calculated. Small negative roots are usually computational zeroes which indicate rigid body modes. Finite negative roots are an indication of modeling problems. If V1 is set to zero, negative eigenvalues are not calculated.
9. A specification for SHFSCL may improve performance, especially when large mass techniques are used in enforced motion analysis. Large mass techniques can cause a large gap between the rigid body and flexible frequencies. If this field is blank, a value for SHFSCL is estimated automatically.
10. On occasion, it may be necessary to compute more roots than requested to ensure that all roots in the range have been found. However, this method will not output the additional roots.
11. NASTRAN SYSTEM(146) (also known as FBSMEM) provides options for I/O reduction during FBS operations according to the following table.

Table 16 SYSTEM(146) Options

SYSTEM(146) (default=0)	Description
-1 or 0	Use available memory to store as much of the factor matrix as possible during FBS operations. System Information Message 4199 is printed in the F04 file.
1	Disable all special memory operations for FBS.
2	Increase memory reserved for sparse method by approximately 200%.
3	Increase memory reserved for sparse method by approximately 300%.
4	Increase memory reserved for sparse method by approximately 400%.

12. For the distributed parallel method, the frequency range between V1 and V2 may be subdivided into segments that can then be analyzed in parallel. V1 and V2 must be specified for the parallel method. NUMS must be specified greater than 1 to take advantage of the parallel method. NUMS may also be specified on the NUMSEG keyword of the NASTRAN statement. Currently, NUMSEG must equal the number of processors and by default NUMSEG is set to the number of processors requested by the DMP keyword. If both are specified, then NUMS takes precedence.

The upper frequencies of each segment may be generated automatically by ALPH or specified directly in Fi. If both are specified, then Fi takes precedence over ALPH as long as they are consistent. ALPH if multiplied by 100 may also be specified on FRQSEQ keyword of the NASTRAN statement.

13. Increasing MAXSET may improve performance for large problems where a large number of eigenvalues are being found. The default is 7 on all machines. SYSTEM(263) may be set in an rcfile to effectively modify the default; however the setting on the EIGRL entry always takes precedence.

The optimal MAXSET, also known as Lanczos block size, should be at least one more than the number of repeated eigenvalues. For example, for a model that has six rigid body modes (six zero-frequency eigenvalues), the recommended block size is 7. Additionally, the MAXSET value can also be increased to help with numerical orthogonalization during the Lanczos recurrence, for models with

many closely spaced roots. Note that there must be sufficient memory to keep 'MAXSET' vectors in memory; otherwise, the MAXSET (Lanczos block size) will be reduced automatically. Maximum value for MAXSET is 30. Activate Lanczos message level 1 (EIGRL field 6) to see Lanczos diagnostic messages. Note also that DIAG 16 is equivalent to Lanczos message level 1.

14. SYSTEM(196), keyword SCRSAVE, controls reuse of scratch files when segment logic is invoked. SYSTEM(196) is useful only when multiple frequency segments are requested on a Lanczos run. (Multiple frequency segments can be requested via the NUMS field in the EIGRL entry and by SYSTEM(197).) Each frequency segment requires a minimum of three scratch files. When multiple frequency segments are used on a single processor computer then each frequency segment is solved serially. In this case, it makes sense to let segment #2 use the scratch files which were used by segment #1 since work for segment #1 has been completed (otherwise it wouldn't be working on #2). Similarly, when work for segment #2 is finished, segment #3 should be able to use #2's scratch files. SYSTEM(196)=1 allows such file reuse and is considered a safe default on Version 70 and later systems.
15. The new buckling shift logic in Version 70.5 tends to shift to 1.0 first. The logic may have difficulty finding the lowest ND roots if a problem requests a small number of roots (ND) when there are thousands of roots below 1. In this case either the loading should be scaled, SHFSCL specified, or a smaller frequency range requested.
16. Because Lanczos performance is tuned for medium to large problems, this has caused difficulties with very small problems. Thus, by default, on problems with fewer than 20 degrees-of-freedom when the LAN method is selected, the method is switched to AHO. The criteria for automatic switching is controlled by SYSTEM(359) on the NASTRAN entry.
17. V2 must be specified if DOMAINSOLVER ACMS or DOMAINSOLVER MODES is also specified in the Executive Control Section.
18. For buckling solutions, the Lanczos algorithm is most reliable if it is allowed to compute the lowest mode first, then the remainder in increasing order of magnitude. The lowest mode is usually the mode of most interest. If the V1 and V2 fields are left blank, an estimate of the first mode eigenvalue is found by a robust, efficient inverse iteration. If ND is set to 1, there is a high probability that the first mode will be computed reliably. If more modes are needed it is easier to fill out the other fields correctly once the location of the lowest mode is known.
19. For buckling solutions, if V1 is explicitly set to 0.0, negative eigenvalues will be calculated based on a negative shift value. This is done to avoid singularities resulting from a shift at 0.0. If V1 is set to a small positive value, then negative eigenvalues will not be calculated. This behavior was changed with the MSC Nastran 2010 release whereas before setting V1 to 0.0 yielded no negative eigenvalues. The best approach, however, is to follow the suggestion from Remark 19.
20. If Modules are present then this entry may only be specified in the main Bulk Data section.

**ELEMUDS****Element Property User Defined Service or Subroutine**

Allows the user to provide element property routines for use with specified Nastran elements.

**Format:**

1	2	3	4	5	6	7	8	9	10
ELEMUDS	PID	PTYPE	GROUP	UNAME	DEPEN	NMLSPD			
	“INT”	IDATA1	IDATA2	IDATA3	IDATA4	IDATA5	IDATA6	IDATA7	
		IDATA8	IDATA9	...	...	IDATA <sub>n</sub>			
	“REAL”	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	
		RDATA8	RDATA9	...	...	RDATA <sub>n</sub>			
	“CHAR”	CDATA1	CDATA2	...	...	CDATA <sub>n</sub>			

**Examples:**

*In FMS Section of Nastran input stream:*

```
CONNECT SERVICE ELEMENT 'SCA.MDSolver.Util.Ums'
```

*In Bulk Data:*

ELEMUDS	17	PBUSH2D	ELEMENT	THPAD	FREQ				
---------	----	---------	---------	-------	------	--	--	--	--

**Describer****Meaning**

PID	Element property identification number that matches the identification number on a PBUSH2D element property entry. (Integer > 0)
PTYPE	The name of the element entry. Currently supported element property entry is: PBUSH2D. (Character; no Default)
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default)
UNAME	User subroutine name associated with the entry. See Remark 6.(Character)
DEPEN	Specifies if element is frequency dependent. DEPEN=NOM or blank; user element is not frequency dependent. DEPEN=FREQ; user element is frequency dependent. (Character default=NOM)
NMLSPD	Nominal speed (cycles per second) used by the CBUSH2DA to calculate nominal stiffness, mass and damping terms. Nominal terms will be used during reduction and real eigenvalue solution. In a frequency-dependent problem, updated values will be calculated at each frequency.
“INT”	Keyword indicating that the following data is integer. (Character)
IDATA <sub>i</sub>	Additional user supplied Integer data not already existing on the specified property entry. (Integer; no Default)
“REAL”	Keyword indicating that the following data is real. (Character)

RDATAi	Additional user supplied Real data not already existing on the specified property entry. (Real; no Default)
“CHAR”	Keyword indicating that the following data is Character. (Character)
CDAi	Additional user supplied Character data not already existing on the specified property entry. (Character; no Default)

**Remarks:**

1. This entry triggers the call to a user element property subroutine for advanced nonlinear materials. The GROUP must match the GROUP field of the CONNECT SERVICE FMS statement.
2. On the FMS CONNECT statement, only the CONNECT SERVICE can be used with this entry.
3. PID must match an existing PID.
4. A CDAi entry cannot be the Character “REAL”, “INT”, or “CHAR”.
5. Certain user subroutines may require integer, real, or character data input as specified in the User Defined Services manual.
6. UNAME must be truncated to 8 characters in the bulk data field
7. If the ROMAC interface is being used then UNAME=THPAD is required. See the THPAD Bulk Data entry (p. 3240) for a description of ROMAC service. (<http://www.virginia.edu/romac/>)

**ELEMUDS****Element Property User Defined Service or Subroutine - SOL 600**

Allows the user to provide element property routines for use with enhanced nonlinear elements in SOL 600.

**Format:**

1	2	3	4	5	6	7	8	9	10
ELEMUDS	PID	PType	GROUP	UNAME					
	“INT”	IDATA1	IDATA2	IDATA3	IDATA4	IDATA5	IDATA6	IDATA7	
		IDATA8	IDATA9	...	...	IDATA <sub>n</sub>			
	“REAL”	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	
		RDATA8	RDATA9	...	...	RDATA <sub>n</sub>			
	“CHAR”	CDATA1	CDATA2	...	...	CDATA <sub>n</sub>			

**Examples:**

ELEMUDS	17	PSHELL	UELEM	RTN1					
ELEMUDS	17	PSHELL	UELEM1	RTN3					
	REAL	.00134	1.467+4	.03					
	INT	8	3						

<b>Describer</b>	<b>Meaning</b>
PID	Element property identification number that matches the identification number on a PSHELL, PSOLID, PCOMP, PCOMPG, PBAR, PBEAM, PSHEAR, or PROD element property entry. (Integer > 0)
PType	The name of the element entry. Currently supported element property entries include: PSHELL, PSOLID, PCOMP, PCOMPG, PBAR, PBEAM, PSHEAR, or PROD. (Character; no Default)
GROUP	The group name used for the FMS section CONNECT SERVICE entry. (Character; no Default)
UNAME	A primary or secondary name to identify the user subroutine. See Remark 6. (Character; Default blank)
“INT”	Keyword indicating that the following data is integer. (Character)
IDATA <sub>i</sub>	Additional user supplied Integer data not already existing on the specified MAT entry. (Integer; no Default)
“REAL”	Keyword indicating that the following data is real. (Character)
RDATA <sub>i</sub>	Additional user supplied Real data not already existing on the specified MAT entry. (Real; no Default)

“CHAR”	Keyword indicating that the following data is Character. See Remark 7. (Character)
CDATAi	Additional user supplied Character data not already existing on the specified MAT entry. (Character; no Default)

**Remarks:**

1. This entry triggers the call to a user element property subroutine for advanced nonlinear materials.
2. PID must match an existing PID.
3. A CDATAi entry cannot be the Character “REAL”, “INT”, or “CHAR”.
4. Certain user subroutines may require integer, real, or character data input as specified in the User Defined Services manual.
5. The ELEMUDS entry may be used instead of the USRSUB6 entry. Both entries should not be used in the same run. EVAL will be stored as a character\*16 name in common block /userch/.
6. UNAME identifies the user subroutine name to be called.
7. Character fields CDATAi are ignored in SOL 600 are not passed to the user subroutine.

## ELIST Element List

Defines a list of CQUAD4 and CTRIA3 structural elements for virtual fluid mass.

### Format:

1	2	3	4	5	6	7	8	9	10
ELIST	LID	E1	E2	E3	E4	E5	E6	E7	
	E8	E9	E10	-etc.-					

### Example:

ELIST	3	51	-62	68	THRU	102	122		
-------	---	----	-----	----	------	-----	-----	--	--

Describer	Meaning
LID	Identification number of list. (Integer > 0)
Ei	Identification number of a structural element. See Remark 1. for the meaning of the negative sign. The string "THRU" may be used to indicate that all existing elements between those referenced in the preceding and succeeding fields are in the list. (Integer ≠ 0 or "THRU")

### Remarks:

1. If the ELIST entry is referenced by field 6 of an MFLUID entry, the wetted side of the element is determined by the presence or absence of a minus sign preceding the element's ID on the ELIST entry. A minus sign indicates that the fluid is on the side opposite to the element's positive normal as determined by applying the right-hand rule to the sequence of its corner points. If the "THRU" option is used, then immediately preceding and succeeding elements must have the same sign.
2. Large open "THRUs" should be avoided.
3. The word "THRUs" must not appear in field 2 or 9 on the parent entry or on any continuations.
4. If any ELIST entry is changed or added on restart then a complete re-analysis may be performed. Therefore, ELIST entry changes or additions are not recommended on restart.

## ENDDATA

### Bulk Data Delimiter

Designates the end of the Bulk Data Section.

**Format:**

ENDDATA

**Remark:**

1. ENDDATA is optional.

**ENDDYNA**

Defines the End of Direct Text to Dytran

All entries between TODAYNA and ENDDYNA will be passed directly by SOL 700 to Dytran. Used in SOL 700 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
ENDDYNA									

**Example:**

TODYNA									
MAT1	345	29.0E6	0.285	0.0004					
ENDDYNA									

Describer	Meaning
TODYNA	
MAT1	
ENDDYNA	

**Remarks:**

See [TODYNA](#) for details of how this entry is used.

## ENTUDS User Defined Logic at Entry Point

Calls user defined logic within a SCA service at the point specified within the solution sequence.

### Format:

1	2	3	4	5	6	7	8	9	10
ENTUDS	ENTID	ENTPNT	GROUP						
	"INT"	IDATA1	IDATA2	IDATA3	IDATA4	IDATA5	IDATA6	IDATA7	
		IDATA8	IDATA9	...	...	IDATA <sub>n</sub>			
	"REAL"	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	
		RDATA8	RDATA9	...	...	RDATA <sub>n</sub>			
	"CHAR"	CDATA1	CDATA2	...	...	CDATA <sub>n</sub>			

### Example:

ENTUDS	1	RCENT1	MY_FUNC						
	INT	2	17						
	REAL	.5	.25						

Describer	Meaning
ENTID	Entry point identification number (Integer > 0)
ENTPNT	The point of entry in the solution sequence. Acceptable values for now: "RCENT1", "RCENT2", "RCOUT1", "RCEXEC1". (Character; Required)
GROUP	The SCA group name used to identify the service (Character; Required)
"INT"	Key word indicating that the following data is integer. (Character)
IDATA <sub>i</sub>	Additional user supplied Integer data not already existing on the specified MAT entry. (Integer; no Default)
"REAL"	Key word indicating that the following data is real. (Character)
RDATA <sub>i</sub>	Additional user supplied Real data not already existing on the specified MAT entry. (Real; no Default)
"CHAR"	Key word indicating that the following data is Character. (Character)
CDATA <sub>i</sub>	Additional user supplied Character data not already existing on the specified MAT entry. (Character; no Default)

### Remarks:

1. This entry is for RC Network solver only.
2. In SINDA input file, there are 4 entry points for users to input customized logics.
  - a. RCENT1 ---- Variable 1 block

- b. RCENT2 ---- Variable 2 block
- c. RCOUT1 ---- Output block
- d. RCEXEC1 ---- Execution block

## EOSDEF

Deflagration - SOL 700 only

EOSDEF defines the properties of the deflagration equation of state, and the reaction rate to model the burning of solid propellants. The burning of the solid propellant produces hot gas.

### Format

1	2	3	4	5	6	7	8	9	10
EOSDEF	MID	GAMMA	B	R	$C_v$	$C_p$	E	RHOS	
	RHOF	W	BETA	SAVR	X	Y			

### Example

1	2	3	4	5	6	7	8	9	10
EOSDEF	3	1.123	0.001	304			IE+6	1600	
	0.1	4E-8	0.85	6000	0.6	0.0			

Field	Contents
MID	Unique material number. (Integer > 0; Required).
GAMMA	Constant $\gamma$ . (Real>0; Required)
B	Gas co-volume. (Real $\geq$ 0; Required)
R	Gas constant. (Real>0; Refer to remark 2.)
CV	Specific heat at constant volume. (Real>0; Refer to remark 3.)
CP	Specific heat at constant pressure. (Real>0; Refer to remark 3.)
E	Chemical energy per unit burned mass. (Real>0.0; Required)
RHOS	Reference density of propellant. (Real>0; Required).
RHOF	$\frac{\text{Density of powder}}{\text{reference density of propellant}}$ (Real>0; Refer to remark 5.)
W	Burning rate coefficient (Real $\geq$ 0; Required).
BETA	Burning rate exponent. (Real $\geq$ 0; Required).
SAVR	Initial surface area divided by volume (Real>0; Required).
X	Parameter form function(Real>0; Required).
Y	Parameter form function(Real>0; Required).

## Remarks

1. EOSDEF – The deflagration Equation of State is explained in *Dytran Theory Manual*, Chapter 4: Models.
2. This equation of state is used with Eulerian elements.
3. The temperature of gas is calculated when one of the constants  $R$ ,  $C_v$  or  $C_p$  are specified. When temperature is not mentioned in an output request, omit the he constants .
4. The pressure in the reaction products is defined by the Noble-Abel equation of state as follows:

$$\rho = (Y - 1) \frac{P}{1 - bP} e \text{ for reacted product,}$$

$$T = \frac{(Y - 1)e}{R} \text{ where } Y, b \text{ are constants and } R \text{ is the gas constant.}$$

The chemical reaction rate for conversion of un-reacted explosive to reaction products is mentioned the relation below:

$$\xi = wSAVR \quad \text{vivacity}$$

$$\phi = (1 - F)^X + YF \quad \text{form function}$$

$$\frac{dF}{dt} = \xi \phi P^\beta \quad \text{time derivative of burn fraction}$$

where;

$$w = \quad \text{burning rate coefficient}$$

$$\beta = \quad \text{burning rate exponent}$$

$$SAVR = \quad \text{initial surface area divided by volume}$$

$$Y = \quad \text{parameter form function}$$

$$S = \quad \text{parameter form function}$$

5. RHOF allows taking into account the air between gunpowder grains. Also, it allows taking into account air inside the combustion chamber. For example If the chamber is filled with 10% real propellant and the rest is filled with air then RHOF = 0.1.
6. To indicate what Eulerian regions can burn, the variable DEFMAT can be used. In regions that can burn DEFMAT=1. DEFMAT can be set on the TICVAL card:  
 TICVAL,14,,DENSITY,1.14,SIE,300000.2,DEFMAT,1.0
7. Ignition of the propellant approached by setting SIE to the flame temperature in specific areas:  
 TICVAL,15,DENSITY,1.14,SIE,4231908.591,DEFMAT,1.0

Where  $SIE_{\text{ignition}} = \text{Flame Temp} \times C_v$

Flame Temp can be extracted from Chemical Energy per unit burned mass and Gas constant:  $T_{\text{flame}}$   
 $= E / R .$

**EOSGAM****Gamma Law Gas Equation of State - SOL 700 only**

Defines the properties of a Gamma Law equation of state where the pressure  $p$  is defined as:

$$p = (\gamma - 1)\rho e$$

where:

$e$  = specific internal energy per unit mass

$\rho$  = overall material density

$\gamma$  = A constant

Used in SOL 700 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
EOSGAM	EID	GAMMA	R	CV	CP	VISC			

**Example:**

EOSGAM	2	1.4	287.0						
--------	---	-----	-------	--	--	--	--	--	--

Describer	Meaning
EID	Unique equation of state number. (Integer > 0, Required)
GAMMA	Constant $\gamma$ . (Real $\geq 0$ , default=blank)
R	Gas constant. See Remarks 1. and 3. (Real > 0, default=blank)
CV	Specific heat at constant volume. See Remarks 1. and 3. (Real > 0, default=blank)
CP	Specific heat at constant pressure. See Remarks 1. and 3. (Real > 0, default=blank)
VISC	Viscosity coefficient. If zero, no viscosity. See Remarks 4., 5., and 6. (Real $\geq 0$ , default=blank)

**Remarks:**

1. The temperature of the gas will be calculated when one of the gas constants,  $R$ ,  $C_v$  or  $C_p$  is specified.
2. The Euler variable name for temperature is TEMPTURE.
3.  $\gamma$ ,  $R$ ,  $C_v$  and  $C_p$  have the following relationships:

$$\gamma = \frac{c_p}{c_v} \quad R = c_p - c_v$$

4. The viscosity coefficient is the dynamic viscosity. It is the ratio between shear stress and velocity gradient. The SI-unit of viscosity is

$$Pa \cdot s = \frac{N_s}{M^2} = \frac{kg}{ms}$$

5. If possible, use (in coupled analysis) the FASTCOUP coupling algorithm because viscous fluxes are computed more accurately for fast coupling than for general coupling.
6. For the single mat solver, viscous stresses can be requested by the use of TXX through TZX. Also, EFFSTS is available. For the multi-material solver, viscous stresses are stored in TXX-VIS, TYY-VIS, TZZ-VIS, TXY-VIS, TYZ-VIS, TZX-VIS. This viscous stresses depend only on the current velocity gradients. The stresses like TXX are elastic-plastic stresses and depend on past stress. The total stress tensor in the element is given by the average of the viscous stress and elastic-plastic stress. The weight factors are the material fraction of viscous fluid and the remaining materials.

## EOSIG

## Ignition and Growth Equation of State - SOL 700 only

Defines the properties of Ignition and Growth equation of state and the reaction rate equation used to model high explosives. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
EOSIG	EID	UNITDEF	DBEXPL	UNITCNV					+
+		AE	BE	R1E	R2E	OMGE	I	G	+
+	A	AP	BP	R1P	R2P	OMGP	X	Y	+
+	Z	R	ECHEM	PRSTOL	ITRMAX				

### Example:

EOSIG	10		LX17	SI					
-------	----	--	------	----	--	--	--	--	--

Describer	Meaning
EID	Unique equation of state number referenced from MATDEOL. (Integer > 0; Required)
UNITDEF	User-defined default unit for the inputs: See Remarks 2. and 3. (Character)
	CCGMS      m/g/μs units
	SI            International System units
	METRIC     Metric units
	IMPER       imperial units
	MMMG       mm/mg/μs units
DBEXPL	Use explosive material from the database (See Remarks 4. and 6.) (Character, NO). The following detonation materials are available in the data base:
	NO            The database is not used. See Remark 5.
	P94A         PBX-9404 (a) explosive
	TATB         TATB explosive
	PENT         PETN explosive
	CTNT         Cast TNT explosive
	LCOMPB     LANL COMP B explosive
	MCOMPB     Military COMP B explosive
	P94B         PBX-9404 (b) explosive
	LX17         LX-17 explosive
UNITCNV	User defined conversion units: (Character; see Remarks 2. and 3.)
	CGMS        cm/g/μs units

Describer	Meaning
	SI International System units
	METRIC Metric units
	IMPER Imperial units
	MMMGS mm/mg/ $\mu s$ units
AE	Constant $A_e$ for un-reacted explosive. See Remark 5. (Real; Required)
BE	Constant $B_e$ for un-reacted explosive. See Remark 5. (Real; Required)
R1E	Constant $R_{1e}$ for un-reacted explosive. See Remark 5. (Real; Required)
R2E	Constant $R_{2e}$ for un-reacted explosive. See Remark 5. (Real; Required)
OMGE	Constant $\omega_e$ for un-reacted explosive
I	First ignition coefficient. See Remark 5. (Real; Required)
G	Second ignition coefficient. See Remark 5. (Real; Required)
A	Density ignition coefficient. See Remark 5. (Real; Required)
AP	Constant $A_p$ for reacted product. See Remark 5. (Real; Required)
BP	Constant $B_p$ for reacted product. See Remark 5. (Real; Required)
R1P	Constant $R_{1p}$ for reacted product. See Remark 5. (Real; Required)
R2P	Constant $R_{2p}$ for reacted product. See Remark 5. (Real; Required)
OMGP	Constant $\omega_p$ for reacted product. See Remark 5. (Real; Required)
X	Surface burning exponent. See Remark 5. (Real, 2./9.)
Y	Surface burning exponent. See Remark 5. (Real, 2./3.)
Z	Pressure exponent. See Remark 5. (Real; Required)
R	Relative density exponent. See Remark 5. (Real, .4)
ECHEM	Chemical energy of high explosive per unit mass. See Remark 5. (Real; Required)
PRSTOL	Tolerance for pressure equilibrium iterations in mixed phase elements. (Real > 0, 1.E-6)
ITRMAX	Maximum number of iterations in pressure equilibrium iterations. (Integer > 0, 16)

**Remarks:**

1. This equation of state can only be used with solid Eulerian elements.
2. The definition of the unit system in which the input values are defined is required information only in case you wish to have an automatic conversion to a different unit system as defined by the UNITCNV field. In case you are using the conversion mechanism, note that the density RHO in the corresponding MATDEUL entry will be interpreted in the unit system defined here. [Table 9-14](#) defines sets of units available:

**Table 9-14      Sets of Units Used in the IG Model**

Quantity	CG $\mu$ s	SI	Metric	Imperial	MMMG $\mu$ s
Length	Centimeter (cm)	Meter (m)	Centimeter (cm)	Inch (in)	Millimeter (mm)
Time	Microsecond ( $\mu$ s)	Second (s)	Second (s)	Second (s)	Microsecond ( $\mu$ s)
Mass	Gram (g)	Kilogram (kg)	Gram (g)	Slug (lbf-s <sup>2</sup> /in)	Milligram (mg)
Force	Teradyne	Newton (N)	Dyne	Pound force (lbf)	kN
Density	g/cm <sup>3</sup>	Kg/m <sup>3</sup>	g/cm <sup>3</sup>	lbf-s <sup>2</sup> /in <sup>4</sup>	mg/ mm <sup>3</sup>
Stress	Mbar	Pascal (Pa)	$\mu$ bar	Lbf/in <sup>2</sup>	GPa
Energy	1012 erg (Mbars-cm <sup>3</sup> )	Joule (J)	Erg	Lbf-in	J
Temperature	Kelvin (K)	Kelvin (K)	Kelvin (K)	Kelvin (K)	Kelvin (K)

3. The UNITCNV field defines the unit system to which the material parameters are converted. In case you are not using one of the database material models, you also have to define the default unit system (UNITDEF) in which you supplied the data.
4. You can use the database containing several detonation materials to start the analysis. The material data are taken from Lee/Tarver (Ref. 1) and Murphy/Lee (Ref. 2) papers in the Theory Manual. The equations of state parameters are given in the [Table 9-15](#).
5. The default setting for DBEXPL is NO, which means you should define the values in the input fields (fields 12 to 36). If the database material name is defined, all values in the input fields will be overridden. The reference density RHO defined on the corresponding MATDEUL entry will be set to the value from the database.
6. The default unit system for the material database parameters is the CGMS unit system. If you wish to use the material base data in a different unit system, you can specify this by defining the target unit system in the UNITCNV field.
7. You can define the shear property and yield model of the material with respectively SHXXX and YLDXX entry. Note that the unit system of data required in these entries should be consistent with the unit system defined in the UNITCNV field.
8. The IG equation of state cannot be used in combination with a spallation model.
9. The following JWL equation of state is used to calculate the pressure of the un-reacted explosive (in "solid" state):

$$p_e = A_e \left( 1 - \frac{\omega_e \eta_e}{R_{1e}} \right) e^{\frac{-R_{1e}}{\eta_e}} + B_e \left( 1 - \frac{\omega_e \eta_e}{R_{2e}} \right) e^{\frac{-R_{2e}}{\eta_e}} + \omega_e \eta_e \rho_e E_e$$

where:

$\eta_e = \rho_e / \rho_0$	the relative density of the unreacted explosive.
$E_e$	the specified internal energy per unit mass of the unreacted explosive
$\rho_0$	the initial density of the explosive
$A_e, B_e, \omega_e, R_{1e}, R_{2e}$	the input constants of the unreacted explosive

Similarly, the pressure in the reaction products (in “gas” state) is defined by another JWL form as follows:

$$p_p^1 = A_p \left( 1 - \frac{\omega_p \eta_p}{R_{1p}} \right) e^{\frac{-R_{1p}}{\eta_p}} + B_p \left( 1 - \frac{\omega_p \eta_p}{R_{2p}} \right) e^{\frac{-R_{2p}}{\eta_p}} + \omega_p \eta_p \rho_p E_p$$

where:

$\eta_p = \rho_p / \rho_0$	=	the relative density of the unreacted explosive
$E_p$	=	the specified internal energy per unit mass of the unreacted explosive
$A_p, B_p, \omega_p, R_{1p}, R_{2p}$		the input constants of the reaction product. The chemical reaction rate for conversion of un-reacted explosive to reaction products is described by the following reaction rate equation:

$$\frac{\partial F}{\partial t} = I(1 - F)^x (\eta_e - 1 - a)^r + G(1 - F)^x F^y (P)^z$$

here  $F$  denotes the burn fraction that is defined as the fraction of the explosive that has already reacted. For more details concerning the implementation of this equation of state, please refer to the Theory Manual

10. You can access the results of the un-reacted explosive and reaction products for IG elements. These EOSIG specific output variables are

Keyword	Description
SIE-E	Specific internal energy per unit mass of un-reacted explosive part
SIE-P	Specific internal energy per unit mass of reaction products part
FMAT	Volume fraction
RHO-E	Density of un-reacted explosive part
RHO-P	Density of reaction products part
MASS-E	Mass of un-reacted explosive part
MASS-P	Mass of reaction products part

The output variables for the burn fraction are

Keyword	Type of Elements	Description
FBURN	Solid Lagrangian Elements	Burn fraction of EOSIG material
	Euler Elements	Not applicable for EOSIG materials. Burn fraction for EOSJWL material
IGBURN	Solid Lagrangian Elements	Not available
	Euler Elements	Burn fraction of EOSIG MATERIAL

11. The ignition of IG material can be initiated by:
- a. Compression of the IG material in a small region, where the compression originates from outside that region. This is the most physical method to initiate ignition. Examples are a shock wave entering the region, a flow boundary that supplies mass to the region and a plate or other structural part that compresses the region. In all these cases the IG material should be initialized with zero pressures. This can be achieved by not specifying the specific energy on the TICVAL entry that prescribes the initial state of the IG material. The specific energy will be computed such that the initial pressure is zero.
  - b. Compression of the IG material in a small region where the compression originates within that region. This can be done by specifying either a density that exceeds the compression limit or a specific energy that gives rise to a sufficiently large pressure.

Table 9-15 Coefficients for the IG Model of Several Explosions in the Database.

Explosive	PBX-9404 (a)	TATB	PETN	Case TNT	LANL COMP B	Military COMP B	PBX-9404 (b)	LX-17

12. EID must unique among all EOSxx entries in one model.

## EOSJWL

## JWL Explosive Equation of State - SOL700

Defines the properties of a JWL equation of state commonly used to calculate the pressure  $p$  of the detonation products of high explosives

$$p = p_0 + A \left(1 - \frac{\omega\eta}{R_1}\right) e^{\frac{-R_1}{\eta}} + B \left(1 - \frac{\omega\eta}{R_2}\right) e^{\frac{-R_2}{\eta}} + \omega\eta\rho_0 e + \frac{\omega\rho\lambda Q}{\rho_0}$$

$$\frac{d\lambda}{dt} = a(1 - \lambda)^m p^n$$

$e$  = specific internal energy per unit mass

$\rho_0$  = reference density

$\rho$  = overall material density

$\eta$  =  $\rho/\rho_0$

$p_0$  = initial pressure

$\lambda$  = fraction that describes the afterburning. It ranges from 0 to 1

$A, B, R_1, R_2, a, m, n$  and  $Q$  are constants.

The last term:  $\frac{\omega\rho\lambda Q}{\rho_0}$  models afterburning.

**Format:**

1	2	3	4	5	6	7	8	9	10
EOSJWL	MID	A	B	R1	R2	OMEGA	P0	Q	
	a	m	N						

**Example:**

EOSJWL	37	5.2E11	0.77E11	4.1	1.1	0.34		0.0	
	0.0	0.0	0.0						

### Format and Example

```
EOSJWL  MID  A      B      R1    R2    OMEGA  P0    Q    +
EOSJWL  37   5.2E11  0.77E11  4.1   1.1   0.34      0.0  +

+      a      m      n
+      0.0    0.0    0.0
```

Describer	Meaning
EID	Unique equation of state number referenced from MATDEUL. (Integer > 0; Required)
A	Constant A. (Real, 0.0)
B	Constant B. (Real, 0.0)
R1	Constant R1. (Real, 0.0)
P2	Constant R2. (Real, 0.0)
OMEGA	Constant $\omega$ . (Real, 0.0)
P0	Initial pressure. See Remark 3. (Real, 0.0)
Q	Initial pressure. (Real, $\geq 0.0$ ). see Remark 6.
a	Initial pressure (Real, 0.0). see Remark 6.
m	Initial pressure (Real, 0.0). see Remark 6.
n	Initial pressure (Real, 0.0). see Remark 6.

### Remarks:

1. This equation of state can be used only with Eulerian elements.
2. A [DETSPL](#) entry must be used to specify the detonation model.
3. This equation of state is discussed in *Dytran Theory Manual*, Chapter 4: Models, [EOSJWL – JWL Equation of State](#).
4. In simulations with ideal gases, the JWL material needs to have an initial pressure to counter balance the pressure of the ideal gas. Similarly, in case of under calculations where an explosive is located at a certain depth, P0 should be preset to equal the initial hydrostatic pressure.
5. The [DETSPL](#) definition of one EOSJWL material also applies to all other EOSJWL materials. Therefore, the blast wave of one explosive can ignite other explosives. To prevent this linked ignition, [PARAM](#), [JWLDET](#), [NOLINK](#) can be used.
6. By default the constants  $a, m, n$  and  $Q$  are zero, and afterburning is not taken into account. To model afterburning all the variables  $Q, a, m$  and  $n$  have to be set to positive constants. The extent of the afterburning can be checked by requesting the Euler element variable AFTERBURN. This variable equals  $\lambda$ . If the afterburning in an Euler element is complete then AFTERBURN = 1.0.

**EOSMG****Mie-Gruneisen Equation of State - SOL 700 only**

Defines the properties of a Mie-Gruneisen equation of state commonly used to calculate the pressure  $p$  in high strain rate processes. Used in SOL 700 only.

$$p = \frac{\rho_0 c^2 n}{(1 - s\eta)^2} \left(1 - \frac{\Gamma_0 \eta}{2}\right) + \Gamma_0 \rho_0 e$$

$$\eta = 1 - \frac{\rho_0}{\rho_1}$$

$$\rho_1 = \min(\rho, \text{RM})$$

where

$e$  = specific internal energy per unit mass. For material at zero pressure,  $e$  has to be initialized as zero.

$\rho_0$  = reference density

$\rho$  = overall material density

$\Gamma_0$  = Gruneisen parameter at reference density.

$s$  = defined by  $U_s = c_0 + sU_p$ , where  $U_s$  and  $U_p$  are respectively the linear shock velocity and particle velocity as obtained from shock data.

$c$  = sound speed at reference density

RM = Cut-off value for density.

**Format:**

1	2	3	4	5	6	7	8	9	10
EOSMG	EID	c	S	R1	RM				

**Example:**

EOSMG	37	2000	1.5	2.0	3000				
-------	----	------	-----	-----	------	--	--	--	--

Descriptor	Meaning
EID	Unique equation of state number referenced from MATDEUL. (Integer > 0; Required)
c	Sound speed at reference density. (Real; Required)
s	Constant $s$ . (Real; Required)
$\Gamma_0$	Gruneisen gamma. (Real; Required)
RM	Cut off value for density. (Real; Required)

**Remarks:**

1. This equation of state can be used only with Eulerian elements.
2. This equation of state is discussed in Equations of State.
3. The cut off value RM is only used for limiting the pressure. To prevent division by zero RM should be less than  $s/s - 1 \rho_{ref}$ . RM can be set slightly below this value. In case the simulation gets instable because of too large pressures RM can be decreased.
4. EID must unique among all EOSxx entries in one model.

## EOSNA

## Noble-Abel equation of state - SOL700

Defines the properties of Noble-Abel equation of state where the pressure  $p$  is defined as:

$$p = (\gamma - 1) \frac{\rho}{1 - b\rho} e$$

where:

- $e$  = specific internal energy per unit mass
- $\rho$  = overall material density
- $\gamma$  = a constant
- $b$  = Gas co-volume

### Format and Example

1	2	3	4	5	6	7	8	9	10
EOSNA	EID	GAMMA	B	R	CV	CP			
EOSNA	35	1.2363	0.001	314.46					

Field	Contents	Type	Default
EID	Unique equation of state number.	$I > 0$	Required
GAMMA	Constant $\gamma$ .	$R \geq 0.0$	Required
B	Gas co-volume .	$R \geq 0.0$	0.0 Refer to Remark 3.
R	Gas constant.	$R > 0.0$	Refer to remark 4.
CV	Specific heat at constant volume.	$R > 0.0$	Refer to remark 4.
CP	Specific heat at constant pressure	$R > 0.0$	Refer to remark 4.

## Remarks

1. Refer to *Dytran Theory Manual*: Chapter 4-Models, for EOSNA – Noble-Abel Equation of State.
2. EOSNA – Noble-Abel Equation of State is used with Eulerian elements only.
3. The parameter B models the interactions between gas particles.
4. The temperature of the gas is calculated when one of the gas constants,  $R$ ,  $C_v$ , and  $C_p$  is mentioned.
5. The Euler variable name for temperature is TEMPTURE.
6. The relation between Gamma,  $R$ ,  $C_v$ , and  $C_p$  is shown below:

$$\gamma = \frac{C_p}{C_v} \quad R = C_p - C_v$$

**EOSPOL****Polynomial Equation of State for Solids - SOL 700 only**

Defines the properties of a polynomial equation of state where the pressure  $p$  is defined in SOL 700 as follows:

In compression ( $\mu > 0$ ),

$$p = a_1\mu + a_2\mu^2 + a_3\mu^3 + (b_0 + b_1 + b_2\mu^2 + b_3\mu^3)\rho_0 e$$

In tension ( $i < 0$ ),

$$p = a_1\mu + (b_0 + b_1\mu)\rho_0 e$$

Where

$$\mu = \eta - 1$$

$$\eta = \rho/\rho_0$$

$p$  = overall material density

$p_0$  = reference density

$e$  = specific internal energy per unit mass

Used in SOL 700 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
EOSPOL	EID	A1	A2	A3	B0	B1	B2	B3	
	HVL	VISC							

**Example:**

EOSPOL	100	80.E6							
	1.1								

Describer	Meaning
EID	Unique equation of state member. (Integer > 0; Required)
A1	Coefficient a1 or Bulk Modulus. (Real; Default = 0.0)
A2	Coefficient a2. (Real; Default = 0.0)
A3	Coefficient a3. (Real; Default = 0.0)
B0	Coefficient b0. (Real; Default = 0.0)
B1	Coefficient b1. (Real; Default = 0.0)

Describer	Meaning
B2	Coefficient b2. (Real; Default = 0.0)
B3	Coefficient b3. (Real; Default = 0.0)
HVL	Hydrodynamic volume limit. (Real > 1.0; Default = 1.1)
VISC	Viscosity coefficient.(Real; Default = 0.0)

**Remarks:**

1. When the relative volume ( $\rho_0/\rho$ ) exceeds HVL, the pressure is cut off to

$$P_{HVL} = f(\mu_{HVL})$$

with

$$\mu_{HVL} = \frac{1}{HVL} - 1$$

e.g., for  $p = a1 \cdot \mu$ , the pressure behavior is as follows:

2. When the PARAM,HVLFail is set to YES, the elements where the relative volume ( $\rho_0/\rho$ ) exceeds HVL fail completely. Their stress state is zero.

**EOSUDS**

## User-defined Equation of State - SOL 700 only

Defines the frequency dependent properties for an isotropic poroelastic material. Use in SOL700 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
EOSUDS	EID	GROUP	UNAME	VISC					

**Example:**

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE water 'SCA.MDSolver.Obj.Uds.Dytran.Materials'
```

*In Bulk Data:*

1	2	3	4	5	6	7	8	9	10
EOSUDS	12	WATER	EXEOS	.01					

Describer	Meaning
EID	Unique equation of state number. (Integer > 0; Required)
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default)
UNAME	User subroutine name associated with the entry. (Character; default=EXEOS)
VISC	Viscosity coefficient $R > 0$ No viscosity. See Remarks 4.and 5.

**Remarks:**

1. The EID must be referenced by a MATDEUL or MAT1 entry.
2. The equation of state name is passed to method usrEOS of the SCAIMDSolver700 interface and can be used to identify the equation of state.
3. The viscosity coefficient is the dynamic viscosity. It is the ratio between shear stress and velocity gradient.
4. For the single mat solver viscous stresses will be stored in the output files by the use of TXX through TZX. Also, EFFSTS is available. For the multi-material solver viscous stresses are stored in TXX-VIS, TYY-VIS, TZZ-VIS, TXY-VIS, TYZ-VIS, TZX-VIS. These viscous stresses only depend on the current velocity gradients. The stresses like TXX are elastic-plastic stresses and depend on past stresses. The total stress tensor in the element is given by the average of the viscous stress and elastic-plastic stress. The weight factors are the material fraction of viscous fluid and the remaining materials.
5. UNAME can be:

Subroutine Name	Function
EXEOS	Standard user defined Equation of State

**EPOINT**

## Extra Point List

Defines extra points for use in dynamics problems.

**Format:**

1	2	3	4	5	6	7	8	9	10
EPOINT	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8	

**Example:**

EPOINT	3	18	1	4	16	2			
--------	---	----	---	---	----	---	--	--	--

**Alternate Format and Example:**

EPOINT	ID1	“THRU”	ID2						
EPOINT	17	THRU	43						

Describer	Meaning
IDI	Extra point identification number. (100,000,000 > Integer > 0; for “THRU” option, ID1 < ID2).

**Remarks:**

1. All extra point identification numbers must be unique with respect to all other structural, scalar, and fluid points for direct methods of solution. For modal methods, they must be larger than the number of eigenvectors retained for analysis.
2. EPOINT is used to define coordinates used in transfer function definitions (see the TF and DMIG entries).
3. If the alternate format is used, extra points ID1 through ID2 are also defined to be extra points.
4. See the *MSC Nastran Dynamic Analysis User's Guide* for a discussion of extra points.

**ERPPNL****Equivalent Radiated Power Definition**

Defines one or more panels by referencing sets of elements or properties.

**Format:**

1	2	3	4	5	6	7	8	9	10
ERPPNL	NAME1	SETID1	NAME2	SETID2	NAME3	SETID3	NAME4	SETID4	
	NAME5	SETID5							

**Example:**

ERPPNL	ROOF	1	DOORLF	16					
--------	------	---	--------	----	--	--	--	--	--

Describer	Meaning
NAMEi	Panel label. (CHAR)
SETIDi	Identification number of a SET3 Bulk Data entry that lists the panel property entries or the panel elements. (Integer > 0)

**Remarks:**

1. The SET3 entries can only refer to 2D and/or 3D structural element types, such as QUAD4, TRIA3, QUADR, CTRIAR, QUAD8, TRIA6, HEXA, PENTA, PYRAM and TETRA, or PSHELL, PCOMP, PCOMPG and PSOLID entry associated with those element types.
2. NAMEi are used in a Case Control SET definition defining *setp* to select the panels in the Case Control command ERP.
3. Duplicate Element IDs are removed if they occur on the referencing SET3 entries prior to the ERP calculation.
4. User does not need to specify the outer face(s) of 3D elements. The outer face(s) or exposed face(s) of 3D elements will be determined automatically. Interior 3D element(s) which has no exposed face(s) will not be included for ERP computation.

## EULFOR

## Body Force Loading on Euler Elements - SOL 700 only

Defines a body force loading (acceleration) on Euler elements per unit mass. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
EULFOR	BID	CID	VALUE	TID	N1	N2	N3		

### Example:

EULFOR	100	5		13	1.	0.	0.		
--------	-----	---	--	----	----	----	----	--	--

Describer	Meaning
BID	Unique body force number. (Integer > 0; Required)
CID	ID of a coordinate system. (Integer ≥ 0; Default = 0)
VALUE	Scale factor for the vector. See Remark 1. (Real ≥ 0.0)
TID	TABLED1 ID describing the scale factor for the load as function of time. See Remark 1. (Integer)
N1, N2, N3	Components of a vector giving the load (acceleration) direction defined in coordinate system CID. At least one must be nonzero. See Remark 2. (Real; Default = 0.0)

### Remarks:

1. Either VALUE or TID must be nonzero.
2. By default the components are zero, but at least one of them should be nonzero.

**EULFOR1****Body force for Eulerian Regions - SOL700**

Alternative way to define an acceleration within a geometric region of the Euler model regions are defined by geometric shapes which are defined by EULFREG entries.

**Format:**

EULFOR1	SID	ESID							
---------	-----	------	--	--	--	--	--	--	--

**Example:**

EULFOR1	300	1							
---------	-----	---	--	--	--	--	--	--	--

Describer	Meaning
SID	Unique EULFOR1 number referenced from a PEULER1 entry .(Integer >0, required)
ESID	Group of geometric region EULFREG ID. (Integer > 0; Required)

**Remarks:**

1. EULFOR1 and EULFREG are only available for the multi-material Euler solver.
2. The combination of Eulerian region and material ID determines where the acceleration field is applied.
3. It is allowed to cover only part of the Euler domain with EULFOR1 definitions.
4. To increase the accuracy of the region definition parameter MICRO can be used.

## EULFREG

## Body force for Eulerian Regions - SOL700

Defines the acceleration field for sets of Eulerian regions, The Eulerian regions are defined by geometric shapes. For each coordinate direction a time-dependend acceleration can be defined.

### Format:

EULFREG	ERID	ESID	TYPE1	VID1	MID1	ACCX	ACCY	ACCZ	
	LEVEL								

### Example:

EULFREG	300	1	BOX	400	100	100	200	300	
	0.0								

Describer	Meaning
ERID	Unique ERID number. (Integer > 0; Required)
ESID	ID of group of Euler regions referenced from the EULFOR1 entry. (Integer > 0; Required)
TYPEi	The type of Eulerian region. (Character; Required)
	SURF            Region inside or outside a multifaceted surface.
	SPHERE        Region inside a sphere.
	CYLINDER     Region inside a cylinder.
	BOX            Region inside a box.
	ELEM           Region defined by element list.
VIDi	Number of a geometric entity, a SET1 number, or number of a SURFINI entry. (Integer > 0; Required)
MIDi	Number of a MATDEUL entry to which the acceleration field will be applied. (Integer > 0; Required)
ACCi	Unique table number that defines the variation of acceleration in time. ACCX, ACCY and ACCZ respectively denote the acceleration in the x-, y- and z-direction. (Integer > 0; Required)
LEVELi	Level indicator for this material and initial values. (Real; default=0.0)

### Remarks:

1. EULFOR1 and EULFREG are only available for the multi-material Euler solver.
2. The combination of Eulerian region and material ID determines where the acceleration field is applied.
3. It is allowed to cover only part of the Euler domain with EULFOR1 definitions.

4. All level indicators  $LEVEL_i$  must have different values. The level indicator can be negative.
5. To increase the accuracy of the region definition parameter  $MICRO$  can be used.

## EXCLUDE

Ignore Bulk Data entries from primary to secondary Module

Specifies Bulk Data entries in the primary Module to be ignored in the secondary (or copied) Module.

### Format:

1	2	3	4	5	6	7	8	9	10
EXCLUDE	ENTRY1	ENTRY2	ENTRY3	-etc.,					

### Example:

EXCLUDE	SPC	FORCE							
---------	-----	-------	--	--	--	--	--	--	--

Describer	Meaning
ENTRYi	Name of a Bulk Data entry to be ignored.

### Remarks:

1. A secondary Module may have its own BEGIN MODULE section but it is not required as long as the user is willing to accept all modeling data from the reference Module because, by default, all entries in the reference Module will be copied to the secondary Module. However, if the user wishes to exclude and/or replace some of the entries from the reference Module in the copy then he simply specifies at least one instance of the entry to be ignored. For example, if the user wants to ignore all FORCE entries from the reference Module then specify a single FORCE entry in the secondary Module's Bulk Data section. Alternatively, the user may specify a list of Bulk Data entries to ignore on the EXCLUDE Bulk Data entry in the secondary Module's Bulk Data section.
2. EXCLUDE must be specified in the secondary (or copied) Module's Bulk Data section.
3. GRID entries cannot be ignored or replaced and EXCLUDE,GRID will cause a fatal error.
4. See [MDBULK](#) for the definition of secondary (or copied) Modules.

## EXTRN Partitioned External Superelement Connection

Defines a boundary connection for an external superelement.

### Format:

1	2	3	4	5	6	7	8	9	10
EXTRN	GID1	C1	GID2	C2	GID3	C3	GID4	C4	
	-etc.-		GID6	"THRU"	GID7	C6	-etc.-		

### Example:

EXTRN	1001	123	1120	123456	1201	123			
-------	------	-----	------	--------	------	-----	--	--	--

Describer	Meaning
GID <sub>i</sub>	Grid identification number to which the exterior superelement matrices will be connected.
C <sub>i</sub>	Component numbers. (Integer 0, blank, or 1 for scalar points; Integers 1 through 6 with no embedded blanks for grids.)

### Remarks:

1. EXTRN can only be specified in partitioned Bulk Data Sections and is ignored in the main Bulk Data Section.
2. Connection grids must be specified in the partitioned Bulk Data Section following BEGIN SUPER = SEID.
3. "THRU" may be specified only in fields 3, 5, or 7.
4. Pairs of blank fields may be entered to allow easier modification of the EXTRN entry.
5. The order of the GID<sub>i</sub> and C<sub>i</sub> pairs must be in the internal order of the grids set in the creation run. But since Nastran no longer re-sequences grids then the pairs are specified in ascending GRID ID order. However, if PARAM,OLDSEQ or the SEQGP entry is specified then the proper order may not be ascending. To determine the internal grid order, add PARAM,USETPRT,0 and PARAM,USETSTR1,A.

## Entries F - L

### FAILJC

Johnson-Cook Failure Model - SOL 700 only

Defines the properties of the Johnson-Cook failure model. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FAILJC	FID	D1	D2	D3	D4	D5	.0 $\epsilon_{pl}$	TROOM	
	TMELT	CP	MTH						

Example:

FAILJC	1	.05	3.44	-2.12	0.002	0.16	1.0	297.0	
	1495	450	CONT						

Descriptor	Meaning
FID	Unique failure model number. Referenced from MATDEUL. (Integer > 0; Required)
D1...D5	Parameters. See Remark 4. (Real; Default = 0.0)
.0 $\epsilon_{pl}$	Reference plastic strain rate. (Real; Default = 1.0)
TROOM	Room temperature. (Real; 0.0)
TMELT	Melt temperature. (Real; 1.E+20)
CP	Heat capacity. (Real; 1.E+20)
MTH	Specifies how failure is applied. (Character; CONT)
	CONT    Continuous failure
	DISC    Discrete failure
	NOFAIL    Damage is not used for failure

Remarks:

1. This failure model is only available for Eulerian materials using the multi-material solver with strength.
2. The use of coupling surfaces is not supported.
3. The variable D can be visualized by adding DAMAGE to the Output request for Euler elements.
4. Defines the properties of a failure model where failure is determined by a damage model. The damage model is given by:

$$D = \sum_{time} \frac{\Delta \epsilon_p}{\epsilon^{frac}}$$

$$\epsilon^{frac} = (D_1 + D_2 \exp(D_3 \sigma^*)) \left( 1 + D_4 \ln \frac{\dot{\epsilon}_{pl}}{\dot{\epsilon}_{pl}^0} \right) (1 + D_5 T^*)$$

$$\sigma^* = \frac{\sigma_m}{\sigma}$$

$$T^* = \frac{T - T_{room}}{T_{melt} - T_{room}}$$

The summation is performed over all past time increments. The variable D measures the damage; T is the temperature,  $\sigma_m$  is the mean stress,  $\sigma$  is the effective stress and  $\epsilon^{frac}$  is the fracture strain. The fracture strain depends on a non-dimensional plastic strain rate  $\dot{\epsilon}_{pl} / \dot{\epsilon}_{pl}^0$ . If D exceeds one it set equal to one.

The damage variable D is transported along with the Eulerian material.

There are two methods to determine when elements fail:

- Continuous failure: The yield stress is reduced by a factor (1-D). When D exceeds 1 the yield stress equals zero and the element fails.
- Discrete failure: the element fails when D equals one.

This failure model applies to high-strain rate deformation of metals. It is less suitable for quasi-static problems.

## FAILMPS

## Maximum Plastic Strain Failure Model - SOL 700 only

Defines the properties of a failure model where failure occurs when the equivalent plastic strain exceeds the specified value. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FAILMPS	FID	MPS							

Example:

FAILMPS	1	.15							
---------	---	-----	--	--	--	--	--	--	--

Describer	Meaning
FID	Unique failure model number referenced from MATDEUL. (Integer > 0; Required)
MPS	Maximum plastic strain that causes failure. (Real; Required)

## FAILUDS

## User Defined Failure For Nonlinear Explicit Analysis - SOL 700 only

User defined simple failure of Eulerian materials. Use in SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FAILUDS	FID	GROUP	UNAME						

Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE usrfail 'SCA.MDSolver.Obj.Uds.Dytran.Materials'
```

*In Bulk Data:*

1	2	3	4	5	6	7	8	9	10
FAILUDS	200	usrfail	EXFAIL						

Describer	Meaning
FID	Unique output number. (Integer > 0; Required)
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default)
UNAME	User subroutine name associated with the entry. (Character; default=EXFAIL)

Remarks:

1. Only can be used for SOL 700.
2. FID has to be referenced by a MATDEUL, MAT1 or MATORT entry.
3. UNAME can be:

Subroutine Name	Function
EXFAIL	Standard user defined failure
EXFAIL1	Alternative 1 user defined failure
EXFAIL2	Alternative 2 user defined failure

4. For option UNAME=EXFAIL2, for each material and for each Euler element a variable will be created that monitors the degree of failure of the material. This variable is denoted by DAMAGE and is between 0 and 1. The EXFAIL2 routine allows updating this damage variable due to the plastic strain increment of the current cycle.
5. For option UNAME=EXFAIL2 there are three ways in which this damage variable can model failure. These are:

- Continuous failure: The yield stress is reduced by a factor  $(1-D)$ . When  $D$  exceeds 1.0, the yield stress equals zero and the element fails.
  - Discrete failure: the element fails when  $D$  equals one.
  - No failure: positive damage values will not lead to failure. This is useful if the failure modeling is done by an YLDUDS routine. Then the yield stress can be reduced depending on the magnitude of the damage variable.
6. `UNAME=EXFAIL2` is only supported by the multi-material Euler solver with strength.
  7. `UNAME=EXFAIL1` is only supported with `MATORT`.
  8. For Lagrangian materials, `UNAME=EXFAIL` or `EXFAIL1` are only available.

## FBADLAY      Dynamic Load Time Delay for FRF Based Assembly (FBA)

Defines the time delay term  $\tau$  in the equations of motion of the dynamic loading function for frequency dependent loads in an FRF Based Assembly (FBA) process.

Format:

1	2	3	4	5	6	7	8	9	10
FBADLAY	SID	COMPID/ COMPNAME	PNTID	C	DELAY				

Examples:

FBADLAY	15	BODY	10	3	0.5				
---------	----	------	----	---	-----	--	--	--	--

FBADLAY	25	30	5	2	0.1				
---------	----	----	---	---	-----	--	--	--	--

Describer	Meaning
SID	Identification number. See Remark 1. (Integer > 0)
COMPID	Identification number of the FRF component whose FRFs have been generated in a previous Nastran execution. (Integer > 0)
COMPNAME	Name of the FRF component whose FRFs have been generated in a a previous Nastran execution. (Up to 8 characters; no blank allowed)
PNTID	Grid or scalar point identification number. See Remark 3. (Integer > 0)
C	Component number. See Remark 3. (Integer 1 through 6 for grid point; blank or 0 for scalar point)
DELAY	Time delay term $\tau$ . See Remark 4. (Real)

Remarks:

- SID is referenced by RLOAD1, RLOAD2 and ACSRCE entries.
- This entry is ignored if the specified COMPID/COMPNAME is not part of the FBA process. A user warning message is issued in this case.
- The component C of the point PNTID specified in this entry must be among the excitation degrees of freedom of the FBA process. If not, the program terminates the job with a user fatal message.
- Refer to RLOAD1, RLOAD2 and ACSRCE entries for the formulas that define the time delay term  $\tau$  in frequency response analysis.
- All FBADLAY entries specified in an FBA process are automatically converted internally by the program to equivalent DELAY entries by replacing the grid/scalar point IDs referenced in these entries by equivalent internal point IDs.

## FBALOAD

## Load Scale Factor Specification for FRF Based Assembly (FBA) Process

Defines the scale factor for frequency dependent loads in an FRF Based Assembly (FBA) process.

Format:

1	2	3	4	5	6	7	8	9	10
FBALOAD	SID	COMPID/ COMPNAME	PNTID	C	A				

Examples:

FBALOAD	10	WING	20	3	2.5				
---------	----	------	----	---	-----	--	--	--	--

FBALOAD	20	30	25	1	1.5				
---------	----	----	----	---	-----	--	--	--	--

Describer	Meaning
SID	Identification number. See Remark 1. (Integer > 0)
COMPID	Identification number of the FRF component whose FRFs have been generated in a previous Nastran execution. (Integer > 0)
COMPNAME	Optional name of the FRF component whose FRFs have been generated in a previous Nastran execution. (Up to 8 characters; no blank allowed).
PNTID	Grid or scalar point identification number. See Remark 3. (Integer > 0)
C	Component number. See Remark 3. (Integer 1 through 6 for grid point; blank or 0 for scalar point)
A	Scale factor. See Remark 4. (Real)

Remarks:

1. SID is referenced by RLOAD1, RLOAD2 and ACSRCE entries.
2. This entry is ignored if the specified COMPID/COMPNAME is not part of the FBA process. A user warning message is issued in this case.
3. The component C of the point PNTID specified in this entry must be among the excitation degrees of freedom of the FBA process. If not, the program terminates the job with a user fatal message.
4. Refer to RLOAD1, RLOAD2 and ACSRCE entries for the formulas that define the scale factor A in frequency response analysis.
5. All FBALOAD entries specified in an FBA process are automatically converted internally by the program to equivalent DAREA entries by replacing the grid/scalar point IDs referenced in these entries by equivalent internal point IDs.

**FBAPHAS**

## Dynamic Load Phase Lead for FRF Based Assembly (FBA)

Defines the phase lead term  $\theta$  in the equations of motion of the dynamic loading function for frequency dependent loads in an FRF Based Assembly (FBA) process.

Format:

1	2	3	4	5	6	7	8	9	10
FBAPHAS	SID	COMPID/ COMPNAME	PNTID	C	PHASE				

Examples:

FBAPHAS	25	FRAME	40	1	10.0				
FBAPHAS	30	50	10	2	5.0				

Descriptor	Meaning
SID	Identification number. See Remark 1. (Integer > 0)
COMPID	Identification number of the FRF component whose FRFs have been generated in a previous Nastran execution. (Integer > 0)
COMPNAME	Name of the FRF component whose FRFs have been generated in a previous Nastran execution. (Up to 8 characters; no blank allowed)
PNTID <sub>i</sub>	Grid or scalar point identification numbers. See Remark 3. (Integer > 0)
C	Component number. See Remark 3. (Integers 1 through 6 for grid points; blank or 0 for scalar points.)
PHASE	Phase lead term $\theta$ . See Remark 4. (Real)

Remarks:

1. SID is referenced by RLOAD1, RLOAD2 and ACSRCE entries.
2. This entry is ignored if the specified COMPID/COMPNAME is not part of the FBA process. A user warning message is issued in this case.
3. The component C of the point PNTID specified in this entry must be among the excitation degrees of freedom of the FBA process. If not, the program terminates the job with a user fatal message.
4. Refer to RLOAD1, RLOAD2 and ACSRCE entries for the formulas that define the phase lead term  $\theta$  in frequency response analysis.
5. All FBAPHAS entries specified in an FBA process are automatically converted internally by the program to equivalent DPHASE entries by replacing the grid/scalar point IDs referenced in these entries by equivalent internal point IDs.

## FBODYLD      Equilibrated Free-Body Applied Load Case Definition

Defines an equilibrated free-body applied load case.

Format:

1	2	3	4	5	6	7	8	9	10
FBODYLD	NAMEL	FBODYSB							
LABEL									

Example:

FBODYLD	WINGLD	WINGSB							
LOAD ON THE RIGHT WING									

Describer	Meaning
NAMEL	User defined name identifying the load case. (Character; Required)
FBODYSB	Name of a FBODYSB Bulk Data entry that defines the subsystem for this load. (Character; Required)
LABEL	A string comprising no more than 64 characters (fields 2 through 9) that identifies and labels the load case. (Character; optional)

Remarks:

1. NAMEL must be unique.
2. The Label is optional.

## FBODYSB

## Equilibrated Free-Body Subsystems Definition

Defines an equilibrated free-body subsystem.

Format:

1	2	3	4	5	6	7	8	9	10
FBODYSB	NAMES	GRIDSET	ELEMSET	XFLAG					
LABEL									

Example:

FBODYSB	WING	1	1	ADM					
RIGHT WING									

Descriptor	Meaning
NAMES	User defined name identifying the submodel. (Character; Required)
GRIDSET	Identification number of a SET1 entry that has a list of Grid Point Force grids to include in defining the subsystem. (Integer > 0)
ELEMSET	Identification number of a SET1 entry that has a list of elements to include in the system (Integer > 0 or blank)
XFLAG	Exclusion flag. Exclude the indicated Grid Point Force types. Default            Blank (no type excluded) S                    SPC forces M                    MPC forces A, L, or P        Applied loads D                    DMIG's (and any other type not described above)
Label	An optional string of up to 64 characters (fields 2 through 9) that identifies the subsystem.

Remarks:

1. Only those Grid Point Forces which have both an included grid point and element (or Grid Point Force type) will be taken into account.
2. If ELEMSET is blank, no contributions are made from the set of elements attached to the grid.
3. Fictitious grids or elements do not produce error or warning messages.
4. The XFLAG data can be any combination of the letters S,M,A,L,P and D (e.g., MAD).
5. The continuation is optional.

## FFCONTR

## Closed Volume Intended for Fluid Filled Containers

Defines the pressure within a closed volume. Intended for the use in (partially) filled containers, where dynamic fluid effects are negligible, e.g. top loading and hot filling. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FFCONTR	FFID	SID	FVOL	PATM	TEMPTAB	DENSTAB	TACTIVE		

Example:

FFCONTR	1	2	1.50E-03	0.1E6	10	20			
---------	---	---	----------	-------	----	----	--	--	--

Describer	Meaning
FFID	Unique FFCONTR identification number. (Integer > 0; Required)
SID	Number of a BSURE, BCBOX, BCPROP, BCMATL or BCSEG entry defining the closed surface. (Integer > 0; Required)
FVOL	Fluid volume in the container. (Real ≥ 0.0; Required)
PATM	Atmospheric pressure. Used for determination of the constant $C$ for $p \cdot V = C$ . (Real > 0.0; Required)
TEMPTAB	A reference to a TABLED1 ID that specifies how temperature of the container changes in time. (Integer ≥ 0; Blank)
DENSTAB	A reference to a TABLED1 ID that specifies how density of the container changes with temperature. (Integer ≥ 0; Blank)
TACTIVE	Time at which the pressure computation of the bottle is started. Until this time the pressure inside the bottle equals the ambient pressure. The volume of the bottle at TACTIVE will be used for the initial pressure computation of the gas in the bottle.

Remarks:

- If TEMPTAB is not set, the gas above the fluid is assumed to be an ideal, iso-thermal gas:  
 $p \cdot V = C$ , where  $C$  is a constant. If TEMPTAB is set, the temperature is applied to both the fluid as well as the gas. Then the gas satisfies  $p \cdot V/T = C$ , where  $T$  is the temperature of the fluid.
- The fluid is assumed incompressible.
- The pressure is based on the uniform pressure gasbag algorithm, where the pressure is uniform in the volume, but variable in time.
- Output for the fluid-filled container is available through a SURFOUT definition. The available variables are: PRESSURE, VOLUME, TEMPTURE, VOLGAS, VOLFLUID, GAUGEPRES and RHOFLUID.
- The normals of the surface referenced by SID are reversed automatically if required.

6. Modeling guidelines are described in the “Getting Started” Section.
7. If DENSTAB is set then volume of the fluid changes according to

$$V^{Fluid} = \frac{\rho(T_0)V_0^{Fluid}}{\rho(T)}$$

Here  $T_0$  and  $V_0^{Fluid}$  are initial values for temperature and fluid volume,  $\rho$  is the fluid density and  $T$  denotes the current temperature. If TEMPTAB is not set the DENSTAB entry will not be used.

8. At time=TACTIVE the gas is assumed to be in contact with the ambient pressure for the last time. This means that at Time = TACTIVE the pressure in the bottle equals the ambient pressure. After TACTIVE the bottle has been closed and there is no longer contact between ambient and gas inside the bottle. Any change in volume of the bottle or temperature or fluid will result in change of pressure of the gas inside the bottle.

## FLFACT Aerodynamic Physical Data

Used to specify density ratios, Mach numbers, reduced frequencies, and velocities for flutter analysis.

Format:

1	2	3	4	5	6	7	8	9	10
FLFACT	SID	F1	F2	F3	F4	F5	F6	F7	
	F8	F9	-etc.-						

Example:

FLFACT	97	.3	.7	3.5					
--------	----	----	----	-----	--	--	--	--	--

Alternate Format and Example:

FLFACT	SID	F1	"THRU"	FNF	NF	FMID			
FLFACT	201	.200	THRU	.100	11	.133333			

Describer	Meaning
SID	Set identification number. (Unique Integer > 0)
F <sub>i</sub>	Aerodynamic factor. (Real)
FNF	Final aerodynamic factor. (Real)
NF	Number of aerodynamic factors. (Integer > 0)
FMID	Intermediate aerodynamic factors. See Remark 4. (Real)

Remarks:

1. Only the factors selected by a FLUTTER entry will be used.
2. Embedded blank fields are not allowed in the first format above.
3. The factors must be specified in the order in which they are to be used within the looping of flutter analysis.
4. *FMID* must lie between *F1* and *FNF*; otherwise, *FMID* will be set to  $(F1 + FNF)/2$ .

Then

$$F_i = \frac{F1(FNF - FMID)(NF - i) + FNF(FMID - F1)(i-1)}{(FNF - FMID)(NF - i) + (FMID - F1)(i-1)}$$

where  $i = 1, 2, \dots, NF$

The use of FMID (middle factor selection) allows unequal spacing of the factors.

$$FMID = \frac{2 \cdot F1 \cdot FNF}{F1 + FNF} \text{ gives equal values to increments of the reciprocal}$$

of  $F_i$ .

5. If method = PK and this entry specifies velocities, then the velocities must be non-zero. Input of negative values produces eigenvector results at a velocity equal to the positive value of the input. Input of positive values provide eigenvalues results without eigenvectors.

## FLOW

## Flow Boundary Condition

Defines the properties of a material for the boundaries of an Eulerian mesh. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FLOW	LID	BCID	MESH	DIR					
	XMIN	XMAX	YMIN	YMAX	ZMIN	ZMAX			
	TYPE1	VALUE1	TYPE2	VALUE2	TYPE3	VALUE3	TYPE4	VALUE4	
	TYPE5	VALUE5							

Example:

FLOW	120	122							
	XVEL	100.0							

Describer	Meaning
LID	Number of a set of flow boundary conditions. (Integer > 0; Required)
BCID	Number of a set of segments, specified by BCSEG entries, where the flow boundary is located. See Remark 5. (Integer ≥ 0)
MESH	Denotes the ID of the Euler mesh to which the boundary condition has to be applied. See Remark 6. (Integer ≥ 0)
DIR	Allowed values are: NEGX, POSX, NEGY, POSY, NEGZ and POSZ. See Remark 7. (Character)
XMIN-ZMAX	Defines a square by specifying the ranges of the x,y,z coordinates. For a square in for example the x-plane it is required that either XMIN = XMAX or that XMAX is left blank. See Remark 8. (Real)
TYPEi	The flow boundary property being defined. (Character)
	Material                      The MATDEUL ID number.
	XVEL                            The material velocity in the x-direction.
	YVEL                            The material velocity in the y-direction.
	ZVEL                            The material velocity in the z-direction.
	PRESSURE                    The pressure of the material at the boundary.
	DENSITY                      The density of the material at inflow.
	SIE                              The specific internal energy at inflow
	FLOW                          The type of flow boundary required.

Describer	Meaning
VALUEi	<p>HYDSTAT                    A Hydrostatic pressure profile using a HYDSTAT entry.</p> <p>The value for the property defined. (Real; Integer or Character; Required)</p> <p>For TYPEi set to FLOW, the value is a character entry being either IN, OUT, BOTH or SYM defining that the flow boundary is defined as an inflow, outflow, possibly an in- or outflow or symmetry boundary. The default is BOTH.</p> <p>VALUEi is required data only if one or more of the TYPEi entries are defined. The TYPEi entries are not required. Thus, a flow boundary by default allows for in- or outflow of the material adjacent to the boundary.</p> <p>For TYPE = HYDSTAT, the value is an integer entry denoting the HYDSTAT entry to be used.</p>

Remarks:

1. LID must be referenced by a TLOAD1 entry.
2. Any material properties not specifically defined have the same value as the element with the flow boundary condition.
3. TLOAD entries referencing FLOW entries must have the TID field blank or zero.
4. In the case of material flow into a multi-material Euler mesh, the density and specific energy have to be set. On the other hand when material flows out of a multi-material Euler mesh it is assumed that each of the materials present in the outflow Euler element contributes to the out flow of mass. The materials are transported in proportion to their relative volume fractions.
5. BCID is optional. If used, all other inputs are ignored. If not used, the flow boundary can be defined by either using DIR or by using XMIN, XMAX, YMIN, etc.
6. The MESH-ID is only used when multiple Euler domains have been defined and when BCID is blank. If multiple Euler domains have been defined but if the MESH-ID is blank all Euler domains will be considered in assigning the boundary condition.
7. DIR is optional. It will only be used when BCID is blank. When DIR is used XMIN, XMAX, YMIN etc. are ignored.
8. XMIN, XMAX, YMIN, etc. are only used when both BCID and DIR are blank. If neither the MIN nor MAX value has been set the default value is respectively -1E+20 and 1E+20 for the MIN and MAX value. If the MIN value has been set the default value of the MAX value is the Min value.
9. Prescribing both pressure and velocity may lead to the instabilities.
10. For TYPE = HYDSTAT, the pressure is set using HYDSTAT, the velocity equals the element velocity. In case of inflow the density follows from the hydrostatic pressure by using the equation of state.

## FLOWC

## Cyclic Flow Boundary Condition

Defines the properties of a material for the boundaries of a Eulerian mesh.

Inflow values can be taken from another boundary condition. This allows cyclic or periodic boundary conditions. Likewise, the outflow of material goes into the other boundary condition.

FLOWC entries have to be defined in pairs. The FID on one entry has to be equal to FID2 of the other entry. For example

```
FLOWC, 10, 30, 20
```

```
FLOWC, 20, 40, 10
```

For FLOWC boundaries, mass flow summaries can be created as time history. Used in SOL700 only

Format:

1	2	3	4	5	6	7	8	9	10
FLOWC	FID	BCID	TYPE	MESH	DIR	FID2			+
+	XMIN	XMAX	YMIN	YMAX	ZMIN	ZMAX			+
+	METHOD	TID							

Example:

FLOWC	1	122	2						
+									
+	2	1							

Field	Contents
FID	Unique number of a FLOWC entry. (Integer > 0; Required)
BCID	Number of a set of segments specified by the BCSEG entries where the flow boundary is located. See Remark 3. (Integer > 0)

Field	Contents
TYPE	<p>Flow boundary types. See Remarks 2.and 3. (Character; Required)</p> <p>IN: Only inflow is allowed. The inflow velocity and pressure can be optionally specified. If not given, the values in the adjacent Euler element will be used. The same holds for the density and sic.</p> <p>OUT: Only outflow is allowed. The inflow velocity and pressure can be optionally specified. If not given, the values in the adjacent Euler element will be used. The outflow boundary will always use material mixture as present in the adjacent Euler element.</p> <p>BOTH: Material is allowed to flow in or out. In or outflow is based on the direction of the velocity in the adjacent Euler element. Only pressure can be optionally defined. If not given the pressure in the adjacent Euler element will be taken.</p>
MESH	Denotes the ID of the Euler mesh to which the boundary condition has to be applied. See Remark 4. (Integer > 0)
DIR	Allowed values are: NEGX, POSX, NEGY, POSY, NEGZ and POSZ. See Remark 5. (Character; no default)
FID2	Referenced FLOWC id from which inflow and outflow values will be taken from. (Integer > 0; Required)
XMIN-ZMAX	Defines a square by specifying the ranges of the x,y,z coordinates. For a square in for example the x-plane it is required that either XMIN = XMAX or that XMAX is left blank. See Remark 6. (Real)
METHOD	<p>Method describing how material properties and pressure are mapped going from one boundary to the other. (Integer &gt; 0; Default=1)</p> <ol style="list-style-type: none"> <li>1. Map both velocity, material flow properties, and pressure loads one-to-one.</li> <li>2. Map velocity, material flow one-to-one. Pressure is given by element pressures.</li> <li>3. Inflow is taken as the average of outflow properties. This applies to both velocity and material properties. Pressure is given by element pressures.</li> </ol>
TID	TABLED1 ID that specifies a time dependent scale factor by which the amount of inflow is multiplied. This will not conserve total mass. (Integer > 0. Default = not used).

Remarks:

1. LID must be referenced by a TLOAD1 entry.
2. TLOAD entries referencing FLOW entries must have the TID field blank or zero.
3. BCID is optional. If used, all other inputs are ignored. If not used, the flow boundary can be defined by either using DIR or by using XMIN, XMAX, YMIN, etc.
4. The MESH-ID is only used when multiple Euler domains have been defined and when BCID is blank. If multiple Euler domains have been defined but if the MESH-ID is blank all Euler domains will be considered in assigning the boundary condition.

5. DIR is optional. It will only be used when BCID is blank. When DIR is used XMIN, XMAX, YMIN etc. are ignored.
6. XMIN, XMAX, YMIN, etc. are only used when both BCID and DIR are blank. If neither the MIN nor MAX value has been set the default value is respectively  $-1E+20$  and  $1E+20$  for the MIN and MAX value. If the MIN value has been set the default value of the MAX value is the Min value.
7. FLOWC can be used to specify flow boundaries for CHEXA's and also for Euler element created by the MESH,BOX option.
8. FLOWC is only supported by the multi-material Euler solver.
9. To enable using the outflow values of FID2 as the inflow values for FID, the boundary faces of FID and FID2 are mapped onto each other. For this mapping, only translations and rotations around coordinate axes are permitted.
10. Consider a cubic Euler mesh and that material flows from the left to the right. At the right side, the boundary condition is imposed

FLOWC,4,30,,5

and at the left side

FLOWC,5,40,,4

These definitions cause all material that flows out of the right side boundary into the left side boundary. Moreover, the Euler element pressures on the right side are put on the Euler elements of the left boundary condition.

In practice, it may be useful to skip the coupling between the two boundaries with regard to pressure. This can be done by setting METHOD equal to 2.

With these definitions, material from boundary 4 still flows into boundary 5 but pressure boundaries are transmitting.

11. TID is useful if several objects have identical outflow that is used as inflow by another object. Then only one object has to be modeled. To account for the other objects when defining inflow, the scale factor can be used. It can also be used to turn off in and outflow. When TID is set, either METHOD=2 or METHOD=3 are recommended and METHOD=1 should not be used.
12. It is allowed that the definition of the FLOWC entry overlaps with FLOW definitions. In that case, the FLOWC definition overrules the other ones

## FLOWDEF

## Default Flow Boundary

Definition of default Eulerian flow boundary condition. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FLOWDEF	FID		TYPEM						
	TYPE1	VALUE1	TYPE2	-etc.-					

Example:

FLOWDEF	25		HYDRO						
	DENSITY	1000							

Describer	Meaning
FID	Unique FLOWDEF number. (Integer > 0; Required)
TYPEM	HYDRO, STRENGTH, MMHYDRO, or MMSTREN. (Character, HYDRO)
TYPEi	The flow boundary property being defined. (Character)
Material	The MATDEUL ID number.
XVEL	The material velocity in the x-direction.
YVEL	The material velocity in the y-direction.
ZVEL	The material velocity in the z-direction.
PRESSURE	The pressure of the material at the boundary.
DENSITY	The density of the material at inflow.
SIE	The specific internal energy at inflow
FLOW	The type of flow boundary required.
HYDSTAT	A Hydrostatic pressure profile using a HYDSTAT entry.
VALUEi	The value for the property defined. (Real; Integer or Character; Required)
	For TYPEi set to flow the value is a character entry being either IN, OUT, or BOTH, defining that the flow boundary is defined as an inflow, outflow, or possibly an in- or outflow boundary. The default is BOTH.
	VALUEi is required data only if one or more of the TYPEi entries are defined. The TYPEi entries are not required. Thus, a flow boundary by default allows for in- or outflow of the material adjacent to the boundary.
	For TYPE = HYDSTAT, the value is an integer entry denoting the HYDSTAT entry to be used.

Remark:

1. If this entry is not specified, a default wall boundary condition is applied to all Eulerian free faces.
2. For TYPE = HYDSTAT, the pressure is set using HYDSTAT, the velocity equals the element velocity. In case of inflow the density follows from the hydrostatic pressure by using the equation of state.

## FLOWT

## Time Dependent Flow Boundary

Defines the material properties for the in- or outflow of material through the boundary of an Euler mesh. Inflow velocity and material properties can be chosen time dependent. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FLOWT	FID	BCID	TYPE	MESH	DIR				
	XMIN	XMAX	YMIN	YMAX	ZMIN	ZMAX			
	VELTYPE	VELOCITY	PRESTYP	PRES					
	MID	DENSTYP	DENSITY	SIETYPE	SIE				

Example:

FLOWT	2	122	IN						
	TABLE	101	TABLE	102					
	91	TABLE	104	TABLE	107				

Describer	Meaning
FID	Unique number of a FLOWT entry. (Integer > 0; Required)
BCID	Number of a set of segments specified by the BCSEG entries where the flow boundary is located. See Remark 3. (Integer ≥ 0)
TYPE	<p>IN                    Inflow boundary. See Remarks 2.and 3. (Character; Required) Only inflow is allowed. The inflow velocity and pressure can be optionally specified. If not given, the values in the adjacent Euler element will be used. The same holds for the density and sie.</p> <p>OUT                    Only outflow is allowed. The inflow velocity and pressure can be optionally specified. If not given, the values in the adjacent Euler element will be used. The outflow boundary will always use material mixture as present in the adjacent Euler element.</p> <p>BOTH                    Material is allowed to flow in or out. In or outflow is based on the direction of the velocity in the adjacent Euler element. Only pressure can be optionally defined. If not given the pressure in the adjacent Euler element will be taken.</p>
MESH	Denotes the ID of the Euler mesh to which the boundary condition has to be applied. See Remark 4. (Integer ≥ 0)
DIR	Allowed values are: NEGX, POSX, NEGY, POSY, NEGZ and POSZ. See Remark 5. (Character)

Describer	Meaning
XMIN-ZMAX	Defines a square by specifying the ranges of the x,y,z coordinates. For a square in for example the x-plane it is required that either XMIN = XMAX or that XMAX is left blank. See Remark 6. (Real)
VELTYPE	Type of velocity definition. (Character, Element) ELEMENT Value of Euler Element CONSTANT Value is constant in time TABLE Value varies in time
VELOCITY	Value of inflow or outflow velocity. If VELTYPE = TABLE it refers to a TABLED1. The velocity direction is normal to the coupling surface or subsurface. A positive velocity corresponds with inflow. See Remark 6. (Integer or Real)
PRESTYP	Type of pressure definition (Character, Element) ELEMENT Value of Euler element CONSTANT Value is constant in time TABLE Value varies in time
PRES	Value of inflow or outflow pressure. If PRESTYPE = TABLE it refers to a TABLED1 ID. (Integer or Real)
MID	MATDEUL ID of inflowing material. Input is not allowed for TYPE = OUT. When MID is specified, it is required to also define density and sie for the inflowing material. (Integer)
DESTYP	Type of density definition. (Character, Default is required when MID is given.) ELEMENT Value of Euler element CONSTANT Value is constant in time TABLE Value varies in time
DENSITY	Value of density. If DENSTYP = TABLE it refers to a TABLED1 ID. (Character; Default is required when MID is given.)
SIETYPE	Type of density definition. (Character; Default is required when MID is given.) ELEMENT Value of Euler element CONSTANT Value is constant in time TABLE Value varies in time.
SIE	Value of specific internal energy. If SIETYPE = TABLE it refers to a TABLED1 ID. (Integer or Real; Default is required when MID is given.)

## Remarks:

1. LID must be referenced by a TLOAD1 entry.
2. TLOAD entries referencing FLOW entries must have the TID field blank or zero.

3. BCID is optional. If used, all other inputs are ignored. If not used, the flow boundary can be defined by either using DIR or by using XMIN, XMAX, YMIN, etc.
4. The MESH-ID is only used when multiple Euler domains have been defined and when BCID is blank. If multiple Euler domains have been defined but if the MESH-ID is blank all Euler domains will be considered in assigning the boundary condition.
5. DIR is optional. It will only be used when BCID is blank. When DIR is used XMIN, XMAX, YMIN etc. are ignored.
6. XMIN, XMAX, YMIN, etc. are only used when both BCID and DIR are blank. If neither the MIN nor MAX value has been set the default value is respectively  $-1E+20$  and  $1E+20$  for the MIN and MAX value. If the MIN value has been set the default value of the MAX value is the Min value.
7. Any material properties not specifically defined have the same value as the element that with the boundary conditions.
8. In the case of material flow into a multi-material Euler mesh, the material number, the density and specific energy have to be set. On the other hand when material flows out of a multi-material Euler mesh it is assumed that each of the materials present in the outflow Euler element contributes to the out flow of mass. The materials are transported in proportion to their relative volume fractions
9. The boundary condition initiates/determines a wave in compressible material like gas and water. This can be either an outgoing or an ingoing wave. For stability it is important that the waves created are compatible with the flow type near the boundary. Relevant flow types are subsonic inflow, subsonic outflow, supersonic inflow and supersonic outflow. For example for subsonic inflow prescribing both pressure and velocity would initiate outgoing waves. Outgoing waves for an inflow boundary condition is known to be instable. However, for supersonic inflow one can specify both pressure and velocities there are no outgoing waves at a supersonic inflow boundary.

## FLOWUDS

## User Defined Flow Boundary.

Defines a flow boundary on an Eulerian mesh specified by a user subroutine. Use in SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FLOWUDS	LID	GROUP	UNAME	BCID	MESH	DIR			
+	XMIN	XMAX	YMIN	YMAX	ZMIN	ZMAX			

Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE myflow 'SCA.MDSolver.Obj.Uds.Dytran.Flow'
```

*In Bulk Data:*

1	2	3	4	5	6	7	8	9	10
FLOWUDS	12	MYFLOW	EXFLOW	300					

Descriptor	Meaning
LID	Unique output number. (Integer > 0; Required)
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default)
UNAME	User subroutine name associated with the entry. (Character; default=EXFLOW)
BCID	Number of a set of segments, specified by BCSEG entries, where the flow boundary is located. See Remark 6. (Integer > 0)
MESH	Denotes the ID of the Euler mesh to which the boundary condition has to be applied. See Remark 7. (Integer > 0)
DIR	Allowed values are: NEGX, POSX, NEGY, POSY, NEGZ and POSZ. See Remark 8. (Character)
XMIN-ZMAX	Defines a square by specifying the ranges of the x,y,z coordinates. For a square in for example the x-plane it is required that either XMIN = XMAX or that XMAX is left blank. See Remark 9. (Real)

Remarks:

1. Only can be used for SOL 700.
2. UNAME can be:

Subroutine Name	Function
EXFLOW	Standard user defined flow boundary on the Euler mesh

3. For multi material models EXFLOW allows for the definition of any material to flow into the Eulerian mesh. The outflow can only be of materials present in the mesh.
4. TLOAD1 entries referencing FLOWUDS entries must have the TID field blank or zero.
5. BCID is optional. If used, all other inputs are ignored. If not used, the flow boundary can be defined by either using DIR or by using XMIN, XMAX, YMIN, etc.
6. The MESH-ID is only used when multiple Euler domains have been defined and when BCID is blank. If multiple Euler domains have been defined but if the MESH-ID is blank all Euler domains will be considered in assigning the boundary condition.
7. DIR is optional. It will only be used when BCID is blank. When DIR is used XMIN, XMAX, YMIN etc. are ignored.
8. XMIN, XMAX, YMIN, etc. are only used when both BCID and DIR are blank. If neither the MIN nor MAX value has been set the default value is respectively  $-1E+20$  and  $1E+20$  for the MIN and MAX value. If the MIN value has been set the default value of the MAX value is the MIN value.

## FLSYM Axisymmetric Symmetry Control

Defines the relationship between the axisymmetric fluid and a structural boundary having symmetric constraints. The purpose is to allow fluid boundary matrices to conform to structural symmetry definitions.

Format:

1	2	3	4	5	6	7	8	9	10
FLSYM	M	S1	S2						

Example:

FLSYM	12	S	A						
-------	----	---	---	--	--	--	--	--	--

Describer	Meaning
M	Number of symmetric sections of structural boundary around the circumference of the fluid being modeled by the set of structural elements. (Even Integers $\geq 2$ )
S1, S2	Description of boundary constraints used on the structure at the first and second planes of symmetry. (Character: "S" means symmetric, "A" means antisymmetric.)

Remarks:

1. This entry is allowed only if an AXIF entry is also present.
2. Only one FLSYM entry is allowed.
3. This entry is not required if there are no planes of symmetry.
4. First plane of symmetry is assumed to be at  $\phi = 0$ . Second plane of symmetry is assumed to be at  $\phi = 360^\circ/M$ .
5. Symmetric and antisymmetric constraints for the structure must, in addition, be provided by the user.
6. The solution is performed for those harmonic indices listed on the AXIF entry that are compatible with the symmetry conditions.
7. For example, if FLSYM is used to model a quarter section of structure at the boundary,  $M = 4$ . If the boundary constraints are "SS", the compatible cosine harmonics are 0, 2, 4, ..., etc. If "SA" is used, the compatible cosine harmonics are 1, 3, 5, ..., etc.

## FLUTTER

## Aerodynamic Flutter Data

Defines data needed to perform flutter analysis.

Format:

1	2	3	4	5	6	7	8	9	10
FLUTTER	SID	METHOD	DENS	MACH	RFREQ	IMETH	NVALUE/ OMAX	EPS	

Example:

FLUTTER	19	K	119	219	319	S	5	1.-4	
---------	----	---	-----	-----	-----	---	---	------	--

Descriptor	Meaning
SID	Set identification number. (Integer > 0)
METHOD	Flutter analysis method. (Character: “K” for K method, “PK” for PK method, “PKNL” for PK method with no looping, “PKS” for PK sweep method, “PKNLS” for PK sweep method with no looping, “KE” for the K method restricted for efficiency.) See Remark 9.
DENS	Identification number of an FLFACT entry specifying density ratios to be used in flutter analysis. (Integer > 0)
MACH	Identification number of an FLFACT entry specifying Mach numbers ( $m$ ) to be used in flutter analysis. (Integer > 0)
RFREQ (or VEL)	Identification number of an FLFACT entry specifying reduced frequencies ( $k$ ) to be used in flutter analysis; for the “PKx” methods, the velocities FLFACT entry is specified in this field. (Integer > 0)
IMETH	Choice of interpolation method for aerodynamic matrix interpolation. See Remark 6. (Character: “L” = linear, “S” = surface; “TCUB” = termwise cubic; Default = “L”.)
NVALUE	Number of eigenvalues beginning with the first eigenvalue for output and plots. (Integer > 0; Default is the number of modal degrees-of-freedom ( $u_h$ ).)
OMAX	For the PKS and PKNLS methods, OMAX specifies the maximum frequency, in Hz., to be used in the flutter sweep. (Real > 0.0; Default = maximum normal mode eigenfrequency)
EPS	Convergence parameter for $k$ . Used in the PK and PKNL methods only. See Remark 4. (Real > 0.0; Default = $10^{-3}$ .) See Remark 9. for the meaning of EPS when the PKS or PKNLS methods are being used.

Remarks:

1. The FLUTTER entry must be selected with the Case Control command FMETHOD = SID.

2. The density is given by  $DENS \cdot RHOREF$ , where RHOREF is the reference value specified on the AERO entry and DENS is the density ratio specified on the FLFACT entry.
3. The reduced frequency is given by  $k = (REFC \cdot \omega / 2 \cdot V)$ , where REFC is given on the AERO entry,  $\omega$  is the circular frequency, and  $V$  is the velocity. If  $k = 0.0$ , as specified on the FLFACT entry, then only the K method may be specified and the Inverse Power method of eigenvalue extraction (INV on the EIGC entry) must be used. Aeroelastic divergence analysis is more appropriately performed using one of the “PKx” methods.
4. For the PK and PKNL methods, an eigenvalue is accepted when:

$$|k - k_{estimate}| < EPS \quad \text{for } k_{estimate} < 1.0$$

$$|k - k_{estimate}| < EPS \cdot k_{estimate} \quad \text{for } k_{estimate} \geq 1.0$$

5. When one of the “PKx” methods is selected, physical displacements will only be generated for the velocities on the FLFACT that are specified as negative values of the requested velocity. Also, structural damping as specified on the GE field of MATi entries is ignored.
  6. If IMETH = “L”, a linear interpolation is performed on reduced frequencies at the Mach numbers specified on the FLFACT entry using the MKAEROi entry Mach number that is closest to the FLFACT entry Mach number. For IMETH = “S”, a surface interpolation is performed across Mach numbers and reduced frequencies. For IMETH = “TCUB” a termwise cubic interpolation on reduced frequency is used. IMETH = “S” is only available for the “K” and “KE” flutter methods. IMETH = “TCUB” is only available for the “PKx” methods. For the “PKx” methods, IMETH = “S” or “L” or blank provides linear interpolation while “TCUB” provides a termwise cubic interpolation.
  7. For the “K”, “KE”, “PK”, and “PKS” methods, all combinations of the FLFACT entry are analyzed. For the “PKNL” and “PKNLS” methods, only ordered pairs are analyzed; i.e.,  $(\rho_1, M_1, V_1), (\rho_2, M_2, V_2) \dots (\rho_n, M_n, V_n)$ . For the PKNL and PKNLS methods, equal number of densities, Mach numbers and velocities must be specified.
  8. “K” and “KE” methods are not supported for design sensitivity and optimization.
  9. The PKS and PKNLS methods determine flutter eigenvalues by performing a sweep of equally spaced reduced frequencies ranging from  $k_{est} = 0.0$  through  $k_{est} = \pi \cdot REFC \cdot OMAX / \text{Velocity}$ . The number of intervals is calculated using  $NINT = INT(1.0/EPS)$ .
- 10.
- The PK method uses only real matrix terms for computing the flutter solution. This means any imaginary terms in any of the matrices, M, B, or K are ignored with the PK method and the imaginary part of the aerodynamic matrix is added as a real matrix to the viscous damping matrix B.
  - For the KE method, the B matrix is ignored while complex stiffness forms of structural damping are supported. Modal viscous damping (TABDMP1 input) will be included when the KDAMP parameter is set to -1.
  - The K method supports all forms of damping.

11. METHOD=K requires a CMETHOD in Case Control pointing to an EIGC Bulk Data entry. It is recommended that the number of roots requested on the EIGC entry be twice the number of normal modes used in the modal flutter analysis.

## FORCE

## Static Force

Defines a static concentrated force at a grid point by specifying a vector.

Format:

1	2	3	4	5	6	7	8	9	10
FORCE	SID	G	CID	F	N1	N2	N3		

Example:

FORCE	2	5	6	2.9	0.0	1.0	0.0		
-------	---	---	---	-----	-----	-----	-----	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
G	Grid point identification number. (Integer > 0)
CID	Coordinate system identification number. (Integer $\geq$ 0; Default = 0)
F	Scale factor. (Real)
Ni	Components of a vector measured in coordinate system defined by CID. (Real; at least one $N_i \neq 0.0$ , unless F is zero)

Remarks:

1. The static force applied to grid point G is given by

$$\vec{f} = F\vec{N}$$

where  $\vec{N}$  is the vector defined in fields 6, 7 and 8. The magnitude of  $\vec{f}$  is equal to F times the magnitude of  $\vec{N}$ .

2. In the static solution sequences, SID must be selected by the LOAD Case Control command. In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
3. A CID of zero or blank (the default) references the basic coordinate system.
4. For scalar points see SLOAD.
5. For TYPE=12 or TYPE=13 on the TLOAD1, G is the ID of a rigid body: the MID of a rigid material MATRIG or the EID of a RBE2. The MID of a rigid material and the EID of RBE2 must be different when both of a RBE2 and a rigid material are used with these TYPEs. SOL 700 only.
6. For axisymmetric elements, the point loads to be entered on the card should be obtained by integrating over 1 radian of the circumference.

## FORCE1

## Follower Force, Alternate Form 1

Defines a concentrated force at a grid point by specification of a magnitude and two grid points that determine the direction.

Format:

1	2	3	4	5	6	7	8	9	10
FORCE1	SID	G	F	G1	G2				

Example:

FORCE1	6	13	-2.93	16	13				
--------	---	----	-------	----	----	--	--	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
G	Grid point identification number. (Integer > 0)
F	Magnitude of the force. (Real)
G1, G2	Grid point identification numbers. (Integer > 0; G1 and G2 may not be coincident.)

Remarks:

1. The force applied to grid point G is given by

$$\vec{f} = F\vec{n}$$

where  $\vec{n}$  is a unit vector parallel to a vector from G1 to G2.

2. In the static solution sequences, SID must be selected by the LOAD Case Control command. In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
3. The follower force effects due to loads from this entry are included in the stiffness in all linear solution sequences that calculate a differential stiffness. The solution sequences are SOLs 103, 105, 107 to 112, 115 and 116 (see also the parameter [FOLLOWK](#)). In addition, follower force effects are included in the force balance in the nonlinear static and nonlinear transient dynamic solution sequences, SOLs 106, 129, 153, 159, 400, if geometric nonlinear effects are turned on with PARAM,LGDISP,1. The follower force stiffness is included in the nonlinear static solution sequences (SOLs 106, 153 and 400) but not in the nonlinear transient dynamic solution sequences (SOLs 129 and 159).
4. For axisymmetric elements, the point loads to be entered on the card should be obtained by integrating over 1 radian of the circumference.

## FORCE2

## Follower Force, Alternate Form 2

Defines a concentrated force at a grid point by specification of a magnitude and four grid points that determine the direction.

Format:

1	2	3	4	5	6	7	8	9	10
FORCE2	SID	G	F	G1	G2	G3	G4		

Example:

FORCE2	6	13	-2.93	16	13	17	13		
--------	---	----	-------	----	----	----	----	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
G	Grid point identification number. (Integer > 0)
F	Magnitude of the force. (Real)
Gi	Grid point identification numbers. (Integer > 0; G1 and G2 may not be coincident; G3 and G4 cannot be coincident.)

Remarks:

1. The direction of the force is parallel to the cross product of vectors from G1 to G2 and G3 to G4.
2. In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
3. The follower force effects due to loads from this entry are included in the stiffness in all linear solution sequences that calculate a differential stiffness. The solution sequences are SOLs 103, 105, 107 to 112, 115 and 116 (see also the parameter [FOLLOWK](#)). In addition, follower force effects are included in the force balance in the nonlinear static and nonlinear transient dynamic solution sequences, SOLs 106, 129, 153, 159, and 400 if geometric nonlinear effects are turned on with PARAM,LGDISP,1. The follower force stiffness is included in the nonlinear static solution sequences (SOLs 106, 153 and 400) but not in the nonlinear transient dynamic solution sequences (SOLs 129 and 159).
4. For axisymmetric elements, the point loads to be entered on the card should be obtained by integrating over 1 radian of the circumference.

## FORCEAX

### Conical Shell Static Force

Defines a static concentrated force on a conical shell ring.

Format:

1	2	3	4	5	6	7	8	9	10
FORCEAX	SID	RID	HID	S	FR	FP	FZ		

Example:

FORCEAX	1	2	3	2.0	0.1	0.2	0.3		
---------	---	---	---	-----	-----	-----	-----	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
RID	RINGAX entry identification number. (Integer > 0)
HID	Harmonic identification number or a sequence of harmonics. See Remark 5. (Integer ≥ 0)
S	Scale factor for the force. (Real)
FR, FP, FZ	Force components in $r$ , $\phi$ , $z$ directions. (Real)

Remarks:

1. FORCEAX is allowed only if an AXIC entry is also present.
2. Axisymmetric shell loads must be selected with the Case Control command LOAD = SID.
3. A separate entry is needed for the definition of the force associated with each harmonic.
4. See [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide* for further discussion.
5. If a sequence of harmonics is to be placed in HID, the form is as follows: “Sn1Tn2” where n1 is the start of the sequence and n2 is the end of the sequence (e.g., for harmonics 0 through 10, the field would contain “S0T10”).

## FORCUDS

### User-defined Enforced Motion at Grid Points

Defines enforced motion at grid points specified by a user subroutine. Used in SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
FORCUDS	LID	GROUP	UNAME						
+	G1	G2	THRU	G3					

Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE extvel 'SCA.MDSolver.Obj.Uds.Dytran.Loads '
```

*In Bulk Data:*

FORCUD	1	EXTVEL							
+	1	2	3	5					

Describer	Meaning
LID	Number of a set of loads.(Integer>0;required)
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; required)
UNAME	User subroutine name associated with the entry. (Character; default=EXTVEL)
Gi	Numbers of the grid points that are constrained. If the word THRU appears between two numbers, all the numbers in the range are included in the list. BY indicates the increment to be used within this range. (Integer or character; required.)

Remarks:

1. LID must be referenced by a TLOAD1 entry.
2. FORCUDS can only be used to specify enforced velocities for grid points. The TYPE field on the TLOAD1 entry must be set to two. The TID on the TLOAD1 entry must be set to zero or blank (no time variation).
3. The GROUP name must be unique from all other GROUP names if more than one FORCUDS is used. Therefore each FORCUDS must have its own group name in a FMS section CONNECT SERVICE statement.
4. The constraint name is passed to the subroutine and can be used to identify the constraint.
5. A THRU specification, including the start and finish points in the range, must be on one line.
6. If the THRU specification is used, all the points in the sequence do not have to exist. Those that do not exist are ignored. The first point in the THRU specification must be a valid grid point. BY can be used to exclude grid points.

7. None of the fields in the list of grid points can be blank or zero, since this designation marks the end of the list.
8. Any number of continuation lines can be used to define the list of grid points.
9. UNAME can be:

Subroutine Name	Function
EXTVEL	user defined velocities on grid points

## FREEPT Fluid Free Surface Point

Defines the location of points on the surface of a fluid for recovery of surface displacements in a gravity field.

Format:

1	2	3	4	5	6	7	8	9	10
FREEPT	IDF	IDP1	PHI1	IDP2	PHI2	IDP3	PHI3		

Example:

FREEPT	3	301	22.5	302	90.0	303	370.0		
--------	---	-----	------	-----	------	-----	-------	--	--

Describer	Meaning
IDF	RINGFL entry identification number. (Integer > 0)
IDPi	Free surface point identification number. (Integer > 0)
PHIi	Azimuthal position on fluid point (RINGFL entry) in the fluid coordinate system. (Real)

Remarks:

1. FREEPT is allowed only if an AXIF entry is also present.
2. All free surface point identification numbers must be unique with respect to other scalar, structural, and fluid points.
3. The free surface points are used for the identification of output data only.
4. Three points may be defined on a single entry.
5. The referenced fluid point (IDF) must be included in a free surface list (FSLIST entry).
6. Output requests for velocity and acceleration can be made at these points.

## FREQ Frequency List

Defines a set of frequencies to be used in the solution of frequency response problems.

Format:

1	2	3	4	5	6	7	8	9	10
FREQ	SID	F1	F2	F3	F4	F5	F6	F7	
	F8	F9	F10	-etc.-					

Example:

FREQ	3	2.98	3.05	17.9	21.3	25.6	28.8	31.2	
	29.2	22.4	19.3						

Descriptor	Meaning
SID	Set identification number. (Integer > 0)
Fi	Frequency value in units of cycles per unit time. (Real ≥ 0.0)

Remarks:

1. Frequency sets must be selected with the Case Control command FREQUENCY = SID.
2. All FREQi entries with the same frequency set identification numbers will be used. Duplicate frequencies will be ignored.  $f_N$  and  $f_{N-1}$  are considered duplicated if

$$|f_N - f_{N-1}| < \text{DFREQ} \cdot |f_{MAX} - f_{MIN}|,$$

where DFREQ is a user parameter, with a default of  $10^{-5}$ .  $f_{MAX}$  and  $f_{MIN}$  are the maximum and minimum excitation frequencies of the combined FREQi entries.

3. In modal analysis, solutions for modal DOFs from rigid body modes at zero excitation frequencies may be discarded. Solutions for nonzero modes are retained.
4. If Modules are present then this entry may only be specified in the main Bulk Data section.

## FREQ1

### Frequency List, Alternate Form 1

Defines a set of frequencies to be used in the solution of frequency response problems by specification of a starting frequency, frequency increment, and the number of increments desired.

Format:

1	2	3	4	5	6	7	8	9	10
FREQ1	SID	F1	DF	NDF					

Example:

FREQ1	6	2.9	0.5	13					
-------	---	-----	-----	----	--	--	--	--	--

Describer	Meaning
SID	Set identification number. (Integer > 0)
F1	First frequency in set. (Real ≥ 0.0)
DF	Frequency increment. (Real > 0.0)
NDF	Number of frequency increments. (Integer > 0; Default = 1)

Remarks:

1. FREQ1 entries must be selected with the Case Control command FREQUENCY = SID.
2. The units for F1 and DF are cycles per unit time.
3. The frequencies defined by this entry are given by

$$f_i = F1 + DF \cdot (i-1)$$

where  $i = 1$  to  $(NDF + 1)$ .

4. All FREQ<sub>i</sub> entries with the same frequency set identification numbers will be used. Duplicate frequencies will be ignored.  $f_N$  and  $f_{N-1}$  are considered duplicated if

$$|f_N - f_{N-1}| < DFREQ \cdot |f_{MAX} - f_{MIN}|,$$

where DFREQ is a user parameter, with a default of  $10^{-5}$ .  $f_{MAX}$  and  $f_{MIN}$  are the maximum and minimum excitation frequencies of the combined FREQ<sub>i</sub> entries.

5. In modal analysis, solutions for modal DOFs from rigid body modes at zero excitation frequencies may be discarded. Solutions for nonzero modes are retained.
6. If Modules are present then this entry may only be specified in the main Bulk Data section.

## FREQ2 Frequency List, Alternate Form 2

Defines a set of frequencies to be used in the solution of frequency response problems by specification of a starting frequency, final frequency, and the number of logarithmic increments desired.

Format:

1	2	3	4	5	6	7	8	9	10
FREQ2	SID	F1	F2	NF					

Example:

FREQ2	6	1.0	8.0	6					
-------	---	-----	-----	---	--	--	--	--	--

Describer	Meaning
SID	Set identification number. (Integer > 0)
F1	First frequency. (Real > 0.0)
F2	Last frequency. (Real > 0.0, F2 > F1)
NF	Number of logarithmic intervals. (Integer > 0; Default = 1)

Remarks:

1. FREQ2 entries must be selected with the Case Control command FREQUENCY = SID.
2. The units for F1 and F2 are cycles per unit time.
3. The frequencies defined by this entry are given by

$$f_i = F1 \cdot e^{(i-1)d}$$

where  $d = \frac{1}{NF} \ln \frac{F2}{F1}$  and  $i = 1, 2, \dots, (NF + 1)$

In the example above, the list of frequencies will be 1.0, 1.4142, 2.0, 2.8284, 4.0, 5.6569 and 8.0 cycles per unit time.

4. All FREQi entries with the same frequency set identification numbers will be used. Duplicate frequencies will be ignored.  $f_N$  and  $f_{N-1}$  are considered duplicated if

$$|f_N - f_{N-1}| < DFREQ \cdot |f_{MAX} - f_{MIN}|$$

where DFREQ is a user parameter, with a default of  $10^{-5}$ .  $f_{MAX}$  and  $f_{MIN}$  are the maximum and minimum excitation frequencies of the combined FREQi entries.

5. In modal analysis, solutions for modal DOFs from rigid body modes at zero excitation frequencies may be discarded. Solutions for nonzero modes are retained.

6. If Modules are present then this entry may only be specified in the main Bulk Data section.

## FREQ3 Frequency List, Alternate 3

Defines a set of excitation frequencies for modal frequency-response solutions by specifying number of excitation frequencies between two modal frequencies.

Format:

1	2	3	4	5	6	7	8	9	10
FREQ3	SID	F1	F2	TYPE	NEF	CLUSTER			

Example:

FREQ3	6	20.0	2000.0	LINEAR	10	2.0			
-------	---	------	--------	--------	----	-----	--	--	--

Describer	Meaning
SID	Set identification number. (Integer > 0)
F1	Lower bound of modal frequency range in cycles per unit time. (Real $\geq$ 0.0 for TYPE = LINEAR and Real = 0.0 for TYPE = LOG)
F2	Upper bound of modal frequency range in cycles per unit time. (Real > 0.0; F2 $\geq$ F1; Default = F1)
TYPE	LINEAR or LOG. Specifies linear or logarithmic interpolation between frequencies. (Character; Default = "LINEAR")
NEF	Number of excitation frequencies within each subrange including the end points. The first subrange is between F1 and the first modal frequency within the bounds. The second subrange is between first and second modal frequencies between the bounds. The last subrange is between the last modal frequency within the bounds and F2. (Integer > 1; Default = 10)
CLUSTER	Specifies clustering of the excitation frequency near the end points of the range. See Remark 6. (Real > 0.0; Default = 1.0)

Remarks:

1. FREQ3 applies only to modal frequency-response solutions (SOLs 111, 146, and 200) and is ignored in direct frequency response solutions.
2. FREQ3 entries must be selected with the Case Control command FREQUENCY = SID.
3. In the example above, there will be 10 frequencies in the interval between each set of modes within the bounds 20 and 2000, plus 10 frequencies between 20 and the lowest mode in the range, plus 10 frequencies between the highest mode in the range and 2000.
4. Since the forcing frequencies are near structural resonances, it is important that some amount of damping be specified.

5. All FREQ<sub>i</sub> entries with the same set identification numbers will be used. Duplicate frequencies will be ignored.  $f_N$  and  $f_{N-1}$  are considered duplicated if

$$|f_N - f_{N-1}| < \text{DFREQ} \cdot |f_{MAX} - f_{MIN}|$$

where DFREQ is a user parameter, with a default of  $10^{-5}$ .  $f_{MAX}$  and  $f_{MIN}$  are the maximum and minimum excitation frequencies of the combined FREQ<sub>i</sub> entries.

6. CLUSTER is used to obtain better resolution near the modal frequencies where the response varies the most. CLUSTER > 1.0 provides closer spacing of excitation frequency towards the ends of the frequency range, while values of less than 1.0 provide closer spacing towards the center of the frequency range. For example, if the frequency range is between 10 and 20, NEF = 11, TYPE = "LINEAR"; then, the excitation frequencies for various values of CLUSTER would be as shown in Table 17.

$$\hat{f}_k = \frac{1}{2}(\hat{f}_1 + \hat{f}_2) + \frac{1}{2}(\hat{f}_2 - \hat{f}_1)|\xi|^{1/\text{CLUSTER}} \cdot \text{SIGN}(\xi)$$

where

$\xi$  =  $-1 + 2(k - 1) / (\text{NEF} - 1)$  is a parametric coordinate between -1 and 1

$k$  = varies from 1 to NEF ( $k = 1, 2, \dots, \text{NEF}$ )

$\hat{f}_1$  = is the lower limit of the frequency subrange

$\hat{f}_2$  = is the upper limit of the subrange

$\hat{f}_k$  = is the k-th excitation frequency

$\hat{f}$  = is the frequency, or the logarithm of the frequency, depending on the value specified for TYPE

Table 17 CLUSTER Usage Example

Excitation Frequency Number	$\xi$	CLUSTER				
		c=0.25	c=0.50	c-1.0	c-2.0	c-4.0
		Excitation Frequencies in Hertz				
1	-1.0	10.00	10.0	10.0	10.00	10.00
2	-0.8	12.95	11.8	11.0	10.53	10.27
3	-0.6	14.35	13.2	12.0	11.13	10.60
4	-0.4	14.87	14.2	13.0	11.84	11.02
5	-0.2	14.99	14.8	14.0	12.76	11.66
6	0.0	15.00	15.0	15.0	15.00	15.00
7	0.2	15.01	15.2	16.0	17.24	18.34

Table 17 CLUSTER Usage Example

Excitation Frequency Number	$\xi$	CLUSTER				
		c=0.25	c=0.50	c=1.0	c=2.0	c=4.0
		Excitation Frequencies in Hertz				
8	0.4	15.13	15.8	17.0	18.16	18.98
9	0.6	15.65	16.8	18.0	18.87	19.40
10	0.8	17.05	18.2	19.0	19.47	19.73
11	1.0	20.00	20.0	20.0	20.00	20.00

7. In design optimization (SOL 200), the excitation frequencies are derived from the natural frequencies computed at each design cycle.
8. In modal analysis, solutions for modal DOFs from rigid body modes at zero excitation frequencies may be discarded. Solutions for nonzero modes are retained.
9. If Modules are present then this entry may only be specified in the main Bulk Data section.

## FREQ4

## Frequency List, Alternate Form 4

Defines a set of frequencies used in the solution of modal frequency-response problems by specifying the amount of “spread” around each natural frequency and the number of equally spaced excitation frequencies within the spread.

Format:

1	2	3	4	5	6	7	8	9	10
FREQ4	SID	F1	F2	FSPD	NFM				

Example:

FREQ4	6	20.0	2000.0	0.30	21				
-------	---	------	--------	------	----	--	--	--	--

Describer	Meaning
SID	Set identification number. (Integer > 0)
F1	Lower bound of frequency range in cycles per unit time. (Real ≥ 0.0; Default = 0.0)
F2	Upper bound of frequency range in cycles per unit time. (Real > 0.0; F2 > F1; Default = 1.0E20)
FSPD	Frequency spread, +/- the fractional amount specified for each mode which occurs in the frequency range F1 to F2. (1.0 > Real > 0.0; Default = 0.10)
NFM	Number of evenly spaced frequencies per “spread” mode. (Integer > 0; Default = 3; If NFM is even, NFM + 1 will be used.)

Remarks:

1. FREQ4 applies only to modal frequency-response solutions (SOLs 111, 146, and 200 and is ignored in direct frequency-response solutions.
2. FREQ4 entries must be selected with the Case Control command FREQUENCY = SID.
3. There will be NFM excitation frequencies between  $(1 - FSPD) \cdot f_N$  and  $(1 + FSPD) \cdot f_N$ , for each natural frequency in the range F1 to F2.
4. In the example above there will be 21 equally spaced frequencies across a frequency band of  $0.7 \cdot f_N$  to  $1.3 \cdot f_N$  for each natural frequency that occurs between 20 and 2000. See [Figure 9-91](#) for the definition of frequency spread.

Figure 9-91 Frequency Spread Definition

Excitation frequencies may be based on natural frequencies that are not within the range (F1 and F2) as long as the calculated excitation frequencies are within the range. Similarly, an excitation frequency calculated based on natural frequencies within the range (F1 through F2) may be excluded if it falls outside the range.

- The frequency spread can be used also to define the half-power bandwidth. The half-power bandwidth is given by  $2 \cdot \xi \cdot f_N$ , where  $\xi$  is the damping ratio. Therefore, if FSPD is specified equal to the damping ratio for the mode, NFM specifies the number of excitation frequency within the half-power bandwidth. See [Figure 9-92](#) for the definition of half-power bandwidth.

Figure 9-92 Half-Power Bandwidth Definition

6. Since the forcing frequencies are near structural resonances, it is important that some amount of damping be specified.
7. All FREQi entries with the same set identification numbers will be used. Duplicate frequencies will be ignored.  $f_N$  and  $f_{N-1}$  are considered duplicated if

$$|f_N - f_{N-1}| < \text{DFREQ} \cdot |f_{MAX} - f_{MIN}|$$

where DFREQ is a user parameter with a default of  $10^{-5}$ . The values  $f_{MAX}$  and  $f_{MIN}$  are the maximum and minimum excitation frequencies of the combined FREQi entries.

8. In design optimization (SOL 200), the excitation frequencies are derived from the natural frequencies computed at each design cycle.
9. In modal analysis, solutions for modal DOFs from rigid body modes at zero excitation frequencies may be discarded. Solutions for nonzero modes are retained.
10. If Modules are present then this entry may only be specified in the main Bulk Data section.

## FREQ5 Frequency List, Alternate Form 5

Defines a set of frequencies used in the solution of modal frequency-response problems by specification of a frequency range and fractions of the natural frequencies within that range.

Format:

1	2	3	4	5	6	7	8	9	10
FREQ5	SID	F1	F2	FR1	FR2	FR3	FR4	FR5	
	FR6	FR7	-etc.-						

Example:

FREQ5	6	20.0	2000.0	1.0	0.6	0.8	0.9	0.95	
	1.05	1.1	1.2						

Describer	Meaning
SID	Set identification number. (Integer > 0)
F1	Lower bound of frequency range in cycles per unit time. (Real ≥ 0.0; Default = 0.0)
F2	Upper bound of frequency range in cycles per unit time. (Real > 0.0; F2 > F1; Default = 1.0E20)
FRi	Fractions of the natural frequencies in the range F1 to F2. (Real > 0.0)

Remarks:

1. FREQ5 applies only to modal frequency-response solutions (SOLs 111, 146, and 200) and is ignored in direct frequency response solutions.
2. FREQ5 entries must be selected with the Case Control command FREQUENCY = SID.
3. The frequencies defined by this entry are given by

$$f_i = FR_i \cdot f_{N_i}$$

where  $f_{N_i}$  are the natural frequencies in the range F1 through F2.

4. In the example above, the list of frequencies will be 0.6, 0.8, 0.9, 0.95, 1.0, 1.05, 1.1, and 1.2 times each natural frequency between 20 and 2000. If this computation results in excitation frequencies less than F1 and greater than F2, those computed excitation frequencies are ignored.

Excitation frequencies may be based on natural frequencies that are not within the range (F1 and F2) as long as the calculated excitation frequencies are within the range. Similarly, an excitation frequency calculated based on natural frequencies within the range (F1 through F2) may be excluded if it falls outside the range.

5. Since the forcing frequencies are near structural resonances, it is important that some amount of damping be specified.

6. All FREQi entries with the same set identification numbers will be used. Duplicate frequencies will be ignored.  $f_N$  and  $f_{N-1}$  are considered duplicated if

$$|f_N - f_{N-1}| < \text{DFREQ} \cdot |f_{MAX} - f_{MIN}|$$

where DFREQ is a user parameter with a default of  $10^{-5}$ . The values  $f_{MAX}$  and  $f_{MIN}$  are the maximum and minimum excitation frequencies of the combined FREQi entries.

7. In design optimization (SOL 200), the excitation frequencies are derived from the natural frequencies computed at each design cycle.
8. In modal analysis, solutions for modal DOFs from rigid body modes at zero excitation frequencies may be discarded. Solutions for nonzero modes are retained.
9. If Modules are present then this entry may only be specified in the main Bulk Data section.

## FRFCOMP

### Frequency Response Function (FRF) Component Specification for FRF Based Assembly (FBA)

Specifies the FRF components that are to be assembled as part of an FRF Based Assembly (FBA) process.

Format:

1	2	3	4	5	6	7	8	9	10
FRFCOMP	COMPID	COMPNAME	MEDIUM	UNITNO	LSCALFAC	FSCALFAC			

Examples:

FRFCOMP	10	LEFTWING	OP2	25					
FRFCOMP	20	FRAME	UF	30	1000.0				

Describer	Meaning
COMPID	ID of the component whose FRFs have been generated in a previous Nastran execution. (Integer > 0)
COMPNAME	Name of the COMPID FRF component. See Remark 1. (Up to 8 characters).
MEDIUM	Medium on which the FRF matrices and other related data are stored. Acceptable character values are DB (for database), OP2 (for OUTPUT2 file) or UF (for Universal file). See Remarks 2., 3. and 4.
UNITNO	Fortran unit number for the OP2 and UF options. (Integer > 0). See Remarks 3. and 4.
LSCALFAC	Length scale factor for the UF option. (Real > 0.0; Default = 1.0). See Remarks 7., 8., 9., 10. and 11.
FSCALFAC	Force scale factor for the UF option. (Real > 0.0; Default = 1.0). See Remarks 7., 8., 9., 10., and 11.

Remarks:

- COMPNAME may be referenced by the ASMOUT keyword in the FRF Case Control command in order to request output for a specific FRF component in the FBA process. Accordingly, COMPNAME may not have the values of CONNINFO, ALL, COMP or ASSEMBLY as these are all reserved words for use with the ASMOUT keyword in the FRF Case Control command.
- If the DB option is specified, then the following type of ASSIGN should be specified in the FMS section of the FBA job to access information on the database for the specified FRF component:  
 ASSIGN dbname = 'frfgen\_job.MASTER  
 DBLOCATE DATBLK = (FRFDB) LOGICAL = dbname

3. If the OP2 option is specified, then the following type of ASSIGN should be specified in the FMS section of the FBA job to access information on the OUTPUT2 file for the specified FRF component:  
ASSIGN INPUTT2 = 'frfgen\_job\_op2' UNIT = 25
4. If the UF option is specified, then the following type of ASSIGN should be specified in the FMS section of the FBA job to access information on the Universal file for the specified FRF component:  
ASSIGN UNVFILE = 'frfgen\_job\_unv' UNIT = 26
5. Component ID of 0 is assigned to the assembled FRF configuration resulting from the FBA process.
6. An FRF generation job using an FRF Case Control command with GEN/GENASM and COMPID and COMPNAME keywords specified in it will automatically generate and save an FRFCOMP Bulk Data entry on the assembly punch (.asm) file for that FRF component for subsequent use in an FBA process.
7. LSCALFAC and FSCALFAC are meaningful only for the UF option. They are ignored for the DB and OP2 options.
8. The FRF and other information on the Universal File (UF) is grouped by so-called Universal Dataset Numbers (UDNs). The heart of the information on the UF for a test FRF component is in UDN 58 which contains FRF data for that component. Also of interest, if present, is UDN 15 which contains grid point coordinate data in single precision or UDN 2411 which contains grid point coordinate data in double precision. Further, if UDN 15 or UDN 2411 is present, the data therein may reference definition or displacement coordinate systems. Such coordinate system data is resident in UDN 18.

Details of the various UDNs and their formats can be obtained from the following websites:

<http://www.sdrl.uc.edu/universal-file-formats-for-modal-analysis-testing-1>

<http://www.sdrl.uc.edu/universal-file-formats-for-modal-analysis-testing-1/file-format-storehouse/file-formats>

9. The points of a test FRF component that are considered by the FBA process are those that are defined in UDN 58 either as response points or as excitation points. Any such point that appears both as a response point and as an excitation point is regarded as a potential connection point of the test FRF component.
10. Connections between test FRF components and other FRF components are determined by what is supplied on the UF as indicated below.
  - a. If UDN 15 or UDN 2411 is supplied on the UF, then connections between the test FRF component grid points and those of other FRF components will be based on *matching coordinates*.
  - b. If neither UDN 15 nor UDN 2411 is supplied, then normally, connections between the test FRF component grid points and those of other FRF components will be based on *matching grid point IDs*. However, the user can override this by specifying FRFCONN entries, thereby causing connections between *user specified grid points*. In any case, when the connections are based on matching grid point IDs or based on FRFCONN entries, it is the user's responsibility to ensure that the connection grid points have the same physical locations in space so that correct results are obtained from the FBA process. The program clearly cannot check for this condition since the coordinates of one or more of the points are not available.
11. For the UF option, LSCALFAC and FSCALFAC are used as follows:

- For Universal Dataset No. (UDN) 15 or 2411 (if present) on the Universal File:  
The X, Y, and Z coordinate values in the UDN are multiplied by LSCALFAC before they are used in the FBA process.
- For Universal Dataset No. (UDN) 58 on the Universal File:  
The FRF response quantities in the UDN are multiplied by appropriate factors as shown in the following table before they are used in the FBA process.

Table 9-16 Multiplication Factors for FRF Response Quantities in UDN 58 of the Universal File

FRF Response Quantity	Type of Excitation	Factor by Which FRF Response Quantity is Multiplied Before It is Used in the FBA Process
Translational displacement, velocity or acceleration at a structural point	Unit force at an excitation point	LSCALFAC/FSCALFAC
	Unit moment at an excitation point	1.0/FSCALFAC
Rotational displacement, velocity or acceleration at a structural point	Unit force at an excitation point	1.0/FSCALFAC
	Unit moment at an excitation point	1.0/(LSCALFAC*FSCALFAC)
Pressure at an acoustic point	Unit force at an excitation point	1.0/(LSCALFAC**2)
	Unit moment at an excitation point	1.0/(LSCALFAC**3)

## FRFCONN

## FRF Component Explicit Connection for FRF Based Assembly (FBA)

Defines explicit connection data for FRF components in an FRF Based Assembly (FBA) process.

Format:

1	2	3	4	5	6	7	8	9	10
FRFCONN	CONNID	COMPID1/ COMPNAM1	POINT1	COMPID2/ COMPNAM2	POINT2				

Examples:

FRFCONN	10	5	100	15	200				
---------	----	---	-----	----	-----	--	--	--	--

FRFCONN	20	STRUT	25	WING	35				
---------	----	-------	----	------	----	--	--	--	--

Describer	Meaning
CONNID	Unique identification number of the FRFCONN entry. (Integer > 0)
COMPIDi	Identification number of an FRF component whose FRFs have been generated in a previous Nastran execution. See Remark 1. (Integer > 0)
COMPNAMEi	Name of an FRF component whose FRFs have been generated in a previous Nastran execution. See Remark 1. (Up to 8 characters; no blank allowed)
POINTi	Grid or scalar point identification number. See Remarks 2. through 6. (Integer > 0)

Remarks:

1. If neither of the FRF components COMPID1/COMPNAME1 and COMPID2/COMPNAME2 is part of the FBA process, then this entry is ignored. However, if one of them is part of the FBA process but not the other, the program terminates the job with a user fatal message.
2. POINTi must be among the connection points of the corresponding FRF component COMPIDi/COMPNAMEi. If not, the program terminates the job with a user fatal message.
3. It is, in general, not necessary to have FRFCONN entries when the connections in the FBA process involve only grid points. In the FBA process, all connection grid points of FRF components that have the same basic coordinates are normally connected automatically without any user intervention or specification.
4. If the connection points of an FRF component in the FBA process consist of coincident grid points, the program identifies such points via a user information message. All such coincident grid points must be referenced on FRFCONN or FRFRELS entries in order to ensure proper connections in the FBA process. In the absence of such specifications for coincident connection grid points, the program terminates the job with a user fatal error.
5. FRFCONN entries are required if the user wants to specify explicit connections between test FRF component grid points whose coordinates are not available and those of other FRF components. See Remark 10. under the description of the FRFCOMP entry for further details.

6. FRFCONN entries are also required if the user wants to combine scalar points of FRF components in the FBA process.

## FRFFLEX

## FRF Component Flexible Connection Specification for FRF Based Assembly (FBA)

Defines properties for flexible connections between FRF components in an FRF Based Assembly (FBA) process.

Format:

1	2	3	4	5	6	7	8	9	10
FRFFLEX	FLEXID	C	COMPID1/ COMPNAM1	POINT1	COMPID2/ COMPNAM2	POINT2	KVALUE/ KTABID	BVALUE/ BTABID	
	GEVALUE/ GETABID								

Examples:

FRFFLEX	10	1	100	15	200	25	100.0	150	
	0.02								

FRFFLEX	20	4	STRUT	120	WING	260	10	0.25	
---------	----	---	-------	-----	------	-----	----	------	--

Descriptor	Meaning
FLEXID	Unique identification number of the FRFFLEX entry. (Integer > 0)
C	A single component number. (Any integer between 1 and 6 for grid points; integer 0 or blank for scalar points.)
COMPIDi	Identification number of an FRF component whose FRFs have been generated in a previous Nastran execution. See Remark 1. (Integer > 0)
COMPNAMi	Name of an FRF component whose FRFs have been generated in a previous Nastran execution. See Remark 1. (Up to 8 characters; no blank allowed)
POINTi	Grid or scalar point identification number. See Remark 2. (Integer > 0)
KVALUE	Elastic property value (force per unit displacement). See Remark 3. (Real > 0.0 or blank)
KTABID	Identification number of a TABLEDi entry that defines the elastic property value (force per unit displacement) as a function of frequency. See Remark 3. (Integer > 0 or blank)
BVALUE	Damping property value (force per unit velocity). See Remark 3. (Real > 0.0 or blank)
BTABID	Identification number of a TABLEDi entry that defines the damping property value (force per unit velocity) as a function of frequency. See Remark 3. (Integer > 0 or blank)
GEVALUE	Damping coefficient value. See Remarks 4., 5. and 6. (Real > 0.0 or blank)
GETABID	Identification number of a TABLEDi entry that defines the damping coefficient value as a function of frequency. See Remarks 4., 5. and 6. (Integer > 0 or blank)

**Remarks:**

1. If neither of the FRF components COMPID1/COMPNAM1 and COMPID2/COMPNAM2 is part of the FBA process, then this entry is ignored. However, if one of them is part of the FBA process but not the other, the program terminates the job with a user fatal message.
2. POINT<sub>i</sub> must be among the connection points of the corresponding FRF component COMPID<sub>i</sub>/COMPNAM<sub>i</sub>. If not, the program terminates the job with a user fatal message.
3. The KVALUE/KTABID and BVALUE/BTABID fields may not both be blank.
4. The continuation entry is not needed if GEVALUE/GETABID is not to be defined.
5. GEVALUE/GETABID may not be specified unless KVALUE/KTABID is specified.
6. To obtain the damping coefficient, multiply the critical damping ratio  $C/C_0$  by 2.0.
7. It is important to note that this entry by itself does *not* define a connection between the specified points. It merely defines properties for flexible connections between two points whose connection is established either explicitly via an FRFCONN entry or is implied by automatic connection.
8. The flexible connection properties for component C of connection points POINT1 and POINT2 may be defined on more than one FRFFLEX entry.
9. In the absence of FRFFLEX data, the program assumes rigid connections between the corresponding components.
10. A grid point component may not appear on both an FRFFLEX entry and an FRFRELS entry. If it does, the program identifies such usage and terminates the job with a user fatal message.

## FRFRELS

## FRF Component Grid Point Release for FRF Based Assembly (FBA)

Defines the degrees-of-freedom of FRF component connection grid points that are not to be connected in an FRF Based Assembly (FBA) process.

Format:

1	2	3	4	5	6	7	8	9	10
FRFRELS	SID	C	COMPID1/ COMPNAM1	GRIDPNT1	COMPID2/ COMPNAM2	GRIDPNT2	COMPID3/ COMPNAM3	GRIDPNT3	

Examples:

FRFRELS	100	45	10	15	BODY	20	FRAME	30	
---------	-----	----	----	----	------	----	-------	----	--

FRFRELS	20	1	WING	25	NACELLE	35			
---------	----	---	------	----	---------	----	--	--	--

Describer	Meaning
SID	Identification number of the FRFRELS entry. (Integer > 0)
C	Component number(s). See Remark 1. (Any unique combination of the integers 1 through 6 with no embedded blanks.)
COMPIDi	Identification number of an FRF component whose FRFs have been generated in a previous Nastran execution. See Remark 2. (Integer > 0)
COMPNAMi	Name of an FRF component whose FRFs have been generated in a previous Nastran execution. See Remark 2. (Up to 8 characters; no blank allowed)
GRIDPNTi	Grid point identification number. See Remarks 3. and 4. (Integer > 0)

Remarks:

1. The grid point component(s) specified by C will not be connected in the FBA process.
2. If FRF component COMPIDi/COMPNAMi is not part of the FBA process, then the release data for that FRF component is ignored.
3. GRIDPNTi must be among the connection points of the corresponding FRF component COMPIDi/COMPNAMi. If not, the program terminates the job with a user fatal message.
4. If GRIDPNTi is not connected to any other grid point in the FBA process, the program ignores the FRFRELS data for this point and issues a warning message indicating this to the user.
5. If the connection points of an FRF component in the FBA process consist of coincident grid points, the program identifies such points via a user information message. All such coincident grid points must be referenced on FRFCONN or FRFRELS entries in order to ensure proper connections in the FBA process. In the absence of such specifications for coincident connection grid points, the program terminates the job with a user fatal error.

## FRFSPC1

## FRF Component Single-Point Constraint for FRF Based Assembly (FBA)

Defines single-point constraints for FRF component connection points in an FRF Based Assembly (FBA) process.

## Format:

1	2	3	4	5	6	7	8	9	10
FRFSPC1	SID	C	COMPID1/ COMPNAM1	POINT1	COMPID2/ COMPNAM2	POINT2	COMPID3/ COMPNAM3	POINT3	

## Examples:

FRFSPC1	100	4	10	12	ENGINE	23	FRAME	31	
FRFSPC1	20	1	STRUT	25	NACELLE	35			

Descriptor	Meaning
SID	Identification number of the single-point constraint set. See Remark 1. (Integer > 0)
C	Component number(s). (Any unique combination of the integers 1 through 6 with no embedded blanks for grid points; integer 0 or blank for scalar points.)
COMPIDi	Identification number of an FRF component whose FRFs have been generated in a previous Nastran execution. See Remark 2. (Integer > 0)
COMPNAMi	Name of an FRF component whose FRFs have been generated in a previous Nastran execution. See Remark 2. (Up to 8 characters; no blank allowed)
POINTi	Grid or scalar point identification number. See Remarks 3. and 4. (Integer > 0)

## Remarks:

1. Single-point constraint sets must be selected with the Case Control command SPC = SID.
2. If FRF component COMPIDi/COMPNAMi is not part of the FBA process, then the single-point constraint data for that FRF component is ignored.
3. POINTi must be among the connection points of the corresponding FRF component COMPIDi/COMPNAMi. If not, the program terminates the job with a user fatal message.
4. If POINTi is not connected to any other point in the FBA process, the program ignores the FRFSPC1 data for this point and issues a warning message indicating this to the user.
5. Unlike in non-FBA jobs, wherein a degree-of-freedom that has SPCs specified for it yields exact zero results, a degree-of-freedom that has an FRFSPC1 specified for it in an FBA job will, in general, not give exact zero results, but will give results that are nearly zero or very close to zero, usually around 1.0E-12 or so.

**FRFXIT**

**Unit Load Degree-of-Freedom Specification for Frequency Response Function (FRF) Computations**

Specifies a single degree-of-freedom where unit loads are to be applied for Frequency Response Function (FRF) generation.

Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
FRFXIT	PNTID	C	LABEL						

Example:

FRFXIT	10	3	UNIT LOAD AT LEFT CORNER						
--------	----	---	--------------------------	--	--	--	--	--	--

Describer	Meaning
PNTID	Grid or scalar point identification number. (Integer > 0)
C	A single component number. (Integer 0 or blank for a scalar point; any integer between 1 and 6 for a grid point.)
LABEL	A string comprising no more than 48 characters (fields 4 through 9) that will be used in the label portion of the FRF output to identify this unit load specification. See Remarks <a href="#">1.</a> and <a href="#">2.</a>

Remarks:

1. The small field format must be employed for this entry. If the free field or large field format is employed, the results are unpredictable and in many cases may lead to fatal errors and subsequent termination of the job.
2. The LABEL data must have a non-blank entry in field 4.
3. The FRFXIT1 Bulk Data entry and the DLOAD Case Control request provide alternate means of unit load specification for FRF generation.
4. Redundant unit load specifications are ignored.
5. If Modules are present then this entry may only be specified in the main Bulk Data section.

## FRFXIT1

## Unit Load Degrees-of-Freedom Specification for Frequency Response Function (FRF) Computations

Specifies degrees-of-freedom where unit loads are to be applied for Frequency Response Function (FRF) generation.

Format:

1	2	3	4	5	6	7	8	9	10
FRFXIT1	C	PNTID1	PNTID2	PNTID3	PNTID4	PNTID5	PNTID6	PNTID7	

Example:

FRFXIT1	123	10	20	30	40				
---------	-----	----	----	----	----	--	--	--	--

Alternate Format and Example:

1	2	3	4	5	6	7	8	9	10
FRFXIT1	C	PNTID1	THRU	PNTID2					
FRFXIT1	123	5	THRU	15					

Describer	Meaning
C	Component numbers. (Any unique combination of integers 1 through 6 with no embedded blanks for grid points; integer 0 or blank for scalar points.)
PNTIDi	Grid or scalar point identification numbers. See Remark 1. (Integer > 0)

Remarks:

1. Points in the THRU range need not all exist.
2. The FRFXIT Bulk Data entry and the DLOAD Case Control request provide alternate means of unit load specification for FRF generation.
3. Redundant unit load specifications are ignored.
4. If Modules are present then this entry may only be specified in the main Bulk Data section.

## FSICTRL

Defines the analysis type for OpenFSI fluid structure analysis simulations in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
FSICTRL	SERV_ID	TYPE	FREQ	ANALYSIS					

Examples:

FSICTRL	scafsi	EXPLICIT	1						
---------	--------	----------	---	--	--	--	--	--	--

Describer	Meaning		
SERV_ID	OpenFSI SCA service name associated with the wetted surface loads (see <a href="#">WETLOAD</a> ). The OpenFSI SCA service is defined using the <code>CONNECT SERVICE</code> file management section statement.	Character	None
TYPE	Type of solution strategy coupling between the external code and SOL 700. TYPE can be either <code>EXPLICIT</code> or <code>IMPLICIT</code> .	Character	EXPLICIT
FREQ	External force and displacement update frequency per time step, for the exchange with the external code using the <code>IMPLICIT</code> solution strategy TYPE.	Integer > 0	1
ANALYSIS	OpenFSI service type, it is either DV or U. The DV indicates the service implements OpenFSI interface, the U means the service implements OpenFSI_Ex interface.	Character	DV

Remarks:

1. This entry is used for nonlinear SOL 400 analysis.
2. In the FMS Section:  
`CONNECT SERVICE SERV_ID 'ExternalCodeVendor.OpenFSI '`
3. The SERV\_ID string must be 8 characters or less.

## FSLIST Free Surface List

Defines the fluid points (RINGFL entry) that lie on a free surface boundary.

Format:

1	2	3	4	5	6	7	8	9	10
FSLIST	RHO	IDF1	IDF2	IDF3	IDF4	IDF5	IDF6	IDF7	
	IDF8	-etc.-							

Examples:

FSLIST	1.0-4	AXIS	432	325	416	203	256	175	
--------	-------	------	-----	-----	-----	-----	-----	-----	--

Describer	Meaning
RHO	Mass density at the surface. (Real > 0.0 or blank; the default is taken from DRHO on the AXIF entry.)
IDF1	Identification number of RINGFL entry. (Integer > 0 or Character = "AXIS" or "LAXIS") See Remark 5.
IDF2-IDFi	Identification number of additional RINGFL entries. (Unique Integers > 0)

Remarks:

1. This entry is allowed only if an AXIF entry is also present.
2. The order of the points must be sequential with the fluid on the right with respect to the direction of travel.
3. The word "AXIS" defines an intersection with the polar axis of the fluid coordinate system.
4. If the fluid density varies along the boundary, there must be one FSLIST entry for each interval between fluid points.
5. If the polar axis of the fluid coordinate system is to occur at the first point use AXIS. If the polar axis of the fluid coordinate system is to occur at the last point use LAXIS. See Remark 2.

## FTGDEF Fatigue Element Definitions

Defines elements and their associated fatigue properties to be considered for fatigue analysis for time domain SOLutions 101, 103, 112 and frequency domain SOLutions 108 and 111.

Format (SOL 101/103/112):

1	2	3	4	5	6	7	8	9	10
FTGDEF	ID	TOPSTR	PFTGID	TOPDMG	NENTS	maxENTS	NHS	HSGATE	
	"ELSET"	ELSID1	PFTGID1	ELSID2	PFTGID2	ELSID3	PFTGID3		
		ELSID4	PFTGID4	...	...	...	...		
		-etc.-							
	"SPOTW"	ELSID1	PFTGID1	ELSID2	PFTGID2	ELSID3	PFTGID3		
		ELSID4	PFTGID4	...	...	...	...		
		-etc.-							
	"SEAMW"	ELSID1	PFTGID1	NDSID1	WELD1	TYPE1			
		ELSID2	PFTGID2	NDSID2	WELD2	TYPE2			
		-etc.-							
	"XELSET"	XELSID1	XELSID2	XELSID3	XELSID4	XELSID5	XELSID6	XELSID7	
		XELSID8	...	...	...	...	...	...	
		-etc.-							

Format (SOL 108/112):

1	2	3	4	5	6	7	8	9	10
FTGDEF	ID	TOPRMS							
	"ELSET"	ELSID1		ELSID2		ELSID3			
		ELSID4		...		...

		XELSID8	...	...	...	...	...	...	
		-etc.-							

Examples:

FTGDEF	22	100.0	3						
--------	----	-------	---	--	--	--	--	--	--

FTGDEF	22								
	ELSET	14	3	15	4				

FTGDEF	22								
	SPOTW	44	1	45	2	46			

FTGDEF	22								
	SEAMW	44	99	31	FILLET	TOE			
		45	99		LASER	ROOT			

Describer	Meaning
ID	Unique identification number called out by the FATIGUE case control. (Integer > 0).
TOPSTR	<b>SOL 101, 103, 112:</b> Top stress percentage. Retains and reports only the percentage of entities with the highest simple stress range. Cannot be used with SOL 200 or for fatigue analysis of spot and seam welds; leave blank. (-100.0 ≤ Real ≤ 100.0; Default = blank - 100% will be used). See Remark 8.
TOPRMS	<b>SOL 108, 111:</b> Top RMS (root mean square) stress percentage. Only entities with RMS stress levels in this top percentage are retained and report results. (0.0 < Real ≤ 100.0; Default = blank - 100% will be used)
PFTGID	<b>SOL 101, 103, 112 only.</b> ID of a PFTG entry for associating fatigue properties to all elements of the model. Ignored if ELSET flag is present and should be left blank in this case. (Optional, Integer > 0). See Remark 2.
TOPDMG	<b>SOL 101, 103, 112 only.</b> Top damage percentage. Retains and reports only the percentage of entities with the highest damage. (0.0 < Real ≤ 100.0; Default = blank). Cannot be used with SOL 200 or for fatigue analysis of spot and seam welds; leave blank. See Remark 8.
NENTS	<b>SOL 101, 103, 112 only.</b> Specifies the number of actual entities to output in order to limit or further reduce output file sizes based on most damage or maximum stress/strain range. A positive value indicates the criterion for entity filtering is based on the most damaged entities. A negative number indicates the filtering criteria is based on maximum stress/strain range. (Integer != 0; Default = blank). Not valid for SOL 200; leave blank. See Remark 10.
maxENTS	<b>SOL 101, 103, 112 only.</b> This is used only if STROUT=4 is specified in the FATIGUE case control. If the number of entities requested is greater than maxENTS, the job stops to avoid performance issues. Setting this to a large number can severely affect performance. (Integer > 0; Default = 100). See Remark 11.
NHS	<b>SOL 101, 103, 112 only.</b> Specifies the number of hot spots to identify in the model. (Integer > 0; Default = blank). This setting overrides TOPSTR and/or TOPDMG. See Remark 8.
HSGATE	<b>SOL 101, 103, 112 only.</b> Number of element layers to keep around each hot spot defined by NHS. Zero (0) indicates that only the hot spot elements are retained. Otherwise HSGATE layers of connected elements around each hot spot element are retained. (Integer ≥ 0; Default = 0).
ELSET	Flag indicating that a list of element set and property pairs will follow, defining the elements and their associated properties for consideration in the fatigue analysis. (Optional, Character = ELSET) See Remark 9.

Describer	Meaning
ELSDi	ID of a SET1, SET3, or SET4 entry listing entities of the model (elements) to be included in the fatigue analysis. (Integer > 0). See Remark 3.
PFTGi	ID of a PFTG entry, which indicates the fatigue property associated to the preceding entities defined by ELSDi. (Optional, Integer > 0). See Remark 2.
SPOTW	<b>SOL 101, 103, 112</b> only. Flag indicating that a list of element set and property pairs will follow, defining the elements and their associated properties for fatigue analysis of spot welds. See Remark 5. and 6.
ELSDi	Same as ELSDi under ELSET above. See Remark 3.
PFTGi	Same as PFTGi under ELSET above.
SEAMW	<b>SOL 101, 103, 112</b> only. Flag indicating that a list of element set and property pairs will follow, defining the elements and their associated properties for fatigue analysis of seam welds. See Remark 5.
ELSDi	Same as ELSDi under ELSET above. These are to elements that make up the seam weld toe, root, or throat. See Remark 3.
PFTGi	Same as PFTGi under ELSET above.
NDSi	ID of a SET1 or SET3 entry listing grids of the elements defined by ELSDi to be retained in the analysis. These grids define the seam line of the seam weld. If left blank, all nodes of the elements are retained. Nodes defined that are not part of ELSDi are ignored. (Optional, Integer >0).
WELDi	Seam weld definition. One of the following: FILLET, OVERLAP, LASER, EDGE, or GENERIC, which define either a fillet, overlap, laser overlap, laser edge overlap or generic seam weld, respectively. (Character; Default=GENERIC). See Remark 7.
TYPEi	The type location on the seam weld that this set of elements represent. One of the following: TOE, ROOT, or THROAT. (Character; Default = TOE for all but WELDi = LASER where Default = ROOT). See Remark 7.
XELSET	Flag indicating that sets of elements to be excluded from the fatigue analysis will follow. (Optional, Character). See Remark 4.
XELSDi	ID of a SET1 or SET3 entry listing elements of the model to be excluded from the fatigue analysis. (Integer>0). See Remark 3.

Remarks:

1. **FTGDEF** bulk data entries are ignored if not selected by a **FATIGUE** case control. If no **FTGDEF** is present for a given fatigue analysis (or only the **FTGDEF** with no **ELSET** line), all elements of the model that have fatigue material properties defined are used with default properties except for fatigue analysis of spot and seam welds. If a mix of standard SN/εN and seam/spot weld analyses is requested, then an **ELSET** line is required, otherwise the standard SN/εN analysis is ignored. See Remark 5. below.
2. If no **PFTGi** or **PTFGi** is specified, default properties are assigned to the entities.

3. If a SET3 is specified, field 3 of the SET3 entry must be set to "ELEM". The SET4 entry must be specified to select elements by property ID. The following elements referenced by PSHELL, PSHEAR, and PSOLID properties are supported for standard S-N and  $\epsilon$ -N fatigue analysis: CQUAD4, CQUADR, CQUAD8, CSHEAR, CTRIA3, CTRIAR, CTRIA6, CHEXA, CPENTA, CPYRAM and CTETRA. The following elements referenced by PBAR, PBEAM, PSOLID, and PWELD properties are supported for fatigue analysis of spot welds: CBAR, CBEAM, CHEXA, CWELD. Only elements referenced by PSHELL properties are available for fatigue analysis of seam welds, excluding TRIA3 as no corner stresses are available from this element.
4. If only the XELSET flag is present, then the entire model is included in the fatigue analysis less the excluded entities.
5. For fatigue analysis of spot or seam welds, the FTGDEF card is required with the corresponding keyword and line defining the elements of interest. If standard SN/ $\epsilon$ N analysis is also requested, then an ELSET line is required, otherwise the standard SN/ $\epsilon$ N analysis is ignored.
6. Elements used to represent spot welds are typically very stiff bar or beam (CBAR/CBEAM) elements, weld (CWELD) elements, or individual solid (CHEXA) elements. These elements connect the two metal sheets defined by shell elements (CSHELL). Bars and beams must connect directly to the grids of the shells, whereas welds and fasteners only need to pierce the shell elements. If individual solid elements are used, face G1-G2-G3-G4 must have its grids connected to shell elements that define the top sheet (sheet 1) via RBE3 rigid elements. And face G5-G6-G7-G8 must have corresponding RBE3 elements connecting the bottom sheet (sheet 2). Some CWELD options auto-generate grids on the top and bottom metal sheets (when only GS grid is defined on CWELD entry with no GA/GB grids); the fatigue results are associated to these generated grids.
7. The normals of the throat elements should point outward toward the welder, except for laser overlap, in which case the normals just need to be consistently the same direction. The elements defining the toe and root of the weld must have the top of the shell (Z2 layer) be the side where the crack is expected to develop. For full descriptions of the throat, root, and toe elements for the various seam welds, please see the *MSC Nastran Embedded Fatigue User's Guide*, which show proper modeling techniques. The WELDi and TYPEi entries are used for labeling purposes only and have no effect on internal calculations.
8. Use of TOPSTR/TOPDMG, or NHS/HSGATE allows the user to significantly speed up the analysis times of very large models and more quickly determine the critical damage locations and reduce output. The preferred method is to use NHS/HSGATE as opposed to TOPSTR and/or TOPDMG. If NHS is defined, it overrides any TOPSTR and/or TOPDMG settings, as they are mutually exclusive.
  - NHS/HSGATE: This method determines high damaged areas called *hot spots*. The algorithm is such that the *hot spots* detected are distinct from one another. In other words, if two adjacent elements show the highest damage, and NHS=2, the two adjacent element only count as one hot spot and another hot spot away from the first one is detected. In order to show nice postprocessing plots, use HSGATE to retain a certain number of element layers around each hot spot element. If HSGATE=0, only a single element for each hot spot is retained, which means that not all the highest damaged elements are likely reported.

- If TOPSTR is used alone (TOPDMG is left unspecified), and is a positive percentage, then a two (2) pass analysis is performed where the first (1st) pass determines the approximate percentage of entities to retain with the highest simple stress range. The second (2nd) pass computes damage on only the remaining elements. The simple range test is done using this equation:

$$\sigma_{assessed} = \sum_k \frac{(Max_k - Min_k) \cdot SCALE_k \cdot \sigma_{vonMises, k}}{LDM_k}$$

where  $Max_k$  and  $Min_k$  are the maximum and minimum values from each channel of loading history (load case  $k$ ). SCALE and LDM are the scale factor and divisor as defined on FTGLOAD entries for each load case  $k$ , otherwise unity is used.

The calculation is similar for strains, except that the output is in strain units, and the calculation of vonMises strain requires a value of the Poisson ratio. For the purposes of this simple ranking procedure, the Poisson ratio is assumed to be 0.3. When the analysis involves a duty cycle (loading sequence), the resulting assessed stress is the largest value from each of the events in the duty cycle.

If a negative percentage is given, then the retained elements are determined based on the actual stress range after combination and superposition using that specified on the FTGPARM entry. As an example, if TOPSTR=10%, and the highest stress range is determined to be 1000MPa, then any entity with stress range higher than 900MPa is retained (10% of 1000 is 100; 1000-100=900). This can have the effect of retaining many less entities than the positive percentage method, but has the drawback of being extremely sensitive to high stress gradients.

- If TOPDMG is used alone (TOPSTR=100% or left unspecified), the percentage of entities returned are simply based on the highest damage. This does not necessarily reduce computation time, but does significantly reduce result recovery time as less entities are retained.
  - If TOPSTR and TOPDMG are both specified, then a 2-pass analysis is performed where the first (1st) pass eliminates all but the highest stressed entities and the second (2nd) pass returns only the percentage of damaged entities based on those retained in the 1st pass.
  - If none of TOPSTR, TOPDMG, or NHS are specified (all are blank or default), then a complete analysis is done on all requested elements. This is the default scenario.
9. Element sets must be the same for all FATIGUE case control IDs that request surface resolved stresses through the FTGPARM entry (SRESOLVE field = YES). Otherwise a fatal condition is flagged and the analysis stops.
  10. This NENTS parameter can be used by itself or in conjunctions with TOPSTR, TOPDMG, or NHS. Only entities that pass this filter are reported in the f06 file and/or output to the OUTPUT2 and/or HDF5 files. If NENTS is used with the SRESOLVE option on the FTGPARM entry, then the number of entities printed may be more as the SRESOLVE option saves the number of grids and each element associated with those grids.
  11. If FATIGUE(STROUT=4) case control is used it is highly recommended that output be limited. Temporary CSV files are created for each entity and F06 output can be enormous if not filtered using the ELSET entries. The analysis fails if maxENTS is less than the number of elements requested using ELSET entries when STROUT=4 is specified. Increase maxENTS if necessary after assessing output needs.

## FTGEVNT

## Fatigue Loading Events

Groups simultaneously applied loads into loading events for pseudo-static fatigue analysis using SOL 101 or modal analysis using SOL 103 or random vibration fatigue using SOL 108 or SOL 111 by referencing FTGLOAD entries.

Format (SOL 101, 103, 108, 111):

1	2	3	4	5	6	7	8	9	10
FTGEVNT	ID	FLOAD1	FLOAD2	FLOAD3	FLOAD4	FLOAD5	FLOAD6	FLOAD7	
		FLOAD8	...	...	...	...	...	...	
		-etc-							
	"NAME"	EVNTNAM							

Example:

FTGEVNT	22	4	11						
	NAME	rough_road							

Descriptor	Meaning
ID	Unique ID. See Remark 1.
FLOADi	ID of a FTGLOAD entry (Integer > 0, no default). See Remark 5.
NAME	Flag indicating that a name is to be associated with this load event. See Remark 2.
EVNTNAM	Event name associated with this event (Character). Can span fields 3 through 9, however for practical purposes, the name is truncated in f06 output. No spaces are allowed. See Remark 3. and 4.

Remarks:

- Each FTGEVNT ID must be unique relative to all other FTGEVNT and FTGSEQ IDs.
- Event names are passed to the f06 print file and displayed as the name of the event as opposed to the event ID. If no name is given, the event is referred to by its ID.
- EVNTNAM cannot have numbers at the start of any field. For example, using 8 character formatted fields, the first character of fields 3-9 cannot be numeric (columns 1, 9, 17, etc. of the EVNTNAM field). These would be acceptable:  
 "Flights" or "F\_l\_i\_g\_h\_t\_s".  
 But these would not be acceptable:  
 "1\_Flights" or "F\_l\_i\_g\_2ts"  
 because the "1" and the "2" are in columns 1 and 9 of the EVNTNAM field.

4. EVNTNAM cannot handle spaces within its field as one might expect. If you wish to use spaces, make sure that once a space is used the next character does not start until the start of the next field. For example, using 8 character formatted fields, the following would be acceptable:  
“My\_flights” or “My Flights”.  
But this would not be acceptable:  
“My Flights”  
and would end up just being displayed as “Myts” because once a space is encountered within the 8 character field, the code interprets that as no more character data until it processes the next 8 character field. It is best not to use spaces in EVNTNAM.
5. For random vibration fatigue (SOL 108 and 111),
- Only one FTGLOAD of TYPE=PSD can be referenced
  - Only one FTGLOAD of TYPE=STATIC can be referenced
  - A FTGEVNT referencing a FTGLOAD of TYPE=STATIC by itself is not allowed
  - A FTGEVNT referencing a FTGLOAD of TYPE=SINE or NARROW by itself (or themselves) is allowed for pure deterministic and/or sine sweeps
  - Only single load PSD random input allows mixed deterministic, sine sweep, and static offsets on random loading. Only a static offset (FTGLOAD of TYPE=STATIC) can be mixed with multi-load PSD random input.
  - FTGSEQ entry referencing FTGEVNT entries cannot mix events containing single load and multi-load PSDs.
  - All multi-load PSD events must all have the same number of channels (input loads).
  - When only FTGLOAD entries of TYPE=SINE or NARROW are referenced (i.e., only deterministic loading with no random loading input), it is recommended that the ATYPE field of the FTGPARM entry be set to SINE.

## FTGLOAD

### Fatigue Cyclic Loading Variation

Defines cyclic loading variation for pseudo-static fatigue analysis using SOL 101 or modal analysis using SOL 103 or random PSD, deterministic, sine sweep and/or static offset loading for SOL 108 and SOL 111.

Format (SOL 101 and 103):

1	2	3	4	5	6	7	8	9	10
FTGLOAD	ID	TID	LCID	LDM	SCALE/ MAX	OFFSET/ MIN	TYPE	CHNL	
	"UNITS"	EQUIV	EQNAME						

Format (SOL 108 and 111):

1	2	3	4	5	6	7	8	9	10
FTGLOAD	ID	TID	LCID		SCALE	OFFSET	TYPE		
	"DETLOAD"	F1	G1/H1	B1	F2	G2/H2	B2		
		F3	G3/H3	B3	...	...	...		
		-etc.-							
	"SWEEP"	F1	G1/H1		F <sub>n</sub>	G <sub>n</sub> /H <sub>n</sub>			
		SWTYPE	SWNUM	SWRATE	NSWEEP	FRFUNIT	LDUNIT		

Examples:

FTGLOAD	55	4	2	1.0	1.0	0.0			
FTGLOAD	23	4	5	1.0	1.0	0.0	DB		
	UNITS	5.5	Flights						

Describer	Meaning
ID	Unique ID which is referenced by a FTGEVNT entry or directly by a FATIGUE case control in the case of SOL 101 only for a single load (Integer > 0). See Remark 1.
TID	<ul style="list-style-type: none"> <li>■ <b>SOL 101, 103:</b> Table ID of a TABLFTG (or TABLED1) entry that defines the time variation of the loading or the ID of a UDNAME entry for external definition of the loading time variation (Integer &gt; 0). See Remarks 2. through 6. Ignored if TYPE=CONST or STATIC.</li> <li>■ <b>SOL 108, 111:</b> leave blank unless: <ul style="list-style-type: none"> <li>■ TYPE=STATIC: UDNAME ID referencing an external OP2 file containing stress results for static loading offsets. Leave blank (and set LCID = 0 if a constant offset defined solely by the OFFSET field is desired).</li> <li>■ TYPE = PSD with TIM2PSD: UDNAME ID referencing an external RPC or CSV file when time history to PSD conversion is requested. A TIM2PSD entry must be present in this case, otherwise TID is ignored.</li> </ul> </li> </ul>
LCID	<ul style="list-style-type: none"> <li>■ <b>SOL 101:</b> Subcase ID of a linear static solution SUBCASE (Integer &gt; 0, no default).</li> <li>■ <b>SOL 103:</b> Mode number for SOL 103 (Integer &gt; 0, no default).</li> <li>■ <b>SOL 108, 111:</b> <ul style="list-style-type: none"> <li>■ TYPE = PSD with no TIM2PSD: SID of RANDPS entry(ies). TID should be left blank in this case.</li> <li>■ TYPE = PSD with TIM2PSD: -1 for fully correlated multi-input loading, -2 for uncorrelated multi-input loading.</li> <li>■ TYPE = STATIC: SUBCASE ID of a static SUBCASE (freq=0.0). A TID must also be defined in this case to point to an external OP2 file. Set to zero (0) if a constant offset solely defined by the OFFSET field is desired. TID should be left blank in this case.</li> <li>■ TYPE=SINE or NARROW: SUBCASE ID of transfer function (TF) used for deterministic or sweep loading. TID should be left blank in this case.</li> </ul> </li> </ul>
LDM	<b>SOL 101, 103 only.</b> Largest magnitude of the applied load (in the same units used to define the load time variation in field TID) used to normalize the load (Real, default=1.0). This effectively scales the stress to simulate a stress state due to a unit load. See Remark 7.
SCALE/ MAX	<p><b>SOL 101, 103:</b> Scale factor applied to the load time history (Real, default=1.0). See Remark 7. Or the 1st peak level of a constant amplitude signal if TYPE=CONST (Real, default=1.0).</p> <p><b>SOL 108, 111:</b> Acts as an additional scale factor on the input PSD. This applies only to TYPE=PSD (Real, default=1.0).</p>

Describer	Meaning
OFFSET/ MIN	<p><b>SOL 101, 103:</b> Offset applied to the load time history (Real, default=0.0). See Remark 7. Or the 2nd peak level of a constant amplitude signal if TYPE=CONST (Real, default = -1.0). MAX can be &lt; or &gt; than MIN for TYPE=CONST.</p> <p><b>SOL 108, 111:</b> Offset of resultant stress PSD in stress units. This has the effect of adding a mean stress effect to the random load response. This only applies to TYPE=STATIC and if TID is blank, this is only a constant offset. With TID a variable offset plus this constant offset is applied (Real, default = 1.0).</p>
TYPE	Flag indicating the type of load being defined. Values can be: blank, "DB", "DAC", "RPC", "CONST", "PSD", "SINE", "NARROW" or "STATIC". Default is blank. See Remarks 2. through 6.
CHNL	<b>SOL 101 and 103 only.</b> Channel of referenced RPC file (TYPE=RPC). (Integer >0, Default is blank). See Remark 12.
"UNITS"	<b>SOL 101 and 103 only.</b> Flag indicating that a fatigue equivalent unit name is defined for this loading. See Remarks 9. and 10.
EQUIV	Number of equivalent units (Real>0.0, default=1.0). See Remarks 9. and 10.
EQNAME	Equivalent name of this loading history. EQNAME can span across fields 4 through 9. If not defined it will be called <i>Repeats</i> (Character). No spaces are allowed. See Remarks 9. and 10.
"DETLOAD"	<p><b>SOL 108 and 111 only.</b> Flag indicating that deterministic load input is to follow for TYPE=SINE or NARROW.</p> <p>Fi Frequency of sine wave for TYPE=SINE or center frequency of narrow band frequency block for TYPE=NARROW. (Real&gt;0.0; no Default).</p> <p>Gi Height of sine wave (Gi) in units of peak amplitude (FE stress units) for TYPE=SINE.</p> <p>Hi Height of narrow band PSD block (Hi) in units of (stress)<sup>2</sup>/Hz for TYPE=NARROW. (Real&gt;=0.0; no Default).</p> <p>Bi Width of narrow band frequency block. Only supplied for TYPE=NARROW. (Real&gt;=0.0; no Default).</p>
"SWEEP"	<p><b>SOL 108 and 111 only.</b> Flag indicating that sine sweep load input is to follow for TYPE=SINE (not supported for NARROW).</p> <p>F1/Fn F1/Fn Frequency of 1st and last sine waves for TYPE=SINE. (Real&gt;0.0; no Default).</p> <p>G1/H1 Height of 1st (G1) and last (Gn) sine waves in units of peak amplitude (FE stress units) for TYPE=SINE. (Real&gt;=0.0; no Default).</p> <p>Gn/Hn</p> <p>SWTYPE The sweep type: Decibel (DB), Octave (OCT), or Linear (HZ). (Character; Default = HZ)</p> <p>SWNUM Number of sine/narrow bands to use (Integer&gt;0 where N=SWNUM+1; Default = 50)</p> <p>SWRATE Sweep rate per second in HZ (default), DB or OCT. (Real&gt;0.0; No Default)</p> <p>NSWEEP Number of sweep passes (Integer&gt;0; No Default).</p>

Descriptor	Meaning
FRFUNIT	Units of loading used to create FRF - can be acceleration (A), velocity (V), displacement (D), or force (F). Used for TYPE=SINE only. (Character; Default = A)
LDUNIT	Units of loading used to define sweep - can be acceleration (A), velocity (V), displacement (D), or force (F). Used for TYPE=SINE only. (Character; Default = A)

Remarks:

1. If a FATIGUE case control command invokes an ID that is present on both an FTGSEQ entry and a FTGLOAD entry, the FTGSEQ request will be honored and the FTGLOAD entry will be ignored unless it is referenced on a FTGEVNT entry.
2. **For SOL 101 and 103**, if the TYPE field is blank then TID references a TABLFTG or TABLED1 entry. For SOL 108 or 111, TYPE must be supplied.
3. **For SOL 101 and 103**, if TYPE=DB, DAC or RPC, then TID references a UDNAME ID. A UDNAME entry must be supplied in this case to specify the file and path of the externally defined load time variation. This file is expected to be in standard DAC file format or channel data in the form of a RPC file. TYPE=DB is the same as TYPE=DAC. You cannot mix TYPE=RPC designations with any other TYPEs within the same fatigue analysis (FATIGUE=FID). If RPC is used, all FTGLOAD entries must use TYPE=RPC. The same RPC file must be referenced via UDNAME for all FTGLOADs of the same event (FTGEVNT). **For SOL 108 and 111**, if TYPE=STATIC or if TYPE=PSD with TIM2PSD entry active, the UDNAME references an external OP2 file or RPC/CSV channel data file, respectively.
4. **For SOL 101 and 103**, if TYPE is STATIC, the TID field should be left blank as it will be ignored. STATIC indicates that the stress state from the specified LCID is to act as a static offset with no load time variation when performing the linear superposition, which will give every element a different offset defined by the stress state at each element of the specified subcase, as opposed to simply specifying the OFFSET field, which gives every element the same offset. If the "STATIC" flag is specified, there must be at least two FTGLOAD entries defined and called out by a FTGEVNT entry, one of which must be time varying (see Remark 7.). **For SOL 108 and 111**, if TYPE is STATIC, the TID field must be supplied.
5. **For SOL 101 and 103**, if TYPE is CONST, the TID, LDM, and CHNL fields are ignored. The MAX and MIN fields are used to define the maximum and minimum values of a constant amplitude cycle. TYPE=CONST cannot be mixed with any other TYPE values for a given fatigue analysis (FATIGUE=FID). All loading must be of TYPE=CONST. This is sometimes referred to as block loading.
6. For modal analysis using **SOL 103**, the referenced load variation defines the modal participation factors for the referenced mode.
7. **For SOL 101 and 103**, the LDM, SCALE, and OFFSET are used together in the following manner to scale/modify the stress state in order to determine the resulting stress time variation:

$$\sigma_{ij}(t) = \left( P(t) \times \frac{\sigma_{ij,l}}{LDM} \times SCALE \right) + OFFSET$$

8. where  $\sigma_{ij}(t)$  is the resulting stress tensor at time  $t$ ,  $\sigma_{ij, l}$  is the stress tensor from the subcase or mode defined by the LCID field, and  $P(t)$  is the  $y$  value of the load-time history at time  $t$  as defined by the TID field. For multiple loads, the principle of linear superposition is used to combine all loads for a single event. For SOL 108 and 111, LDM and SCALE act as a divisor and multiplier, respectively, to the defined loading. OFFSET is only used for TYPE=STATIC and acts as an additional constant offset over all entities.
9. If the "UNITS" flag is absent, the default fatigue equivalent unit is 1.0 *Repeats* of the stress time history. If this FTGLOAD is referenced by a FTGEVNT, then the equivalent units on this entry are ignored and those on the FTGSEQ entry take precedent. Only if a FTGLOAD is directly referenced by a FATIGUE case control are the fatigue equivalent units used as defined on the FTGLOAD entry.
10. Example of using equivalent units: If one repeat of the defined time history is equivalent to 5 times around a test track, the equivalent unit name, EQNAME, might be "*laps*," and the equivalent unit, EQUIV, would be 5.0. Fatigue life will be reported in these units if defined, otherwise they are reported as *Repeats* of the loading. Life output is reported in both *Repeats* and the fatigue equivalent units, if defined.
11. All FTGLOAD entries referenced by a FTGEVNT should reference different SUBCASEs for SOL 101 (or modes for SOL 103) and must have time variations consisting of the same number of points.
12. CHNL is only used for TYPE=RPC for SOL 101 and 103. If supplied, the specified channel of the referenced RPC file is used. If it is left blank, the next available channel sequentially from the last one referenced will be used. For example, if there are three FTGLOAD entries for a specific event and CHNL is blank for all three, the 1st one will use channel 1, the 2nd one will use channel 2 and the 3rd will use channel 3. If in this example the 1st specifies CHNL=11 and the others are blank, then the channels used will be 11, 12, and 13. If the 1st is left blank and the 2nd references CHNL=12, then the channels used will be 1, 12, and 13.

## FTGPARM

## Fatigue Parameters

Defines parameters for a fatigue analysis in time domain SOLs 101, 103, and 112 and in frequency domain SOLs 108 and 111.

Format (SOLs 101, 103, 112):

1	2	3	4	5	6	7	8	9	10
FTGPARM	ID	TYPE	FACTOR	NTHRD	LOGLVL	LAYER			
	"STRESS" or "STRAIN"	COMB	CORR	PLAST	LOC	INTERP	RECOVER	SRESOLVE	
		NANGLE							
	"CERTNTY"	SURV							
	"FOS"	OPTION	LIFE	BACKACC	MAXFAC	MINFAC			
	"SPOTW"	COMB	CORR	NANGLE	SWLOC	MIDDLE	TORSION		
	"SEAMW"	COMB	CORR	THICK	LOCSM	RESENT			
	"MULTI"	MMTHD	NONLWR	NONUPR	BIAXLWR	BIAXMID	BIAXUPR	ZERO	
		GATE							
	"NAVG"	MTHD	OUTPUT	NORMAL					

Format (SOLs 108, 111):

1	2	3	4	5	6	7	8	9	10
FTGPARM	ID	TYPE			LOGLVL	LAYER			
	"STRESS"	COMB	CORR	PLAST	LOC		RECOVER		
	"FOS"		LIFE						
	"VIBFTG"	ATYPE	MAXSTR	CLIPLVL	MAXPEAK	STRBINS	MAXFREQ	NCALC	

Examples:

FTGPARM	22	EN							
---------	----	----	--	--	--	--	--	--	--

FTGPARM	22	SN							
	STRESS	SGVON	NONE		NODA		CUBIC		

FTGPARM	22	SN							
	SEAMW		FKM	0					

FTGPARM	22	SN							
	SPOTW	STNDRD	SIMPLE	18	3	0	0		

FTGPARM	22	EN							
	MULTI	AUTO	0.25	0.5	-0.6	0.25	0.6	10.0	
		20.0							

Describer	Meaning
ID	Unique ID of the FTGPARM entry called out by a FATIGUE case control (Integer > 0). See Remark 1.
TYPE	<p><b>SOL 101, 103, 112:</b> Type of fatigue analysis: "SN" or "EN" (Character, Default=SN).</p> <p><b>SOL 108, 111:</b> Type of fatigue analysis: "SN" or "EN" (Character, Default=SN). This is used only when there is a conflict with the defined material properties, i.e., both S-N and <math>\epsilon</math>-N properties exist for the same material MID. Otherwise it is ignored and the material properties define the type of fatigue analysis to be performed..</p>
FACTOR	<b>SOL 101, 103, 112</b> only. Global scale factor to be applied to combined resultant stress output (Real>0.0, Default=1.0).
NTHRD	<b>SOL 101, 103, 112</b> only. Number of threads to use for parallel processing for this fatigue analysis (Integer $\geq$ 0; Default = Blank). Blank denotes that the number of threads used is based on SMP setting and the existence of an SMP license. Zero (0) is used as a flag to tell the code to use all available threads. Otherwise the number of threads designated is used if available. An SMP license is only necessary to take advantage of multiple treads if left blank.
LOGLVL	<p><b>SOL 101, 103, 112:</b> Level of messaging sent to the log file (Integer <math>\geq</math> 0, Default = 0; 0=None, 1=Error, 2=Info, 3=Low, 4=Medium, 5=High). Note that setting LOGLVL &gt;0 can result in a significant performance penalty and should be used for debugging purposes only and limited to the entities of interest. LOGLVL=5 produces an HDF5 or a .dtout file that shows all parameter settings. This file can be significantly large.</p> <p><b>SOL 108, 111:</b> Level of output to generate (Integer <math>\geq</math> 0, Default = 0; 0=Standard, 1=Output all PSD responses, 2=Additionally output all Rainflow data). Note that LOGLVL &gt;0 can result in a significant performance penalty and should be used for debugging purposes only and limited to the entities of interest only. See Remark 13.</p>
LAYER	For shell elements, the output results layer to print to the f06 file. Values can be 0=Worst, 1=Top(Z2), 2=Bottom(Z1). (Integer, Default = 0). This is for printed output only. The analysis produces results for both layers, which are always available through the MASTER/DBALL, Output2, or other files for graphical postprocessors. See the <a href="#">FATIGUE</a> case control entry.
"STRESS" or	Flag indicating that stress is used in the fatigue calculation. See Remark 2.

Describer	Meaning
"STRAIN"	SOL 101, 103, 112 only. Flag indicating that strain is used in the fatigue calculation. Not valid for TYPE = SN. See Remark 2.
COMB	Stress/strain combination to use in the fatigue analysis. Acceptable values are listed in Table 9-17 after the Remarks below (Character; Default t= ABSMAXPR).
CORR	Mean stress correction to use in the fatigue analysis. Acceptable values are listed in Table 9-18 and Table 9-19 after the Remarks below (Character; Default=None).
PLAST	SOL 101, 103, 112: Plasticity correction for TYPE = EN. Value can currently only be "NEUBER" for Neuber method. (Character; Default=NEUBER). See Remark 3.
LOC	SOL 108, 111: Only NEUBER correction is available. SOL 101, 103, 112: Location to report fatigue lives. Valid values are "NODA", "NODE", or "ELEM" based on nodal averaged, element nodal, or element centroid stresses or strains, respectively. (Character; Default = NODA). See the RECOVER field and Remark 4. Also see the "NAVG" field and parameters.
INTERP	SOL 108, 111: Location to report fatigue lives. Valid values are "NODE", "NODA", or "ELEM" based on element nodal, nodal averaged, or element center stresses, respectively. (Character; Default = NODA). See the RECOVER field and Remark 4. SOL 101, 103, 112 only. Interpolation limit for multi-curve mean stress correction method (Integer $\geq 0$ ; 0=Use Max Curve, 1=Extrapolate; Default = 0).
RECOVER	Stress recovery method to determine stresses/strains for the fatigue calculation. Valid values are "SGAGE", "CORNER", "BILIN", "CUBIC" or "CENTER" (Character; Default = CORNER if LOC=NODA or NODE; Default = CENTER if LOC=ELEM and any other setting is ignored). These are the same values used for the STRESS (or STRAIN) case control output request. See LOC field and Remark 4.
SRESOLVE	SOL 101, 103, 112 only. Request for surface resolved, 2D stress state. Used only for 3D solid elements. (Character YES or NO; Default = NO). See Remark 5.

Describer	Meaning
NANGLE	The number of calculation angles for 2D critical plane analysis (COMB=CRITICAL) ( $1 \leq \text{Integer} \leq 360$ ; Default = 36, i.e. every 10 degrees). Practical values are 360, 180, 120, 90, 72, 60, 45, 40, 36, 30, 24, 18, 15, 12, 10, 9, 8, 6, 5, 4 for every 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 20, 24, 30, 36, 40, 45, 60, 72, 90 degrees, respectively. The more angles computed, the more compute intensive the analysis will be. In actuality, only half the angles are computed since the principals are the same 180 degrees opposite any computed angle.
"CERTNTY"	SOL 101, 103, 112 only. Flag indicating that the parameter that follows defines the certainty of survival in fatigue analysis.
SURV	Certainty of survival based on the scatter in the S-N or e-N curves. ( $0.1 \leq \text{Real} \leq 99.9$ ; Default = 50). See Remark 6.
"FOS"	SOL 101, 103, 112: Flag indicating that parameters that follow are used in a factor of safety analysis. The presence of this flag triggers a factor of safety analysis. See Remark 7. and 11.
	SOL 108, 111: Flag indicating that the total signal time duration desired is to be specified for use in calculating margin of safety. Only the LIFE field is required in this case and defaults to 1.0. A margin of safety is always calculated.
OPTION	Supported option is LIFE, requesting a life-based factor of safety analysis or NONE. (Character; default = LIFE).
LIFE	SOL 101, 103, 112: The targeted design life given in user defined life units (such as laps, miles, etc.) as defined by "UNITS" line on FTGSEQ or FTGLOAD entry, or <i>Repeats</i> of the cyclic loading if no "UNITS" line exists (Real>0, no default).
	SOL 108, 111: Total time duration required for margin of safety calculation in time units specified by TUNIT field on FTGSEQ entry.
BACKACC	SOL 101, 103, 112 only. The back calculation accuracy used to control back calculation iterations that determine the scale factor on the applied stress level to achieve the target design life. Defined as a percentage error on the target design life. ( $0.01 < \text{Real} \leq 100.0$ , Default = 1.0).
MAXFAC	SOL 101, 103, 112 only. The maximum safety factor to calculate and report. When this threshold is exceeded, the analysis will go on to the next element and report the maximum for the exceeded element ( $2.0 \leq \text{Real} \leq 5.e6$ , Default = 5.0).
MINFAC	SOL 101, 103, 112 only. The minimum safety factor to calculate and report. If the result is below this threshold, the analysis will report MINFAC as the safety factor for this element and go on to process the next element. ( $0.0 < \text{Real} \leq 0.5$ , Default = 0.2).

Describer	Meaning
"SPOTW"	SOL 101, 103, 112 only. Flag indicating that parameters for fatigue analysis of spot welds are to follow. See Remark 8.
COMB	Stress combination to use in the fatigue analysis. Acceptable values are listed in Table 9-17 after the Remarks below (Character; Default=STNDRD, which is basically a critical plane analysis).
CORR	Mean stress correction to use in the fatigue analysis of spot welds. Only NONE, FKM, or SIMPLE are valid for fatigue analysis of spot welds. See Table 9-18 and Table 9-19 below. (Character; Default = NONE).
NANGLE	The number of calculation angles in 360 degrees around the spot weld. ( $10 \leq \text{Integer} \leq 360$ ; Default = 18, i.e., every 20 degrees)
SWLOC	Location on the spot welds to report fatigue life. Zero (0) reports worst case angle and location (top/bottom sheet or nugget); one (1) reports worst case angle for each location; two (2) reports worst case location for each angle; three (3) reports all locations and angles. (Integer 0, 1, 2, or 3, Default=0).
MIDDLE	Whether to process middle sheets if there are more than two sheets in the weld. (Integer 0 or 1, Default = 1- process middle sheets). See Remark 10.
"SEAMW"	SOL 101, 103, 112 only. Flag indicating that parameters for fatigue analysis of seam welds are to follow. See Remark 8.
COMB	Stress/strain combination to use in the fatigue analysis of seam welds. Only ABSMAXPR and CRITICAL are supported. See Table 9-17 below. (Character; Default = ABSMAXPR).
CORR	Mean stress correction to use in the fatigue analysis of seam welds. Only NONE or FKM are valid for fatigue analysis of seam welds. See Table 9-18 and Table 9-19 below. (Character; Default=NONE).
THICK	Thickness correction to be applied. (Integer 0 or 1; Default =0 - no correction)
LOCSM	Location on seam weld to report life. Valid values are "NODE", "SGAGE", "CORNER", "BILIN", or "CUBIC" (Character; Default = NODE). If "STRESS" line is also include, LOCSM must be the same as LOC. LOC=ELEM is not valid for fatigue analysis of seam welds and cannot be mixed with LOC = NODE. See Remark 4.
RESENT	Result entity type used in the fatigue analysis of seam welds; only STRESS is currently supported. (Character; Default = STRESS).
"MULTI"	SOL 101, 103, 112 only. Flag indicating that parameters for biaxial/multiaxial assessment are to follow. See Remark 9. and 11.

Describer	Meaning
MMTHD	<p>Can be set to the following:</p> <ul style="list-style-type: none"> <li>■ NONE = No multiaxial assessment is done.</li> <li>■ SIMPLE = Calculates simple biaxiality ratios only.</li> <li>■ STANDard =Standard method of assessment, which merely returns the results of the assessment.</li> <li>■ AUTO = Performs the standard method, but then may recalculate fatigue damage depending on the results of the assessment.</li> </ul>
NONLWR NONUPR	<p>Used only when MMTHD = AUTO. Lower and Upper thresholds used to check if the loading is proportional. This is used in combination with the biaxiality ratio thresholds.</p> <p>NONLWR: (<math>0 &lt; \text{Real} \leq \text{NONUPR}</math>, Default = 0.25)  NONUPR: (<math>\text{NONLWR} &lt; \text{Real}</math>, Default = 0.5)  NONUPR not used if TYPE=SN</p>
BIAXLWR BIAXMID BIAXUPR	<p>Used only when MMTHD = AUTO. Lower, Middle, and Upper threshold ratios used to check if the loading is proportional. This is used in combination with the non-proportionality factor thresholds.</p> <p>For TYPE=EN:  BIAXLWR: (<math>-1 \leq \text{Real} \leq \text{BIAXMID}</math>, Default = -0.6)  BIAXMID: (<math>\text{BIAXLWR} \leq \text{Real} \leq \text{BIAXUPR}</math>, Default = 0.25)  BIAXUPR: (<math>\text{BIAXMID} \leq \text{Real} \leq 1</math>, Default = 0.6)</p> <p>For TYPE=SN:  BIAXLWR: (<math>-1 \leq \text{Real} \leq 0</math>, Default = -0.6)  BIAXMID: Not used  BIAXUPR: (<math>0 &lt; \text{Real} \leq 1</math>, Default = 0.6)</p>
ZERO	<p>Used only when MMTHD = AUTO. Stress range below which damage is assumed zero and therefore no recalculation is performed. Specified as a percentage of UTS. (<math>0 &lt; \text{Real} \leq 100</math>, Default=10.0).</p>
GATE	<p>Used only when MMTHD = AUTO. This gate value is used to prevent small stresses from adversely affecting the biaxiality calculation. Stresses below this value are not included in the biaxiality calculation; their biaxiality ratio will be set to zero (0). The value is set as a percentage of UTS. (<math>0 &lt; \text{Real} \leq 100</math>, Default=20.0).</p>

Describer	Meaning
"NAVG"	<p>SOL 101, 103, 112 only. Flag indicating that parameters for nodal (grid point) stress (or strain) averaging are to follow. The LOC field must be set to NODA, otherwise this line is ignored. These parameters are the same as those specified in the SURFACE and VOLUME case control for requesting grid point stresses/strains and the user is referred to the OUTPUT(POST) section for more details. All defaults are used if this line is omitted. See Remark 12.</p>
MTHD	<p>Method to calculate average grid point stresses/strains:</p> <ul style="list-style-type: none"> <li>■ TOPO = Topological method (default)</li> <li>■ GEOM = Geometric method.</li> </ul>
OUTPUT	<p>Coordinate system in which to translate stresses/strains before averaging:</p> <ul style="list-style-type: none"> <li>■ -1 : Specifies the element coordinate system for output</li> <li>■ 0 : Specifies the basic coordinate system for output (default)</li> <li>■ CID : Specifies the coordinate system defined on a CORDij bulk data entry for output</li> </ul> <p>The X-axis of this system is used to define the X stress direction. For shell elements the X-axis of the specified coordinate system is projected onto the surface or, that is, the resulting averaged stresses are a projection onto the surface.</p>
NORMAL	<p>For shell elements defining a surface, this specifies the method to define the surface normal. For solid elements defining a volume, this specifies the method to define the stress Z-axis. Indirectly this also sets the reference direction for positive fiber and shear stress output, but has no effect when OUTPUT=-1. Can be set to R (default), X1, X2, or X3.</p> <p>M Specifies the reverse of the direction given by R, X1, X2, or X3 and must be entered as MR, MX1, MX2, or MX3 with no space between the M and the following letter. R Specifies the radius vector from the origin of reference coordinate system to the grid point.</p> <p>The Y stress direction is the cross product of the Z and X stress directions defined by the NORMAL and the X-axis of the OUTPUT coordinate system.</p>
"VIBFTG"	<p>SOL 108, 111 only. Flag indicating that vibration fatigue parameters follow. The line is optional and defaults are used if not present.</p>
ATYPE	<p>Analysis method to use to generate the PDF of rainflow ranges: DIRLIK, NARROW, STEIN, SINES. (Character; default = DIRLIK)</p>

Describer	Meaning
MAXSTR	Maximum stress to use as a function of the number of RMS stress levels to determine maximum stress in the rainflow cycle count. (Real>0.0; Default=10.0).
CLIPLVL	Value of stress where all stresses are "clipped" (kept at that level) when doing fatigue life calculation. Real>0.0; (Default CLIPLVL=MAXSTR). CLIPLVL=6 means +/- 3*RMS amplitudes or 6*RMS in terms of range.
MAXPEAK	Used to calculate an estimation of maximum and minimum stress (number of RMS levels) in the random response. It is not used in any way to calculate damage or life. This is also used when the maximum elastic-plastic peak strain is calculated. Where a mean load is included the peak stress is calculated as the mean_stress + MAXPEAK*RMS and the minimum stress is calculated as the mean_stress - MAXPEAK*RMS. This is similar to the time domain approach where the maximum and minimum stress are retained from the rainflow cycle count. (Real>0; Default=CLIPLVL/2 or, if CLIPLVL not defined, MAXSTR/2).
STRBINS	Number of bins to generate in rainflow cycle count. Default = 1280 for ATYPE=SINES otherwise 32. Not recommended to use anything over 5000.
MAXFREQ	Percentage of frequency content retained as a function of the first spectral moment $m_0$ of the PSD defining the maximum frequency used to integrate the spectral moments for $m_1$ , $m_2$ , and $m_4$ . $0 \leq \text{Real} \leq 100.0$ ; Default=99.9). 100% is not a recommended setting as it can cause numerical instability related to the calculation of the 4th spectral moment.
NCALC	Alternative options for the way "N" (life to failure) is calculated for a given stress bin. Valid values are MID, UPR, or AVG for middle, upper or average. (Character; Default=AVG). See <a href="#">Table 9-20</a> .

Remarks:

1. FTGPARM bulk data is ignored if not selected by a FATIGUE case control entry. If a FTGPARM entry is not defined, default properties are used for the requested fatigue analysis.
2. **SOL 101, 103, 112:** For total life or stress-life (TYPE=SN), only STRESS results can be used. For crack initiation or strain-life (TYPE=EN), the fatigue analyzer may use either STRESS or STRAIN results from the finite element analysis. This selection should make no difference to the final results of a crack initiation calculation, as strains will always be calculated. The exception is when shell results are used. In this case, STRESS should be selected because only 2D results are available and the absence of the out-of-plane strains will cause incorrect calculation of combined parameters. It is an error to have both STRESS and STRAIN lines. If both are missing, then STRESS will be assumed with its default values.
3. **SOL 101, 103, 112:** PLAST can only be set to NEUBER. Please note that NEUBER can be used universally for uniaxial stress states. PLAST is only valid for TYPE=EN.

4. If LOC=ELEM (element center), fatigue lives are calculated based on stresses/strains at element centroids (not recommended for anything but shell or 2D solid elements (plane stress/strain and axisymmetric) and the RECOVER field is ignored or automatically set to CENTER.

If LOC=NODE, the fatigue lives are calculated from the stresses/strains at the element nodes, resulting in multiple damage values per node. Note that for LOC=NODE, the RECOVER field can be set to SGAGE, BILIN, CUBIC, or CORNER to control which stresses are used in the fatigue analysis for element nodal stresses and correspond to the same options as on the STRESS case control.

If LOC is set to NODA, the same RECOVER options as LOC=NODE apply, however:

**SOL 101, 103, 112:** With LOC=NODA, fatigue lives are based on stresses/strains from nodal averaged (grid point) stresses, resulting in a single damage value at each node as opposed to using LOC=NODE where the fatigue lives are calculated from the stresses/strains at the element nodes, resulting in multiple damage values per node. The grid point stresses are generated using Nastran's GPSTRESS output request internally (it is not required to include the GPSTRESS case control unless you wish to view the grid point stress also). See the NAVG line settings also on how to control grid point stress calculations.

**SOL 108, 111:** With LOC=NODA, after the nodal transfer function (TF) stresses for each element contribution are converted to the requested stress combination (e.g. COMB=SGVON), the stresses are summed and averaged at each node. This is done at every frequency to give a single TF of stress at each node. Thus a single damage and fatigue life per node is reported as opposed to slightly different values when LOC=NODE. Please note that the coordinate system in which the elements are defined should be consistent (the same). Otherwise the nodal averaging will not be done using consistent coordinate systems. Thus, for solid element, setting CORDM on the PSOLID entry to the Basic coordinate system or a specified CID is required and setting CID=-1 or -2 (element systems) is not recommended. For shell elements, MCID should be set on the respective element entry.

This parameter cannot be changed on a RESTART since it would require a different set of stress/strain data, which is not allowed on a RESTART for a pure fatigue analysis.

LOC=NODE generally gives more conservative answers than LOC=NODA since no averaging of the stresses/strains is done from the contributions of the surrounding elements.

5. **SOL 101, 103, 112:** SRESOLVE is applicable for all three values of LOC, i.e.: LOC = ELEM, NODE or NODA. SRESOLVE is an option to evaluate surface stresses instead of volume stresses. When surface resolved stresses are requested from 3D solid elements, a thin layer of 2D shell elements is internally created encompassing the volume of the elements defined on the FTGDEF entry from which the 2D stress state is then determined. This parameter is necessary if a multiaxial assessment of a model made of 3D elements is necessary, otherwise 3D elements are ignored during a multiaxial assessment. Fatigue life and multiaxial statistics are only reported for these newly defined 2D elements (or reduced set of nodes) on the surface of the volume (free surface). Interior nodes are not included in the fatigue calculation. The internal element IDs generated by this option can be controlled by using MSC Nastran SYSTEM cell 183 (Default is set to 200000000).

Element sets must be the same for all FATIGUE case control IDs that request surface resolved stresses. Otherwise a fatal condition is flagged and the analysis stops.

6. Certainty of survival is based on scatter in the S-N or  $\epsilon$ -N curves. It is used to modify the curves according to the standard error parameters ( $SE_n$ ) defined in the MATFTG material entry. A higher reliability level requires a larger certainty of survival.
7. **SOL 101, 103, 112:** This FOS option will calculate a type of safety factor for over design analysis to be performed. This analysis is in addition to the normal fatigue life/damage output and must be requested by the presence of this FOS flag and its parameters. This analysis method can be very useful for those components which predict infinite life, providing a measure of the risk of fatigue failure. The results of this analysis are factors by which the stress would have to be scaled to attain the specified design life. A value of one suggests that the specified life will be exactly attained whereas a factor less than one means the desired life will not be attained. Factors greater than one are, therefore, most desirable. By definition the resulting life values will be the target life, thus only the scale factor and maximum/minimum stress results are of interest when FOS is defined.

**SOL 108, 111:** This FOS option is actually a margin of safety (MOS) calculation, which requires only the desired or required duration of entire loading sequence in time units. By default this is set to 1.0 and the time units are those defined by the TUNIT field on the FTGSEQ entry.

8. For fatigue analysis of spot and seam welds, besides the “SPOTW” and “SEAMW” lines themselves, “CERTNTY”, and “FOS” are also applicable. “MULTI” is applicable to seam weld, but not spot welds. All others are ignored. TYPE field is ignored as an SN analysis is forced for fatigue of spot and seam welds.
9. Biaxial/Multiaxial assessment can be requested for all but fatigue analysis of spot welds and is ignored by SOL 200 optimization runs. These assessments require a 2D state of stress. For this reason only shell elements are supported with this feature. MMTHD=AUTO is not allowed for fatigue analysis of seam welds.
10. The Rupp method for spot weld life prediction has not been validated for the prediction of fatigue damage occurring at the middle sheets for spot welds joining more than two sheets. It should also be noted that such failures are relatively rare, difficult to reproduce in the laboratory, and difficult to detect in practice. Scrutinize middle sheet results carefully as they may give a false positive failure prediction.
11. Factor of Safety (FOS) analysis is only compatible with the MMTHD=SIMPLE if doing a multi-axial/biaxial (MULTI) assessment in the same run. MMTHD=AUTO is not allowed in fatigue analysis of seam welds (SEAMW). The stress/strain combination (COMB) is ignored if MMTHD=AUTO because the program will determine whether to use a critical plane or absolute maximum principal combination method.
12. When LOC=NODA for requesting nodal average stresses, the grid point stresses generator is used to determine the nodal averaging. A limited set of controls is provided on the NAVG line to control how the averaging method. Internally, SURFACE and/or VOLUME definitions are created for the grid point stress request, just as if the GPSTRESS case control, with its associated OUTPUT(POST) commands, were given. However, only one SURFACE and/or VOLUME is determined based on the elements defined on the FTGDEF entry for requesting fatigue analysis. The user should be aware of possible stress discontinuities that can result from this.

13. By default the response PSD at the most critical location is output using LOGLVL=0 via a `<jobname>PSD.csv` file. If LOGLVL=1, response PSDs for all requested locations are output to that same file. Also a `<jobname>RCC.csv` file is produced with limited data showing the summation of damages from the rainflow cycle count. If LOGLVL=2, both files are created and in the latter, addition the stress and damage BIN data for each event is included. Be aware that this can create a lot of data, resulting in huge output files, and can severely degrade performance. Please use this option with care and limit the output to only the critical elements of interest.

Table 9-17 Allowable Values for the COMB Field

Stress/Strain Combination	SOL 101, 103, 112* Valid for TYPE	SOL 108, 111 Valid for TYPE	Meaning
ABSMAXPR	SN (+Seam Weld) EN	SN EN	Absolute Maximum Principal (default)†
MAXPRINC	SN	SN EN	Maximum Principal Stress‡
SGVON	SN EN	SN EN	Signed von Mises Stress (recommended for SOL 108, 111 but not default)
SGMAXSHR	SN EN		Signed Maximum Shear
CRITICAL	SN (+Seam Weld), EN		Critical Plane Analysis - every 10 degrees by default unless NANGLE is specified otherwise for standard SN/EN analysis only- Not valid for 3D solid or CSHEAR elements - element must have an in-plane stress state.
STNDRD	SN (Spot Weld only)		This is basically a critical plane analysis with calculations being done at NANGLEs around the circumference of the spot weld.
COMPX COMPY COMPZ COMPXY COMPYZ COMPZX		SN EN	Individual stress components

\* In time domain, six multiaxial components of the stress tensor are resolved into one uniaxial, combined value for fatigue calculations at each entity per time step since damage models are based on uniaxial theories. For S-N analysis, the signed von Mises (SGVON) will be smaller than the Absolute Maximum Principal (ABSMAXPR) when there is positive biaxiality and hence this selection would be less conservative. (Note also that some BS weld classes require shear stress to be used.) The signed parameters use the sign of the absolute maximum principal value for conservative fatigue life estimates. It is not recommended to use non-signed values, thus they are not supported.

† In frequency domain, this is a Maximum Principal calculation using accurate phase scanning.

‡ In frequency domain, this is a fast Maximum Principal calculation using an approximate algorithm and is less accurate than ABSMAXPR, but improves computational speed.

Table 9-18 Allowable Values for the CORR Field

Mean Stress Correction	SOL 101, 103, 112 Valid for TYPE	SOL 108, 111 Valid for TYPE	Meaning
NONE	SN (+Spot/Seam Weld) EN	SN EN	No mean stress correction (default)
GOODMAN	SN	SN EN	Goodman mean stress correction
GERBER	SN	SN EN	Gerber mean stress correction
GDMANT	SN	SN EN	Tension only Goodman mean stress correction
GRBERT	SN	SN EN	Tension only Gerber mean stress correction
FKM	SN (+Spot/Seam Weld)		FKM mean stress correction method. Uses M1, M2, M3, M4 slopes as defined in <a href="#">MATFTG</a> entry. See remarks in <a href="#">MATFTG</a> entry.
SIMPLE	SN (Spot Weld only)		Modified FKM mean stress correction method where $M1=M2=M3=M4=-MSS$ as defined in the <a href="#">MATFTG</a> entry.
INTERP	SN		Interpolation method used with multiple SN curves only. TYPE field of <a href="#">MATFTG</a> entry must be set to MEAN, RRATIO, or LIFE. Requires that there be multiple curves defined, one at $R=-1$ for TYPE=RRATIO, or zero (0) mean stress for TYPE=MEAN.
SWT	EN	SN EN	Smith-Watson-Topper mean stress correction
MORROW	EN	EN	Morrow mean stress correction
WALKER		EN	Walker mean stress correction
MMPDS		SN EN	Walker mean stress correction built into the MMPDS-01 material curves

Table 9-19 Allowable S-N vs. Mean Stress Correction Methods for SOLs 101, 103, 112

Mean Stress Correction	S-N Method				
	Standard	Multi Mean Curve	Multi R-Ratio Curve	Haigh	Bastenaire
NONE	YES	YES*	YES†	NO	YES
GOODMAN	YES	YES*	YES†	NO	YES
GERBER	YES	YES*	YES†	NO	YES
GDMANT	YES	YES*	YES†	NO	YES
GRBERT	YES	YES*	YES†	NO	YES
FKM	YES	YES*	YES†	NO	YES
SIMPLE‡	YES	NO	NO	NO	NO
INTERP	NO	YES	YES	YES	NO

\* Allowed but a curve at zero mean stress must be present.

† Allowed but a curve at R = -1 must be present.

‡ Spot Welds only.

Table 9-20 Alternative NCALC options to calculate “N” (cycles to failure)

NCALC option	Meaning
AVG	Calculation of “N” is done by adding up all the values of N within the BIN and then dividing through by the number of N values used. In this context the average value of N is calculated over the BIN.
MID	“N” is extracted at the mid (stress) point of the BIN.
UPPER	“N” is extracted at the upper (stress) point of the BIN.

## FTGSEQ

## Fatigue Load Sequence

Defines the loading sequence for pseudo-static fatigue analysis using SOL 101 or modal transient fatigue analysis using SOL 103 or SOL 112 or vibration fatigue using SOL 108 or SOL 111.

Format (SOL 101, 103, 112):

1	2	3	4	5	6	7	8	9	10
FTGSEQ	ID	EVNTOUT	METHOD						
	FID1	N1	FID2	N2	FID3	N3	FID4	N4	
	FID5	N5	...	...	...	...	...	...	
	-etc.-								
	"UNITS"	EQUIV	EQNAME						

Format (SOL 108, 111):

1	2	3	4	5	6	7	8	9	10
FTGSEQ	ID	EVNTOUT		TUNIT	LDM				
	FID1	N1	FID2	N2	FID3	N3	FID4	N4	
	FID5	N5	...	...	...	...	...	...	
	-etc.-								
	"UNITS"	EQUIV	EQNAME						

Examples:

FTGSEQ	1								
	6	1 5							

Descriptor	Meaning
ID	Unique ID with respect to all other FTGSEQ and FTGEVNT entries called out by a FATIGUE case control. (Integer>0) See Remark 1.
EVNTOUT	Flag for requesting fatigue output for each event individually. (Integer; 0=no or 1=yes; Default = 0). See Remark 7. For SOL 108 and 111, this also controls the written output request for spectral statistics (m0, m1, m2, m4, etc.).
METHOD	SOL 101, 103, 112 only. Event processing method. 0=independent, 1=Combined Full, 2=Combined Fast (Integer; Default = 0). This entry is only honored from the controlling FTGSEQ entry when called out by the FATIGUE case control. Otherwise it is ignored. See Remark 2.
TUNIT	SOL 108, 111 only. Time units of Ni values. SECS, MINS, HRS, DAYS, WKS, MTHS, YRS for seconds, minutes, hours, days, weeks, months, or years, respectively (Character; Default=SECS).

Describer	Meaning
LDM	<b>SOL 108, 111</b> only. FE load magnitude used to create transfer function. Used to normalize the transfer function stresses (Real, Default=1.0).
FIDi	<ul style="list-style-type: none"> <li>■ <b>SOLs 101, 103</b>: ID of a FTGEVNT or another FTGSEQ entry for pseudo-static fatigue analysis using SOL 101 or a modal analysis using SOL 103 (Integer &gt; 0). See Remark 3. and 4.</li> <li>■ <b>SOL 112</b>: A subcase ID that represents the loading event or another FTGSEQ entry for modal transient fatigue analysis using SOL 112. (Integer &gt; 0). See Remark 3. and 4.</li> <li>■ <b>SOL 108, 111</b>: ID of a FTGEVNT entry for random vibration fatigue using SOLs 108 or 111. Nested FTQSEQs are not allowed.</li> </ul>
Ni	<ul style="list-style-type: none"> <li>■ <b>SOLs 101, 103, 112</b>: Number of repeats of this loading sequence or event (Real&gt;0.0, Default=1.0). Ignored if only one event is defined. For METHOD equal 1 and 2, Ni must be a whole number, i.e., 1.0, 2.0, 3.0, etc. In other words, fractions of events are not allowed. Fractional events are also not allowed for any METHOD if the corresponding FID references a FTGSEQ entry. See Remark 3. and 4.</li> <li>■ <b>SOL 108, 111</b>: Duration of each event in TUNIT units. This value is not used for random loading only. These values are also not needed and overwritten if SWRATE/NSWEEP are provided on a FTGLOAD entry of TYPE= SINE (sine sweep). (Real&gt;0.0; Default=1.0).</li> </ul>
"UNITS"	Flag indicating that a fatigue equivalent unit name is applied to this loading. See Remark 5. and 6.
EQUIV	Number of equivalent units. (Real>0.0; Default=1.0 ). See Remark 5. and 6.
EQNAME	Equivalent name of this loading event. EQNAME can span across fields 4 through 9. If not defined it will be called <i>Repeats</i> (Character). No spaces are allowed. See Remark 5. and 6.

**Remarks:**

1. FTGSEQ bulk data are called out by FATIGUE case control.
2. Processing of events can be done by determining the damage due to each event independently (default) and then summing the damage due to all events. Or the events can be concatenated and damage determined after rainflow cycle counting over all events. The advantage of the independent method over the combined methods is computational expense versus accuracy. The combined method will close all cycles, whereas the individual method may miss a large damaging cycle if the cycle begins in one event and ends or closes in a subsequent event. The combined fast method performs a rainflow count data reduction to speed up the analysis and determine the most critical locations first and then redoes a full analysis on the critical locations.

3. Once a FTGSEQ bulk data entry is referenced in an FIDi field, it can't be referenced again in any other FTGSEQ entries (within its own associations - the same fatigue analysis) to avoid infinite loops. And if it is referenced by the FATIGUE case control, it cannot appear in any FIDi field of the FTGSEQ bulk data.
4. Different FTGEVNTs can be set up and the user can construct each sequence by specifying how many times to repeat each event in a sequence. One sequence could then be referenced in another sequence to tell the new sequence how many times to repeat that sequence. As an example, assume there are three events an automobile is subjected to: cobble stones, pot holes, speed bumps. One sequence might be five (5) "cobble stones," six (6) "potholes" and three (3) "speed bumps." This sequence may be called "torture track." Also define two more events called "cornering left" and "cornering right." A load sequence of ten (10) "cornering left" and ten (10) "cornering right" might be called "country road." Now with a nested FTGSEQ you can put these together any way you want. So one fatigue analysis might use a sequence of only "country road," another of only "torture track" and another of a combined six (6) "torture tracks," five (5) "country roads," followed by one (1) more "torture track" and one (1) more "country road" This would result in 3 fatigue analyses as shown in [Table 9-21](#) below.
5. If the "UNITS" flag is absent, the default fatigue equivalent unit is 1.0 *Repeats* of the resulting stress time history sequence. Equivalent units specified on FTGLOAD entries are ignored when FTGSEQ entries are used
6. Example of using equivalent units: If one repeat (or total duration) of the sequence is equivalent to five (5) times around a test track, the equivalent unit name, EQNAM, might be "*laps*," and the equivalent unit, EQUIV, would be five (5). Fatigue life will be reported in these units if defined, otherwise they are reported as repeats of the loading sequence. Life output is reported in both *Repeats* and the fatigue equivalent units, if defined.
7. For SOL 200 only EVNTOUT=0 is supported. Also some additional output file formats are not supported if EVNTOUT>0. See the [FATIGUE case control entry](#) for STROUT=4 limitations.
8. **SOL 108, 111:** For vibration fatigue a FTGSEQ cannot reference both an event with single input random loading and multiple input random loading.

Table 9-21 Example of nested FTGSEQ entries

```

SET 1=22,33,44
FATIGUE=1
BEGIN BULK
$
FTGSEQ,22          $<-- 1 country road only
,2
FTGSEQ,33          $<-- 1 torture track only
,3
$combined
FTGSEQ,44          $<-- 6 torture track, 5 country road, + 1 of each
,3,6.0,2,5.0,3,1.0,2,1.0
$country road:
FTGSEQ,2
,8,10.0,9,10.0    $<-- 10 cornering left + 10 cornering right
$torture track:
FTGSEQ 3
,5,5.0,6,6.0,7,3.0 $<-- 5 cobble stones, 6 potholes, 3 speed bumps
$

```

FTGEVNT,5... \$cobble stones  
FTGEVNT,6... \$potholes  
FTGEVNT,7... \$speed bumps  
  
FTGEVNT,8... \$cornering right  
FTGEVNT,9... \$cornering left

## GBAG Gas-Bag Pressure Definition

Defines the pressure within an enclosed volume. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
GBAG	GID	BSID	TRIGGER	TRIGGERV	PORID	INFID	HTRID	INTID	
	CPGAS	GPGASV	RGAS	PENV		REVERSE	CHECK	PINIT	
	TINIT	TENV							

Examples:

GBAG	101	37			11	12			
	CONSTANT	1000.	297.0	101325.		ON	ON		
	293.0								

Describer	Meaning		
GID	Unique gas-bag number.	I > 0	Required
BSID	Identification number of a BSURE, BCBOX, BCPROP, BCMATL, or BCSEG entry defining the surface of the gas-bag.	I > 0	Required
TRIGGER	The time-dependent parameters are offset in time.	Character	TIME
	TIME The offset is defined at TRIGGERV.		
TRIGGERV	The value of the offset in time.	Real	Required
PORID	Number of a set of LEAKAGE entries, that defines the porosity (permeability) and holes for the gas-bag surface and/or subsurfaces.	Integer > 0	No porosity
INFID	Number of a set of ABINFL entries, that defines the one or more inflators on subsurface(s) of the GBAG surface.	Integer > 0	No inflators
HTRID	Number of a set of HEATLOS entries, that defines the heat transfer definitions for the gas-bag surface and/or subsurfaces.	I > 0	No heat transfer
INTID	ID of an INITGAS entry specifying the initial gas composition for this GBAG.	I > 0	No initial gas composition

Describer	Meaning		
CPGAS	The variation of the specific heat constant at constant pressure. CONSTANT The specific heat is constant and specified in CPGASV.	Character	CONSTANT
CPGASV	The specific heat of the gas.	Real	Required
RGAS	Gas constant of the inflowing gas.	Real	Required
PENV	Environmental pressure surrounding the gas bag.	Real	Required
REVERSE	Normal auto-reverse switch.  ON The normals of the surface are automatically reversed if necessary so that they point in the same direction and provide a positive volume.  OFF The normals are not automatically reversed.	C	ON
CHECK	Normal checking switch.  ON The normals of the surface are checked to see if they all point in the same direction and provide a positive volume.  OFF The normals are not checked.  If REVERSE is set to ON, CHECK is automatically set to ON.	C	ON
PINIT	Initial pressure inside the gas bag.	Real	PENV
TINIT	Initial temperature inside the gas bag. See Remark 4.	Real	Required.
TENV	Environmental Temperature.	Real > 0	TINIT

Remarks:

1. The BSURF entry referenced by the BSID field must form a closed volume.
2. The pressure in the gas bag is applied to all the faces of the outer boundary.
3. TINIT is the temperature of the gas inside the volume at  $time = 0$ . At  $time = 0$ , the mass of the gas inside the gas bag is calculated as

$$m = \frac{P_{init}V}{RT_{init}}$$

where,  $P_{init}$  the initial pressure,  $V$  the volume,  $R$  the gas constant, and  $T_{init}$  the initial gas temperature.

- The flow through exhaust openings, leakage areas and user-specified outflow rate is accumulated. The volumetric porosity contributes to the outflow of gas as

$$\dot{m}_{out} = \rho \cdot Q = \frac{p}{R \cdot T} \cdot Q$$

where

$Q$	= volumetric flow rate
$\rho$	= density inside the bag
$p$	= pressure inside the bag
$R$	= gas constant
$T$	= temperature inside the bag
$\dot{m}_{out}$	= mass outflow rate

The value of  $Q$  can be specified as a constant, as a function of the pressure difference, or as a function of time. Negative values for the volumetric flow rate are not allowed, since this would mean inflow of outside air.

- A mixture of BSURF, BCBOX, BCPROP, BCMATL or BCSEG with the same BSID is allowed. However multiple BSID of the same type is not allowed. When using this option, special care must be taken to assure the same element is not part of multiple BSID definitions.

## GBAGCOU

### General Coupling to Gas-Bag Switch

Defines a switch from full gas dynamics to uniform pressure formulation. Used in SOL 700 only.

**Format:**

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
GBAGCOU	ID	CID	GID	TSTART	PERCENT				

**Examples:**

GBAGCOU	1	100	101	0.0	5				
---------	---	-----	-----	-----	---	--	--	--	--

Describer	Meaning		
ID	Unique number of a GBAGCOU entry.	I > 0	Required
CID	Number of a COUPLE entry.	I > 0	Required
GID	Number of a GBAG entry.	I > 0	0.0
TSTART	Time after which the coupling algorithm checks if a switch to the uniform pressure method is valid. It is valid when the following is true:  $\text{Max} \left[ \frac{P_{max} + P_{average}}{P_{average}}, \frac{P_{average} - P_{min}}{P_{average}} \right] < \frac{\text{PERCENT}}{100}$ where Pmax = maximum Eulerian pressure exerted on the SURFACE Pmin = minimum Eulerian pressure exerted on the SURFACE Paverage = average Eulerian pressure exerted on the SURFACE	Real ≥ 0	0.0
PERCENT	Value used in validity check as defined previously.	R ≥ 0.	0.0

**Remarks:**

1. The BSID referenced by the COUPLE entry CID and by the GBAG entry GID must be the same.
2. All Eulerian and general coupling calculations are deactivated after transition from gas dynamics to uniform pressure.

**GENEL**

**General Element**

Defines a general element.

Format:

1	2	3	4	5	6	7	8	9	10
GENEL	EID		UI1	CI1	UI2	CI2	UI3	CI3	
	UI4	CI4	UI5	CI5	-etc.-				

UI<sub>m</sub> -- The last item in the UI list will appear in one of fields 2, 4, 6, or 8.

	"UD"		UD1	CD1	UD2	CD2	-etc.-		
--	------	--	-----	-----	-----	-----	--------	--	--

UD<sub>n</sub> -- The last item in the UD list will appear in one of fields 2, 4, 6, or 8.

	"K" or "Z"	KZ11	KZ21	KZ31	-etc.-	KZ22	KZ32		
	-etc.-		KZ33	KZ43	-etc.-				

KZ<sub>mm</sub> -- The last item in the K or Z matrix will appear in one of fields 2 through 9.

	"S"	S11	S12	-etc.-		S21	-etc.-		
--	-----	-----	-----	--------	--	-----	--------	--	--

S<sub>mn</sub> -- The last item in the S matrix will appear in one of fields 2 through 9.

Example:

GENEL	629		1	1	13	4	42	0	
	24	2							
	UD		6	2	33	0			
	Z	1.0	2.0	3.0	4.0	5.0	6.0	7.0	
	8.0	9.0	10.0						
	S	1.5	2.5	3.5	4.5	5.5	6.5	7.5	
	8.5								

Descriptor	Meaning
EID	Unique element identification number. (Integer > 0)
UI <sub>i</sub> , CI <sub>i</sub> UD <sub>j</sub> , CD <sub>j</sub>	Identification numbers of degrees-of-freedom in the UI or UD list, in sequence corresponding to the [K], [Z], and [S] matrices. UI <sub>i</sub> and UD <sub>i</sub> are grid point numbers, and CI <sub>i</sub> and CD <sub>j</sub> are the component numbers. If a scalar point is given, the component number is zero. (Integer ≥ 0)
KZ <sub>ij</sub>	Values of the [K] or [Z] matrix ordered by columns from the diagonal, according to the UI list. (Real)

Describer	Meaning
Sij	Values of the [S] matrix ordered by rows according to the UD list. (Real)
“UD”, “K”, “Z”, and “S”	Character strings that indicate the start of data belonging to the UD list or the [K], [Z], or [S] matrices.

Remarks:

1. The stiffness approach:

$$\begin{Bmatrix} f_i \\ f_d \end{Bmatrix} = \begin{bmatrix} K & -KS \\ -S^T K & S^T K S \end{bmatrix} \begin{Bmatrix} u_i \\ u_d \end{Bmatrix}$$

The flexibility approach:

$$\begin{Bmatrix} u_i \\ f_d \end{Bmatrix} = \begin{bmatrix} Z & S \\ -S^T & O \end{bmatrix} \begin{Bmatrix} f_i \\ u_d \end{Bmatrix}$$

where

$$\begin{aligned} \{u_i\} &= [u_{i1}, u_{i2}, \dots, u_{im}]^T \\ \{u_d\} &= [u_{d1}, u_{d2}, \dots, u_{dn}]^T \\ [KZ] &= \begin{bmatrix} KZ11 & \dots & \dots & \dots \\ KZ21 & KZ22 & \dots & \dots \\ KZ31 & KZ32 & \dots & \dots \\ \vdots & \vdots & \vdots & \vdots \\ KZ_{m1} & \dots & \dots & KZ_{mm} \end{bmatrix} \text{ and } [KZ]^T = [KZ] \end{aligned}$$

$$[S] = \begin{bmatrix} S11 & \dots & S1n \\ S21 & \dots & \dots \\ S31 & \dots & \dots \\ \vdots & \vdots & \vdots \\ S_{m1} & \dots & S_{mn} \end{bmatrix}$$

The required input is the  $\{u_i\}$  list and the lower triangular portion of  $[K]$  or  $[Z]$ . Additional input may include the  $\{u_d\}$  list and  $[S]$ . If  $[S]$  is input,  $\{u_d\}$  must also be input. If  $\{u_d\}$  is input but  $[S]$  is omitted,  $[S]$  is internally calculated. In this case,  $\{u_d\}$  must contain six and only six degrees-of-freedom.

The forms shown above for both the stiffness and flexibility approaches assume that the element is a free body with rigid body motions that are defined by  $\{u_i\} = [S]\{u_d\}$ . See [General Element Capability \(GENEL\)](#) (Ch. 3) in the *MSC Nastran Reference Guide* for further discussion.

2. When the stiffness matrix  $K$  is input, the number of significant digits should be the same for all terms.
3. Double-field format may be used for input of  $K$  or  $Z$ .
4. The DMIG entry or the INPUTT4 module offer alternative methods for inputting large matrices.
5. The general element entry in the example above defines the following:

$$[u_i] = [1-1, 13-4, 42, 24-2]^T$$

$$\{u_d\} = [6-2, 33]^T$$

where i-j means the j-th component of grid point i. Points 42 and 33 are scalar points.

$$[Z] = \begin{bmatrix} 1.0 & 2.0 & 3.0 & 4.0 \\ 2.0 & 5.0 & 6.0 & 7.0 \\ 3.0 & 6.0 & 8.0 & 9.0 \\ 4.0 & 7.0 & 9.0 & 10.0 \end{bmatrix} \quad [S] = \begin{bmatrix} 1.5 & 2.5 \\ 3.5 & 4.5 \\ 5.5 & 6.5 \\ 7.5 & 8.5 \end{bmatrix}$$

**GENUDS**

User Data for Notify User Defined Service or Subroutine

The GENUDS defines integer, real and character type data that will be passed to the notify method in runtime info interface. The notify method will be called at start of load case, start of increment, end of increment and end of load case.

Format:

1	2	3	4	5	6	7	8	9	10
GENUDS	SRV_ID								
	“INT”	IDATA1	IDATA2	IDATA3	IDATA4	IDATA5	IDATA6	IDATA7	
		IDATA8	IDATA9	...	IDATA <sub>n</sub>				
	“REAL”	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	
		RDATA8	RDATA9	...	RDATA <sub>n</sub>				
	“CHAR”	CDATA1	CDATA2	...	CDATA <sub>n</sub>				

Example:

GENUDS	MY_SRV								
	INT	1	2	100					

Descriptor	Meaning
SRV_ID	The service identifier used in the CONNECT SERVICE statement. (Character, no default)
“INT”	Keyword indicating that the following data is integer. (Character)
IDATA <sub>i</sub>	User supplied integer data. (Integer, no default)
“REAL”	Keyword indicating the following data is real. (Character)
RDATA <sub>i</sub>	User supplied real data. (Real, no default)
“CHAR”	Keyword indicating the following data is character. (Character)
CDATA <sub>i</sub>	User supplied character data. (Character, no default)

Remarks:

1. The SRV\_ID is the service identifier of SCA service in the CONNECT SERVICE statement. The SCA service should have implemented the RuntimeInfo interface.
2. A CDATA<sub>i</sub> entry cannot be the character “INT”, “REAL” or “CHAR”.

## GMBNDC

## Geometric Boundary - Curve

Defines a geometric boundary consisting of element edges along a curve interface. The boundary may consist of edges of shell, beam, or solid elements.

Format:

1	2	3	4	5	6	7	8	9	10
GMBNDC	BID	GRID1	GRIDF						
	ENTITY	ID1	ID2	ID3	ID4	ID5	ID6	ID7	
	ID8	-etc.-							

Examples:

GMBNDC	1	101	106						
	GRID	102	103	104	105				

Describer	Meaning
BID	Boundary identification number to be referenced by a CINTC entry. (Integer > 0)
GRID1	Initial grid identification number for boundary. (Integer > 0)
GRIDF	Final grid identification number for boundary. (Integer > 0)
ENTITY	Entity type for defining boundary. GRID (Character)
IDi	Entity identification numbers for boundary of subdomain. Values in the list must be unique. (Integer > 0)

Remarks:

1. All boundary identification numbers must be unique.
2. GRID1 and GRIDF define the end points of the boundary.
3. For each boundary, GRID is required.
4. For the GRID entity type, the entities should be listed in order from the GRID1 to the GRIDF. The GRID1 and GRIDF need not be repeated in the IDi list.
5. Multiple continuation entries may be specified for additional entity identification numbers, IDi.
6. Interface elements may generate high or negative matrix/factor diagonal ratios. If there are no other modelling errors, these messages may be ignored and PARAM,BAILOUT,-1 may be used to continue the run.

## GMNURB

## 3D Contact Region Made Up of NURBS in SOL 600

Defines a 3D contact region made up of NURBS using the MSC Marc style used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
GMNURB	ID	NPTU	NPTV	NORU	NORV	NSUBU	NSUBV	NTRIM	
		G1 or X1	G2 or Y1	G3 or Z1	G4 or X2	G5 or Y2	G6 or Z2	G7	
		G8 or X3	G9 or Y3	G10 or Z3	etc.		[abs(nptu)*n ptv vaues]	See Remark 3	
		Homo1	Homo2	Homo3	Homo4	Homo5	Homo6	Homo7	
		Homo8	Homo9	Homo10	Homo11	etc	[nptu*nptv values]		
		Knot1	Knot2	Knot3	Knot4	Knot5	Knot6	Knot7	
		Knot8	Knot9	Knot10	etc.		[(nptu+noru) +(nptv+norv) values]		
		IDtrim	NPTUtrim	NORUtrim	NSUBtrim		(repeat this and all following lines NTRIM times)		
			Xisoparam	Yisoparam			(NPTUtrim entries)		
			Homo1	Homo2	Homo3	etc	(NPTUtrim entries)		
			Knot1	Knot2	Knot3	etc	(NPTUtrim +NORUtrim entries)		

Example:

GMNURB	901	9	5	4	4	20	5		
		101	102	103	104	105	106	107	
		108	109	110	111	112	113	114	
		115	116	117	118	119	120	121	
		122	123	124	125	126	127	128	
		129	130	131	132	133	134	135	
		136	137	138	139	140	141	142	
		143	144	145					
		1	1	1	1	1	1	1	
		1	1	1	1	1	1	1	
		1	1	1	1	1	1	1	
		1	1	1	1	1	1	1	
		1	1	1	1	1	1	1	
		1	1	1	1	1	1	1	
		1	1	1					
		0	0	0	0	0.16667	0.33333	0.5	
		0.66667	0.833333	1	1	1	1	0	
		0	0	0	0.5	1	1	1	
		1							

Describer	Meaning
ID	Identification number of a surface defined by NURBS. ID is called out on a BCBODY entry with a NURBS2 header. (Integer > 0; Required)
NPTU	Absolute value of the number of control points. Enter NPTU as a positive number if the control points are to be input using GRID points. Enter NPTU as a negative number if the control points are to be entered using x,y,z. (Integer > 0; Required)
NPTV	Number of control points in V direction. (Integer > 0; Required)
NORU	Order along U direction. (Integer > 0; Required)
NORV	Order along V direction. (Integer > 0; Required)
NSUBU	Number of subdivisions in U direction. (Integer > 0; Required)
NSUBV	Number of subdivisions in V direction. (Integer > 0; Required)
NTRIM	Number of trimming curves. (Integer ≥ 0 or blank)
G1, G2, G3, etc.	Grid point IDs defining control points (Integer > 0; Required). There must be NPTU*NPTV entries.
X1, Y1, Z1, X2, Y2, Z2, etc.	Alternate method to define control points without using GRID points. There must be abs(NPTU)*NPTV (x,y,z) entries.

Describer	Meaning
Homo1, Homo2, Homo3, etc	Homogeneous coordinates (0.0 to 1.0). There must be NPTU*NPTV entries. (Real)
Knot1, Knot2, Knot3, etc	Knot vectors (0.0 to 1.0) in the V direction. There must be (NPTU+NORU)+(NPTV+NORV) entries. (Real)
IDtrim	ID of trimming vector. There must NTRIM of these entries and those entries that follow. (Integer > 0)
NPUTtrim	Number of control points for this trimming vector. (Integer > 0)
NORUtrim	Order for this trimming vector. (Integer > 0)
NSUBtrim	Number of subdivisions for this trimming vector. (Integer > 0)
Xisoparam	First coordinate of point in isoparametric space. (Real)
Ysoparam	Second coordinate of point in isoparametric space (Real)
Homo1, Homo2, Homo3, etc	Homogeneous coordinates (0.0 to 1.0) of this trimming vector. There must be NPTUtrim entries. (Real)
Knot1, Knot2, Knot3, etc	Knot vectors (0.0 to 1.0) of this trimming vector. There must be NPTUtrim+NORUtrim entries. (Real)

#### Remarks:

1. GMNURB is recognized only in SOL 600.
2. **WARNING:** For rigid contact, the right hand rule determines the interior side of the rigid surface. A deformable surface which contacts a rigid surface must be on the exterior side of the rigid surface (i.e. in the direction opposite to the right hand rule). If a rigid surface is described backwards, contact will not occur because the deformable body is already inside the rigid body at the start of the analysis. For 3D patches, if all need to be reversed, the parameter PARAM,MARCREVR,1 may be entered to automatically reverse all 3D patches.
3. For NURBS, enter either IDs of NPTU\*NPTV grid points as G1, G2, G3 etc. (set positive NPTU) or coordinates of abs(NPTU)\*NPTV grid point as (X1, Y1, Z1), (X2, Y2, Z2), etc. (set negative NPTU).

**GMOVR3**

RBE3 SOL400 Rigid = Lagrange perturbation coincident grid override.

Allows override values to the MDLPRM, GMOVR3 entry.

Format:

1	2	3	4	5	6	7	8	9	10
GMOVR3	ELEM1	$\Delta X_1$	$\Delta Y_1$	$\Delta Z_1$	$\Delta$ GMOVR3T1				
	ELEM2	$\Delta X_2$	$\Delta Y_2$	$\Delta Z_2$	$\Delta$ GMOVR3T2				
	-etc.-	-etc.-	-etc.-	-etc.-	-etc.-				

Example:

GMOVR3	36955001	0.1							
--------	----------	-----	--	--	--	--	--	--	--

Describer	Meaning
ELEMi	RBE3 element ID. (Integer>0)
$\Delta X_i$	Perturbation value of X coordinate (Real; default = 0.01)
$\Delta Y_i$	Perturbation value of Y coordinate (Real; default = 0.01)
$\Delta Z_i$	Perturbation value of Z coordinate (Real; default = 0.01)
$\Delta$ GMOVR3Ti	Adjustment to MDLPRM, GMOVR3T value. Zero Tolerance = $\text{GMOVR3T} + \Delta$ GMOVR3T $\geq 0.0$ . (Real; Default=0.0)

Remarks:

1. This entry is only active if MDLPRM,GMOVR3,3 or MDLPRM,GMOVR3,4 is present on the MDLPRM Bulk Data entry.
2. This entry only affects RBE3 elements meeting the following criterion:
  - a. Let  $x^q, y^q, z^q$  be the coordinates of the REFGRID and  $x^k, y^k, z^k$  the coordinates of one of the connected Gi,j nodes.
  - b. If  $|x^k - x^q|, |y^k - y^q|$ , and  $|z^k - z^q|$  are all less than or equal to  $\text{GMOVR3T} + \Delta$ GMOVR3T) for ALL connected Gi,j nodes, the grids are considered coincident.

Any entry not meeting the above requirements will be ignored.

## GMQVOL

### Define Volumetric Heat Loads

Defines a rate of volumetric heat generation in a conduction element.

Format:

1	2	3	4	5	6	7	8	9	10
GMQVOL	LID	METHOD	FIELD1		EID1	EID2	EID3	EID4	
	EID5	etc.							

Example:

GMQVOL	100	TABLE	20		18	23	7		
--------	-----	-------	----	--	----	----	---	--	--

Describer	Meaning		
LID	Load set identification number.	Integer > 0	Required
METHOD	Method used to specify the data (EQUATION, TABLE, CONSTANT). See Remark 2.	Character	Required
FIELD1	Volumetric heat load data. See Remark 2.	Integer or Real	Required
EID <sub>i</sub>	A list of heat conduction elements.	Integer > 0	Required

Remarks:

- For steady-state analysis, the load set is selected in the Case Control Section (LOAD=LID).
- METHOD specifies the data type of FIELD1 to be constants, equation IDs, or table IDs. Values in FIELD1 and FIELD2 are:

METHOD	FIELD1
EQUATION	ID of a DEQATN entry defining the volumetric heat generation rate as a function of location (Integer > 0).
TABLE	ID of a TABLE3D entry defining the volumetric heat generation rate as a function of location (Integer > 0).
CONSTANT	Value of volumetric heat generation rate (Real).

Note that the fifth field will be reserved for the future development of temperature dependent functions.

## GRAV Acceleration or Gravity Load

Defines acceleration vectors for gravity or other acceleration loading.

Format:

1	2	3	4	5	6	7	8	9	10
GRAV	SID	CID	A	N1	N2	N3	MB		

Example:

GRAV	1	3	32.2	0.0	0.0	-1.0			
------	---	---	------	-----	-----	------	--	--	--

Describer	Meaning
SID	Set identification number. (Integer > 0)
CID	Coordinate system identification number. (Integer ≥ 0; Default = 0)
A	Acceleration vector scale factor. (Real)
Ni	Acceleration vector components measured in coordinate system CID. (Real; at least one Ni ≠ 0.0)
MB	Indicates whether the CID coordinate system is defined in the main Bulk Data Section (MB = -1) or the partitioned superelement Bulk Data Section (MB = 0). Coordinate systems referenced in the main Bulk Data Section are considered stationary with respect to the assembly basic coordinate system. See Remark 10. (Integer; Default = 0)

Remarks:

- The acceleration vector is defined by  $\vec{a} = A\vec{N}$ , where  $\vec{N}$  is the vector defined by (N1, N2, N3).  
The magnitude of  $\vec{a}$  is equal to A times the magnitude of  $\vec{N}$ . The static loads generated by this entry are in the direction of  $\vec{a}$ .
- A CID of zero references the basic coordinate system.
- Acceleration or gravity loads may be combined with “simple loads” (e.g., FORCE, MOMENT) only by specification on a LOAD entry. That is, the SID on a GRAV entry may not be the same as that on a simple load entry.
- In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- At most nine GRAV entries can be selected in a given run either by Case Control or the LOAD Bulk Data entry. Multiples or reflections of a given acceleration or gravity load can be economically accomplished by use of the LOAD Bulk Data entry.

6. In cyclic symmetry solution sequences, the T3 axis of the coordinate system referenced in field 3 must be parallel to the axis of symmetry. In dihedral cyclic symmetry (where STYPE = "DIH" on the CYSYM entry), the T1 axis must, in addition, be parallel to Side 1 of segment 1R of the model.
7. For image superelements, the coordinate system must be rotated if the image is rotated relative to its primary superelement.
8. Acceleration or gravity loads do not include effects due to mass on scalar points.
9. The RFORCE entry may be used to specify rotational accelerations.
10. The coordinate systems in the main Bulk Data Section are defined relative to the assembly basic coordinate system which is fixed. This feature is useful when a superelement defined by a partitioned Bulk Data Section is rotated or mirrored and the gravity load is more conveniently defined in terms of coordinates which are fixed.
11. If Modules are present then this entry may only be specified in the main Bulk Data section.

## GRDSET

### GRID Entry Defaults

Defines default options for fields 3, 7, 8, and 9 of all GRID entries.

Format:

1	2	3	4	5	6	7	8	9	10
GRDSET		CP				CD	PS	SEID	

Example:

GRDSET		16				32	3456		
--------	--	----	--	--	--	----	------	--	--

Descriptor	Meaning
CP	Identification number of coordinate system in which the location of the grid points are defined. (Integer $\geq 0$ or blank)
CD	Identification number of coordinate system in which the displacements, degrees-of-freedom, constraints, and solution vectors of the grid point are defined. (Integer $\geq -1$ or blank)
PS	Permanent single-point constraints on the grid point. (Any combination of Integers 1 through 6 with no embedded blanks, or blank.)
SEID	Superelement identification number. (Integer $\geq 0$ or blank)

Remarks:

1. The contents of fields 3, 7, 8, or 9 of this entry are assumed for the corresponding fields of any GRID entry whose field 3, 7, 8, and 9 are blank. If any of these fields on the GRID entry are blank, the default option defined by this entry occurs for that field. If no permanent single-point constraints are desired, one of the coordinate systems is basic, or the grid is assigned to the residual structure then the default may be overridden on the GRID entry by making one of fields 3, 7, 8, or 9 zero (rather than blank). Only one GRDSET entry may appear in the Bulk Data Section.
2. The primary purpose of this entry is to minimize the burden of preparing data for problems with a large amount of repetition (e.g., two-dimensional pinned-joint problems).
3. At least one of the fields CP, CD, PS, or SEID must be specified.

## GRID Grid Point

Defines the location of a geometric grid point, the directions of its displacement, and its permanent single-point constraints.

Format:

1	2	3	4	5	6	7	8	9	10
GRID	ID	CP	X1	X2	X3	CD	PS	SEID	

Example:

GRID	2	3	1.0	-2.0	3.0		316		
------	---	---	-----	------	-----	--	-----	--	--

Free Field Large Format Example:

GRID\*, 2, , 1.0, -2.0,

\*, 3.0, , 136

Translates to:

1	2	3	4	5	6	7	8	9	10
GRID*	2				1.0		-2.0		+
*+	3.0				136				

The comma immediately following the -2.0 is required if NASTRAN IFPSTAR=NO is used. The comma is always recommended even if NASTRAN IFPSTAR=YES (Default) is used.

Describer	Meaning
ID	Grid point identification number. (0 < Integer < 100,000,000, see Remark 7.)
CP	Identification number of coordinate system in which the location of the grid point is defined. (Integer ≥ 0 or blank*)
X1, X2, X3	Location of the grid point in coordinate system CP. (Real; Default = 0.0)
CD	Identification number of coordinate system in which the displacements, degrees-of-freedom, constraints, and solution vectors are defined at the grid point. (Integer ≥ -1 or blank, see Remark 3.)*
PS	Permanent single-point constraints associated with the grid point. (Any of the Integers 1 through 6 with no embedded blanks, or blank*.)
SEID	Superelement identification number. (Integer ≥ 0; Default = 0)

\*See the GRDSET entry for default options for the CP, CD, PS, and SEID fields.

## Remarks:

1. All grid point identification numbers must be unique with respect to all other structural, scalar, fluid and extra (EPOINT) points.
2. The meaning of X1, X2, and X3 depends on the type of coordinate system CP as follows (see the CORDij entry descriptions):

Type	X1	X2	X3
Rectangular	X	Y	Z
Cylindrical	R	$\theta$ (degrees)	Z
Spherical	R	$\theta$ (degrees)	$\phi$ (degrees)

See [Grid Point and Coordinate System Definition](#) in the *MSC Nastran Reference Guide*, for a definition of coordinate system terminology.

3. The collection of all CD coordinate systems defined on all GRID entries is called the global coordinate system. All degrees-of-freedom, constraints, and solution vectors are expressed in the global coordinate system. It is recommended that points on the z-axis not have their displacement directions defined with cylindrical or spherical coordinates. (See further remarks on the CORD1S, CORD2S, CORD1C, and CORD2C.)
4. The SEID field can be overridden by use of the SESET entry.
5. If CD = -1, then this defines a fluid grid point in coupled fluid-structural analysis. This type of point may only connect the CAABSF, CHACBR, CHACAB, CHEXA, CPENTA, CPYRAM, and CTETRA elements to define fluid elements.
6. A zero (or blank if the GRDSET entry is not specified) in the CP and CD fields refers to the basic coordinate system.
7. For SOL 600, ID may range from 1 to  $2^{31} - 1$  (2147483647) if there are no OUTR options specified on the SOL 600 entry. If any OUTR option is specified the limit is 100000000.
8. For RC network solver in thermal analysis, the CD, PS and SEID are ignored.

## GRIDA

## Associative GRID for PAA

Defines an associative GRID point to be used in the COMBINE step of PAA.

Format:

1	2	3	4	5	6	7	8	9	10
GRIDA	GID	ORIG_GID							
PARTNAME									

Example:

GRIDA	1	1000							
Left_outboard_wing_tank									

Descriptor	Meaning
GID	GRID ID to be used in the current run. (Integer > 0)
ORIG_GID	GRID ID in Part being referenced. (Integer > 0)
PATNAMEi	Name of Part ORIG_GID is in. (Character, C64, no internal blank spaces)

Remarks:

- GRIDA entries are used only in the COMBINE step of PAA processing. They are used to allow the other entries in the current bulk data to reference GRID points or SPOINTs in Parts that are being combined to create the Assembly.
- ORIG\_GID must exist in the referenced Part. If the Part has been reduced, it must be a boundary GRID for that Part (in the A-set of that Part).
- The GRIDA id may be treated the same as if it were defined using a GRID or SPOINT entry in the current run. The program will handle the connection to the referenced GRID/SPOINT in the Part.
- Only dof which are in the Part A-set will be available for connection. If a GRIDA references a GRID in a Part, which has fewer than 6 dof in the Part A-set (dof available in the Part matrices), although the GRIDA will have 6 dof, only the dof which exist in the Part matrices will be connected to the Part.

**GRIDB**

## Axisymmetric Grid Point

Defines the location of a geometric grid point on a fluid point (RINGFL entry) for an axisymmetric fluid model and/or axisymmetric structure. Also defines the boundary of the fluid.

Format:

1	2	3	4	5	6	7	8	9	10
GRIDB	ID			PHI		CD	PS	IDF	

Example:

GRIDB	30			30.0		3	345	20	
-------	----	--	--	------	--	---	-----	----	--

Describer	Meaning
ID	Grid point identification number. (0 < Integer < 1000000)
PHI	Azimuthal position of the fluid in degrees. (Real)
CD	Identification number of the coordinate system in which the displacements are defined at the grid point. (Integer ≥ 0 or blank)
PS	Permanent single-point constraints associated with grid point. (Any combination of the Integers 1 through 6 with no embedded blanks, or blank.)
IDF	Identification number of a RINGFL entry. (Integer > 0)

Remarks:

1. GRIDB is allowed only if an AXIF entry is also present. The AXIF entry must define a fluid coordinate system.
2. All GRIDB identification numbers must be unique with respect to other scalar, structural, fluid and extra (EPOINT) points.
3. The referenced RINGFL entry must be present and be included in a boundary list (BDYLIST entry).
4. If no harmonic numbers on the AXIF entry are specified, no fluid elements are necessary.
5. The collection of all CD coordinate systems defined on all GRID and GRIDB entries is called the global coordinate system.
6. Fields 3, 4, and 6 are ignored, which facilitates the conversion of GRID entries to GRIDB entries. Note that the fields are the same except for fields 1 and 9 when a cylindrical coordinate system is used.

## GRIDF Fluid Point

Defines a scalar degree-of-freedom for harmonic analysis of a fluid.

Format:

1	2	3	4	5	6	7	8	9	10
GRIDF	ID	R	Z						

Example:

GRIDF	23	2.5	-7.3						
-------	----	-----	------	--	--	--	--	--	--

Describer	Meaning
ID	Identification number of axisymmetric fluid point. (0 < Integer < 1000000)
R	Radial location of point in basic coordinate system. (Real > 0.0)
Z	Axial location of point in basic coordinate system. (Real)

Remarks:

1. This entry is allowed only if an AXSLOT entry is also present.
2. ID must be unique with respect to all other scalar, structural, fluid and extra (EPOINT) points.
3. Grid points on slot boundaries are defined on GRIDS entries. Do not also define them on GRIDF entries.
4. For plotting purposes, the R location corresponds to the basic X coordinate. The Z location corresponds to the basic Y coordinate. Pressures will be plotted as displacements in the basic Z direction.
5. Load and constraint conditions are applied as if GRIDF were a scalar point. Positive loads correspond to inward flow. A single-point constraint causes zero pressure at the point.

## GRIDS

## Slot Surface Point

Defines a scalar degree-of-freedom with a two-dimensional location. Used in defining pressure in slotted acoustic cavities.

Format:

1	2	3	4	5	6	7	8	9	10
GRIDS	ID	R	Z	W	IDF				

Example:

GRIDS	25	2.5	-7.3	0.5					
-------	----	-----	------	-----	--	--	--	--	--

Describer	Meaning
ID	Identification number of the slot point. (Integer > 0)
R	Radial location of point in basic coordinate system. (Real $\neq$ 0.0)
Z	Axial location of point in basic coordinate system. (Real)
W	Slot width or thickness at the GRIDS point. (Real $\geq$ 0.0 or blank)
IDF	Identification number to define a GRIDF point. (Integer > 0 or blank)

Remarks:

1. This entry is allowed only if an AXSLOT entry is also present.
2. ID (and IDF if present) must be unique with respect to all other scalar, structural, fluid and extra (EPOINT) points.
3. If W is blank, the default value on the AXSLOT entry will be used.
4. The IDF number is referenced on the CAXIFi entry for central cavity fluid elements next to the interface. The IDF number is entered only if the grid point is on an interface. In this case, the IDF should also be defined on a GRIDF entry.
5. If IDF is nonzero, then R must be greater than zero.
6. For plotting purposes, the R location corresponds to the basic X coordinate. The Z location corresponds to the basic Y coordinate. The slot width, W, corresponds to the basic Z coordinate. The pressure will be plotted in the basic Z direction.
7. Load and constraint conditions are applied as if the GRIDS is a scalar point. Positive loads correspond to inward flow. A single-point constraint causes zero pressure at the point.

## GUST

## Aerodynamic Gust Load Description

Defines a stationary vertical gust for use in aeroelastic response analysis.

Format:

1	2	3	4	5	6	7	8	9	10
GUST	SID	DLOAD	WG	X0	V				

Example:

GUST	133	61	1.0	0.	1.+4				
------	-----	----	-----	----	------	--	--	--	--

Describer	Meaning
SID	Gust set identification number. (Integer > 0)
DLOAD	Set identification number of a TLOADi or RLOADi entry that defines the time or frequency dependence. (Integer > 0)
WG	Scale factor (gust velocity/forward velocity) for gust velocity. (Real ≠ 0.0)
X0	Streamwise location in the aerodynamic coordinate system of the gust reference point. (Real)
V	Velocity of vehicle. See Remark 5. (Real > 0.0)

Remarks:

1. The GUST entry must be selected with the Case Control command GUST = SID.
2. The gust angle is in the +z direction of the aerodynamic coordinate system. The value is

$$WG \cdot T\left(t - \frac{X - X0}{V}\right)$$

where  $T$  is the tabular function.

3. In random analysis, a unit gust velocity ( $WG = 1/\text{velocity}$ ) is suggested. The actual rms value is entered on the TABRNDG entry.
4. X0 and V may not change between subcases under one execution.
5. V must be equal to VELOCITY on the AERO Bulk Data entry.

## HADACRI Mesh Adaptivity Criterion and Corresponding Parameters - SOL 101 & 400 (Linear)

Specifies Mesh refinement criterion for adaptive mesh refinement and corresponding parameters.

Format:

1	2	3	4	5	6	7	8	9	10
HADACRI	CRITID	TYPE	F1	F2	F3	F4	F5	F6	

Example:

HADACRI	1	1	0.9						
---------	---	---	-----	--	--	--	--	--	--

Describer	Meaning
CRITID	Identification number referenced by the CRITID field in the HADAPTL Bulk Data entry. (Integer > 0; no Default)
TYPE	Type of Mesh refinement adaptivity criteria. See Remark 2. (Integer $\geq 1$ and $\leq 4$ ; Default = 1)
F1 to F8	Criteria specific parameters. See Remark 2. (Real; no Default)

Remarks:

1. The mesh refinement criteria currently available (and selected in the TYPE field) are:

TYPE	Name of Mesh Refinement Criterion
1	Error indicator based
2	Element within a spatial spherical region
3	Elements within a spatial cubic region
4	Elements in contact criteria

2. The following table describes the different refinement criteria and corresponding parameters:

TYPE	Description
1	<p>In this case a scalar error indicator <math>E_e</math> is computed for all elements 'e' in the finite element mesh. Then, an element 'e' will be refined if</p> $E_e^2 \geq F_1 \bar{E}^2$ <p>where <math>F_1</math> is a weight factor (<math>0 \leq F_1 \leq 1</math>) specified in the F1 field and <math>\bar{E}</math> is the quadratic mean of the error indicator defined as</p> $\bar{E}^2 = \frac{1}{N} \sum_{e=1}^N E_e^2$ <p>with <math>N</math> the total number of elements in the element set where element 'e' belongs. For this criteria the fields F2 to F6 are ignored.</p>
	<p>The elemental error indicator <math>E_e</math> is computed using the grid point stresses following the procedure utilized by the ELSDCON Case Control command and described in <a href="#">Mesh Stress Discontinuities at Grid Points</a> in the <i>MSC Nastran Reference Guide</i>. This procedure can be summarized as follows:</p> <ul style="list-style-type: none"> <li>Let                     <math display="block">\sigma_{aij} = \sum_{e=1}^{N_a} W_a^e \sigma_{aij}^e</math> <p>be the weighted average over all elements 'e' concurrent to a given node 'a' of each component 'ij' of the grid point stresses <math>\sigma_{aij}^e</math> where <math>W^e</math> is a weighting factor assigned to element 'e' and <math>N_a</math> is the number of elements connected to the given node 'a'.</p> </li> <li>An estimate of the error in a particular component of stress 'ij' at a grid point 'a' is then be computed as                     <math display="block">E_{aij}^2 = \sum_{f=1}^N W_a (\sigma_{aij}^e - \sigma_{aij})^2</math> </li> <li>Averaging the latter over the different stress components, 'ij', over the different shell fibers (for shell elements) and over the different grid points 'a' connected by a given element 'e' we obtain the elemental, scalar error indicator <math>E_e</math>.</li> </ul>

TYPE	Description
2	In this case the user specifies a spherical region in space with center given by (F1,F2,F3) and radius given by F4. Then, all elements with at least one node with basic coordinates (X,Y,Z) with the spherical region (i.e., such that $\ (X, Y, Z) - (F1, F2, F3)\  < F4$ ) will be refined. For this criteria the fields F5 and F6 are ignored.
3	In this case the user specifies a hexahedral region in space, aligned with the basic coordinates system, with corners given by (F1,F2,F3) and (F4,F5,F6). Then, all elements with at least one node with basic coordinates (X,Y,Z) within the specified hexahedral region (i.e., such that $F1 \leq X \leq F4$ , $F2 \leq Y \leq F5$ , $F3 \leq Z \leq F6$ ) will be refined.
4	In this case all elements with at least one node involved in contact either as touching or touched nodes in deformable contact bodies are refined. For this criteria the fields F1 to F6 are ignored.

3. Each criteria must have a unique ID (specified by the CRITID field and referenced by the CRITID field of the Bulk Data entry, [HADAPTL](#)).
4. The user might need to adjust the VARPHI parameter to ensure proper singular geometric feature detection (such as sharp edges or corners) (See the Parameter, [VARPHI](#)).

## HADAPTL

## Local Adaptive Mesh Refinement Control Parameters - SOL 101 & 400 (Linear)

Specifies Local Adaptive Mesh Refinement control parameters.

Format:

1	2	3	4	5	6	7	8	9	10
HADAPTL	ID			REPEAT	CRITID	WHEREMET	WHEREID	SNAPMETH	
	MAXLEVEL								

Example:

HADAPTL	1			10	1	PROP	5		
---------	---	--	--	----	---	------	---	--	--

Descriptor	Meaning
ID	Identification number referenced by the Case Control HADAPT command. (Integer > 0; no Default)
REPEAT	Maximum number of analysis performed before the adaptive mesh refinement process is stopped. See Remark 3. (Integer ≥ 0; Default = 6)
CRITID	Identification number of a mesh refinement criterion to be selected with the HADACRI Bulk Data entry. See Remarks 1. and 2. and the HADACRI Bulk Data entry. (Integer > 0; no Default)
WHEREMET	Method to specify the mesh refinement region subjected to the refinement criterion referenced by the field CRITID. It can take the values: "ALL" or "SUPER" or "PROP". See Remark 4. (Character; Default = ALL)
WHEREID	ID of the mesh refinement region subjected to the refinement criterion referenced by the field CRITID. Must be specified if WHEREMET is "SUPER" or "PROP". If WHEREMET=ALL, this field will be ignored. See Remark 4. (Integer ≥ 0; Default = 0)
SNAPMETH	Method to project, snap or relax new grid pints created on mid-edge or mid-faces on the mesh boundary during the refinement process onto the analysis domain boundary: 0 No projection; New grids are placed in the mid-side of edges. 1 New grid points are projected onto a smooth approximation of the analysis domain boundary interpolated from the initial mesh boundary. (Integer ≥ 0; Default = 0)
MAXLEVEL	Maximum refinement level allowed for each individual element in the mesh. No elements in the mesh will be refined to a level bigger then MAXLEVEL. (Integer > 0; Default = REPEAT)

Remarks:

1. The adaptive mesh refinement occurs when a particular refinement criterion is satisfied. Data for the refinement criterion is specified by the Bulk Data entry HADACRI referenced by the CRITID field.

2. Multiple mesh refinement criteria can be selected in different subsets of the model. To this end, the user needs to define multiple HADAPTL entries with the same ID. Each entry might specify a different criteria (referenced in the CRITID field and defined on the corresponding HADACRI Bulk Data entry) on different subsets of the mesh (defined in the WHEREMET and WHEREID fields).
3. When multiple HADAPTL entries with the same ID are specified, NASTRAN will chose for the REPEAT, SNAPMETH, and MAXLEVEL field the maximum among all multiple instances.
4. The fields WHEREMET and WHEREID refer respectively to the Method to specify the mesh refinement region (subjected to the refinement criterion referenced by the field CRITID and defined with the Bulk Data entry, [HADACRI](#)) and its corresponding ID. For example, WHEREMET=SUPER, WHEREID=3 means that local adaptive mesh refinement (with the criteria referenced by the CRITID field) should be effected only in superelement 3. Likewise, WHEREMET=PROP, WHEREID=5 (see the previous Example) means that local adaptive mesh refinement (with the criteria referenced by the CRITID field) should be effected only in those element with Property ID equal to 5. Finally, WHEREMET=ALL imply mesh refinement in all elements.
5. In partitioned superelements, the HADAPT entry must be specified in the main bulk data section. Entries specified in the Bulk Data Section corresponding to individual parts (sections beginning with BEGIN SUPER) will be ignored.
6. When using regular superelements, the Bulk Data Section must begin with BEGIN SUPER as opposed to BEGIN BULK, in order for the refinement to be appropriately propagated across superelement boundaries. If BEGIN BULK is used, grid points on the superelement boundaries will be duplicated and not shared by the joining superelements.
7. The user should avoid the use of MPC sets 90000000 to 99999999 which are reserved for hanging nodes constraints generated during the adaptive mesh refinement process.
8. The user might need to adjust the VARPHI parameter to ensure proper singular geometric feature detection (such as sharp edges or corners) (See the Parameter, [VARPHI](#)).
9. When SNAPMETH=0, all mid-edge nodes belonging to straight edges are placed on the mid-side of its edge. By contrast, when SNAPMETH=1, mid-edge nodes belonging to the boundary of the mesh are projected to a smooth approximation of the analysis domain boundary interpolated from the mesh boundary.
10. Mid-face nodes belonging to bilinear quadrilateral faces are placed at the baricenter of its face.

## HEATLOS

## Heat Loss Through Convection or Radiation of the Airbag Surface - SOL 700

Defines the heat-transfer model to be used with GBAG or COUPLE. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
HEATLOS	HID	HTRID	SUBID	HTRTYPE	HTRTYPID	COEFF	COEFFV		

Example:

HEATLOS	101	83		HTRCONV	2	TABLE	14		
---------	-----	----	--	---------	---	-------	----	--	--

Describer	Meaning
HID	Unique number of a HEATLOS entry. (Integer > 0; Required)
HTRID	Number of a set of HEATLOS entries HTRID must be referenced from a GBAG or COUPLE entry. (Integer > 0; Required)
SUBID	(Integer ≥ 0, 0) > 0            Number of a BSURF, BCBOX, BCPROP, BCMATL or BCSEG, which must be a part of the surface as defined on the GBAG or COUPLE entries. = 0            HEATLOS definitions are used for the entire surface as defined on the GBAG or COUPLE entries.
HTRTYPE	Defines the type of heat transfer. (Character; Required) HTRCONV    The HTRCONV logic is used to model heat transfer through convection in an air bag. The area of convection through which the energy is transported is equal to the area of the subsurface multiplied by COEFFV. A value of COEFFV = 1.0 will expose the complete subsurface area, while a value of COEFFV = 0.0 will result in no heat transfer through the subsurface. HTRRAD     The HTRRAD logic is used to model heat transfer through radiation in an air bag. The area of convection through which the energy is transported is equal to the area of the subsurface multiplied by COEFFV. A value of COEFFV = 1.0 will expose the complete subsurface area, while a value of COEFFV = 0.0 will result in no heat transfer through the subsurface.
HTRTYPID	Heat transfer ID. References existing HTRTYPE entry. (Integer > 0; Required)
COEFF	Method of defining the area coefficient. (Character, CONSTANT) CONSTANT    The area coefficient is constant and specified on COEFFV.

Describer	Meaning	
	TABLE	The area coefficient varies with time. COEFFV is the number of a TABLED1 entry giving the variation with time.
COEFFV		The area coefficient or the number of a TABLED1 entry depending on the COEFF entry. ( $0.0 \leq R \leq 1.0$ or $1 > 0, 1.0$ )

### Remarks

1. A combination of multiple HEATLOS with different HTRTYPEs is allowed.
2. It allows for setting up the exact same model for either a uniform pressure model (GBAG to HEATLOS) or an Eulerian model (COUPLE to HEATLOS). It is then possible to set up the model using the switch from full gas dynamics to uniform pressure (GBAGCOU).
3. For the same BSURF multiple, different types of heat transfer may be defined.
4. A more detailed description can be found in Porosity in Air Bag for more details.

## HGSUPPR

## Hourglass Suppression Method - SOL700

Defines the hourglass suppression method and the corresponding hourglass damping coefficients. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
HGSUPPR	HID	PROP	PID	HGTYPE	HGCMEM	HGCWRP	HGCTWS	HGCSOL	
+	RBRCOR	VALUE							

Example:

HGSUPPR	1	SHELL	100	FBV	0.1	0.1	0.1		
+	YES	10000							

Describer	Meaning
HID	Hourglass suppression definition number. (Integer > 0; Required.)
PROP	Property type. (Character; See Remark 1.)
PID	Property number. (Integer > 0; See Remark 1.)
HGTYPE	Hourglass suppression method: (Character; See Remark 2.)
FBV	For shells only (default for shells)
FBS	For shells and solids (default for solids)
Dyna	For solids only
HGCMEM	Membrane damping coefficient. (0.0 ≤ Real ≤ 0.15; default=0.1)
HGCWRP	Warping damping coefficient. (0.0 ≤ Real ≤ 0.15; default=0.1)
HGCTWS	Twisting damping coefficient. (0.0 ≤ Real ≤ 0.15; default=0.1)
HGCSOL	Solid damping coefficient. (0.0 ≤ Real ≤ 0.15; default=0.1)
RBRCOR	Rigid body rotation correction: (Character; default=NO)
NO	No rigid-body rotation correction is applied to hourglass resisting forces.
YES	Rigid-body rotation correction is applied to hourglass resisting forces.
VALUE	Number of steps. (Integer > 0; See Remark 3.)

Remarks:

1. The property type definition and the property number are required. Since property numbers are unique within a certain class of element types, the property type and the property number uniquely define to what elements the hourglass suppression method and coefficients apply. The following property types are valid entries:

BAR	For bar elements
BEAM	For beam elements
BELT	For belt elements
COMP	For composite shell elements
DAMP	For damper elements
ELAS	For spring elements
EULER	For Eulerian elements
ROD	For rod elements
SHELL	For shell elements
SOLID	For solid Lagrangian elements

It must be noted however, that only shell CQUAD4 and Lagrangian CHEXA and CPENTA elements can suffer from undesired hourglass modes. All HGSUPPR entries referring to other types of elements are ignored.

2. There are three types of hourglass suppression methods available in Nastran. These are standard DYNA viscous (DYNA) hourglass damping, the Flanagan-Belytschko Stiffness (FBS) hourglass damping, and the Flanagan-Belytschko Viscous (FBV) hourglass damping.  
 Lagrangian solid elements can address DYNA and FBS suppression; shell elements can address DYNA and FBV suppression. The default for the Lagrangian solid elements is FBS. The default for the shell elements is FBV.
3. The rigid-body rotation correction on the hourglass forces is only necessary in cases where shell elements undergo a large rigid-body rotation. If the RBRCOR field is set to YES, and the VALUE field is left blank, the correction is applied during each time step. If the VALUE field is set to a number, the rotation correction is applied only when the rigid-body rotation would result in a rotation of the element over 90° in less than VALUE time steps. Usually, if the rigid-body rotation correction is necessary; 10000 is a good value. This option saves some CPU time.  
 The RBRCOR option applies to the Key-Hoff shell formulation only; for all other element types and formulations, the option is ignored.
4. The membrane, warping and twisting coefficients apply to shell elements only; for all other element types, the data is ignored. The solid damping coefficient applies to solid Lagrangian elements only; for all other element types, the data is ignored.

## HTRCONV

## Air Bag Convection

Defines the heat transfer through convection for a COUPLE and/or GBAG surface.

Convection is heat transfer from the air bag to the environment through the air bag surface. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
HTRCONV	HTRID	HTRCFC	HTRCFT	TENV					

Example:

HTRCONV	8		14	293.0					
---------	---	--	----	-------	--	--	--	--	--

Describer	Meaning
HTRID	Unique number of a HTRCONV entry. Referenced from HEATLOS. (Integer > 0; Required)
HTRCFC	Constant heat transfer convection coefficient. See Remark 3. (Real ≥ 0)
HTRCFT	The heat transfer convection coefficient is a tabular function of time. The number given here is the number of a TABLED1 entry. See Remark 3. (Integer ≥ 0)
TENV	Environmental temperature. (Real > 0; Required)

Remarks:

1. The HTRCONV entry can be referenced from a HEATLOS entry.
2. When used with Euler, the entry can only be used with the single material hydrodynamic Euler solver using an EOSGAM (ideal gas) equation of state. Two of the four gas constants ( $\gamma$ ,  $R$ ,  $c_v$  and/or  $c_p$ ) have to be defined on the EOSGAM entry.
3. Either HTRCF-C or HTRCF-T must be specified.
4. Energy will only transfer out of the air bag if the temperature inside the air bag is higher than the environmental temperature.

## HTRRAD

## Air Bag Radiation

Defines the heat transfer through radiation for a COUPLE and/or GBAG surface.

Radiation is heat transfer from the air bag to the environment through the air bag surface. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
HTRRAD	HTRID	GASBMI-C	GASEMI-T	TENV	SBOLTZ				

Example:

HTRRAD	2	0.15		293.0	5.676E-8				
--------	---	------	--	-------	----------	--	--	--	--

Descriptor	Meaning
HTRID	Unique number of a HTRRAD entry. Referenced from HEATLOS. (Integer > 0; Required)
GASBMI-C	Constant gas emissivity. See Remark 3. (Real ≥ 0)
GASEMI-T	The gas emissivity is a tabular function of time. The number given here is the number of a TABLED1 entry. See Remark 3. (Integer ≥ 0)
TENV	Environmental temperature. (Real > 0; Required)
SBOLTZ	Stephan-Boltzman constant. (Real > 0; Required)

Remarks:

1. The HTRRAD entry can be referenced from a HEATLOS entry.
2. When used with Euler, the entry can only be used with the single material hydrodynamic Euler solver using an EOSGAM (ideal gas) equation of state. Two of the four gasconstants ( $\gamma$ ,  $R$ ,  $c_v$  and/or  $c_p$ ) have to be defined on the EOSGAM entry.
3. Either GASEMI-C or GASEMI-T must be specified.
4. Energy will only transfer out of the air bag if the temperature inside the air bag is higher than the environmental temperature.

## HYBDAMP

## Hybrid Modal Damping for Direct Dynamic Solutions

Specifies hybrid damping parameters.

Format:

1	2	3	4	5	6	7	8	9	10
HYBDAMP	ID	METHOD	SDAMP	KDAMP	PRTEIG				

Example:

HYBDAMP	101	2000	2001	NO	YES				
---------	-----	------	------	----	-----	--	--	--	--

Describer	Meaning
ID	Identification number of HYBDAMP entry (Integer > 0; Required)
METHOD	Identification number of METHOD entry for modes calculation. (Integer > 0; Required)
SDAMP	Identification number of TABDMP1 entry for modal damping specification. (Integer > 0; Required)
KDAMP	Selects modal “structural” damping. See Remark 1. (Character: “Yes” or “NO”; Default = “NO”)
PRTEIG	Print eigenvalue summary from hybrid damping calculation (Character: “Yes” or “NO”; Default = “NO”)

Remarks:

1. For KDAMP = “YES”, the viscous modal damping is entered into the complex stiffness matrix as structural damping.
2. Hybrid damping is generated using modal damping specified by the user on TABDMP entries.

$$BH = [M] \begin{bmatrix} \phi_1 & \phi_2 & \dots & \phi_n \end{bmatrix} \begin{bmatrix} b(\omega_1) & & & \\ & b(\omega_2) & & \\ & & \ddots & \\ & & & b(\omega_n) \end{bmatrix} \begin{bmatrix} \phi_1^T \\ \phi_2^T \\ \vdots \\ \phi_n^T \end{bmatrix} [M]$$

For KDAMP = “YES”

$$KH = [M] \begin{bmatrix} \phi_1 & \phi_2 & \dots & \phi_n \end{bmatrix} \begin{bmatrix} g(\omega_1) \\ g(\omega_2) \\ \vdots \\ g(\omega_n) \end{bmatrix} \begin{bmatrix} \phi_1^T \\ \phi_2^T \\ \vdots \\ \phi_n^T \end{bmatrix} [M]$$

where

$\phi_i$  = modes of the structure

$[M]$  = structural mass matrix

$b(\omega_i)$  = modal damping values,  $b(\omega_i) = g(\omega_i)\omega_i m_i$

$g(\omega_i)$  = twice the critical damping ratio determined from user specified TABDMP entry

$\omega_i$  = natural frequency of mode  $\phi_i$

$m_i$  = generalized mass of mode  $\phi_i$

3. Hybrid damping is based on a modal solution and the mass matrix. Even if user requested all the modes and specified a flat value of G the result is still dependent on the Rank of the Mass matrix. Also note that Hybrid damping does not include residual vectors to compensate for high frequency contribution and other possible massless degrees of freedom effects in the Rank of the mass matrix. PARAM, COUPMASS, 1 may improve the mass rank.
4. HYBDAMP is referenced by the DAMPING and ROTHYBD Bulk Data entries.
5. When hybrid damping is used during FRF component generation, it is recommended to set the KDAMP field to YES on the HYBDAMP entry. See remarks under SDAMPING Case Control description for further details.
6. If Modules are present then this entry may only be specified in the main Bulk Data section.

## HYDROC

### Hydrostatic Pressure Loading on Surface and Faces of Shell or Solid Elements using fluid cavities.

Defines a hydrostatic pressure load on a face of a CHEXA, CPENTA, CPYRAM, CTETRA, CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, or CQUADR element using fluid cavity data. The HYDROC entry is NOT supported in SOL101 because SOL 101 does not support the Fluid Structure Interface.

Format:

1	2	3	4	5	6	7	8	9	10
HYDROC	SID	PSOLID	PNOM	G	PCH	PLD4	OVRD		
	CID/GRD	HGHTB	HABOV						

Example:

HYDROC	66	33	42.	980.		1			
	99	0.	10.						

Descriptor	Meaning
SID	Load set identification number. (Integer > 0)
PSOLID	PSOLID ID of the cavity. Fluid density will be obtained from the associated MAT10 entry. (Integer > 0); HYDROC requires ACMODL,DIFF (the default value).
PNOM	Nominal or atmosphere pressure. If G=0.0, PNOM only is applied. (Real; default = 0.0)
G	Acceleration (e.g. of gravity) in the direction from HABOV toward the origin defined by the CID/GRD field. (Real; Default = 1.0)
PCH	0 - default (no punch); 1 - Punch Set of structural grids. 2 - Punch Set of structural elements. 3 - Punch both structural grids and structural elements. (Integer ≥ 0)
PLD4	0 - default (no punch); 1 - Punch the resulting PLOAD4 entries. (Integer ≥ 0)
OVRD	0-default. If PARAM, INREL, is present and G not equal to 1.0, then a fatal error message will be issued. 1 - Allow non unit value of G.
CID/GRD	Coordinate ID of a reference coordinate system to measure the coordinate z-direction. If Integer ≥ 0; a coordinate system ID is used. If Integer < 0; a GRID ID is used with the z-direction of the GRID, CD field. Note: A spherical coordinate system will result in a fatal error. See Remark 1.; (Integer - default 0 -basic).

Describer	Meaning
HGHTB	The z-distance to the lowest fluid point measured from reference origin. See Remark 1.. (Real; Default = 0.0)
HABOV	The height of the fluid above the lowest point measured in the z-direction from reference origin. See Remark 1. (Real; Default = 0.0)

## Remarks:

- On the HYDROC entry, HGHTB along with the z-coordinate direction, are used to determine the location of the “bottom” of the fluid body in the case where the fluid cavity is full and there is no free surface.

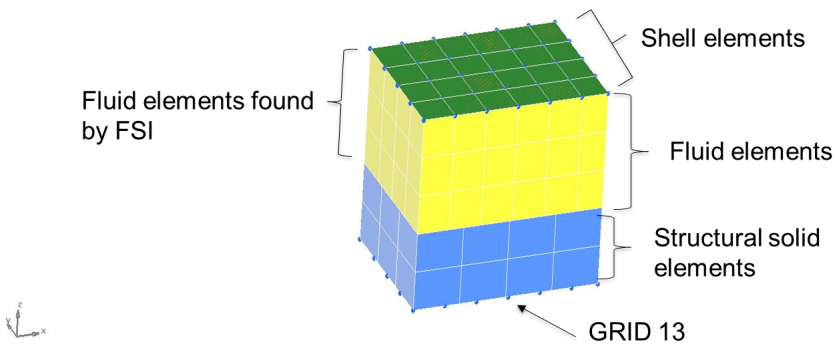

In the case where a free fluid surface has been modeled in the cavity, CID/GID and HGHTB are for reference only. The lowest fluid level is determined as the lowest wetted grid in the FSI coupling measure in the direction defined by CID/GID. From the FSI coupling, free surface formed by examining wetted grids may not be perpendicular to the z-direction of CID/GID. Hence, HABOV will be considered as average free surface and hydrostatic pressure will be computed with respect to HABOV. However, a fatal message will occur if the average free surface specified by HABOV is significantly above the free surface of wetted grids. Also note that some wetted grids/elements may not get loaded if HABOV is too low.

2. The HYDROC entry will internally be converted to an equivalent set of PLOAD4 entries with the same load SID
3. Each fluid cavity should have a unique PSOLID entry as HYDROC uses the PSOLID to identify the cavity.
4. The PNOM is applied only from fluid surface to bottom of fluid.
5. HYDROC interaction with the Fluid Structure Interface (FSI) algorithm is shown in the two figures below. The top figure shows a column of fluid over some structural elements. The column of fluid is 30 units high, however, only its bottom surface is in contact with structural elements. Therefore, the FSI will only see a fluid that is 10 units high. A HYDROC entry for this model, with a HABOV = 50 units would fail to compute any hydrostatic loading, because 50 units is well outside the tolerance of the FSI interface, which is at 30 units.

The second figure shows the same fluid column, but a layer of shell elements has been laid on top of the fluid column.

HYDROC	66	5	0.	980.	1
	-13	20.	50.		

In this case, the FSI sees a column of fluid 50 units high. Thus a HABOV = 50 units will generate PLOAD4 entries using a height of 30 units for the fluid. For this model, any HABOV with values (30 units ≤ HABOV ≤ 50 units) will yield valid PLOAD4 entries on the fluid structure interface of the structural solid elements with the height used depending on the value of HABOV.

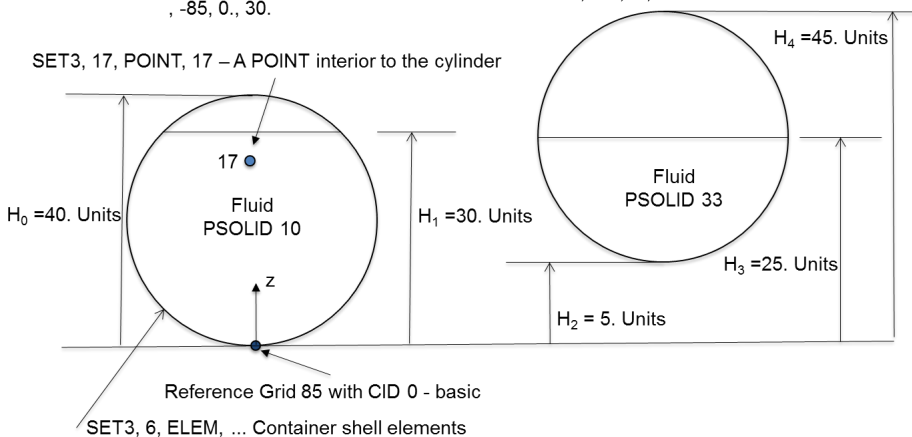

- The figures below show additional HYDROC PNOM rules associated with the FSI interface. Also note how fluid cavities are defined by PSOLID ID.

HYDROS (1) applies a hydrostatic loading of 55. + 0.\*h\*0. interior to the cylinder with POINT 17  
 HYDROC (2) applies a hydrostatic loading 0. + ρ\* h \* 980.  
 HYDROC (3) applies a hydrostatic loading 42. + ρ\* h \* 980. – above the fluid there is no pressure of 42. units

1. HYDROS, 66, 55., 0., 0., 6, ,1 , ,  
 , -85, 0., 40., 17

2. HYDROC, 66, 10, 0., 980., 0, 1, , ,

Reference origin with CID

Staggered grid for flooding simulation.

**HYDROS**

**Hydrostatic Pressure Loading on Surface and Faces of Shell or Solid Elements using element or grid sets**

Defines a hydrostatic pressure load on a face of a CHEXA, CPENTA, CPYRAM, CTETRA, CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, or CQUADR element using element set data.

Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
HYDROS	SID	PNOM	RHO	G	SETE	SETG	PLD4	OVRD	
	CID/GRD	HGHTB	HABOV	CNTL					

Example:

HYDROS	77	55.	0.08	17.	300		1		
	200		97.	83					

Describer	Meaning
SID	Load set identification number. (Integer > 0)
PNOM	Nominal or atmosphere pressure. If G=0.0, PNOM only is applied. (Real; Default = 0.0)
RHO	Mass density. (Real > 0.0)
G	Acceleration (e.g. of gravity) in the direction from HABOV toward the origin defined by the CID/GRD field. (Real; Default = 1.0)
SETE	The ID of a SET3 entry using (DES= ELEM) or SET1 to identify the element IDs of structure elements at fluid-structure interface used for hydrostatic loading. (Integer ≥ 0)
SETG	The ID of a SET3 entry using (DES= GRID) or SET1 to identify the element grid IDs of structure elements at fluid-structure interface used for hydrostatic loading. (Integer ≥ 0)
PLD4	0 - default (no punch); 1 - Punch the resulting PLOAD4 entries. (Integer ≥ 0)
OVRD	0-default. If PARAM, INREL, is present and G not equal to 1.0, then a fatal error message will be issued. 1 - Allow non unit value of G.
CID/GRD	Coordinate ID of a reference coordinate system to measure the coordinate z-direction. If Integer ≥ 0; a coordinate system is used. If Integer < 0; a GRID ID is used with the z-direction of the GRID, CD field. Note: A spherical coordinate system will result in a fatal. See Remark 1.; (Integer - default 0 -basic). Note: A spherical coordinate system will result in a fatal error.
HGHTB	The z-distance to the lowest fluid point measured from reference origin. (Real; Default = 0.0)

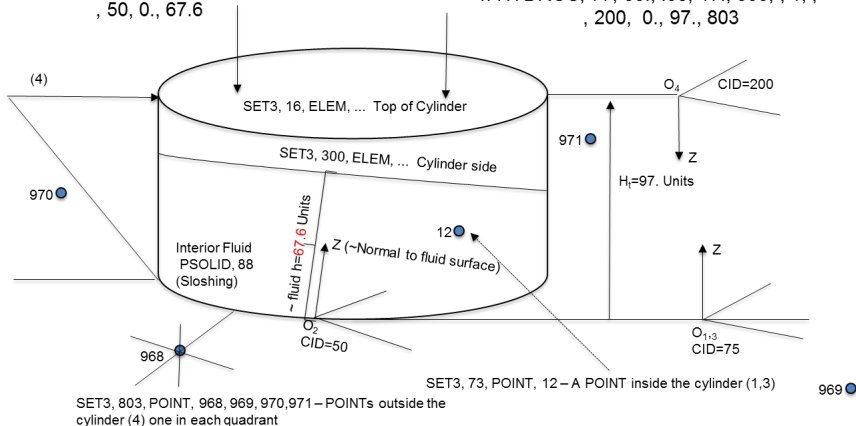

Describer	Meaning
HABOV	The height of the fluid above the lowest point measured in the z-direction from reference origin. (Real; Default = 0.0)
CNTL	SET3 ID of control grids to get pressure application direction. (Integer ≥0, see Remark 2.).

Remarks:

- The HYDROS entry will internally be converted to an equivalent set of PLOAD4 entries with the same load SID.

HYDROS (1) applies a hydrostatic loading of  $25. + .08 \cdot h \cdot 0$ . interior to the cylinder with POINT 12  
 HYDROC (2) applies a hydrostatic loading  $0. + \rho \cdot h \cdot 1$ ; h – measured normal to sloshed surface  
 HYDROS (3) applies a hydrostatic loading  $55. + .08 \cdot h \cdot 980$ . (h is constant 97. units for this set)  
 HYDROS (4) applies a hydrostatic loading  $55. + .08 \cdot h \cdot 17$ . for all elements on exterior cylinder side.

- |   |  |
|---|--|
| 1. HYDROS, 77, 25., .08, 0., 300, , 1, ,<br>, 75, 0., 97., 73 | 3. HYDROS, 77, 55., .08, 980., 16, , 1, ,<br>, 75, 0., 97., 73   |
| 2. HYDROC, 77, 88, 0., 1., 0, 1, , ,<br>, 50, 0., 67.6        | 4. HYDROS, 77, 55., .08, 17., 300, , 1, ,<br>, 200, 0., 97., 803 |

SET3, 803, POINT, 968, 969, 970, 971 – POINTS outside the cylinder (4) one in each quadrant

2. The pressure direction can be defined with or without CNTL entry in HYDR0S card for closed and open geometries.
  - For closed geometry like sphere, cylinder, cube, etc., SET3 id should have only one grid defined inside the geometry. Use of inside grid, will result in internal pressure to be applied. If the external pressure needs to be applied, then change the sign of Pnom and Gravity in the HYDR0S card. ( $P = P_{nom} + \rho \cdot g \cdot h$ )
  - For open geometry, the direction of the pressure is based on the relation between the direction of control point grid to the element and the element normal. Refer 1(a) and 1(b) for direction of pressure for an open geometry.
  - Without control point defined in the HYDR0S card the pressure direction is aligned with the element normal direction. If the element normal is outward, then the pressure direction is outward and vice versa.

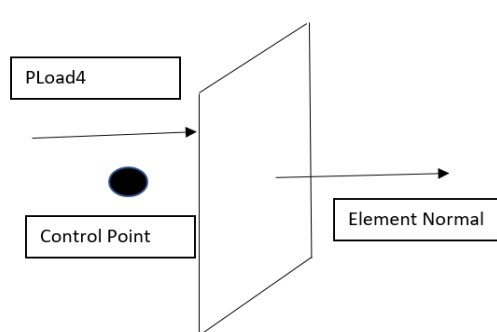

Figure 1 (a)

Figure 1 (b)

## HYDSTAT

## Hydrostatic Preset of Density in Euler Elements

Initializes the Euler element densities in accordance to a hydrostatic pressure profile. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
HYDSTAT	HID	MID	GID	CID	XCG	YCG	ZCG	PATM	

Example:

HYDSTAT	101	4			0.0	0.0	0.0	100000.	
---------	-----	---	--	--	-----	-----	-----	---------	--

Describer	Meaning
HID	Identification number of the HYDSTAT entry referenced from the COUPLE entry. (Integer > 0; Required)
MID	Material MATDEUL id to which the hydrodynamic pressure profile will be applied. (Integer > 0; Required)
GID	Number of a grid point at the free surface. See Remark 4. (Integer ≥ 0)
CID	Local coordinate system. See Remark 4. (Integer ≥ 0)
XCG,YCG, ZCG	Coordinates of a point at the free surface. See Remark 4. (Real)
PATM	Pressure at free surface. (Real; Required)

Remarks:

1. It is assumed that each Euler domain contains at most two Eulerian materials and includes the GRAV entry. One material has to be a fluid using EOSPOL the other a gas or void. This EOSPOL material is given by the MID entry. The interface between gas and fluid is the free surface and is assumed to be normal to the gravity vector as specified on the GRAV entry. For example if the gravity vector points in the z-direction then the interface between the gas and the fluid has to be horizontal.
2. The hydrostatic preset changes the density of the fluid like material in order to conform to the hydrostatic preset. It overrules the material densities as specified on the TICEL and TICVAL entries. Densities of the gas like material are not changed.
3. The free surface has to match with material fractions as defined in the initialization of Euler elements by the TICEL and TICEUL entries. The hydrostatic preset only changes densities, it does not change material fractions.
4. There are two options to enter the location of the free surface. The first option is to enter a grid point number. In that case the fields CID and XCG-ZCG have to be left blank. The GRIDPOINT entry already has the option of using a local coordinate system. When coordinates are used then the field GID has to be left blank.

5. If there is no structural grid point indicating the free surface then a new grid point can be defined that will only be used for determining the free surface level. If the Gravity vector points in the z-direction, only the z-coordinate of the grid point will be used. The x and y ordinate can be chosen arbitrarily. Similar remarks hold when the gravity vector is in one of the other coordinate directions. The same holds when using coordinates instead of a grid point.
6. PATM should be equal to the pressure in the air.
7. When coupling surfaces are present then the HYDSTAT ID needs to be referenced by at least one coupling surface. For each coupling surface a different HYDSTAT entry can be defined. Several COUPLE entries can refer to the same HYDSTAT ID. If no HYDSTAT ID is specified on a COUPLE entry then Euler elements associated to this coupling surface will not be initialized with a hydrostatic preset.

## IMPCASE

Defines a collection of imperfection cases

Defines a collection of imperfection cases by listing of identification numbers of IMPGEOM entries. Used in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
IMPCASE	ID	IMPFID1	IMPFID2	...	IMPFIDi				

Example:

IMPCASE	5	1	2						
---------	---	---	---	--	--	--	--	--	--

Describer	Meaning
ID	Identification number (integer > 0, required)
IPMFIDi	Identification number of imperfection case (integer >0, required)

Remarks:

1. When the ID is referenced by case control IMPERFECT command, the list of IMPGEOM entries are used to apply geometric imperfections.
2. "THRU" can be used to specify IMPFIDi.

## IMPGEOM

### Defines Geometric Imperfection

Defines geometric imperfection by selecting subcases, steps, mode numbers or increments from imperfection input files. Used in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
IMPGEOM	IPMFID			SETID	SCALE		UNIT	MODID	
	SUBCASE1	STEP1	MODEINC1	SETID1	SCALE1		UNIT1	MODID1	
	SUBCASE2	STEP2	MODEINC2	SETID2	SCALE2		UNIT2	MODIDi	
	etc.								

Example:

IMPGEOM	1								
	1	3	1		0.011		34		
	1	3	2		0.002		34		

Describer	Meaning
IPMFID	Identification number of imperfection case (integer >0, required)
SETID	Default of SETIDi (integer ≥ 0, default=0)
SCALE	Default of SCALEi (real, default=0.0)
UNIT	Default of UNITi (integer ≥ 0, default=0)
MODID	Default of MODIDi (integer ≥ -1, default=-1), see remark 11.
SUBCASEi	Identification number of a subcase (integer ≥ 0, default=0)
STEPi	Identification number of a step (integer ≥ 0, default=0)
MODEINCI	Mode number if the selected step by SUBCASEi and STEPi or subcase by SUBCASEi is a result of buckling analysis or modal analysis, increment number if the selected result is from a static analysis. (integer ≥ 0, default=0)
SETIDi	Identification number of a SET1 or SET3 bulk entry (integer ≥ 0, default = 0). When it is defined, only the grid points with the id listed in SET1 or SET3 have geometric imperfection effect. If a SET3 is used, it must be GRID type.
SCALEi	Scale factor (real, default = 0.0)
UNITi	Imperfection file unit number specified by ASSIGN HDF5IN, INPUTT2 or IMPFIN FMS command.
MODIDi	Module ID (integer ≥ -1, default=-1), see remark 11.

Remarks:

1. All IMPGEOM identification numbers must be unique. An IMPGEOM entry is referenced by IMPERFECT case control directly or by an IMPCASE bulk entry.
2. Geometric imperfection effect is applied to grid points as coordinates variation, the variation is superposed by eigenvectors of multiple modes or displacement of increments defined in multiple continuation lines.
3. An imperfection input file can be an MSC Nastran HDF5 result file, a Nastran op2 file or a text based file called IMPF. To use it, an ASSIGN HDF5IN, INPUTT2 or IMPFIN FMS command is required.
4. The imperfection input file of HDF5 or op2 can be a result file of SOL 101, 103, 105 or a SOL 400 with ANALYSIS type of BUCK, MODES, STATIC, NLSTATIC or NLTRAN, and must contain eigenvectors or displacement results.
5. IMPF file format is described in remark 12. It can be DISP format or GEOM format. If an IMPF file is used in an IMPGEOM entry, only one continuation line of IMPGEOM is allowed, and SUBCASEi, STEPi and MODEINCi are ignored. If format is GEOM, SCALE and SCALEi are ignored too.
6. SUBCASEi must be specified if the imperfection input file is an op2 or hdf5 file.
7. STEPi is ignored when the imperfection input file is a result of SOL 101, 103 or 105. It must be specified for a SOL 400 result file.
8. MODEINCi is ignored when the file is a result of SOL 101 or a linear static step of SOL 400. It is required for other cases if the imperfection file is an hdf5 or op2 file.
9. UNITi must be specified if UNIT is 0 or not specified.
10. Geometric imperfection is applied to residual structure for superelement models. In the case of part superelement, it is advised to adjust boundary grid point searching tolerance due to geometry changing. This can be done by adding or modifying SEBULK or SECONCT entries.
11. MODID and MODIDi are only used when modules are present. -1 means the whole model, 0 or a positive number is a module identification number.
12. Format of IMPF file

The IMPF file is a csv-like file, delimiters of a line can be spaces, a comma or a tab space. A line starting with a "\$" or "#" is a comment line. If the first line is a comment line and contains string "GEOM" or "GRID", then it is a GEOM file, i.e., the grid coordinates provided here will replace the grid coordinates in the FE model; otherwise it is a DISP file, i.e., the displacements provided in the file will be superimposed to the coordinates of the corresponding grids.

For each line, the first column is grid point id, followed by x,y and z. For DISP format, x,y and z are coordinate variations from the original coordinates, and coordinate system is MSC Nastran global system, this means that x,y,z are in the coordinate system indicated by CD field of GRID entries in the original input file. For GEOM format, x,y and z are "imperfect" coordinates of the grid points, coordinate system is MSC Nastran input system, this means the values of x,y,z respect CP field of the GRID entries in the original input file.

When modules are present, BEGIN MODULE=modid and ENDMODULE can be used to specify module id for a section of grids.

Below is a DISP format of IMPF file.

disp\_1.impf

**INCLUDE**

## Insert External File

Inserts an external file into the input file. The INCLUDE statement may appear anywhere within the input data file.

**Format:**

```
INCLUDE 'filename'
```

**Describer:**

filename	Physical filename of the external file to be inserted. The user must supply the name according to installation or machine requirements. It is recommended that the filename be enclosed by single right-hand quotation marks.
----------	---

**Example:**

The following INCLUDE statement is used to obtain the Bulk Data from another file called MYBULK.DATA:

```
SOL 101  
CEND  
TITLE = STATIC ANALYSIS  
LOAD = 100  
BEGIN BULK  
INCLUDE 'MYBULK.DATA'  
ENDDATA
```

**Remarks:**

1. INCLUDE statements may be nested; that is, INCLUDE statements may appear inside the external file. The nested depth level must not be greater than 10.
2. The total length of any line in an INCLUDE statement must not exceed 72 characters. Long file names may be split across multiple lines. For example the file:

```
/dir123/dir456/dir789/filename.dat
```

may be included with the following input:

```
INCLUDE '/dir123  
                  /dir456  
                  /dir789/filename.dat'
```

3. See the for more examples.

## INFLCG

## Airbag Cold Gas Inflator Model

Defines the cold gas-inflator characteristics of a COUPLE and/or GBAG subsurface. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
INFLCG	INFLID	TANKVOL	INITPRES	INITTEMP	INITMAS	$\gamma$ GASNAM	$C_v$	R	
	$C_p$								

Example:

INFLCG	11	0.875	131325	293	1.37	1.4		286	

Describer	Meaning
INFLID	Unique number of an INFLCG entry. Referenced from ABINFL. (Integer > 0; Required)
TANKVOL	Tank Volume. (Real > 0; Required)
INITPRES	Initial tank pressure. (Real > 0; Required)
INITTEMP	Initial tank temperature. (Real > 0; Required)
INITMAS	Initial gas mass of inflator. (Real > 0; Required)
$\gamma$ , GASNAM	Ratio of specific heat constants if real. Name of an INFLGAS entry if character. See Remarks 4. and 5. (Real > 0 or 1)
$C_v$	Specific heat at constant volume. See Remark 6. (Real > 0)
R	Gas constant. See Remark 6. (Real > 0)
$C_p$	Specific heat at constant pressure. See Remark 6. (Real > 0)

Remarks:

1. The INFLCG entry can be referenced from an ABINFL entry.
2. When used in an Euler coupled analysis, the entry can only be used with the single material hydrodynamic Euler solver using an EOSGAM (ideal gas) equation of state.
3. Either INITPRESS or INITMASS has to be specified, but not both. The relation between INITMASS and INITPRESS is given by

$$INITPRES = R \frac{INITMAS}{TANKVOL} INITTEMP$$

4. The cold gas inflator is a reservoir filled with high pressure gas. It is assumed that the volume stays constant at TANKVOL. The mass inside the inflator will steadily decrease due to flow into the Euler domain or to a GBAG. Due to inertia it can happen that the pressure of the inflator becomes less than the outside pressure. In that case some inflow into the inflator occurs. Transport between inflator and the Euler domain or GBAG is based on the constancy of total temperature. This is equivalent to the pressure method.
5. If this field contains a real entry real or is left blank, the inflator gas constants are given on the INFLTR entry itself. Otherwise, the entry will be read as the name of an INFLGAS entry. In this case, the remaining entries must be left blank.
6. Specify only two of the four gas constants. They are related as:

$$\nu = \frac{c_p}{c_v} \quad R = c_p - c_v$$

## INFLFRC

## Hybrid Inflator Gas Fraction Definition

Defines the gas fractions as a function of time for hybrid inflators. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
INFLFRC	FRACID	TYPE							
	"TIME"	TIME1	FRAC1	FRAC2	FRAC3	etc.			
	"TIME"	TIME2	FRAC1	FRAC2	FRAC3	etc.			

Example:

INFLFRC	12								
	TIME	14.0E-3	11.342	13.391	9.626	57.019	7.31	1.312	
	0.0	0.1	0.2						
	TIME	14.1E-3	43.332	6.2817	4.5155	26.747	3.4291	0.4898	
	15.077	0.0	0.4						

Descriptor	Meaning
FRACID	Unique number of an INFLFRC entry.(Integer > 0, required.)
TYPE	Specifies whether mass fractions or molar fractions will be given (Character, default=MASS.)  MASS The fractions on INFLFRC are mass fractions.  MOLAR The fractions on INFLFRC are molar fractions. See Remark 5.
TIMEID	Defines a new line of data (Character, required.)  TIME Specifies that data for a new time increment will be given. See Remark 3.
TIMEi	Time for which the gas fractions are given. (Real≥0.0, required.)
FRACi	Fraction of gas i at the specified time..See Remark 7. (Real≥0.0, required.)

Remarks:

1. The INFLFRC entry is referenced with FRACID from an AIRBAG entry with the option "INFLATOR" or from INFLHB.
2. Fraction values of the inflowing gas will be linearly interpolated between the specified time increments.
3. Use as many continuation lines as necessary to completely define the gas fractions. The data for a time step are preceded by a TIME keyword. Missing entries will be set to 0.0.

4. The order of the gases for which the fractions are specified is identical to the order in which the gases are specified on the AIRBAG entry with the option "INFLATOR".
5. At least one line of gas fractions must be given.
6. If molar fractions (TYPE=MOLAR) are to be used, the universal gas constant must be specified through PARAM, UGASC.
7. At least one of the fractions for each time step must have a value greater than 0.0.
8. Fractions for each timestep should add up to 1.0. If this is not the case, they will be scaled so that they do.

## INFLGAS

### Inflator Gas Definition

Defines a thermically ideal gas to be used with a standard or hybrid inflator. Used in SOL 700 only.

Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
INFLGAS	GASNAM	TYPE	VALUE	CPGAS	V1	V2	V3	V4	

Example:

INFLGAS	101	RSPEC	189.	CONSTAN T	846.				
---------	-----	-------	------	--------------	------	--	--	--	--

Describer	Meaning	
GASNAM	Unique number of an INFLGAS entry. (Integer; Required)	
TYPE	Specific gas constant or molar weight specified. (Character; RSPEC)	
	RSPEC	Specific gas constant
	MOLWT	Molar weight, see Remark 2.
VALUE	Value of the variable TYPE. (Real > 0; Required)	
CPGAS	The variation of the specific heat constant at constant pressure. (Character; CONSTANT)	
	CONSTANT	The specific heat is constant and specified in V1.
	TABLE	The specific heat constant is temperature-dependent. V1 is the number of a TABLED1 entry giving the variation of the specific heat with the temperature.
	POLY	The specific heat constant is temperature-dependent. V1 through V4 are the coefficients of a polynomial expression, see Remark 3.
V1	The specific heat constant, the number of a TABLED1 entry or the first polynomial coefficient, depending on the value of CPGAS. (Real or Integer > 0; Required)	
V2, V3, V4	Coefficients of polynomial expression when CPGAS equals POLY. (Real; 0.0)	

Remarks:

1. INFLGAS can be referenced by an INFLTR, INFLHB or INITGAS entry.
2. When the molar weight is given, the universal gas constant  $R_{uni}$  must be specified using PARAM, UGASC, so that:

$$R_{spec} = R_{uni} / MOLWT$$

3. A polynomial expression for  $c_p$  is given by:

$$c_p(t) = V1 + V2 \cdot T + V3 \cdot T^2 + \frac{V4}{T^2}$$

4. The specific heat constant at constant volume  $c_v$  is calculated from the specific heat constant at constant pressure  $c_p$ , the universal gas constant and the molecular weight according to:

$$c_v = c_p(T) - R_{spec}$$

5. The ratio of specific heats is given as:

$$\gamma = c_p/c_v$$

## INFLHB

## Hybrid Inflator Model

Defines the hybrid-inflator characteristics of a COUPLE and/or GBAG subsurface. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
INFLHB	INFLHID	MASFLRT	TBMPT	TEMPC	FRAC				
	GASNAM1	GASNAM2	GASNAM3	-etc.-					

Example:

INFLHB	9	15		650.	12				
	22	25	3						

Describer	Meaning
INFLID	Unique number of an INFLHB entry. (Integer > 0; Required)
MASFLRT	Table number of a TABLED1 entry specifying the massflow-rate as a function of time. (Integer > 0; Required)
TEMPT	Table number of a TABLED1 entry specifying the static temperature of the inflowing gas as a function of time. See Remark 3. (Integer > 0)
TEMPC	Constant value of the temperature of the inflowing gas. See Remark 3. (Real > 0.0)
FRAC	Number of an INFLFRC entry specifying the fractions of the inflowing gas as a function of time. (Integer > 0; Required)
GASNAMi	ID of an INFLGAS entry. See Remark 4. (Integer)

Remarks:

1. The INFLHB entry can be referenced from a [ABINFL](#) entry.
2. When used in an Euler coupled analysis, the entry can only be used with the single material hydrodynamic Euler solver using an EOSGAM (ideal gas) equation of state.
3. Either TEMPC or TEMPT must be specified. The INFLHB entry uses the specified temperature as the static temperature of the inflowing gas. In literature the static temperature is also known as total-, rest-, or stagnation temperature and refers to the temperature of the gas when brought to rest from its moving condition as opposed to the dynamic temperature that refers to the temperature of the moving gas.
4. At least one inflator gas must be specified using an INFLGAS entry. There is no limit to the number of inflator gases per INFLHB.

## INFLTNK

## Airbag Tanktest Inflator Model

Defines the Tanktest-inflator characteristics of a COUPLE and/or GBAG subsurface. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
INFLTNK	INFLID	METHOD	TPTABLE	TANKVOL	INFLMAS	INITPRES	ENDTPRES	INITTEMP	
	ENDTEMP	$\gamma$	$c_v$	$R$	$c_p$	IPTABLE	INFLPRES	INFLTEMP	
	INFLAREA	SFTP	SFIP						

Example:

INFLTNK	111	AVTEMP	10	0.12	0.01	0.0			
		1.4		286.					

Describer	Meaning
INFLID	Unique number of an INFLTNK entry. (Integer > 0; Required)
METHOD	Method of calculating the mass-flowrate: (Character; Required)
AVTEMP	Average Temperature Method
INFPRES	Inflator Pressure Method
TPTABLE	Table number of a TABLED1 entry specifying the tank pressure as a function of time. (Integer > 0; Required)
TANKVOL	Tank Volume. (Real > 0; Required)
INFLMAS	Total gas mass generated by inflator. (Real > 0; Required)
INITPRES	Initial tank pressure. See Remark 3. (Real > 0; Required)
ENDPRES	End tank pressure. See Remarks 4. and 5. (Real > 0; Required)
INITTEMP	Initial tank temperature. See Remark 5. (Real > 0; Required)
ENDTEMP	End tank temperature. See Remark 5. (Real > 0; Required)
$\gamma$	Ratio of specific heat constants. See Remark 7. (Real > 0)
$c_v$	Specific heat at constant volume. See Remark 7. (Real > 0)
$R$	Gas Constant. See Remark 7. (Real > 0; Required)
$c_p$	Specific heat at constant pressure. See Remark 7. (Real > 0)
IPTABLE	Table number of a TABLED1 entry specifying the inflator pressure as a function of time. See Remark 5. (Integer > 0; Required)
INFLPRES	Initial inflator pressure. See Remarks 5. and 6. (Real > 0; Required)
INFLTEMP	Temperature of inflowing gas: See Remark 5. (Real > 0 or Character; ATM)

Describer	Meaning	
	ATM	Use average temperature of AVTEMP method.
	Real value	User specified temperature.
INFLAREA	Total area of inflator holes. See Remark 5. (Real > 0; Required)	
SFTP	Scale factor for tank pressure. See Remark 5. (Real > 0; 1.0)	
SFIP	Scale factor for inflator pressure. See Remark 5. (Real > 0, 1.)	

Remarks:

1. The INFLTNK entry can be referenced from an ABINFL entry.
2. When used in an Euler coupled analysis, the entry can only be used with the single material hydrodynamic Euler solver using an EOSGAM (ideal gas) equation of state.
3. The initial tank pressure entry (INITPRES) is interpreted as an absolute pressure and used to define reference pressure at  $t=0$  in the tank. The different between INITPRES and the pressure value at  $t=0$  from the table will be added to the entire pressure curve of TPTABLE.
4. The end tank pressure entry (ENDPRES) is interpreted as an absolute pressure at  $t=tend$  of tank pressure table (TPTABLE). This value is used for calculation of total generated mass in the tank.
5. This field must be specified only when Inflator Pressure Method (INFPRES) is defined in the METHOD field.
6. The initial inflator pressure entry (INFLPRES) is interpreted as an absolute pressure and used to define reference pressure at  $t=0$  in the inflator. The different between INFLPRES and the pressure value at  $t=0$  from the table will be added to the entire pressure curve of IPTABLE.
7. Specify only two of the four gas constants. They are related as:

$$\gamma = \frac{c_p}{c_v} \quad R = c_p - c_v$$

## INFLTR

## Airbag Inflator Model

Defines the inflator characteristics of a COUPLE and/or GBAG subsurface. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
INFLTR	INFLID	MASFLRT	TEMPT	TEMPC	$\gamma$ GASNAME	$c_v$	$R$	$c_p$	
	MID								

Example:

INFLTR	5	100		907.0	1.5	283.0			
	0	0	0						

Describer	Meaning
INFLID	Unique number of an INFLTR entry. (Integer > 0; Required)
MASFLRT	Table number of a TABLED1 entry specifying the massflow-rate as a function of time. (Integer > 0; Required)
TEMPT	Table number of a TABLED1 entry specifying the static temperature of the inflowing gas as a function of time. See Remark 3. (Integer > 0)
TEMPC	Constant value of the static temperature of the inflowing gas. See Remark 3. (Real > 0)
$\gamma$ , GASNAM	Ratio of specific heat constants if real. Name of an INFLGAS entry if character. See Remarks 4. and 5. (Real > 0 or Character)
$c_v$	Specific heat at constant volume. See Remark 5. (Real > 0)
$R$	Gas constant. See Remark 5. (Real > 0)
	Specific heat at constant pressure. See Remark 5. (Real > 0)
MID	Material MATDEUL ID of the Inflator material. See Remark 2. Only used for MMHYDRO solver. (Integer $\geq$ 0)

### Remarks:

1. The INFLTR entry can be referenced from an ABINFL entry.
2. When used in combination with the single material hydrodynamic Euler solver an EOSGAM (ideal gas) equation of state is required. In that case the material number MID can be left blank. When using the Multi-material solver the Material number MID has to point to one of the Eulerian materials and the equation of state of that material has to be of type EOSGAM. The Multi-material solver does not allow the use of gas fractions.

3. Either TEMP-C or TEMP-T must be specified. The INFLTR entry uses the specified temperature as the static temperature of the inflowing gas. In literature the static temperature is also known as total-, rest-, or stagnation temperature and refers to the temperature of the gas when brought to rest from its moving condition, as opposed to the dynamic temperature which refers to the temperature of the moving gas.
4. If this field contains a real entry real or is left blank, the inflator gas constants are given on the INFLTR entry itself, see Remark 5. Otherwise, the entry will be read as the name of an INFLGAS entry. In this case, the remaining entries must be left blank.
5. Specify only two of the four gas constants. They are related as:

$$\gamma = \frac{c_p}{c_v} \quad R = c_p - c_v$$

## INITGAS

## Gasbag or Coupling Surface Initial Gas Fraction Definition

Specifies the initial gas composition inside a gasbag or Euler coupling surface. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
INITGAS	INTID		GASNAM1	FRAC1	GASNAM2	FRAC2	-etc.		

Example:

INITGAS	4		14	0.4	32	0.11			
---------	---	--	----	-----	----	------	--	--	--

Describer	Meaning
INTID	Unique number of an INITGAS entry. (Integer > 0; Required)
GASNAMi	ID of an INFLGAS entry. See Remark 3. (Integer > 0)
FRACi	Mass fraction of gas i. See Remark 4. (Real ≥ 0.0)

Remarks:

1. The INITGAS entry can be used to specify the initial gas composition for a gasbag or for an Eulerian coupling surface. The INTID must be referenced either from a GBAG cad or a COUPLE entry.
2. Use as many continuation lines as necessary to completely define the gas fractions.
3. At least one INFLGAS reference must be given.
4. Fractions should add up to 1.0. If this is not the case, they will be scaled so that they do.

## IPSTRAIN Initial Equivalent Plastic Strain Values in SOL 400

Defines initial equivalent plastic strain values. This is the initial plastic strain option used in SOL 400 only. (NOTE: This entry is SINGLE FIELD ONLY! Double field will fatal)

Format:

1	2	3	4	5	6	7	8	9	10
IPSTRAIN	EID1	EID2	INT1	INTN	LAY1	LAYN	STRAIN		

Example:

IPSTRAIN	2001	2020	1	4	1	5	0.025		
----------	------	------	---	---	---	---	-------	--	--

Describer	Meaning
EID1	First Element ID to which these strains apply. (Integer > 0)
EID2	Last Element ID to which these strains apply. (Integer; Default = EID1)
INT1	First Integration point for which the strain applies. (Integer > 0; Default = 1)
INTN	Last Integration point for which the strain applies. (Integer > 0; Default = 4)
LAY1	First element layer for which the strain applies. (Integer > 0; no Default. Enter zero or leave blank if the model does not contain beams or shells.)
LAYN	Last element layer for which the strain applies. (Integer > 0; no Default. Enter zero or leave blank if the model does not contain beams or shells.)
STRAIN	Equivalent plastic strain value at start of analysis. (Real; Default is 0.0)

Remarks:

1. This entry only applies to SOL 400 advanced nonlinear elements (selected with PSHLN1, PSLDN1, etc.) and is ignored for other solutions.
2. This entry is normally used for metal forming and represents the amount of plastic deformation that the model was previously subjected to. It is used in work (strain) hardening models.

## IPSTRN Initial Equivalent Plastic Strain Values in SOL 600

Defines initial equivalent plastic strain values. This is the MSC Marc's initial plastic strain option used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
IPSTRN	EID1	EID2	INT1	INTN	LAY1	LAYN	STRAIN		

Example:

IPSTRN	2001	2020	1	4	1	5	0.025		
--------	------	------	---	---	---	---	-------	--	--

Describer	Meaning
EID1	First Element ID to which these strains apply. (Integer > 0)
EID2	Last Element ID to which these strains apply. (Integer; Default = EID1)
INT1	First Integration point for which the strain applies. (Integer > 0; Default = 1)
INTN	Last Integration point for which the strain applies. (Integer > 0; Default = 4)
LAY1	First element layer for which the strain applies. (Integer > 0; no Default. Enter zero or leave blank if the model does not contain beams or shells.)
LAYN	Last element layer for which the strain applies. (Integer > 0; no Default. Enter zero or leave blank if the model does not contain beams or shells.)
STRAIN	Equivalent plastic strain value at start of analysis. (Real; Default is 0.0)

Remarks:

1. This entry only applies to SOL 600 advanced nonlinear elements and is ignored for other solutions.
2. This entry is normally used for metal forming and represents the amount of plastic deformation that the model was previously subjected to. It is used in work (strain) hardening models.
3. For SOL 600 only, if the extra precision available with large field formats is not required and small field precision is adequate, the header IPSTRAIN may be used instead of IPSTRN.

## ISTRESS Initial Stress Values in SOL 400 and SOL 600

Defines initial stress values. This is used in SOL 400 and MSC Marc's initial stress option via SOL600 only.

Format:

1	2	3	4	5	6	7	8	9	10
ISTRESS	EID1	EID2	INT1	INTN	LAY1	LAYN	STRESS1	STRESS2	
	STRESS3	STRESS4	STRESS5	STRESS6	STRESS7				
	"COORD"	CID							

Example:

ISTRESS	2001	2020	1	4	1	5	45000.	-2000.	
	0.0	4500.	0.0	2350.					

Describer	Meaning
EID1	First Element ID to which these stresses apply. (Integer > 0)
EID2	Last Element ID to which these stresses apply. (Integer; Default = EID1)
INT1	First Integration point for which the stress applies. (Integer > 0; Default = 1)
INTN	Last Integration point for which the stress applies. (Integer > 0; Default = 4)
LAY1	First element layer for which the stress applies. (Integer > 0; no Default. Enter zero or leave blank if the model does not contain beams or shells.)
LAYN	Last element layer for which the stress applies. (Integer > 0; no Default. Enter zero or leave blank if the model does not contain beams or shells.)
STRESS(i)	Up to 7 stress components may be entered. (Real; Default = 0.0)
"COORD"	Indicate that this line defines coordinate system in which STRESS(i) are evaluated
CID	= -1: element coordinate; = 0: basic coordinate (Integer ≥ -1 ≤ 0; default=-1)

Remarks:

1. This entry only applies when using SOL 400 and SOL 600 (where MSC Marc is executed from Nastran) and is ignored for other solutions.
2. Initial stresses must be self-equilibrating and may not produce material nonlinearity.
3. Stress components are as follows:  
 Definitions:  
 s - normal type stress  
 t - shear type stress  
 x,y,z in global system  
 1,2,3 in element local system

3D solid elements (for example type 7)

1 - sxx

2 - syy

3 - szz

4 - txy

5 - tyz

6 - tzx

7 - hydrostatic pressure (Herrmann elements only, otherwise 7 should be blank)

Thick shells (for example type 75)

1 - s11

2 - s22

3 - t12

4 - t23

5 - t31

Thin shells (for example type 72)

1 - s11

2 - s22

3 - t12

Beams (for example type 14 or 98)

1 - s - axial

2 - t - twist

4. STRESS(i) by default are in element coordinate (CID=-1); if CID=0, STRESS(i) will be transformed from basic to element coordinate, for CQUAD4 and CTRIA3 only.

## ITER Iterative Solver Options

Defines options for the iterative solver in SOLs 101, 106, 108, 111, 153 and 400.

Format:

1	2	3	4	5	6	7	8	9	10	
ITER	SID									
		OPTION1VALUE1 OPTION2VALUE2 -etc.-								

Example:

ITER	100									
		ITSEPS=1.0E0-7, MSGFLG=YES, PRECOND=BICWELL, IPAD=3								

Describer	Meaning
SID	Set identification number. (Integer > 0).
PRECOND	Preconditioner option. (Character; Default = "BIC" for real analysis, "BICCMPLX" for complex analysis) See Remarks 3. and 4.
J	Jacobi
JS	Jacobi with diagonal scaling.
C	Incomplete Cholesky.
CS	Incomplete Cholesky with diagonal scaling.
RIC	Reduced incomplete Cholesky.
RICS	Reduced incomplete Cholesky with diagonal scaling.
BIC	Block incomplete Cholesky for real problems.
BICCMPLX	Block incomplete Cholesky for complex problems.
CASI	Element-based third party iterative solver.
USER	User given preconditioning. For direct frequency response (SOL 108): a decomposition will be done for 1st frequency and the factor will be used for all subsequent frequencies as a preconditioner with the iterative solver. Other solutions require a DMAP alter. Please refer to the <i>MSC Nastran Numerical Methods User's Guide</i> description of the SOLVIT module.
CONV	Convergence criterion. (Character; Default = "AREX")
AR	$\ r\ /\ b\ $ where r is the residual vector of current iteration and b is the initial load vector; internal criterion.
GE	Alternative convergence criterion using geometric progression and the differences between two consecutive solution updates; internal criterion.

Describer	Meaning	
	AREX	Same criterion as AR but with the additional consideration of the external convergence criterion. See Remark 2. (Default).
	GEEX	Same criterion as GE but with the additional consideration of the external convergence criterion. See Remark 2.
MSGFLG	Message flag. (Character; Default = "NO")	
	YES	Messages will be printed for each iteration.
	NO	Only minimal messages will be printed from the iterative solver (Default).
ITSEPS	User-given convergence parameter epsilon. (Real > 0.0)	
	Default= 1.E-4	for PRECOND = "CAS1"
	Default= 1.E-8	for PRECOND = "CAS1" with contact in the model
	Default= 1.E-6	for all other PRECOND options
ITSMAX	Maximum number of iterations. (Integer > 0; Default = N/4 where N is the number of rows in the matrix)	
IPAD	Padding value for RIC, RICS, BIC, and BICCMPLX preconditioning. (Integer > 0)	
	Default = 0	for PRECOND = "RIC" or "RICS"
	Default = 2	for PRECOND = "BIC" for purely three-dimensional models and three for two-dimensional and mixed element models. IPAD may be reset automatically by the program to the best value.
	Default = 5	for PRECOND = "BICCMPLX".
IEXT	Extraction level in reduced incomplete Cholesky preconditioning. Block structuring method in block incomplete Cholesky preconditioning. (Integer = 0 thought 7; Default = 0)	
	0	Uses USET/SIL tables (Default).
	1 - 7	The default value of 0 is recommended for all problems. The values 1 - 7 use a heuristic algorithm with a maximum block size equal to IEXT. Although setting IEXT to a value other than 0 could lead to slightly improved performance or reduced disk space use, it should be considered exploratory without the expectation of a benefit.
PREFONLY	Specifies early termination of the iterative solver. (Integer = 0 or -1; Default = 0)	
	0	Runs to completion (Default).
	-1	Terminates after preface giving resource estimates.

Remarks:

1. The optional ITER Bulk Data entry is selected by the SMETHOD Case Control command and is only required to override the defaults specified above.

- The external epsilon is computed as follows:

$$\varepsilon = \frac{(r, x)}{(b, x)}$$

where  $r$  is the final residual vector,  $x$  is the final solution vector and  $b$  is the initial load vector ( $r, x$ ) indicates the inner product of  $r$  and  $x$  and  $(b, x)$  indicates the inner product of  $b$  and  $x$ .

- See the *MSC Nastran Numerical Methods User's Guide* for more information on these options.
- The element-based iterative solver is primarily intended for the solution of very large solid element structural analysis problems. The following restrictions apply:
  - SOLs 101, 200 and 400 only. SOL 200 availability is limited to topology optimization and thus cannot be used for COMPLIANCE, FRMASS, WEIGHT, and VOLUME in DRESP1.
  - SOL 101 convergence parameter epsilon of 1.E-4 may be too large for some models and a decrease to 1.E-8 may be necessary.
  - Solver selection criteria and parameters cannot vary across subcases.
  - No GENEL elements allowed
  - x2GG/x2PP direct input matrix selection is allowed; however, the matrix size is limited to 100 grid points and must be symmetric.
  - No ASET/OMIT reduction allowed
  - Inertia relief is supported in SOL 101 for PARAM,INREL,-1. A SUPORT entry is required. PARAM,INREL,-2 and -4 are not supported.
  - No transfer functions allowed
  - No RFORCE or PLOADX follower forces allowed
  - Follower force stiffness must be symmetricized
  - No heat transfer allowed
  - DMP is not supported with the CASI solver.

Only BAR, BEAM, BUSH, ROD, CONMi, CONROD, DAMPi, ELASi, HEXA, MASSi, PENTA, QUAD4, QUAD8, QUADR, SEAM, SHEAR, TRIA3, TRIA6, TRIAR, TETRA, VISC and WELD elements are allowed.

- GPGPU devices are not supported for iterative methods.
- If Modules are present then this entry may only be specified in the main Bulk Data section.

**LBSH3DG** Tables used by an NLBSH3D to find force as function of displacement, velocity and rotor speed

Defines the force tables of NLBSH3D nonlinear loads as function of relative displacement or velocity and current rotor speed.

Format:

FORM = **ASYM** (Asymmetric matrix representation)

1	2	3	4	5	6	7	8	9	10
LBSH3DG	LID	FORM	MIN_FREQ	MAX_FREQ					
	P11	P12	P13	P14	P15	P16			
	P21	P22	P23	P24	P25	P26			
	P31	P32	P33	P34	P35	P36			
	P41	P42	P43	P44	P45	P46			
	P51	P52	P53	P54	P55	P56			
	P61	P62	P63	P64	P65	P66			

FORM = **DIAG** (Only Diagonal terms representation)

1	2	3	4	5	6	7	8	9	10
LBSH3DG	LID	FORM	MIN_FREQ	MAX_FREQ					
	P11	P22	P33	P44	P55	P66			

FORM = **SYM** (Symmetric matrix representation)

1	2	3	4	5	6	7	8	9	10
LBSH3DG	LID	FORM	MIN_FREQ	MAX_FREQ					
	P11								
	P21	P22							
	P31	P32	P33						
	P41	P42	P43	P44					
	P51	P52	P53	P54	P55				
	P61	P62	P63	P64	P65	P66			

Descriptor	Meaning
LID	Load identification group number for a NLBSH3D. (Integer > 0; Required)
FORM	Type of Input Curves. (Character; Default SYM)
SYM	Symmetric, only lower triangular terms needed
DIAG	Only diagonal terms are needed

Describer	Meaning
	<b>ASYM</b> Asymmetric, all terms are needed
MIN_FREQ	Minimum valid rotor speed for all the table lookups provided. (Real). See remark 4.
MAX_FREQ	Max valid rotor speed for all the table lookups provided. (Real > 0.0 Required). Refer remark 4.
Pij	TABLED5 Id that provides TABLED1 ids as a function of rotor speed in cycles per unit time. The TABLED1 will have force as a function of relative displacement and/or velocity.

### Remarks:

1. Values for the nonlinear forces will be determined using interpolation based on rotor speed and relative deflection/velocity of grid pair. If the rotor speed is beyond the range specified by MIN\_FREQ and MAX\_FREQ, a FATAL message will be produced. (Extrapolation will NOT be used beyond this range).
2. At selected rotor speeds ( $X_i$ ), force vs displacement (for LID-1) or force vs velocity (for LID-2) tables (TID $_i$ ) are defined on TABLED1 entries.
3. For an arbitrary rotor speed  $n$ , linear interpolation is used to determine the force  $f_{x_n}$  to be applied for the displacement/velocity. The illustration shows a graphic representation of interpolation for force vs displacement between tables defined for rotor speeds  $X_1$  and  $X_2$ .

4. For SYNC analysis, rotor speed is obtained from NLFREQ / NLFREQ1 bulk data card. For ASYNC analysis, rotor speed is obtained from RGYRO bulk data card.
5. All the tables (TABLED5 Pij) should provide lookup tables (TABLED1) for the range of rotor speeds between Min\_FREQ and Max\_Freq.

## LEAKAGE

## Mass Loss Through Holes or Permeability of the GBAG or COUPLE Surface

Defines the porosity model to be used with GBAG or COUPLE. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
LEAKAGE	LID	PORID	SUBID	PORTYPE	PORTYPID	COEFF	COEFFV		

Example:

LEAKAGE	7	100	365	PERMEAB	63		0.99		
---------	---	-----	-----	---------	----	--	------	--	--

Describer	Meaning	
LID	Unique number of a LEAKAGE entry. (Integer > 0; Required)	
PORID	Number of a set of LEAKAGE entries PORID must be referenced from a GBAG or COUPLE entry. (Integer > 0; Required)	
SUBID	> 0	Number of a BSURF, BCBOX, BCPROP, BCMATL or BCSEG, which must be a part of the surface, as defined on the GBAG or COUPLE entry.
	= 0	LEAKAGE definitions are used for the entire surface as defined on the GBAG or COUPLE entry.
PORTYPE	Defines the type of porosity. (Character; Required)	
	PORFLOW	The PORFLOW logic is used to model a constant flow boundary in the coupling surface. The flow boundary acts on the open area of the coupling surface. The open area is equal to the area of the (sub) surface multiplied by COEFFV. A hole can be modeled when COEFFV is set to 1.0. A closed area results for COEFFV = 0.0. The characteristics of the flow are defined on a PORFLOW entry, with ID as defined on the PORTYPID.
	PORFLWT	The PORFLWT logic is used to model a time dependent flow boundary in the coupling surface. The flow boundary acts on the open area of the coupling surface. The open area is equal to the area of the (sub) surface multiplied by COEFFV. A hole can be modeled when COEFFV is set to 1.0. A closed area results for COEFFV = 0.0. The characteristics of the flow are defined on a PORFLWT entry, with ID as defined on the PORTYPID.

Describer	Meaning
PORHOLE	The PORHOLE logic can be used to model small holes in an air bag. A BSURF defines the hole. The open area of the hole is equal to the area of the (sub) surface multiplied by COEFFV. A value of COEFFV = 1.0 will open up the complete area of the hole, while a value of COEFFV = 0.0 will result in a closed hole. The characteristics for the flow are defined on a PORHOLE entry, with ID as defined on the PORTYPID.
PERMEAB	The PERMEAB logic is used to model permeable air-bag material. The permeable area can be defined for a BSURF or for the entire coupling surface. The velocity of the gas flow through the (sub) surface is defined as a linear or tabular function of the pressure difference between the gas inside the air bag and the environmental pressure. The function is specified on a PERMEAB entry, with ID as defined on the PORYPID. The area actually used for outflow is the subsurface area multiplied by the value of COEFFV
PORFGBG	The PORFGBG logic can be used to model gas flow through a hole in the coupling surface connected to a GBAG. A BSURF defines the hole. The open area of the hole is equal to the area of the surface multiplied by COEFFV. A value of COEFFV = 1.0 will open up the complete area of the hole, while a value of COEFFV = 0.0 will result in a closed hole. The characteristics for the flow are defined on a PORFGBG entry, with ID as defined on the PORTYPID.
PERMGBG	The PERMGBG logic is used to model gas flow through a permeable area in the coupling surface connected to a GBAG. The permeable area can be defined for a BSURF or for the entire coupling surface. The velocity of the gas flow through the (sub) surface is defined as a linear or tabular function of the pressure difference. This function is specified on a PERMGBG entry, with ID as defined on the PORYPID. The area actually used for outflow is the subsurface area multiplied by the value of COEFFV.
PORFCPL	The PORFCPL logic can be used to model gas flow through a hole in the coupling surface connected to another coupling surface. A BSURF defines the hole. The open area of the hole is equal to the area of the (sub) surface multiplied by COEFFV. A value of COEFFV = 1.0 will open up the complete area of the hole, while a value of COEFFV = 0.0 will result in a closed hole. The characteristics for the flow are defined on a PORFCPL entry, with ID as defined on the PORTYPID.
PORHYDS	Prescribes a hydrostatic pressure profile.
PORTYPID	Porosity ID. References existing PORTYPE entry. (Integer > 0; Required)
COEFF	Method of defining the porosity coefficient. (Character; CONSTANT)

Describer	Meaning	
	CONSTANT	The porosity coefficient is constant and specified on COEFFV.
	TABLE	The porosity coefficient varies with time. COEFV is the number of a TABLED1 entry giving the variation with time.
COEFFV		The porosity coefficient or the number of a TABLED1 entry depending on the COEFF entry. (0.0 < Real < 1.0 or Integer < 0, 1.0)

Remarks:

1. The combination of multiple LEAKAGEs with different PORTYPEs is allowed.
2. It allows for setting up the exact same model for either a uniform pressure model (GBAG to LEAKAGE) or an Eulerian model (COUPLE to LEAKAGE). It is then possible to set up the model using the switch from full gas dynamics to uniform pressure (GBAGCOU).

The options PORFGBG and PERMGBG can be used to model air bags with multiple compartments.

## LOAD Static Load Combination (Superposition)

Defines a static load as a linear combination of load sets defined via FORCE, MOMENT, FORCE1, MOMENT1, FORCE2, MOMENT2, DAREA (if these entries have been converted), PLOAD, PLOAD1, PLOAD2, PLOADB3, PLOAD4, PLOADX1, SLOAD, RFORCE, and GRAV, ACCEL and ACCEL1 entries (as well as SPCD and SPCR for SOL 600 only). In addition, all the thermal loads are also supported in the NASTRAN thermal analysis (SOL 153 and SOL 400 with analysis=hstat) such as QBDY1, QBDY2, QBDY3, QVECT, QVOL, SLOAD, QHBDY Bulk Data entries.

Format:

1	2	3	4	5	6	7	8	9	10
LOAD	SID	S	S1	L1	S2	L2	S3	L3	
	S4	L4	-etc.-						

Example:

LOAD	101	-0.5	1.0	3	6.2	4			
------	-----	------	-----	---	-----	---	--	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
S	Overall scale factor. (Real)
Si	Scale factor on Li. (Real)
Li	Load set identification numbers defined on entry types listed above. (Integer > 0)

Remarks:

1. The load vector  $\{P\}$  is defined by

$$\{P\} = S \sum_i S_i \{P_{Li}\}$$

2. Load set IDs (Li) must be unique.
3. This entry must be used if acceleration loads (GRAV entry) are to be used with any of the other types.
4. In the static solution sequences, SID must be selected by the LOAD Case Control command. In dynamic solution sequences the EXCITEID of a RLOADi or TLOADi may refer to a LOAD entry.
5. A LOAD may be referenced by another LOAD entry. Nested LOAD references are permitted. A LOAD entry may not reference itself.
6. Note that the LOAD entry scaling for RFORCE uses the square root of the absolute  $S \times S_i$  in rotor dynamics. Thus it is recommended that the LOAD entry not be used with RFORCE in rotor dynamics with a value other than  $S=1.0$  and  $S_i=1.0$  value. See Remark 21. of the RFORCE entry.

7. LOAD Bulk Data entry will not combine an SPCD load entry except for SOL 600. In the static solution sequences, the set ID of the SPCD entry (SID) is selected by the LOAD Case Control command. In dynamic analysis refer to Remark 2. of the [SPCD](#) entry.
8. If Modules are present then this entry may only be specified in the main Bulk Data section.

## LOADCLID

### Define Solution Load Combinations Using Part Load ID

Define a loading combination in PAA using the Load ID from SUBCASEs of the Parts.

Format:

1	2	3	4	5	6	7	8	9	10
LOADCLID	LID	S							
	S1	LID1							
	PARTNAME1								
	S2	LID2							
	PARTNAME2								
	Etc.								

Example:

LOADCLID	202	1.00							
	1.00	101							
	first_part_name								
	1.0	301							
	second_part_name								

Descriptor	Meaning
LID	Load set ID. Selected by the LOAD Case Control command. (Integer > 0)
S	Overall scale factor. (Similar to LOAD Bulk Data entry) (Real < > 0)
Si	Scale factor applied to Load ID loads. (Real < > 0)
LIDi	Load ID specified during GENERATE by LOAD or CLOAD Case Control directive. (Integer > 0)
PARTNAMEi	Name of Part. (64 -Characters maximum)

Remarks:

- LOADCLID entries are used only in the COMBINE and SOLVE steps of PAA processing.
- The LOADCLID allows a loading combination to be created using the Load id (LIDi) from case control. In each PAA run, each SUBCASE may have a LIDi provided. These are used by the LOADCLID to define a loading combination.
- As with other loading entries, all loads with the same LID are combined. Therefore, care must be exercised when using loading combinations.

## LOADCNAM

## Define Solution Load Combination by Load Name

Used only in PAA to define a loading combination using the LOADNAMEs used in Case Control for Parts.

Format:

1	2	3	4	5	6	7	8	9	10
LOADCNAM	LID	S							
	S1								
	LOADNAME1								
	PARTNAME1								
	S2								
	LOADNAME2								
	PARTNAME2								
	Etc.								

Example:

LOADCNAM	101	1.00							
	2.5								
	gravity_x								
	outboard_right_side_engine_nacelle								
	1.1								
	gravity_x_on_another_part								
	second_part_name								

Describer	Meaning
LID	Load set ID. Selected by the LOAD Case Control command. (Integer > 0)
S	Overall scale factor. (Similar to LOAD Bulk Data entry) (Real < > 0)
Si	Scale factor applied to LOADNAME loads. (Real < > 0)
LOADNAMEi	Name of Load for that Part. (64 -Characters maximum)
PARTNAMEi	Name of Part. (64 -Characters maximum)

Remarks:

- LOADCNAM entries are used only in the COMBINE and SOLVE steps of PAA processing.
- The LOADCNAM allows a loading combination to be created using the LOADNAME from case control. In each PAA run, each SUBCASE may have a LOADNAME provided. These LOADNAMEs are used by the LOADCNAM to define a loading combination.
- All loads with the same LID are combined. Therefore, care must be exercised when using loading combinations.

## LOADCSUB

### Define Solution Load Combinations Using Subcase Number

Used only in PAA to define a loading combination using the LOADNAMEs used in Case Control for Parts.

Format:

1	2	3	4	5	6	7	8	9	10
LOADCSUB	LID	S							
	S1	SUB1							
	PARTNAME1								
	S2	SUB2							
	PARTNAME2								
	Etc.								

Example:

LOADCSUB	1001	1.0							
	1.0	1							
	part_we_are_using_subcase_1_from								
	1.0	3							
	part_we_are_using_subcase_3_from								

Describer	Meaning
LID	Load set ID. Selected by the LOAD Case Control command. (Integer > 0)
S	Overall scale factor. (Similar to LOAD Bulk Data entry) (Real < > 0)
Si	Scale factor applied to Load ID loads. (Real < > 0)
SUBi	Subcase Number specified during GENERATE or COMBINE run. (Integer > 0)
PARTNAMEi	Name of Part. (Character, C64)

Remarks:

- LOADCSUB entries are used only in the COMBINE and SOLVE steps of PAA processing.
- The LOADCSUB allows a loading combination to be created using the SUBCASE ids from case control. In each PAA run, each SUBCASE has an id. These ids are used by the LOADCSUB to define a loading combination.
- All loads with the same LID are combined. Therefore, care must be exercised when using loading combinations.

## LOADCYH

### Harmonic Load Input for Cyclic Symmetry

Defines the harmonic coefficients of a static or dynamic load for use in cyclic symmetry analysis.

Format:

1	2	3	4	5	6	7	8	9	10
LOADCYH	SID	S	HID	HTYPE	S1	L1	S2	L2	

Example:

LOADCYH	10	1.0	7	C	0.5	15			
---------	----	-----	---	---	-----	----	--	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
S	Scale Factor. (Real)
HID	Harmonic. See Remark 6. (Integer or blank)
HTYPE	Harmonic type. (Character: “C”, “S”, “CSTAR”, “SSTAR”, “GRAV”, “RFORCE”, or blank).
Si	Scale factor on Li. (Real)
Li	Load set identification number. See Remark 10. (Integer > 0)

Remarks:

1. The LOADCYH entry is selected with the Case Control command LOAD = SID.
2. If HTYPE is blank, the load will be applied to all applicable types in the problem.
3. If HTYPE is “GRAV” or “RFORCE”, GRAV or RFORCE entry loading will be used. Harmonic loads for appropriate available harmonics will be generated automatically in these cases.
4. L1 and L2 may reference LOAD entries. However, the LOAD entry in such a case must not reference load sets defined via RFORCE and/or GRAV entries.
5. If L1 refers to a set ID defined by an SPCD entry, the same ID must not reference any nonzero loading specified by the other Bulk Data loading entries given via FORCE, MOMENT, FORCE1, MOMENT1, FORCE2, DAREA (if these entries have been converted), MOMENT2, PLOAD, PLOAD1, PLOAD2, PLOAD4, PLOADX, and SLOAD or converted DAREA entries. In other words, an enforced deformation loading via the SPCD entry is specified by a load set ID L1 or L2 and a zero magnitude loading via a load (such as FORCE) with the same ID.
6. If HTYPE is “GRAV” or “RFORCE”, the entry in HID will be ignored and therefore may be blank. S2 and L2 must be blank for this case.
7. Load set IDs L1 or L2 may not be referenced by load set ID L1 or L2 of LOADCYN entries.
8. If HTYPE = “C”, “S”, “CSTAR”, or “SSTAR”, the load on component (HTYPE) of harmonic (HID) is  $L = S(S1 \cdot L1 + S2 \cdot L2)$ .

9. S must be nonzero. In addition, either S1 or S2 must be nonzero.
10. L1 and L2 may reference any of the static or dynamic loading entries including GRAV and RFORCE.

## LOADCYN

### Physical Load Input for Cyclic Symmetry

Defines a physical static or dynamic load for use in cyclic symmetry analysis.

Format:

1	2	3	4	5	6	7	8	9	10
LOADCYN	SID	S	SEGID	SEGTYPE	S1	L1	S2	L2	

Example:

LOADCYN	10	1.0	1	R	0.5	17			
---------	----	-----	---	---	-----	----	--	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
S	Scale Factor. (Real)
SEGID	Segment identification number. (Integer)
SEGTYPE	Segment type. (Character: "R", "L", or blank)
Si	Scale Factors. (Real)
Li	Load set ID numbers. See Remark 8. (Integer > 0)

Remarks:

1. The LOADCYN entry is selected by the LOAD Case Control command.
2. If SEGTYPE is blank, both R and L segments will be used in DIH-type symmetry.
3. L1 and L2 may reference LOAD entries. However, the LOAD entry in such a case must not reference load sets defined via RFORCE and/or GRAV entries.
4. If L1 refers to a set ID defined by SPCD loading entry, the same ID must not reference any nonzero loading specified by the other Bulk Data loading entries given via FORCE, MOMENT, FORCE1, MOMENT1, FORCE2, DAREA (if these entries have been converted), MOMENT2, PLOAD, PLOAD1, PLOAD2, PLOAD4, PLOADX1, and SLOAD entries. In other words, an enforced deformation loading via the SPCD entry is specified by a load set ID L1 or L2 and a zero magnitude loading via a load (such as FORCE) with the same ID.
5. Load set IDs L1 or L2 may not be referenced by load set ID L1 or L2 of LOADCYH entries.
6. The load on the segment (or half-segment) is  $L = S(S1 \cdot L1 + S2 \cdot L2)$ .
7. S must be nonzero. In addition, either S1 or S2 must be nonzero.
8. L1 and L2 may reference any of the static or dynamic loading entries except GRAV and RFORCE.
9. For cyclic buckling loads may only be applied to the first segment and only zero harmonic loads may be applied so the LOADCYH entry should be used.

## LOADCYT

### Table Load Input for Cyclic Symmetry

Specifies loads as a function of azimuth angle by references to tables that define scale factors of loads versus azimuth angles. This entry is used only when STYPE = "AXI" on the CYSYM entry.

Format:

1	2	3	4	5	6	7	8	9	10
LOADCYT	SID	TABLEID1	LOADSET1	METHOD1	TABLEID2	LOADSET2	METHOD2		

Example:

LOADCYT	10	19	27		21	26	1		
---------	----	----	----	--	----	----	---	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
TABLEIDi	Table ID for table load input for load set Li. See Remark 3. (Integer > 0)
LOADSETi	Load set Li. (Integer > 0)
METHODi	Method of interpolation. See Remark 5. (Integer: 0 or 1; Default = 0)
	0 Interpolate the load with the Fourier coefficients specified in the table up to the specified number of harmonics. (Default)
	1 Interpolate the magnitude of the load at corresponding grid points in all segments.

Remarks:

- The LOADCYT entry is selected by the LOAD Case Control command.
- The load set ID given in fields 4 or 7 of this entry may refer to FORCE, MOMENT, PLOAD, PLOAD2, PLOAD4, SPCD, TEMP, or TEMPP1 Bulk Data entries.
- Either TABLED1 or TABLED2 type tabular data of azimuth angle (Xi) versus scale factors (Yi) may be used. The azimuth angle values must be in degrees.
- The scale factors given in the tables referenced by TABLEDi entries will be applied only to the magnitudes of the loads defined by LOADSET IDs given in fields 4 or 7.
- For grid point loading entries, (like FORCE, MOMENT, SPCD, and TEMP Bulk Data entries) METHODi = 1 option should be used. For element loading entries (like PLOAD, PLOAD2, PLOAD4, and TEMPP1 Bulk Data entries) either METHODi = 0 or METHODi = 1 option can be used. In particular, if harmonic output of element stresses under temperature loading via TEMPP1 Bulk Data entry, METHODi = 0 option should be used to specify TEMPP1 load set.

**LOADOF** Specifies Table IDs for Individual Degrees of Freedom for the Static Loads with Tables Described using LOADT Entries

Specifies table IDs for individual degrees of freedom for the static loads with tables described using LOADT entries for SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
LOADOF	T0	T1	T2	T3	T4	T5	T6		

Example:

LOADOF	100	101	102	103	104	105	106		
--------	-----	-----	-----	-----	-----	-----	-----	--	--

Describer	Meaning
T0	Table ID specified as a negative Ti value on a LOADT entry (specified as a positive value on this entry. (Integer > 0; no Default)
Ti (i=1 to 6)	ID of a TABLEL1 entry that specifies the time history of each degree of freedom for the loads specified by Li, -Ti on LOADT entries. Up to 6 degrees of freedom may be specified. See Remark 2. (Integer; no Default)

Remarks:

1. LOADOF can only be used in SOL 600
2. This entry must not be used unless there is a negative value of Ti on one or more LOADT entries.

## LOADT Specifies Static Loads that use a Table to Describe Their Variation with Pseudo-Time

Specifies static loads that will use a table to describe their variation with pseudo-time. Available static entries are FORCE, MOMENT, FORCE1, MOMENT1, FORCE2, MOMENT2, PLOAD, PLOAD1, PLOAD2, PLOAD4, PLOADX1, SPCD, SPCR, RFORCE and GRAV for SOL 600.

Format:

1	2	3	4	5	6	7	8	9	10
LOADT	SID	L1	T1	L2	T2	L3	T3	L4	
	T4	L5	T5	etc.					

Example:

LOADT	101	1	51	2	52	3	53		
-------	-----	---	----	---	----	---	----	--	--

Descriptor	Meaning
SID	Load set identification number which must have a matching Bulk Data entry LOAD with the same SID. (Integer > 0; no Default)
Li	Load set identification numbers defined on entry types listed above. (Integer > 0)
Ti	ID of a TABLEL1 or TABL3D0 entry that specifies the time history of the entry type. See Remarks 4. through 6. (Integer or Blank; no Default)

Remarks:

- LOADT can only be used in SOL 600.
- In SOL 600 applied displacements must use SPCD (or SPCD) rather than SPC.
- In SOL 600, if any LOADT entries are found in the model, the following parameters are automatically set:
  - PARAM,MARCVERR,11 (Allows table-driven inputs)
  - PARAM,MRCONVER,11 (Uses contact compatible with Version 11)
  - PARAM,MARCTOTT,1 (Allows loads with tables)
- If Ti is positive, the table will be used for all degrees of freedom for the loads specified by Li. If Ti is negative, the absolute value of Ti will be used as the ID of a LOADOF entry providing the table IDs for each degree of freedom for which Li applies.
- If more than one Li references the same force, moment pload4, etc, the first Ti encountered for that entity will be used for all occurrences of that entity for that subcase. Therefore, the 2nd and subsequent occurrences of Ti for these common entities may be left blank. An example can be found in ETL example mloadt03.

6. It is strongly suggested that for a particular dof of a FORCE, MOMENT, etc. that only one table describe the variation for all subcases in the model. For example, if there are 3 subcases the time should normally cover the entire range of 0.0 to 3.0 (rather than having three tables, one for the range 0.0 to 1.0, a second for the range of 1.0 to 2.0 and a third from 2.0 to 3.0).

## LORENZI

## Fracture Mechanics J-Integral in SOL 600

This option gives an estimation of the J-Integral for a crack configuration using the domain integration method. The domain integration method has the advantage that it can also be used for problems with thermal behavior and for dynamic analysis. This procedure is only available for continuum elements. Only the nodes defining the crack front (crack tip in two dimensions) need to be defined. The program automatically finds integrations paths according to the format below. The complete J-Integral is evaluated and output. For the case of linear elastic material with no external loads on the crack faces, the program automatically separates mode I, mode II, and mode III (3-D only) stress intensity factors from the J-Integral.

### Format:

1	2	3	4	5	6	7	8	9	10
LORENZI	IDCR		MSEP	ITYPE	G2D	ISET0			
	DIRECT	ISETD	SV1	SV2	SV3				
	TOP	NREG	JTYPE	TOL	SV1	SV2	SV3		
	GEOM	NREG	JTYPE	TOL	SV1	SV2	SV3	RAD	
		CYLIN							

### Example:

LORENZI	1		0	1	1				
	DIRECT	101	0.0	-2.0E-3	0.0				
	DIRECT	102	0.0	-2.0E-3	0.0				

LORENZI	1		0	1	1				
	TOP	2	1						

Describer	Meaning
IDCR (4-2)	Identification of this particular crack. (Integer > 0; Required field) IDCR must be unique among all LORENZI cracks.
MSEP (3-1)	Enter 0 for no mode separation or 1 for mode separation. (Integer; Default = 1)
ITYPE (4-1)	Type of crack propagation (Integer; Default = 2) <ol style="list-style-type: none"> <li>1 The “rigid region” will be described using direct inputs of nodes or elements.</li> <li>2 The “rigid region” will be described using an automatic search based on topology.</li> <li>3 The “rigid region” will be described using an automatic search based on geometry.</li> </ol>

Describer	Meaning
G2D (5 for 2D)	If the crack is 2D, enter the grid ID of the node at the crack tip. If the crack is 3D, leave this field blank. (Integer; no Default)
ISET0 (5 for 3D)	If the crack is 3D, enter the ID of a SET3 entry that defines an ordered set of grids or elements along the crack tip (for example in the thickness direction of the crack). If the crack is 2D, enter the grid ID of the node at the crack tip. (Integer; no Default)
DIRECT (Start of 5a)	Enter the string DIRECT if ITYPE=1, otherwise skip this line. See Remark 4. (Character,)
ISETD (6a)	Enter the ID of a SET3 entry defining an ordered set of grids or elements within the rigid region. See Remark 4. (Integer; no Default)
SV1 (7a-1 or 6b-1 or 6c-1)	First component of shift vector. (Real; Default = .0.)
SV2 (7a-2 or 6b-2 or 6c-2)	Second component of shift vector. (Real; Default = 0.0)
SV3 (7a-3 or 6b-3 or 6c-3)	Third component of shift vector, enter only for 3D. (Real; Default = 0.0)
TOP (Start of 5b)	Enter the string TOP if ITYPE=2, otherwise skip this line. (Character)
NREG (5b-1 or 5c-1)	Number of regions for which crack growth is to be estimated. See Remark 5. (Integer; Default = 1)
JTYPE (5b-2 or 6b-2)	Enter 0 if SV1, SV2, SV3 on this line are to be used or enter 1 for automatic determination of SV1, SV2 and SV3. (Integer; Default = 1)
TOL (5b-3 or 5c-3)	Enter tolerance for multiple grids at the crack tip. (Real; Default = 0.0)
GEOM (Start of 5c)	Enter the string GEOM if ITYPE=3, otherwise skip this line (Character)
RAD (7c-1)	Radius of the rigid region to be found. (Real; no Default) Enter only if ITYPE=3.
CYLIN (7c-2)	Relative length of cylinder for the path search. (Real; no Default) Enter only if ITYPE=3.

Remarks:

1. This entry corresponds to Marc's LORENZI model definition option.
2. (i,j) corresponds to Marc Vol C LORENZI entry ith datablock jth field.
3. Repeat the LORENZI as many times as necessary to define all cracks for which J-Integrals should be evaluated.

4. If the DIRECT input is used, repeat the DIRECT line as many times as necessary to define different regions from which crack growth should be estimated. In some cases it is informative to calculate crack growth for several regions and compare the results of these calculations. For example, in the model shown below, the crack tip is at the center on the left side. It might be informative to compare crack growth using a region including all nodes in the first ring (of node) around the crack with that produced by two rings.
5. For the TOP and GEOM methods, only one line per crack should be entered.
6. The continuation line for GEOM is not required except for 3D cracks.
7. For the previous examples, the crack tip is at grid 1 in the following figure. For the direct input, SET3 with ID 101 would reference all grids on and within the ring closest to the crack tip. SET3 with ID 102 would reference all grids on and within the two rings closest to the crack tip. Both examples provide identical results. The topology input is considerably simpler and therefore recommended.
8. The definition of shift vector is the function  $q_1$  in the equation and text described below.

### Background

The J-integral evaluation is based upon the domain integration method. A direct evaluation is not very practical in a finite element analysis due to the difficulties in defining the integration path. In the domain integration method for two dimensions, the line integral is converted into an area integration over the area inside the path. This conversion is exact for the linear elastic case and also for the nonlinear case if the loading is proportional, that is, if no unloading occurs. By choosing this area as a set of elements, the integration is straightforward using the finite element solution. In two dimensions, the converted expression is

$$\bar{J} = \int_A \left( \sigma_{ij} \frac{\partial u_j}{\partial x_1} - W \delta_{1i} \right) \frac{\delta q_1}{\delta x_i} dA$$

for the simplified case of no thermal strains, body forces or pressure on the crack faces.  $A$  is the area inside the integration path and  $q_1$  is a function introduced in the conversion into an area integral. The function can be chosen fairly generally, as long it is equal to one at the crack tip and zero on. The form of the function chosen is that it has the constant value of one at all nodes inside, and decreases to zero over the outermost ring of elements. It can be interpreted as a rigid translation of the nodes inside while the nodes on remain fixed. Thus, the contribution to the above equation comes only from the elements in a ring away from the crack tip. This interpretation is that of virtual crack extension and this method can be seen as a variant of such a technique, although it is extended with the effects of thermal strains, body forces, and pressure on the crack faces. The set of nodes moved rigidly is referred to as the *rigid region* and the function  $q_1$  in the above equation as the **shift vector**. For the evaluation of the J-integral the direction of the shift vector is simply the  $x$  axis in the local crack tip system.

In three dimensions, the line integral becomes an area integral where the area is surrounding a part of the crack front. In this case, the selection of the area is even more cumbersome than in two dimension. The converted integral becomes a volume integral which is evaluated over a set of elements. The rigid region is a set of nodes which contains a part of the crack front, and the contribution to the integral comes from the elements which have at least one but not all its nodes in the rigid region.

## LSEQ Static Load Set Definition

Defines a sequence of static load sets.

Format:

1	2	3	4	5	6	7	8	9	10
LSEQ	SID	EXCITEID	LID	TID					

Example:

LSEQ	100	200	1000	1001					
------	-----	-----	------	------	--	--	--	--	--

Describer	Meaning
SID	Set identification of the set of LSEQ entries. See Remark 5. (Integer > 0)
EXCITEID	The EXCITEID set identification assigned to this static load vector. See Remark 5. (Integer > 0)
LID	Load set identification number of a set of static load entries such as those referenced by the LOAD Case Control command. (Integer > 0 or blank)
TID	Temperature set identification of a set of thermal load entries such as those referenced by the TEMP(LOAD) Case Control command. (Integer > 0 or blank)

Remarks:

1. LSEQ will not be used unless selected in the Case Control Section with the LOADSET command.
2. The number of static load vectors created for each superelement depends upon the type of analysis. In static analysis, the number of vectors created is equal to the number of unique EXCITEIDs on all LSEQ entries in the Bulk Data; in dynamic analysis, the number of vectors created is equal to the number of unique EXCITEIDs on all RLOAD1, RLOAD2, TLOAD1, TLOAD2 and ACSRCE entries in the Bulk Data.
3. EXCITEID may be referenced by CLOAD, RLOAD1, RLOAD2, TLOAD1, and TLOAD2 entries in order to apply the static load in nonlinear, static and dynamic analysis.
4. Element data recovery for thermal loads is not currently implemented in dynamics.
5. The SID-EXCITEID number pair must be unique with respect to similar pairs on all other LSEQ entries in the Bulk Data.
6. In a nonsuperelement analysis, LID and TID cannot both be blank. In superelement analysis, they may both be blank as long as static loads are prescribed in the upstream superelements.
7. It is no longer necessary to employ LOADSET/LSEQ data to specify static loading data for use in dynamic analysis. In the absence of LSEQ Bulk Data entries, all static loads whose load set IDs match the EXCITEIDs on all RLOAD1, RLOAD2, TLOAD1, TLOAD2 and ACSRCE entries in the Bulk Data are automatically processed.

## Entries M - O

### MACREEP

### AUTO CREEP Iteration Control in SOL 600

Controls a transient creep analysis. This entry or the MTCREEP entry is required if ITYPE is not zero on the MPCREEP entry in SOL 600.

Format:

1	2	3	4	5	6	7	8	9	10
MACREEP	ID	Tinc	Ttot	Nmax	NIM	NIK	Tstab	VV1	
	VV2	VV3	IABS						

Example:

MACREEP	1	1.0	1000.	99999	5	1		.01	
	100.	.05	0						

Describer	Meaning
ID	Identification number of a matching Case Control NLPARM command (for statics) or command (for dynamics). (Integer; Required Field)
Tinc	Suggested time increment for creep analysis - The specified value will automatically be adjusted. (Real; Required Value) (2,1)
Ttot	Total time (final time) of the creep analysis. (Real; Required Value) (2,2)
Nmax	Maximum number of time increments allowed in the creep analysis (Integer; Default = 50) (2,3)
NIM	Maximum number of iterations allowed to modify a time step (Integer; Default = 5) (2,4)
NIK	Number of increments between stiffness matrix updates (Integer; Default = 1) (2,5)
Tstab	Stable time step, if known, must be entered for viscoplasticity (Real; Required field for viscoplasticity) (2,7)
VVT	Tolerance value #1. (Real; see below for Defaults) (3,1)
	IABS=0      Enter the tolerance on the creep strain increment divided by the elastic strain (Default = 0.5).
	IABS=1      Enter the maximum creep strain increment allowed. (Default = 0.1)
VV2	Tolerance value #2. (Real, see below for defaults) (3,2)
	IABS=0      Enter the tolerance on the stress change divide by the total stress. (Default = 0.1)
	IABS=1      Enter the maximum stress increment. (Default = 100.0)

Describer	Meaning
VV3	Tolerance on low stress point cutoff. Points with a stress lower than this ratio relative to the maximum stress in the structure are not used in the creep tolerance checking (Real; Default = 0.05) (3,3)
IABS	Flag controlling relative or absolute convergence testing. (Integer; Default = 0) (3,5)
	0            Relative checking is used
	1            Absolute checking is used

Remarks:

1. This entry maps to Marc's AUTO CREEP entry.
2. This entry will be used instead of AUTO STEP or AUTO INCREMENT entries in the Marc file for creep analysis. It is suggested that if this entry is used, NLAUTO and NLSTRAT should not be specified (and will be ignored if entered).
3. Bulk Data entry MPCREEP must also be entered in addition to this entry.
4. (i,j) refer to Marc's AUTO CREEP (data block, field).
5. Bulk Data entries MACREEP and MTCREEP should not be entered in the same input file.

**MARCIN**

Inserts a Text String in Marc from SOL 600

Inserts a text string directly in the Marc input file used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10	
MARCIN	ILOC	ICONT	String							

Example:

MARCIN	-1	0	feature,2301							
--------	----	---	--------------	--	--	--	--	--	--	--

<b>Describer</b>	<b>Meaning</b>	
ILOC	Identification of the location in the Marc file where the string will be placed. (Required; Integer)	
	-1	String is placed at end of Marc's Parameter Section
	0	String is placed at the end of Marc's Model Definition Section
	N (N > 0)	String is placed in load case N after the AUTO STEP, AUTO INCREMENT, etc. entry.
ICONT	(Required; Integer)	
	-1	String is used as the name of an include file which contains all of the direct Marc input data for that portion of Marc (parameter, model definition, etc.). Only one include file per Marc Section is allowed. The string must be entirely in lower case and the include file must be in lower case, except for PC systems where the case does not matter.
	0	Entry is not a continuation of previous MARCIN entry.
	1	Entry is a continuation of previous MARCIN entry and the strings will be placed one after the other on the same Marc line
String	(Required; Character)	
	0	The desired text string. The string is limited to 48 characters per entry. Multiple entries will be placed in the order entered within each Marc location.
	-1	String is an include file name limited to 48 characters.

Remarks:

- Standard Nastran fields 4-9 are ignored for this entry. The string may be entered anywhere within fields 4-9 and will be translated directly to Marc.
- If a long line for the Marc data is required, enter as many MARCIN entries as necessary to describe the entire Marc string using ICONT=1 for each except the first.

3. The total string length including continuation lines is limited to 160 characters.
4. As many MARCIN entries as necessary may be entered to define all desired input.
5. Each entry in the Nastran data file must start with the MARCIN header. Each line in an include file will be translated directly to Marc (there should be no MARCIN, ILOC or ICONT information in the include file(s)).
6. If the direct Marc input is placed in include file(s), separate files are necessary for each portion of Marc (parameter, model definition, etc.) requiring direct input.
7. As part of the Nastran input process, all strings are converted to uppercase. The internal Marc translator will convert them to lower case. For input entered without include files, this will normally make any difference. For include file names, file names must be entirely lower case for computer systems that are case sensitive.
8. MARCIN entries are not always recognized in restart runs and are not recommended.
9. ILOC greater than zero is not available for SOL 600 heat transfer analysis or structural analysis if table-driven loads are requested (for example, by specifying param,marctott,1).
10. For ILOC > 0 if STRING starts with "\$", "comment", or "COMMENT", the string will usually be skipped and no continuation lines should be entered.

## MARCOUT

## Selects Data Recovery Output in SOL 600

Selects output to be saved on the Marc t16 end/or t19 file(s) used in SOL 600 only. This entry is available using the small field format only and should normally be used only when post-processing using the T16 file is to be done (in other words, it should not normally be used if OUTFR on the SOL 600 entry is selected - see PARAM,MARROUTT).

Format:

1	2	3	4	5	6	7	8	9	10
MARCOUT	LAYCODE	IO1	IO2	IO3	IO4	IO5	IO6	IO7	
	IO8	IO9	etc.						

Example:

MARCOUT	125	E11	E21	E41	N1	N2	N35		
---------	-----	-----	-----	-----	----	----	-----	--	--

Describer	Meaning
LAYCODE	Specifies which shell or beam layers are to be output. (Integer; Default is all layers from 1 to the value of PARAM,MARCSLHT) This parameter also applies to composites whether made of shells or solids. For options less than 100, output will be all integration points. For options 100-200, output will only be at the element center. See Remark 13.
0	All shell and beam layer results from 1 to MARCSLHT are output, solid output is available only at the centroid. This option also requires PARAM,MROUTLAY to be set to the maximum numbers of layers desired (MARCSLHT and MROUTLAY should be set to the same values).
1	Top and Bottom layer shell, beam and solid bottom layer results only are output (Marc layer codes 1 and 1000).
2	Top, Bottom and Middle layer results for shell beams and centroid results for solids only are output (Marc layer codes 1, 5000 and 10000)
3	Top and Bottom layer shell, beam and solid bottom layer results are output. In addition, composite layer output listed in the Bulk Data entry, MLAYOUT will be included.
100	Same as option 0 except output is only at the center of each layer
101	Same as option 1 except output is only at the center of each layer
102	Same as option 2 except output is only at the center of each layer
103	Same as option 3 except output is only at the center of each layer.
IO(i)	Indicates the type of Marc output requested according to the following table:

Element Output	Description
-9999	If -9999 is entered in field 3, the defaults for the post file of the Marc version being run will be used. Fields 4-9 must be blank and no continuation lines should be entered. No OUTR options on the SOL 600 entry are available with this option.
“E-USER”*	First user-defined element post code(s) are generated by user subroutine plotv.f
“E-USER1”*	2 <sup>nd</sup> user-defined element post code(s)
“E-USER2”*	3 <sup>rd</sup> user-defined element post code(s)
“E-USER3”*	4 <sup>th</sup> user-defined element post code(s)
“E-USER99”*	100 <sup>th</sup> user-defined element post code(s)
*These outputs are only available in the t16 file, not in op2, xdb, f06, punch. A maximum number of 100 user-defined element post codes may be entered for SOL 600).	
E1 to E7	strain components, VM strain
E8	Equivalent plastic strain
E9	Total Temperature (combined heat/structural analysis)
E10	Incremental Temperature (combined heat/structural analysis)
E11 to E17	stress components, VM stress, Mean stress
E18	Mean normal stress
E20	Element Thickness (thickness can change vs time)
E21 - E27	plastic strain components, VM plastic strain
E28	Plastic strain rate
E29	Value of second state variable if applicable
E31 to E37	Creep strain components and equivalent creep strain
E38	Total swelling strain
E39	Value of third state variable if applicable
E41 to E47	Cauchy stress components, VM Cauchy stress
E49	Thickness strain for plane stress, Mooney or Ogden material
E58	Elastic strain energy density
E59	Equivalent stress/yield stress
E60	Equivalent stress/yield stress at current temperatures
E48	Strain Energy Density
E68	Plastic strain energy density
E69	Current Volume
E71 to E76	Components of thermal strain (separated from total strain)
E78	Original Volume

Element Output	Description
E79	Grain size if applicable
E80	Damage indicator for Cockroft-Latham, Oyane and principal stress criteria
E81 to E86	Components of cracking strain if applicable
E91 to E107	Failure indices associated with failure criteria from MATF
E108 to E109	Interlaminar shear for thick composite shells
E110	Interlaminar shear bond index for thick composite shells
E111 to E116	Components of stress in “preferred coordinate system”
E121 to E126	Elastic strain components
E127	Equivalent elastic strain
E128	Major engineering strain
E129	Minor engineering strain
E171	Porosity
E172	Void ratio
E173	Pore pressure
E174	Preconsolidation pressure
E175	Equivalent viscoplastic strain rate (powder material)
E176	Relative density (powder material)
E177	Void volume fraction (damage model)
E178	Lemaitre damage factor
E179	Lemaitre relative damage
E180	Total temperature (same as E9)
E181 to E183	Components of temperature gradient
E184 to E186	Components of flux
E241	Gasket pressure if applicable
E242	Gasket closure if applicable
E243	Plastic Gasket closure if applicable
E244	Exponential powder parameter kappa
E245	Exponential powder parameter x
E251 to E253	Components of interlaminar normal stress in basic coordinate system
E254 to E256	Components of interlaminar shear stress in basic coordinate system
E257	Interlaminar shear bond index for composite solids
E216	Beam axis or Orientation of CBUSH/CFAST elements
E261	Beam Axis

Element Output	Description
E264-E269	Beam/Bar or Bush Element Forces
	The next 6 lines are for CBUSH Force output (CBUSH stress/strain output and can be obtained with standard stress/strain codes if the stress/strain recovery. Coefficients are defined on the PBUSH entries.)
E264	CBUSH Axial Force (local bush coord sys)
E265	CBUSH Moment Mxx (local bush coord sys)
E266	CBUSH Moment Myy (local bush coord sys)
E267	CBUSH Shear Force Vxy (local bush coord sys)
E268	CBUSH Shear Force Vyx (local bush coord sys)
E269	CBUSH Torque (local bush coord sys)
E270	Bimoment (for beam element)
E301	Total strains tensor
E311	Stress tensor
E321	Plastic strain tensor
E331	Creep strain tensor
E341	Cauchy stress tensor
E371	Thermal strain tensor
E381	Cracking strain tensor
E391	Stress in composite ply (“preferred”) direction
E401	Elastic strain tensor
E411	Stress tensor in basic coordinate system
E421	Elastic strain tensor in basic coordinate system
E431	Plastic strain tensor in basic coordinate system
E441	Creep strain tensor in basic coordinate system
E451	Velocity strains (for fluids)
E461	Elastic strain in preferred direction tensor
E471	Rebar stress components in basic coordinate system in undeformed config if applicable
E481	Rebar stress components in basic coordinate system in deformed config if applicable
E487	Rebar angle
E501	Interlaminar normal stress
E511	Interlaminar shear stress
E531	Volume fraction of Martensite

Element Output	Description
E541	Phase transformation strain tensor
E547	Equivalent phase transformation strain
E548	Equivalent TWIN strain
E549	Equivalent TRIP strain
E551	Equivalent plastic strain in a multiphase aggregate
E552	Equivalent plastic strain in Austenite
E553	Equivalent plastic strain in Martensite
E557	Yield stress of multiphase aggregate
E610 to E617	Strength ratios based on MATF failure modes
E641	Generalized strain curvatures tensor
E661	Generalized stress moments tensor
E681	True strain tensor for continuum elements
E691	Element orientation vector 1
E694	Element orientation vector 2
E697	Layer orientation angle
E704	Real harmonic axial force
E705	Real harmonic Moment Mxx
E706	Real harmonic Moment Myy
E707	Real harmonic Shear force Vxy
E708	Real harmonic Shear force Vyx
E709	Real harmonic Torque
E710	Real harmonic Bimoment
E714	Imaginary harmonic axial force
E715	Imaginary harmonic Moment Mxx
E716	Imaginary harmonic Moment Myy
E717	Imaginary harmonic Shear force Vxy
E718	Imaginary harmonic Shear force Vyx
E719	Imaginary harmonic Torque
E720	Imaginary harmonic Bimoment
E721	Cauchy Stress Tensor in Preferred (Material) Coordinate System
E731	Curvature Tensor (for shell elements)
E741	Moment Tensor (for shell elements)

Nodal Output	Description
“N-USER”*	First user-defined nodal post cod are generated by user subroutine upstnd.f
“N-USER1”*	2 <sup>nd</sup> user-defined nodal post cod are generated by user subroutine upstnd.f
“N-USER2”*	3 <sup>rd</sup> user-defined nodal post cod are generated by user subroutine upstnd.f
“N-USER3”*	4 <sup>th</sup> user-defined nodal post cod are generated by user subroutine upstnd.f
“N-USER4”*	5 <sup>th</sup> user-defined nodal post cod are generated by user subroutine upstnd.f
“N-USER99”*	100 <sup>th</sup> user-defined nodal post cod are generated by user subroutine upstnd.f, etc.
*User-defined outputs are only available in the t16 file, not in op2, xdb, f06, punch. A maximum of 100 user-defined nodal post codes may be entered for SOL 600.	
N1,N2	displacements, rotations
N3,N4	Applied forces & moments
N5,N6	reaction forces & moments
N7	Fluid velocity if applicable
N8	Fluid pressure if applicable
N9	External fluid force if applicable
N10	Reaction fluid force if applicable
N11	Sound pressure if applicable
N12	External sound pressure if applicable
N13	Reaction sound pressure if applicable
N14	Temperature
N15	External heat flux
N16	Reaction heat flux
N23	Pore pressure if applicable (soil analysis)
N24	External mass flux if applicable
N25	Reaction mass flux if applicable
N26	Bearing pressure if applicable
N27	Bearing force if applicable
N28,N29	Velocity
N30,N31	Acceleration
N32,N33	Modal mass and rotational modal mass
N34,N35	Contact normal stress/force
N36,N37	Contact friction stress/force
N38,N39	Contact status, Contact touched body

Nodal Output	Description
N40	Herrmann variable
N46,N48	Tying force and moments
N47	Coulomb Force
N49	Generalized nodal stress
N50	Generalized nodal strain
N51,N52	Inertia relief force and moment
N53	J-Integral
N54	Stress Intensity, Mode I
N55	Stress Intensity, Mode II
N56	Stress Intensity, Mode III
N57	Energy release
N58	Energy release rate I
N59	Energy release rate II
N60	Energy release rate III
N62	Crack system local X
N63	Crack system local Y
N64	Crack system local Z
N65	Contact Separation Distance
N66	Normal Breaking Index
N67	Tangential Breaking Index
N68	Total Breaking Index
N69	Normal Delamination Index
N70	Tangential Delamination Index
N71	Total Delamination Index
N73	Glue deactivation status
N74	VCCT Failure Index
N76	Lorentz Force
N77	Wear Index
N78	Wear Rate

**Remarks:**

1. MARCOUT is only available when Marc is executed from within Nastran and controls what results are available in the Marc t16 file. All elements or nodes of each type selected will be placed on the t16 file (in other words, it is not possible to control this output by selecting various sets). Some, but not all, of the results in the t16 file may be used to obtain .op2, .xdb, punch or .f06 results output by specifying OUTF options on the SOL 600 Executive Control statement. They type of results which may be placed in the .op2, .xdb, punch or .f06 files are the same as those available in SOL 106 or 129. Other types of results are only available for postprocessing using the t16 file. Whenever possible, i.e., if your gui allows it, the t16 file should be used instead of .op2, .xdb, punch, or .f06 files for postprocessing.
2. Values such as E1, E21 correspond to Marc's postcodes 1 and 21, respectively.
3. Outputs produced by MARCOUT are the same for all subcases, load steps, iterations, etc.
4. The MARCOUT entry may be repeated as many times as desired, or all entries may be placed on continuation lines.
5. For entries E1, E11 and E21 corresponding entries E2-E7, E12-E17 and E22-E27 will be generated automatically. These terms correspond to 3 normal stress (or strain) and 3 shear stress/strain values plus the equivalent von Mises value. See Marc volume C POST description for more details.
6. If this entry is not used, the following defaults are entered automatically: E301, E341, E47, N1, N2, N35, N37, N39. When creep or heat transfer is present, additional items are added appropriately. If the MARCOUT entry is entered, only those items specified will be output.
7. Only displacements, rotations, Cauchy stresses and one type of strains (total, plastic or elastic) may be transferred to the Nastran database.
8. Displacements, at least one stress tensor and one strain tensor must be selected if any OUTF options are to be used.
9. For SOL 600, Nastran Case Control commands such as SET ID=, DISP=, STRESS=, and STRAIN= only control the output in the .OP2, .XDB, punch, .F06 and jid.marc.out files. The Case Control requests do not affect the t16 output.
10. Default MARCOUT options are sufficient for most needs and it is recommended that the MARCOUT entry only be employed by advanced users.
11. If some (but not all) forces (E264-E269) are specified, the missing ones will be added automatically since the t16op2 conversion requires all be present (this capability is available starting in MD Nastran R2 and the MSC Nastran 2006 release, prior to that, all needed to be specified if any OUTF options were requested.)
12. LAYCODE values 100-103 will automatically set PARAM,MARCCENT,1
13. For LAYCODE=1, if op2.xdb,f06 or punch output is requested element stress/strain results which normally are output at the center of the element will be output on the bottom surface of the element. For composite solids, if output at all layers is desired, postprocessing using the t16 file is required.
14. Additional outputs described in Marc Vol C (POST Section) may be available for certain types of SOL 600 analyses.

**MARPRN**

## Defines "Print" Options for SOL 600

This option corresponds to Marc's PRINT parameter which controls a variety of output and other information. for the most used options, PARAM,MARCPRN should be used.

## Format:

1	2	3	4	5	6	7	8	9	10
MARPRN	IP1	IP2	IP3	IP4	IP5	IP6	IP7	IP8	
	IP9	-etc.-							

## Example:

MARPRN	2	5	39						
--------	---	---	----	--	--	--	--	--	--

Describer	Meaning
IPi	"Print" code from list shown below (Integer; no Default). Include as many options as desired
1	Output element stiffness matrices (this also prints out the shell surface metric for doubly curved shells 4, 8, and 24), consistent mass matrix, and equivalent nodal loads. <b>CAUTION:</b> This produces significant output.
2	Output of the matrices used in tying. (TYING, SERVO LINK, UFORMS.)
3	Forces the solution of a nonpositive definite matrix. This is only recommended for the AUTO INCREMENT option to pass collapse points in the collapse analysis. This can be entered on the CONTROL option.
5	To obtain additional information concerning gap convergence. In contact analysis, set to 5 to obtain information concerning nodes touching or separating from surfaces and also to print out the maximum residual and reaction forces.
6	To obtain output of nodal value array during rezoning.
8	To obtain incremental displacements in local system in contact problems.
9	To obtain latent heat output.
10	To obtain the stress-strain relation in the local coordinate system.
11	To obtain additional information on the interlaminar stress calculation.
12	To output the right-hand side and solution vector. <b>CAUTION:</b> This produces significant output.
13	To obtain additional information regarding CPU resources used.
15	To obtain additional information regarding surface energy balances.
20	To obtain information regarding the evaluation of tables.

Describer	Meaning
21	To obtain information about application of kinematic boundary conditions when table input is used.
22	To obtain information about distributed loads, point loads, films, foundations, and initial conditions when table input is used.
26	To print additional information regarding sink points.
27	To obtain reaction forces at tied nodes.
28	To obtain additional information about convective terms in heat transfer and fluid analysis.
34	To print a description of what independent variables may be used with a physical quantity.
36	To obtain CASI solver debug information (has the least details).
37	To obtain CASI solver debug information (has more details).
38	To obtain CASI solver debug information (has the most details).
39	To obtain detailed information about memory allocation.
43	To obtain information about VCCT
44	To obtain information during progressive failure calculations

**Remark:**

1. See PARAM,MARCP RN for a simpler way to enter the most used print options.

## MASSET

## Mass Combination Definition

The MASSET bulk data entry defines a linear combination of mass cases to form the subcase-dependent mass which is selected by associated MASSET case control. The subcase mass is defined as follows by the MASSET bulk:

$$M_{ID} = S_0 \sum_i S_i M_i$$

Where,  $i$  refers to the MASSID qualifier:  $i = 0$  is the base mass case,  $i > 0$  are the incremental mass cases. ID's of mass combinations defined by MASSET bulk data entry and mass increments defined by MASSID bulk data sections should be unique.

Format:

1	2	3	4	5	6	7	8	9	10
MASSET	ID	S0	S1	ID1	S2	ID2	S3	ID3	
	S4	ID4							

Example:

MASSET	11	1.0	1.0	0	1.0	101			
--------	----	-----	-----	---	-----	-----	--	--	--

Describer	Meaning
ID	Set identification number referenced by MASSET case control. (Integer > 0; Required)
S0	The overall scale factor for the linear combination (Real >= 0.0; Default = 0.0)
Si	The scale factor for the ith mass increment (Real >= 0.0; Default = 0.0)
IDI	The MASSID for the ith mass increment (Integer > 0; No Default)

## MATBV

## Material Bulk Viscosity - SOL700

Defines the bulk viscosity for materials. Used in SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATBV	MID	BULK TYP	BULKQ	BULKL	CSCALE	DMPFAC	IIMMREL		

Example:

MATBV	7		1.2						
-------	---	--	-----	--	--	--	--	--	--

Descriptor	Meaning
MID	Material identification. See Remark 1. (Integer > 0, Required.)
BULK TYP	Bulk viscosity type. (Character: default=DYNA) DYNA                   Standard DYNA3D model. DYTRAN                Enhanced DYNA model.
BULKL	Linear bulk-viscosity coefficient. (Real ≥ 0.0; default=1.0)
BULKQ	Quadratic bulk-viscosity coefficient. (Real ≥ 0.0; default=0.0)
CSCALE	When this material model is used with MEMB shell elements (See PSHELL1), the compressive stresses in the principal directions will be scaled with this factor. CSCALE=0.0 results in a tension only material. See Remark 2. (Real ≥ 0.0; default=1.0)
DMPFAC	When this material model is used with MEMB shell elements, damping is applied to the stresses. DMPFAC = 0.05 results in 5% damping applied to membrane stresses. See Remark 2. (Real ≥ 0.0; default=0.0)
IIMMREL	Relaxation factor used with the Initial Metric Method. This option is only used when this material model is used with MEMB shell elements and the IMM method is activated. See Remark 3. (0.0 < Real < 1.0; default=1.0e-3)

Remarks:

- The material number must refer to a basic material definition such as MAT1/MAT2/MAT8/MATORT/MATHE.
- For air bag modeling the following values of CSCALE and DMPFAC are suggested:  
CSCALE = 0.1  
DMPFAC= 0.05 to 0.20
- The Initial Metric Method relaxation factor is used to slow down the expansion of the membrane elements during the calculation. The default is sufficient in most simulations.

## MAT1 Isotropic Material Property Definition

Defines the material properties for linear isotropic materials.

Format:

1	2	3	4	5	6	7	8	9	10
MAT1	MID	E	G	NU	RHO	A	TREF	GE	
	ST	SC	SS	MCSID					

Example:

MAT1	17	3.+7		0.33	4.28	6.5-6	5.37+2	0.23	
	20.+4	15.+4	12.+4	1003					

Describer	Meaning
MID	Material identification number. (Integer > 0)
E	Young's modulus. (Real $\geq$ 0.0 or blank)
G	Shear modulus. (Real $\geq$ 0.0 or blank)
NU	Poisson's ratio. (-1.0 < Real $\leq$ 0.5 or blank)
RHO	Mass density. See Remark 5. (Real)
A	Thermal expansion coefficient. (Real)
TREF	Reference temperature for the calculation of thermal loads, or a temperature-dependent thermal expansion coefficient. See Remarks 9. and 10. (Real; Default = 0.0 if A is specified.)
GE	Structural element damping coefficient. See Remarks 8., 9., and 4. (Real)
ST, SC, SS	Stress limits for tension, compression, and shear are optionally supplied, used only to compute margins of safety in certain elements; and have no effect on the computational procedures. (Real $\geq$ 0.0 or blank). See Remark 14.
MCSID	Material coordinate system identification number. Used only for PARAM,CURV processing. See Parameters. (Integer $\geq$ 0 or blank)

Remarks:

- The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MAT9, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
- The following rules apply when E, G, or NU are blank:
  - E and G may not both be blank.
  - If NU and E, or NU and G, are both blank, then both are set to 0.0.

- If only one E, G, or NU is blank, then it will be computed from the equation:  
 $E = 2 \cdot (1 + \text{NU}) \cdot G$ . If this is not desired, then the MAT2 entry is recommended. If E, G, or NU are made temperature dependent by the MATT1 entry, then the equation is applied to the initial values only. Caution: Inconsistent E and G can result in  $\text{NU} > .5$  which for three dimensional elasticity results in negative stress for positive strain. This can cause large max ratios.
3. If values are specified for all of the properties E, G, and NU, then it is recommended that the following relationship be satisfied:

$$\left| 1 - \frac{E}{2 \cdot (1 + \text{NU}) \cdot G} \right| < 0.01$$

If this relationship is not desired, then the MAT2 entry is recommended.

It should also be noted that some of the properties are not applied in the stiffness formulation of certain elements as indicated in Table 18. Therefore, it is recommended that only the applicable properties be specified for a given element.

Table 18 Material Property Usage Versus Element Types

Element Entry	E	NU	G
CROD CBEAM CBAR	Extension and Bending	Not Used	Torsion Transverse Shear
CQUADi CTRIAi CCONEAX	Membrane, including In-plane Shear, and Bending		Transverse Shear
CSHEAR		Not Used	Shear
CRAC2D		All Terms	Not Used
CHEXA CPENTA CTETRA CRAC3D		All Terms	Not Used
CTRIAX6	Radial, Axial, Circumferential	All Coupled Ratios	Shear

4. MAT1 materials may be made temperature-dependent by use of the MATT1 entry. In SOL 106, linear and nonlinear elastic material properties in the residual structure will be updated as prescribed under the TEMPERATURE Case Control command.
5. The mass density RHO will be used to compute mass for all structural elements automatically.
6. Weight density may be used in field 6 if the value 1/g is entered on the PARAM,WTMASS entry, where g is the acceleration of gravity (see Parameters).
7. MCSID must be nonzero if PARAM,CURV is specified to calculate stresses or strains at grid points on plate and shell elements only.

8. To obtain the damping coefficient GE, multiply the critical damping ratio  $C/C_0$ , by 2.0.
9. TREF and GE are ignored if the MAT1 entry is referenced by a PCOMP/PCOMPG entry.
10. TREF is used in two different ways (See Remarks 6. and 7. of TEMPERATURE Case Control entry for details.):
  - Except for SOL106 and SOL400 nonlinear analysis, TREF is used as the reference temperature for the calculation of thermal loads. TEMPERATURE(INITIAL) may be used for this purpose, in which case, TREF is ignored.
  - In SOL106 and SOL400 nonlinear analysis, TREF is used only for the calculation of a temperature-dependent thermal expansion coefficient. The reference temperature for the calculation of thermal loads is obtained from the TEMPERATURE(INITIAL) set selection.

Figure 9-92 Use of TREF in Calculation of Thermal Loads

$$\varepsilon_T = A(T) \cdot (T - TREF) - A(T_0) \cdot (T_0 - TREF)$$

where  $T$  is requested by the TEMPERATURE(LOAD) command and  $T_0$  is requested by the TEMPERATURE(INITIAL) command.

## Notes:

- A is a secant quantity.
- TREF is obtained from the same source as the other material properties; e.g., ASTM, etc.
- If  $A(T)$  constant, then  $\epsilon_T = A \cdot (T - T_0)$
- If PARAM,W4 is not specified, GE is ignored in transient analysis. See [Parameters](#).

11. In nonlinear static analysis (SOL 106) the QUAD4 and TRIA3 thermal loads are computed using the secant (default) method. To use the more accurate integral method, specify 'PARAM,EPSILON,INTEGRAL' in bulk data. See [Parameters](#).
12. For SOL 600, E must not be blank or zero.
13. Negative values for ST, SC, and SS lead to no margins of safety being computed.
14. ST, SC, and SS are not used in SOL 400 with advanced elements or SOL 600. Use MATF instead.

## MAT1A Additional Material Properties for MAT1- SOL700

Specifies additional the material properties of MAT1 for solid elements. Use SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
MAT1A	MID	EID							

Example:

MAT1A	101	201							
-------	-----	-----	--	--	--	--	--	--	--

Describer	Meaning
MID	Identification number of MAT1. (Integer > 0; required.)
EID	EOSxxx ID. (Integer > 0; required.)

Remarks:

- MAT1A always required for solid elements when MATEP is used. However, when RYIELD option of MATEP is set to VMISES, ORTHOCR or SOIL, MATEOS is not required.

## MAT1F

## Isotropic Material Frequency Dependence

Specifies frequency-dependent material properties on MAT1 entry fields via TABLEDi entries.

Format:

1	2	3	4	5	6	7	8	9	10
MAT1F	MID	E	G	NU	RHO			GE	

Example:

MAT1F	33	15	22	16					
-------	----	----	----	----	--	--	--	--	--

Describer	Meaning
MID	Material property identification number that matches the identification number on MAT1 entry. (Integer > 0)
E	Identification number of a TABLEDi entry for the Young's modulus. (Integer > 0 or blank)
G	Identification number of a TABLEDi entry for the shear modulus. (Integer > 0 or blank)
NU	Identification number of a TABLEDi entry for the Poisson's ratio. (Integer > 0 or blank)
GE	Identification number of a TABLEDi entry for the structural damping coefficient. (Integer > 0 or blank)
RHO	Identification number of a TABLEDi entry for the mass density. (Integer > 0 or blank). This table is only used for isotropic poroelastic material with BEGIN BULK TRMC and is applicable to that trim component only.

Remarks:

- Fields 3, 4, etc., of this entry correspond, field-by-field, to fields 3, 4, etc., of the MAT1 entry referenced in field 2. The value in a particular field of the MAT1 entry is replaced by the table referenced in the corresponding field of this entry. Blank or zero entries mean that there is no frequency dependence of the fields on the MAT1 entry.
- The user is reminded that on the MAT1 entry, if any one of the entries E, G, or, NU is left blank, they are connected by the relationship  $G=E/(2(1+NU))$ . Therefore, this entry requires that if any E, G, or NU is to be frequency dependent then Table references must be present for all three of the E, G, NU even if this requires a table of constant values.
- Table references must be present for each item that is frequency dependent.
- IF GE=0.0 on corresponding MAT1 then GE table must be blank or 0.

## MAT2 Shell Element Anisotropic Material Property Definition

Defines the material properties for linear anisotropic materials for two-dimensional elements.

Format:

1	2	3	4	5	6	7	8	9	10
MAT2	MID	G11	G12	G13	G22	G23	G33	RHO	
	A1	A2	A3	TREF	GE	ST	SC	SS	
	MCSID	GE11	GE12	GE13	GE22	GE23	GE33		

Example:

MAT2	13	6.2+3			6.2+3		5.1+3	0.056	
	6.5-6	6.5-6		-500.0	0.002	20.+5			
	1003								

Describer	Meaning
MID	Material identification number. See Remark 1. (Integer > 0)
Gij	The material property matrix. (Real) See Remarks 4., 5., 6., and 9.
RHO	Mass density. (Real)
Ai	Thermal expansion coefficient vector. (Real)
TREF	Reference temperature for the calculation of thermal loads, or a temperature-dependent thermal expansion coefficient. See Remarks 10., 11. and 14. (Real or blank)
GE	Structural element damping coefficient. See Remarks 8., 10., and 13. (Real)
ST, SC, SS	Stress limits for tension, compression, and shear are optionally supplied (these are used only to compute margins of safety in certain elements) and have no effect on the computational procedures. (Real or blank). See Remark 17.
MCSID	Material coordinate system identification number. Used only for PARAM, CURV processing. See Parameters. (Integer ≥ 0 or blank)
GEij	Structural damping matrix. See Remark 17. (Real)

Remarks:

1. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MAT9, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
2. MAT2 materials may be made temperature dependent by use of the MATT2 entry. In SOL 106, linear and nonlinear elastic material properties in the residual structure will be updated as prescribed under the TEMPERATURE Case Control command.
3. The mass density, RHO, will be used to automatically compute mass for all structural elements.

4. The convention for the  $G_{ij}$  in fields 3 through 8 are represented by the matrix relationship

$$\begin{Bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{Bmatrix} = \begin{bmatrix} G_{11} & G_{12} & G_{13} \\ G_{12} & G_{22} & G_{23} \\ G_{13} & G_{23} & G_{33} \end{bmatrix} \begin{Bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \gamma_{12} \end{Bmatrix} - (T - T_0) \begin{Bmatrix} A_1 \\ A_2 \\ A_3 \end{Bmatrix}$$

The  $G$  matrix, including  $G_{13}$  and  $G_{23}$  is an extension to conventional orthotropic plane stress behavior that allows membrane-shear coupling. If the MAT2 is used for plane stress elements or referenced as MID1 or MID2 in a PSHELL, the  $G$  matrix must be invertible and positive definite.

5. When MAT2 is referenced as a MID3 in a PSHELL, then it is used as:

$$\begin{Bmatrix} \tau_{13} \\ \tau_{23} \end{Bmatrix} = \begin{bmatrix} G_{11} & G_{12} \\ G_{12} & G_{22} \end{bmatrix} \begin{Bmatrix} \gamma_{13} \\ \gamma_{23} \end{Bmatrix}$$

This may lead to user warning message 6134 which may be ignored. See *The NASTRAN Theoretical Manual*, Section 4.2.

6. When MAT2 is referenced as a MID4 in a PSHELL, then only  $G_{13}$  and  $G_{23}$  are required. One will observe a user warning message 9994, The Material Property Matrix is not positive definite which may be ignored.
7. MCSID must be nonzero if PARAM,CURV is specified to extrapolate element centroid stresses or strains to grid points on plate and shell elements only. CQUAD4 element corner stresses are not supported by PARAM,CURV.
8. To obtain the damping coefficient  $GE$ , multiply the critical damping ratio  $C/C_0$  by 2.0.
9. Unlike the MAT1 entry, data from the MAT2 entry is used directly without adjustment of equivalent  $E$ ,  $G$ , or  $NU$  values.
10. TREF and  $GE$  are ignored if this entry is referenced by a PCOMP/PCOMPG entry.
11. TREF is used in two different ways (See Remarks 6. and 7. of TEMPERATURE Case Control entry for details.):
- Except for SOL106 and SOL400 nonlinear analysis, TREF is used as the reference temperature for the calculation of thermal loads. TEMPERATURE(INITIAL) may be used for this purpose, in which case, TREF is ignored.
  - In SOL106 and SOL400 nonlinear analysis, TREF is used only for the calculation of a temperature-dependent thermal expansion coefficient. The reference temperature for the calculation of thermal loads is obtained from the TEMPERATURE(INITIAL) set selection. See Figure 9-92 in Remark 10 of the MAT1 description.
12. If PARAM,W4 is not specified,  $GE$  is ignored in transient analysis. See [Parameters](#).

13. PCOMP/PCOMPG entries generate MAT2 entries starting from 100,000,001 onwards. Explicitly specified MAT2 IDs must not conflict with internally generated MAT2 IDs. Furthermore, the A1, A2 and A3 fields of MAT2 generated by Nastran from PCOMP that's used for PSHELL's MID4 has a special format. They are  $[G4] \times [\alpha 4]$  and not  $[\alpha 4]$ . These generated MAT2 entries have MID greater than 100,000,000. User supplied MAT2 should avoid using MID greater than 100,000,000 if it's used for MID4 of a PSHELL entry. If MIDs larger than 99999999 are used, PARAM,NOCOMPS,-1 must be specified to obtain stress output.
14. In nonlinear static analysis (SOL 106) the QUAD4, TRIA3, QUADR, and TRIAR thermal loads are computed using the secant (default) method. To use the more accurate integral method, specify 'PARAM,EPSILON,INTEGRAL' in bulk data. See [Parameters](#).
15. Negative values for ST, SC, and SS lead to no margins of safety being computed.
16. If the MAT2 is referenced by the PCOMP/PCOMPG entry, the transverse shear flexibility for the referenced lamina is zero.
17. Defines structural damping matrix data for advanced composites. If the GEij values are present, then Nastran will ignore the GE value given on the first continuation entry field (6) and the GE entry given in field (8) of the PCOMP/PCOMPG entry and use the given GEij values. The rationale of these entries is that with composite materials made of a viscoelastic resin system, the damping matrix does not scale with the stiffness matrix. For example, in the directions where you have more fibers, the stiffness is higher because you have more fibers but the damping coefficient is smaller because you have less resin matrix which is the main source of damping. To use this feature in composites, the PCOMP/PCOMPG MIDi entries must refer to MAT2 entries.

For any ply that does not point to a MAT2 with extended GEij, the GE value will be taken from the GE field of the corresponding MATi entry (MAT1 field 9, MAT2 field 6 of first continuation, MAT8 field 2 of second continuation.).

The damping when extended GEij is in effect is applied in element material routines by forming the product  $GE_{ij} * G_{ij}$  when forming the  $K_4$  damping matrix. For any ply not using an extended GEij of MAT2 the product  $GE * G_{ij}$  is used.

## MAT2F

## Shell Element Anisotropic Frequency Dependence

Specifies frequency-dependent material properties on MAT2 entry fields via TABLEDi entries.

Format:

1	2	3	4	5	6	7	8	9	10
MAT2F	MID	G11	G12	G13	G22	G23	G33		
					GE				
		GE11	GE12	GE13	GE22	GE23	GE33		

**Example:**

MAT2F	34								
		47	48	51	47	48	51		

Describer	Meaning
MID	Material property identification number that matches the identification number on MAT2 entry. (Integer > 0)
Gij	Identification number of a TABLEDi entry for the material property matrix. (Integer > 0 or blank)
GE	Identification number of a TABLEDi entry for the element structural damping coefficient. (Integer > 0 or blank)
GEij	Identification number of a TABLEDi entry for the element structural damping coefficients. (Integer > 0 or blank)

Remarks:

- Fields 3, 4, etc., of this entry correspond, field-by-field, to fields 3, 4, etc., of the MAT2 entry referenced in field 2. The value in a particular field of the MAT2 entry is replaced by the table referenced in the corresponding field of this entry. Blank or zero entries mean that there is no frequency dependence of the fields on the MAT2 entry.
- Table references must be present for each item that is frequency dependent.
- If the GEij values are present on the MAT2 entry for any ply, then Nastran will ignore the GE value given on the first continuation entry field (6) and the GE entry given in field (8) of the PCOMP/PCOMPG entry and use the given GEij values. The rationale of these entries is that with composite materials made of a viscoelastic resin system, the damping matrix does not scale with the stiffness matrix. For example, in the directions where you have more fibers, the stiffness is higher because you have more fibers but the damping coefficient is smaller because you have less resin matrix.

which is the main source of damping. To use this feature in composites, the PCOMP/PCOMPG MIDi entries must refer to MAT2 entries. See Remarks 17. and of MAT2 entry. The damping is applied in element material routines by forming the product  $GE_{ij} * G_{ij}$  when forming the  $K_4$  damping matrix.

4. IF GE=0.0 on corresponding MAT2 then GE table must be blank or 0. For any  $GE_{ij}=0.0$  on corresponding MAT2 the corresponding  $GE_{ij}$  table must be blank or 0.

## MAT3

## CTRIAX6 or PSHLN2 or PLCOMP Material Property Definition

Defines the material properties for linear orthotropic materials used by the CTRIAX6 element entry. It also is allowed with orthotropic materials on the PSHLN2 and PLCOMP entries.

Format:

1	2	3	4	5	6	7	8	9	10
MAT3	MID	EX	ETH	EZ	NUXTH	NUTHZ	NUZX	RHO	
			GZX	AX	ATH	AZ	TREF	GE	

Example:

MAT3	23	1.0+7	1.1+7	1.2+7	.3	.25	.27	1.0-5	
			2.5+6	1.0-4	1.0-4	1.1-4	68.5	.23	

Describer	Meaning
MID	Material identification number. (Integer > 0)
EX, ETH, EZ	Young's moduli in the $x$ , $\theta$ , and $z$ directions, respectively. (Real > 0.0)
NUXTH, NUTHZ, NUZX	Poisson's ratios (coupled strain ratios in the $x\theta$ , $\theta z$ , and $zx$ directions, respectively). (Real)
RHO	Mass density. (Real)
GZX	Shear modulus. (Real > 0.0)
AX, ATH, AZ	Thermal expansion coefficients. (Real)
TREF	Reference temperature for the calculation of thermal loads or a temperature-dependent thermal expansion coefficient. See Remark 10. (Real or blank)
GE	Structural element damping coefficient. See Remarks 9. and 11. (Real)

Remarks:

1. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MAT9, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
2. MAT3 materials may be made temperature dependent by use of the MATT3 entry. In SOL 106, linear and nonlinear elastic material properties in the residual structure will be updated as prescribed under the TEMPERATURE (INIT) Case Control command.
3. The few numbers EX, ETH, EZ, and GZX must be present.
4. A warning message will be issued if any value of NUXTH or NUTHZ has an absolute value greater than 1.0.

5. MAT3 materials may only be referenced by the CTRIAX6 entry or the PSHLN2 or PLCOMP entries.
6. The mass density RHO will be used to automatically compute mass for the CTRIAX6 element.
7. The x-axis lies along the material axis (see [Figure 9-80](#) in the CTRIAX6 entry). The  $\theta$ -axis lies in the azimuthal direction. The z-axis is normal to both.
8. The strain-stress relationship is

$$\begin{Bmatrix} \varepsilon_x \\ \varepsilon_\theta \\ \varepsilon_z \\ \gamma_{zx} \end{Bmatrix} = \begin{bmatrix} \frac{1}{EX} & \frac{NUTHX}{ETH} & \frac{NUZX}{EZ} & 0 \\ \frac{NUXTH}{EX} & 1 & \frac{NUZTH}{EZ} & 0 \\ \frac{NUXZ}{EX} & \frac{NUTHZ}{ETH} & \frac{1}{EZ} & 0 \\ 0 & 0 & 0 & \frac{1}{GZX} \end{bmatrix} \begin{Bmatrix} \sigma_x \\ \sigma_\theta \\ \sigma_z \\ \sigma_{zx} \end{Bmatrix} + (T - TREF) \begin{Bmatrix} AX \\ ATH \\ AZ \\ 0 \end{Bmatrix}$$

Note that:

$$\begin{aligned}
 \frac{NUXTH}{EX} &= \frac{NUTHX}{ETH} \\
 \frac{NUZX}{EZ} &= \frac{NUXZ}{EX} \\
 \frac{NUTHZ}{ETH} &= \frac{NUZTH}{EZ}
 \end{aligned}$$

The compliance matrix as shown must be positive definite. This requires that EX, ETH, EZ, and GZX be positive. There are additional restrictions as well, see a standard text on elasticity.

9. To obtain the damping coefficient GE, multiply the critical damping ratio  $C/C_0$  by 2.0.
10. TREF is used in two different ways (See Remarks 6. and 7. of TEMPERATURE Case Control entry for details.):
  - Except for SOL106 and SOL400 nonlinear analysis, TREF is used as the reference temperature for the calculation of thermal loads. TEMPERATURE(INITIAL) may be used for this purpose, in which case, TREF is ignored.
  - In SOL106 and SOL400 nonlinear analysis, TREF is used only for the calculation of a temperature-dependent thermal expansion coefficient. The reference temperature for the calculation of thermal loads is obtained from the TEMPERATURE(INITIAL) set selection. See [Figure 9-92](#) in Remark 10 of the MAT1 description.
11. If PARAM,W4 is not specified, GE is ignored in transient analysis. See [Parameters](#).

## MAT4 Heat Transfer Material Properties, Isotropic

Defines the constant or temperature-dependent thermal material properties for conductivity, heat capacity, density, dynamic viscosity, heat generation, reference enthalpy, and latent heat associated with a single-phase change.

Format:

1	2	3	4	5	6	7	8	9	10
MAT4	MID	K	CP	$\rho$	H	$\mu$	HGEN	REFENTH	
	TCH	TDELTA	QLAT						

Example:

MAT4	17	6.66-4	5.01-5	456.2		1.03-6			
------	----	--------	--------	-------	--	--------	--	--	--

Describer	Meaning
MID	Material identification number. (Integer > 0)
K	Thermal conductivity. (Blank or Real > 0.0)
CP	Heat capacity per unit mass at constant pressure (specific heat). (Blank or Real $\geq$ 0.0)
$\rho$	Density. (Real $\geq$ 0.0; Default = 1.0)
H	Free convection heat transfer coefficient. (Real or blank)
$\mu$	Dynamic viscosity. See Remark 2. (Real > 0.0 or blank)
HGEN	Heat generation capability used with QVOL entries. (Real $\geq$ 0.0; Default = 1.0)
REFENTH	Reference enthalpy. (Real or blank)
TCH	Lower temperature limit at which phase change region is to occur. See Remark 6. (Real or blank)
TDELTA	Total temperature change range within which a phase change is to occur. (Real $\geq$ 0.0 or blank)
QLAT	Latent heat of fusion per unit mass associated with the phase change. (Real > 0.0 or blank)

Remarks:

1. The MID must be unique with respect to all other MAT4 and MAT5 entries. MAT4 may specify material properties for any conduction elements as well as properties for a forced convection fluid (see CONVM). MAT4 also provides the heat transfer coefficient for free convection (see CONV).
2. For a forced convection fluid,  $\mu$  must be specified.
3. REFENTH is the enthalpy corresponding to zero temperature if the heat capacity CP is a constant. If CP is obtained through a TABLEM lookup, REFENTH is the enthalpy at the first temperature in the table.

4. Properties specified on the MAT4 entry may be defined as temperature dependent by use of the entry.
5. For RC network solver in thermal analysis, the REFENTH, TCH, TDELTA and QLAT are ignored.
6. The advanced nonlinear elements should be used for phase change to achieve accurate results.

## MAT5 Thermal Material Property Definition

Defines the thermal material properties for anisotropic materials.

Format:

1	2	3	4	5	6	7	8	9	10
MAT5	MID	KXX	KXY	KXZ	KYY	KYZ	KZZ	CP	
	RHO	HGEN							

Example:

MAT5	24	.092			.083		0.20	0.2	
	2.00								

Describer	Meaning
MID	Material identification number. (Integer > 0)
Kij	Thermal conductivity. (Real)
CP	Heat capacity per unit mass. (Real ≥ 0.0 or blank)
RHO	Density. (Real > 0.0; Default = 1.0)
HGEN	Heat generation capability used with QVOL entries. (Real ≥ 0.0; Default = 1.0)

Remarks:

1. The thermal conductivity matrix has the following form:

$$K = \begin{bmatrix} KXX & KXY & KXZ \\ KXY & KYY & KYZ \\ KXZ & KYZ & KZZ \end{bmatrix}$$

2. The material identification number may be the same as a MAT1, MAT2, or MAT3 entry but must be unique with respect to other MAT4 or MAT5 entries.
3. MAT5 materials may be made temperature-dependent by use of the MATT5 entry.
4. When used for axisymmetric analysis (CTRIAX6), material properties are represented where:  
KXX = radial conductivity component  
KYY = axial conductivity component
5. The KZZ is required if using the advanced nonlinear Shell element with temperature across thickness called out by NLMOPTS, TEMPP, LINE or QUAD option.

## MAT8 Shell Element Orthotropic Material Property Definition

Defines the material property for an orthotropic material for isoparametric shell elements.

Format:

1	2	3	4	5	6	7	8	9	10
MAT8	MID	E1	E2	NU12	G12	G1Z	G2Z	RHO	
	A1	A2	TREF	Xt	Xc	Yt	Yc	S	
	GE	F12	STRN						
	“HFAIL”	HF1	HF2	HF3	HF4	HF10	HF11		
	“HTAPE”	HT1	HT2	HT3	HT4	HT5	HT6	HT10	
		H11	HT12						
	“HFABR”	HFB1	HFB2	HFB3	HFB4	HFB5	HFB6	HFB10	
		HFB11	HFBT12						

Example:

MAT8	171	30.+6	1.+6	0.3	2.+6	3.+6	1.5+6	0.056	
	28.-6	1.5-6	155.0	1.+4	1.5+4	2.+2	8.+2	1.+3	
	1.-4		1.0						
	“HFAIL”	1010.	1020.	33.	34.	1011.	1012.		
	“HTAPE”	2001.	2002.	35.	36.	2003.	1.0	1004.	
		1007.	1008.						
	“HFABR”	3001.	3002.	3003.	3004.	1005.	1005.	1006.	
		1007.	1008.						

Describer	Meaning
MID	Material identification number. Referenced on a PSHELL, PCOMP or PCOMPG entry only. (0 < Integer < 100,000,000)
E1	Modulus of elasticity in X material coordinate direction, also defined as the fiber direction or 1-direction. (Real > 0.0)
E2	Modulus of elasticity in Y material coordinate direction, also defined as the matrix direction or 2-direction. (Real > 0.0)
NU12	Poisson’s ratio ( $\epsilon_2/\epsilon_1$ for uniaxial loading in 1-direction). Note that $\nu_{21} = \epsilon_1/\epsilon_2$ for uniaxial loading in 2-direction is related to $\nu_{12}$ , $E_1$ , and $E_2$ by the relation $\nu_{12}E_2 = \nu_{21}E_1$ . (Real)
G12	In-plane shear modulus. (Real > 0.0; Default = 0.0)
G1Z	Transverse shear modulus for shear in 1-Z plane. (Real $\geq$ 0.0 or blank; Default implies infinite shear modulus.)

Describer	Meaning
G2Z	Transverse shear modulus for shear in 2-Z plane. (Real $\geq 0.0$ or blank; Default implies infinite shear modulus.)
RHO	Mass density. (Real)
Ai	Thermal expansion coefficient in i-direction. (Real)
TREF	Reference temperature for the calculation of thermal loads, or a temperature-dependent thermal expansion coefficient. See Remarks 4. and 5. (Real or blank)
Xt, Xc	Allowable stresses or strains in tension and compression, respectively, in the longitudinal direction. Required if failure index is desired. See the FT field on the PCOMP/PCOMPG entry. (Real $> 0.0$ ; Default value for Xc is Xt.)
Yt, Yc	Allowable stresses or strains in tension and compression, respectively, in the lateral direction. Required if failure index is desired. (Real $> 0.0$ ; Default value for Yc is Yt.)
S	Allowable stress or strain for in-plane shear. See the FT field on the PCOMP/PCOMPG entry. (Real $> 0.0$ )
GE	Structural damping coefficient. See Remarks 4. and 6. (Real)
F12	Interaction term in the tensor polynomial theory of Tsai-Wu. Required if failure index by Tsai-Wu theory is desired and if value of F12 is different from 0.0. See the FT field on the PCOMP/PCOMPG entry. (Real)
STRN	For the maximum strain theory only (see STRN in PCOMP/PCOMPG entry). Indicates whether Xt, Xc, Yt, Yc, and S are stress or strain allowables. (Real = 1.0 for strain allowables; blank (Default) for stress allowables.)
“HFAIL”	Keyword indicating that Hashin failure criterion, to calculate its four failure indices.
HF1	Maximum fiber tensile stress, no default
HF2	Maximum fiber compressive stress, default=HF1
HF3	Maximum matrix tensile stress, no default
HF4	Maximum matrix compressive stress, default=HF3
HF10	Maximum in-plane shear stress, no default
HF11	Maximum transverse shear stress, default=HF10
“HTAPE”	Keyword indicating that Hashin-Tape criterion, a variant of the Hashin criterion, adapted for tape type of materials are calculated.
HT1	Maximum tape fiber tensile stress, no default
HT2	Maximum tape fiber compressive stress, default=HT1
HT3	Maximum tape cross-fiber tensile stress, no default
HT4	Maximum tape cross-fiber compressive stress, default=HT3
HT5	Maximum fiber tensile stress for matrix compression; Required if HT6=1.0, otherwise not used.

Describer	Meaning
HT6	Contribution factor for HT5 (Real, 0.0 or 1.0, default = 0.0)
HT10	Maximum in-plane shear stress, no default
HT11	Maximum transverse shear stress, default=HT10
HT12	Maximum z-x transverse shear stress, default=HT11
“HFABR”	Keyword indicating that Hashin-Fabric criterion, a variant of the Hashin criterion, adapted for fabric type of materials are calculated.
HFB1	Maximum first fiber tensile stress, no default
HFB2	Maximum first fiber compressive stress, default=HFB1
HFB3	Maximum second cross-fiber tensile stress, no default
HFB4	Maximum second cross-fiber compressive stress, default=HFB3
HFB5	Maximum thickness tensile stress, no default
HFB6	Maximum thickness compressive stress, default=HFB5
HFB10	Maximum in-plane shear stress, no default
HFB11	Maximum transverse shear stress, default=HFB10
HFB12	Maximum z-x transverse shear stress, default=HFB11

**Remarks:**

1. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MAT9, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
2. If G1Z and G2Z values are specified as zero or blank, then transverse shear flexibility calculations will not be performed, which is equivalent to zero shear flexibility (i.e., infinite shear stiffness). If MAT8 is referenced by Advanced Nonlinear Element, G1Z and G2Z must be positive.
3. An approximate value for G1Z and G2Z is the in-plane shear modulus G12. If test data are not available to accurately determine G1Z and G2Z for the material and transverse shear calculations are deemed essential; the value of G12 may be supplied for G1Z and G2Z. In SOL 106, linear and nonlinear elastic material properties in the residual structure will be updated as prescribed in the TEMPERATURE Case Control command.
4. Xt, Yt, and S are required for composite element failure calculations when requested in the FT field of the PCOMP/PCOMPG entry. Xc and Yc are also used but not required.
5. TREF and GE are ignored if this entry is referenced by a PCOMP/PCOMPG entry.
6. TREF is used in two different ways (See Remarks 6. and 7. of TEMPERATURE Case Control entry for details.):
  - Except for SOL106 and SOL400 nonlinear analysis, TREF is used as the reference temperature for the calculation of thermal loads. TEMPERATURE(INITIAL) may be used for this purpose, in which case, TREF is ignored.

- In SOL106 and SOL400 nonlinear analysis, TREF is used only for the calculation of a temperature-dependent thermal expansion coefficient. The reference temperature for the calculation of thermal loads is obtained from the TEMPERATURE(INITIAL) set selection. See [Figure 9-92](#) in Remark 10 of the MAT1 description.
7. If PARAM,W4 is not specified, GE is ignored in transient analysis. See [Parameters](#).
  8. In nonlinear static analysis (SOL 106) the QUAD4 and TRIA3 thermal loads are computed using the secant (default) method. To use the more accurate integral method, specify 'PARAM,EPSILONT,INTEGRAL' in bulk data. See [Parameters](#).
  9. If MAT8 with Hashin is used in SOL 400 with PSLDN1 then Hashin FT will be ignored with an appropriate warning message to include MATF instead.

## MAT8A Orthotropic Failure Material Properties - SOL700

Defines the failure properties for an orthotropic material for shell elements. Used in SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
MAT8A	MID	FT	NV	S	ALPHA	TRSFAIL	F12		
	XT	XC	YT	YC	PFD	VALUE	PFDST		
	FBTEN	FBCOM	MXTEN	MXCOM	MXSHR				
	PRDFT	PRDFC	PRDMT	PRDMC	PRDSH				

Example:

MAT8A	7	COMBINAT		100.					
+	200.0	150.0	100.0	110.0	STEPS	200.0			
+	CHANG	STRSS	MODSAI	MODTSAI	STRSS				
+									
+					0011				

Describer	Meaning
MID	Material identification. See Remark 1. (Integer > 0, Required.)
FT	Failure theory to be used to test whether the element layer fails. See Remark 2. (Character; default=blank) Blank            No failure HILL            Tsai-Hill theory TSAI            Tsai-Wu theory MODTSAI      Modified Tsai-Wu theory STRSS           Maximum stress CHANG        Chang-Chang theory COMBINAT    Combination (See Remark 6.) HASHIN        Hashin theory
NV	Number of additional history variables for a user model. See Remark 8. Currently it is not available. (0 < Integer < 10; default=0)
S	Failure stress for in-plane shear. See Remark 4. (Real > 0.0; required.)
ALPHA	Nonlinear shear coefficient. See Remark 5. (Real ≥ 0.0; default=0.0)
TRSFAIL	Transverse shear failure. (Character; default=SUBL)

Describer	Meaning
	ELEM Failure if element fails
	SUBL Failure if sublayer fails
F12	Interaction term in Tsai-Wu theory. (Real, default=0.0)
XT	Tensile failure stress in the large structural direction. See Remark 4. (Real $\geq$ 0.0; default=0.0)
XC	Compressive failure stress in the large structural direction. See Remark 4. (Real $\geq$ 0.0; default=0.0)
YT	Tensile failure stress in the lateral direction. See Remark 4. (Real $\geq$ 0.0; default=0.0)
YC	Compressive failure stress in the lateral direction. See Remark 4. (Real $\geq$ 0.0; default=0.0)
PFD	Post-failure degradation model. See Remark 8. (Character; default=STEPS)
	STEPS Degrade stresses by time steps
	TIME Degrade stresses by time
	VELOC Degrade stresses by velocity
VALUE	Depending on PFD, VALUE gives the number of time steps, time interval, or propagation velocity. (Real > 0; default=100.0)
PFDST	Post-failure degradation start. See Remark 8. (Character; default=INDV)
	INDV Stresses are degraded per distinct failure mode.
	ALL Stresses are degraded if all elastic constants are zero.
FBTEN	Tensile failure modes in fiber direction for individual failure definition. See Remark 6. (Character; required.)
FBCON	Compressive failure modes in fiber direction for individual failure definition. See Remark 6. (Character; required.)
MXTEN	Tensile failure modes in matrix direction for individual failure definition. See Remark 6. (Character; required.)
MXCOM	Compressive failure modes in matrix direction for individual failure definition. See Remark 6. (Character; required.)
MXSHR	Shear failure modes for individual failure definition. See Remark 6. (Character; required.)
PRDFT	Property degradation due to fiber-tension failure. See Remark 7. (Integer; default=1111)
PRDFC	Property degradation due to fiber-compression failure. See Remark 7. (Integer; default=1010)
PRDMT	Property degradation due to matrix-tension failure. See Remark 7. (Integer; default=0110)

Describer	Meaning
PRDMC	Property degradation due to matrix-compression failure. See Remark 7. (Integer; default=0110)
PRDSH	Property degradation due to in-plane shear failure. See Remark 7. (Integer; default=0001)

Remarks:

- The material number must refer to a MAT8 material definition.
- If a failure theory is selected other than COMBINAT, the theory defines the following failure modes:

CHANG	Fiber tension, matrix tension/compression
HILL	All modes
TSAI	All modes
MODTSAI	Matrix tension/compression
STRSS	All modes
HASHIN	Fiber tension/compression Matrix tension/compression

For an element to fail completely, both fiber and matrix in all sublayers must fail.

- This material model can only be referenced from a PCOMP entry.
- Failure stresses are required if a failure theory is selected.
- ALPHA is used for all failure theories to define a nonlinear stress-strain relation.
- The individual failure modes are defined according to the corresponding mode in the theory as listed under FT. To be relevant, the theory must define the failure mode (see Remark 2.). You must enter data if FT is set to COMBINAT.
- The property degradation rules due to the various failure modes are listed below:

Material Constant	Failure Mode				
	Fiber Tens	Fiber Comp	Matrix Tens	Matrix Comp	Shear
E1	X	X			
E2	X		X	X	
V12	X	X	X	X	
G12	X				X

The Poisson's ratio Nu21 is treated the same as Nu12.

To override the default model, an integer value is defined as a packed word in the following order:

- 1 Denotes property degradation.
- 0 Denotes no degradation.

The last five fields of the MAT8A Bulk Data entry are input for the user to specify the degradation behavior for each mode of failure.

8. The PFD entry indicates how the stresses are degraded to zero. The PFDST indicates when the stresses start to degrade.

Using ALL means that degradation starts when all material constants (E1, E2, V12, G12) are degraded to zero as specified by the FT entry and the property degradation rules. Note that property degradation means that the stress increments are zero but that the stresses degrade according to PFD.

INDV means that stress degradation starts for the fiber stress if E1=0.0, for matrix stress if E2=0.0, and for shear stress if G12=0.0.

9. Any failure theory introduces five additional sublayer variables. The PFDST entry introduces three additional variables. The number of user variables is defined by NV.

**MAT8F****Shell Element Orthotropic Material Frequency Dependence**

Specifies frequency-dependent material properties on MAT8 entry fields via TABLEDi entries.

Format:

1	2	3	4	5	6	7	8	9	10
MAT8F	MID	E1	E2	NU12	G12	G1Z	G2Z		
	GE								

Example:

MAT8F	76								
	97								

Descriptor	Meaning
MID	Material property identification number that matches the identification number on MAT8 entry. (Integer > 0)
E1	Identification number of a TABLEDi entry for the Modulus of elasticity in longitudinal direction, also defined as the fiber direction or 1-direction. (Integer > 0 or blank)
E2	Identification number of a TABLEDi entry for the Modulus of elasticity in lateral direction, also defined as the matrix direction or 2-direction. (Integer > 0 or blank)
NU12	Identification number of a TABLEDi entry for Poisson's ratio. (Integer > 0 or blank)
G12	Identification number of a TABLEDi entry for the in-plane shear modulus. (Integer > 0 or blank)
G1Z	Identification number of a TABLEDi entry for the transverse shear modulus for shear in 1-Z plane. (Integer > 0 or blank)
G2Z	Identification number of a TABLEDi entry for the transverse shear modulus for shear in 2-Z plane. (Integer > 0 or blank)
GE	Identification number of a TABLEDi entry for the element structural damping coefficient. (Integer > 0 or blank)

Remarks:

- Fields 3, 4, etc., of this entry correspond, field-by-field, to fields 3, 4, etc., of the MAT8 entry referenced in field 2. The value in a particular field of the MAT8 entry is replaced by the table referenced in the corresponding field of this entry. Blank or zero entries mean that there is no frequency dependence of the fields on the MAT8 entry.
- Table references must be present for each item that is frequency dependent.
- IF GE=0.0 on corresponding MAT8 then GE table must be blank or 0.

**MAT9** Solid Element (and Shell Element for SOL 600 only) Anisotropic Material Property Definition

Defines the material properties for linear, temperature-independent, anisotropic materials for solid isoparametric elements (see PSOLID entry description).

Format:

1	2	3	4	5	6	7	8	9	10
MAT9	MID	G11	G12	G13	G14	G15	G16	G22	
	G23	G24	G25	G26	G33	G34	G35	G36	
	G44	G45	G46	G55	G56	G66	RHO	A1	
	A2	A3	A4	A5	A6	TREF	GE		
	GE11	GE12	GE13	GE14	GE15	GE16	GE22	GE23	
	GE24	GE25	GE26	GE33	GE34	GE35	GE36	GE44	
	GE45	GE46	GE55	GE56	GE66				

Example:

MAT9	17	6.2+3						6.2+3	
					6.2+3				
	5.1+3			5.1+3		5.1+3	3.2	6.5-6	
	6.5-6					125.	.003		

Descriptor	Meaning
MID	Material identification number. (Integer > 0)
Gij	Elements of the 6 x 6 symmetric material property matrix in the material coordinate system. (Real)
RHO	Mass density. (Real)
Ai	Thermal expansion coefficient. (Real)
TREF	Reference temperature for the calculation thermal loads, or a temperature-dependent thermal expansion coefficient. See Remark 7. (Real or blank)
GE	Structural element damping coefficient. See Remarks 6. and 8. (Real)
GEij	Structural damping matrix. See Remark 9. (Real)

Remarks:

1. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.

- MAT9 materials may be made temperature-dependent by use of the MATT9 entry. In nonlinear static analysis (e.g., SOL 106), linear and nonlinear elastic material properties in the residual structure will be updated as prescribed under the TEMPERATURE Case Control command.
- The mass density RHO will be used to compute mass in a structural dynamics problem automatically.
- The third continuation entry is optional.
- The subscripts 1 through 6 refer to x, y, z, xy, yz, and zx of the material coordinate system (see the CORDM field on the PSOLID entry description). The stress-strain relationship is

$$\begin{Bmatrix} \sigma_x \\ \sigma_y \\ \sigma_z \\ \tau_{xy} \\ \tau_{yz} \\ \tau_{zx} \end{Bmatrix} = \begin{bmatrix} G11 & G12 & G13 & G14 & G15 & G16 \\ & G22 & G23 & G24 & G25 & G26 \\ & & G33 & G34 & G35 & G36 \\ & & & G44 & G45 & G46 \\ & \text{symmetric} & & & G55 & G56 \\ & & & & & G66 \end{bmatrix} \begin{Bmatrix} \epsilon_x \\ \epsilon_y \\ \epsilon_z \\ \gamma_{xy} \\ \gamma_{yz} \\ \gamma_{zx} \end{Bmatrix} = \begin{Bmatrix} A1 \\ A2 \\ A3 \\ A4 \\ A5 \\ A6 \end{Bmatrix} (T - TREF)$$

- The damping coefficient GE is given by

$$GE = \frac{2.0 \cdot C}{C_0}$$

- TREF is used in two different ways (See Remarks 6. and 7. of TEMPERATURE Case Control entry for details.):
  - Except for SOL106 and SOL400 nonlinear analysis, TREF is used as the reference temperature for the calculation of thermal loads. TEMPERATURE(INITIAL) may be used for this purpose, in which case, TREF is ignored.
  - In SOL106 and SOL400 nonlinear analysis, TREF is used only for the calculation of a temperature-dependent thermal expansion coefficient. The reference temperature for the calculation of thermal loads is obtained from the TEMPERATURE(INITIAL) set selection. See [Figure 9-92](#) in Remark 10 of the MAT1 description.
- If PARAM,W4 is not specified, GE is ignored in transient analysis. See [Parameters](#).
- Defines structural damping matrix data for advanced composites. If the GEij values are present, the Nastran will ignore the GE value given on the third continuation entry field (8) and use the given GEij values. The rationale of these entries is that with composite materials made of a viscoelastic resin system, the damping matrix does not scale with the stiffness matrix. For example, in the directions where you have more fibers, the stiffness is higher because you have more fibers but the damping coefficient is smaller because you have less resin matrix which is the main source of damping. To use this feature in composites, the PCOMPLS MIDi entries must refer to MAT9 entries.

The damping is applied in element material routines by forming the product  $GE_{ij} * G_{ij}$  when forming the K4 damping matrix in EMG.

## MAT9F Solid Element Anisotropic Frequency Dependence

Specifies frequency-dependent material properties on MAT9 entry fields via TABLEDi entries.

Format:

1	2	3	4	5	6	7	8	9	10
MAT9F	MID	G11	G12	G13	G14	G15	G16	G22	
	G23	G24	G25	G26	G33	G34	G35	G36	
	G44	G45	G46	G55	G56	G66			
							GE		
	GE11	GE12	GE13	GE14	GE15	GE16	GE22	GE23	
	GE24	GE25	GE26	GE33	GE34	GE35	GE36	GE44	
	GE45	GE46	GE55	GE56	GE66				

Example:

MAT9F	101	5						5	
					5				
				5		5			

Describer	Meaning
MID	Material property identification number that matches the identification number on MAT9 entry. (Integer > 0)
Gij	Identification number of a TABLEDi entry for the material property matrix. (Integer > 0 or blank)
GE	Identification number of a TABLEDi entry for the element structural damping coefficient. (Integer > 0 or blank)
GEij	Identification number of a TABLEDi entry for the element structural damping coefficients. (Integer > 0 or blank)

Remarks:

- Fields 3, 4, etc., of this entry correspond, field-by-field, to fields 3, 4, etc., of the MAT9 entry referenced in field 2. The value in a particular field of the MAT9 entry is replaced by the table referenced in the corresponding field of this entry. Blank or zero entries mean that there is no frequency dependence of the fields on the MAT9 entry.
- Table references must be present for each item that is frequency dependent.
- IF GE=0.0 on corresponding MAT9 then GE table must be blank or 0. For any GEij=0.0 on corresponding MAT9, the corresponding GEij table must be blank or 0.

## MAT10 Fluid Material Property Definition

Defines material properties for fluid elements in coupled fluid-structural analysis.

Format:

1	2	3	4	5	6	7	8	9	10
MAT10	MID	BULK	RHO	C	GE	ALPHA			

Example:

MAT10	103	0.656	0.011						
-------	-----	-------	-------	--	--	--	--	--	--

Describer	Meaning
MID	Material identification number. (Integer > 0)
BULK	Bulk modulus. (Real > 0.0)
RHO	Mass density. (Real > 0.0)
C	Speed of sound. (Real > 0.0)
GE	Fluid element damping coefficient. (Real)
ALPHA	Normalized admittance coefficient for porous material. See Remark 7. (Real or blank)

Remarks:

- MAT10 is referenced, with MID, by the PSOLID entry only.
- The material identification numbers must be unique for all MAT1, MAT2, MAT3, MAT9, and MAT10 entries.
- The mass density RHO will be used to compute the mass automatically.
- BULK, RHO, and C are related by

$$\text{BULK} = C^2 \cdot \text{RHO}$$

Two out of the three must be specified, and the other will be calculated according to this equation. If all three are specified and are inconsistent in values, the supplied values of BULK and RHO are used in the computations.

- To obtain the damping coefficient GE, multiply the critical damping ratio  $C/C_0$ , by 2.0.
- If PARAM,W4FL is not specified, GE is ignored in transient analysis. See [Parameters](#).
- If a value of ALPHA is entered, BULK RHO and GE may have negative values.
- The value defined in the ALPHA field always defines the normalized admittance coefficient for porous material but it is differently interpreted depending on the value defined in the FCNT field of the referencing PSOLID entry.

- a. If the MAT10 entry is referenced in a PSOLID entry where FFLUID option is selected, the value defined for ALPHA is considered as the normalized admittance coefficient calculated at unit circular excitation frequency ( $\omega = 1$ ). Its value will be automatically calculated by the program, at each excitation frequency, considering the current circular excitation frequency as scaling factor.
  - b. If the MAT10 entry is referenced in a PSOLID entry where PFLUID option is selected, the value defined for ALPHA has no special meaning but it is only the normalized admittance coefficient calculated by the user at the most appropriate excitation frequency (defined in order to have good results in the frequency range of interest).
9. For Poro-Elastic Material, PEM, user is expected to provide adiabatic BULK modulus for fluid-phase of PEM which is equal to GAMMA, fluid ratio of specific heats (see MATPE1 for detailed), times isothermal BULK modulus. Isothermal BULK modulus is BULK modulus at constant temperature for fluid itself.
  10. When used in conjunction with PSLDN1, only pyramid elements can be associated with the MAT10 fluid property. CHEXA, CPENTA, CTETRA elements using MAT10 are not supported with PSLDN1.
  11. The terms of the fluid mass matrix are not multiplied by the value of PARAM and WTMASS.

## MAT10F Fluid Frequency Dependence

Specifies frequency-dependent material properties on MAT10 entry fields via TABLEDi entries.

Format:

1	2	3	4	5	6	7	8	9	10
MAT10F	MID	BULK	RHO	C	GE	ALPHA			

Example:

MAT10	103	666							
-------	-----	-----	--	--	--	--	--	--	--

Describer	Meaning
MID	Material property identification number that matches the identification number on MAT10 entry. (Integer > 0)
BULK	Identification number of a TABLEDi entry for the Bulk modulus. (Integer > 0 or blank)
RHO	Identification number of a TABLEDi entry for the mass density. Used only in SOL108. (Integer > 0 or blank)
C	Identification number of a TABLEDi entry for the speed of sound. Used only in SOL108. (Integer > 0 or blank)
GE	Identification number of a TABLEDi entry for the element structural damping coefficient. (Integer > 0 or blank)
ALPHA	Identification number of a TABLEDi entry for the normalized admittance coefficient for porous material. See Remark 4.

Remarks:

- Fields 3, 4, etc., of this entry correspond, field-by-field, to fields 3, 4, etc., of the MAT10 entry referenced in field 2. The value in a particular field of the MAT10 entry is replaced by the table referenced in the corresponding field of this entry. Blank or zero entries mean that there is no frequency dependence of the fields on the MAT10 entry. The nominal value of GE defined on MAT10 needs to be non-zero to get frequency dependent damping defined in the GE table on MAT10F.
- Table references must be present for each item that is frequency dependent.
- When ALPHA on MAT10 is specified it is multiplied by the excitation frequency in radians/unit time. If F(ALPHA) is specified then the value supplied by F(ALPHA) will take precedence and ALPHA WILL NOT BE MULTIPLIED by the excitation frequency.

**MATDEUL****General Constitutive Model to be Used for the Eulerian Materials - SOL 700**

Defines a complete constitutive model as a combination of an equation of state, a shear model, a yield model, a failure model, a spall model (PMIN), and corotational frame. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATDEUL	MID	RHO	EID	SID	YID	FID	PID		
	BULKL	BULKQ			BULKTYP				

Example:

MATDEUL	22	3000.	100	109	307	308	402		
---------	----	-------	-----	-----	-----	-----	-----	--	--

Describer	Meaning
MID	Unique material number. (Integer > 0; Required)
RHO	Density. (Real > 0.0; Required)
EID	Number of an EOSxxx entry defining the pressure/density characteristic of the material. (Integer > 0; Required)
	EOSGAM      Gamma Law Gas Equation of State
	EOSIG      Ignition and Growth Equation of State
	EOSJWL      JWL Explosive Equation of State
	EOSMG      Mie-Gruneisen Equation of State
	EOSPOL      Polynomial Equation of State
	EOSTAIT      Tait Equation of State
SID	Number of a SHRxxx entry defining the shear properties of the material. (Integer ≥ 0; Hydrodynamic shear model)
	SHREL      Elastic Shear Model
	SHRPOL      Polynomial Shear Mode
YID	Number of a YLDxxx entry defining the yield model for the material. (Integer ≥ 0; Hydrodynamic yield model)
	YLDHY      Hydrodynamic Yield Model
	YLDJC      Johnson-Cook Yield Model
	YLDMC      Mohr-Coulomb Yield Model
	YLDMSS      Multi-surface yield model for Snow
	YLDPOL      Polynomial Yield Model
	YLDRPL      Rate Power Law Yield Model

Describer	Meaning
	YLDYG Steinberg-Guinan Yield
	YLDTM Tanimura-Mimura Yield Model
	YLDVM von Mises Yield Model
	YLDZA Zerilli-Armstrong Yield Model
FID	Number of a FAILMPS entry defining the failure model for the material. (Integer $\geq 0$ ; no failure)
	FAILMPS Maximum Plastic Strain Failure Model
PID	Number of a PMINC entry defining the spallation characteristics of the material. See Remark 3. (Integer $> 0$ )
BULKL	Linear bulk-viscosity coefficient. (Real $\geq 0.0$ ; 0.0)
BULKQ	Quadratic bulk-viscosity coefficient. (Real $> 0.0$ ; 1.0)
BULKTYP	Bulk viscosity type. (Character, DYNA)
	DYNA Standard DYNA3D model.
	DYTRAN Enhanced DYNA model.

Remarks:

1. If YID is blank or zero, a hydrodynamic yield model is used.
2. If the TYPE field on the PEULER entry is set to HYDRO, then YID is either blank or references a YLDHY entry, and SID is blank. Conversely, if the TYPE field is set to STRENGTH, a nonhydrodynamic yield model is specified.
3. If no PMINC entry is referenced, a minimum pressure of zero is assumed for the Eulerian elements. The PMINC entry will be ignored when a cavitation model through the EOSTAIT entry has been given.

## MATDIGI Material Digimat

Defines material data for the advanced composites with Digimat from e-Xstream engineering (SOL 400 only). For more information about e-Xstream engineering and Digimat, please contact [support@e-xstream.com](mailto:support@e-xstream.com) or consult <http://www.e-xstream.com/>

Format:

1	2	3	4	5	6	7	8	9	10
MATDIGI	MID	UDID					RHO		

Example:

MATDIGI	5	10					3000.		
---------	---	----	--	--	--	--	-------	--	--

Describer	Meaning
MID	Material identification number. (Integer > 0)
UDID	References UDNAME entry (Required, Integer>0)
RHO	Density (Real>0.0 or blank)

Remarks:

1. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
2. SOL400 uses only the MID, UDID and RHO entries. All other entries are ignored by SOL400.
3. The entry UDSESV is required input to define the number of state variables which will be used by MATDIGI. The number of state variables (NSTATS) must be larger than 1.
4. License feature NASTRAN\_DIGIMAT must be present to use this feature. For parallel computations, NASTRAN\_DIGIMAT\_DMP must be present.
5. The use of MATDIGI is limited to shell and solid elements.
6. MATDIGI should not be used in SOL 400 perturbation steps.

MATEP

Elasto-Plastic Material - SOL 400

Elasto-plastic material properties for SOL 400 only.

Format: Note that the primary entry is required. All other continuation lines are required only for certain options and only one such option may be entered.

1	2	3	4	5	6	7	8	9	10
MATEP	MID	FORM	Y0	FID	RYIELD	WKHARD		H	
	“Reffect”	OPTION	RTID	C	P				
	“Aniso”	N/A	R11 or M	R22 or C1	R33 or C2	R12 or C3	R23 or C6	R31	
	“Press”	OPTION	ALPHS	BETA					
	“Chaboche”	R0	Rinf	B	C	Gam	Kap	N	
		Qm	$\mu$	$\eta$					
	“JhCook”	A	B	N	C	M	Tmelt	Troom	
		$\epsilon 0DOT$							
	“IMPCREEP”	VMISES							

Example:

MATEP	100	TABLE		20		HILL			
	ANISO		1.1	0.9		1.02			

Describer	Meaning
MID	Identification number of MAT1, MAT2, MATORT, MAT8 or MAT9 entry. (Integer > 0).
FORM	Selects a form of stress-plastic strain function to be specified (Character): SLOPE Defines nonzero H. (Default) TABLE Defines the function using TABLES1, TABLEST or TABL3D entries. Units of table are unspecified PERFECT Defines perfectly plastic material (H is zero or blank and FID blank). See Remarks 2.
Y0	Initial yield stress $Y_0$ or hydrostatic stress for Mohr-Coulomb materials. See Remark 2. (Real > 0 or blank)
FID	Identification number of TABLES1 or TABL3D entry. See Remarks 2, 3, and 4. (Integer > 0 or blank)
RYIELD	Enter on of the following yield criteria rules. (Character; Default = VMISES) See Remarks 12.

Describer	Meaning
	VMISES                      von Mises yield criteria (Default)
	HILL                              Hill's 1948 yield criteria
	BARLAT                        Barlat's 1991 yield criteria
	LINMOHR                      Linear Mohr-Coulomb yield criteria
	PBLMOHR                     Parabolic Mohr-Coulomb yield criteria
	IMPCREEP                    Implicit creep model combining both plasticity and creep, von Mises yield criteria.
WKHARD	Selects a hardening rule defined by various work-hardening rules (Character). See Remarks <a href="#">12</a> .
	ISOTROP                        Isotropic hardening. (Default)
	KINEM                            Kinematic hardening.
	COMBINE                      Combination between kinematic and isotropic hardening. (Default kinematic fraction=0.5).
	CHABOCHE                    Caboche formulation - like combined (see MSC Nonlinear User Guide (SOL 400)) for details of this model).
	JHCOOK                        For Johnson-Cook formulation (see MSC Nonlinear User Guide (SOL 400)) for details of this model).
	See Remark <a href="#">5</a> .
H	Workhardening slope. See Remarks <a href="#">2</a> , <a href="#">3</a> , and <a href="#">4</a> . (Real $\geq 0$ ; Default = 0)
"Reffect"	A keyword signifying that the following data pertains to the rate-dependent material properties (do not enter rate-dependent effects if they are not to be included). If TABL3D is entered and one of the independent variables is strain rate, this field and its options should not be specified.
OPTION	Selects an option for strain-rate dependent yield stress (Character):
	TABLE                            Specifies that TABLES1 input used to define rate-dependency. (Default)
	COWPER                        Specifies the Cowper and Symonds rate-dependency model. See Remark <a href="#">6</a> .
RTID	TABLES1 ID for strain-rate effects on yield stress, i.e., the table defines yield stress as a function of strain-rate starting from zero strain-rate. The yield stresses in this table should comprise the initial yield stress specified on Y0 or FID field at zero strain-rate.
C	Specifies the constant C for Cowper and Symonds model. (Real; Default = 1)
P	Specifies the constant P for Cowper and Symonds model. (Real; Default = 1)
"Aniso"	A keyword signifying that the following data (Rij) pertain to the Hill's (Rij) or Barlat's (M, Ci) yield criteria. an isotropic material option. See Remark <a href="#">7</a> . and MSC Nonlinear User Guide (SOL 400) (specify only if RYIELD = HILL or BARLAT).

Describer	Meaning
Rij	Stress ratios of initial yield stresses in various material directions to the reference yield stress from FID/Y0 field. (Real > 0; Default = 1.0 for R11, R22, R33, R12, R23, R31, respectively for Hill) or
M	Barlat M coefficient
C1	Barlat C1 coefficient
C2	Barlat C2 coefficient
C3	Barlat C3 coefficient
C6	Barlat C6 coefficient
“Press”	A keyword signifying that the following data pertain to the pressure-dependent yield criteria. Enter only if Ryield = LinMohr or PblMohr cracking is to be simulated. See Remarks 8. and 9.
OPTION	Selects an option for pressure-dependent yield criteria. (Character): LIN                                      Linear Mohr-Coulomb model. (Default) PBL                                      Parabolic Mohr-Coulomb model.
ALPHA	Specifies the parameter alpha for linear Mohr-Coulomb model. (Real > 0 or blank)
BETA	Specifies the parameter beta for parabolic Mohr-Coulomb model. (Real > 0 or blank)
“Chaboche”	A keyword specifying the following data pertains to the Chaboche model. (Enter only if WKHARD=CHABOCHE.)
R0	R0 for isotropic hardening (Real)
Rinf	Rinfinity for isotropic hardening (Q0 in case of using plastic-strain-range memorization) (Real)
B	Coefficient B for isotropic hardening (Real)
C	C coefficient C for kinematic hardening (Real)
Gam	Gamma coefficient for kinematic hardening (Real)
Kap	Kappa value for viscosity model (Real)
N	Coefficient N for viscosity model (Real)
Qm	Coefficient Qm for isotropic hardening (Real)
μ	Coefficient μ for isotropic hardening (Real)
η	Coefficient η to introduce progressive memory (Real)
“JhCook”	A keyword specifying the following data pertains to the Johnson-Cook model (see the MSC Nonlinear User Guide (SOL 400) for more details. Enter only if WKHARD = JHCOOK).
A	Coefficient A. (Real)
B	Coefficient B. (Real)
N	Exponent n. (Real)

Describer	Meaning
C	Coefficient C. (Real)
M	Exponent m. (Real)
Tmelt	Melting temperature. (Real)
Troom	Ambient temperature. (Real)
$\epsilon_0$ Dot	Reference strain rate. (Real)
“IMPCREEP”	A keyword specifying that the equivalent (von Mises) tensile yield stress will be entered in the next field (used only when RYIELD = IMPCREEP).
VMISES	Equivalent (von Mises) stress. Defines the yield stress for the plasticity element. When used in conjunction with an implicit creep model. If not specified, only the Creep mechanism is active.

Remarks:

1. Unless continuation entry is present specifying various material models, von Mises yield criterion is used as default.
2. If FORM = SLOPE, the one defines the initial yield stress with  $Y_0$  and a single workhardening slope

is entered as  $H$ .  $H = \frac{\partial \bar{\sigma}}{\partial \bar{\epsilon}^p}$ . In a uniaxial test,  $\epsilon_0$  is the strain at which yielding first occurs is often considered the 0.2% offset strength.

If FORM = TABLE, then the table ID is entered using FID field,  $Y_0$  is not used. The table can be entered as TABLES1 or TABL3D.

When using TABLES1 entry with Type=1, one is defining  $\bar{\sigma} = \bar{\sigma}(\bar{\epsilon})$  as shown in [Figure 9-95](#).

When using TABLES1 entry with Type=2, or TABL3D entry, one is defining  $\bar{\sigma} = \bar{\sigma}(\bar{\epsilon}^p)$  as shown in [Figure 9-96](#).

Figure 9-94 Single Workhardening Slope

Figure 9-95 Stress vs Total Strain TABLES1(TYPE1)

Figure 9-96 Stress vs Plastic Strain TABLES1(TYPE2) or TABL3D

If FORM = PERFECT,  $Y_0$  is the yield stress and  $H$  and FID should be blank. This is known as elastic-perfectly plastic behavior. If temperature-dependent yield is present, then FORM = TABLE should be used and the temperature-dependent yield entered through TABL3D.

3. For temperature-dependent materials, one can either define the temperature variation through the TABL3D option or include the MATTEP option. The first procedure is recommended.
4. In a large displacement analysis (LGDISP = 1, 2, 11, 12), the Cauchy stress and logarithmic strain are used.
5. The plastic deformation starts when the effective stress ( $\bar{\sigma}$ ) exceeds the yield stress.

The yield stress is initially defined by the initial yield point, which is subsequently modified by the hardening rule to account for strain hardening. Under the isotropic hardening rule, the size of the yield surface expands as a function of effective plastic strain ( $\bar{\epsilon}^p$ ). Under the kinematic hardening rule, the center of the yield surface moves in stress space while keeping the same size and shape.

Ziegler's law is used to define the translation of the yield surface. Under the combined hardening, the initial hardening is assumed to be entirely isotropic, but the elastic range attains a constant value (i.e., behaving like kinematic hardening) after some plastic straining. The effective stress for von Mises is expressed as

$$\bar{\sigma} = \sqrt{\frac{1}{2}[(\sigma_x - \sigma_y)^2 + (\sigma_y - \sigma_z)^2 + (\sigma_z - \sigma_x)^2] + 3(\tau_{xy}^2 + \tau_{yz}^2 + \tau_{zx}^2)}$$

where the stress components are measured from the center of yield surface.

- The Cowper and Symonds model scales the initial yield stress as a function of strain-rate, i.e.,

$$Y(\dot{\varepsilon}) = Y_0 \left[ 1 + \left( \frac{\dot{\varepsilon}}{C} \right)^{1/P} \right]$$

7. Hill's anisotropic model introduces orthotropic plastic material. The plastic anisotropy proposed by Hill introduces six parameters to the von Mises yield function, from which an effective stress may be derived as

$$\bar{\sigma} = \sqrt{F(\sigma_y - \sigma_z)^2 + G(\sigma_z - \sigma_x)^2 + H(\sigma_x - \sigma_y)^2 + 2L\tau_{yz}^2 + 2M\tau_{zx}^2 + 2N\tau_{xy}^2}$$

in which the material parameters can be related to the yield stress ratios by

$$F = \frac{1}{2} \left( \frac{1}{R_{22}^2} + \frac{1}{R_{33}^2} - \frac{1}{R_{11}^2} \right)$$

$$G = \frac{1}{2} \left( \frac{1}{R_{33}^2} + \frac{1}{R_{11}^2} - \frac{1}{R_{22}^2} \right)$$

$$H = \frac{1}{2} \left( \frac{1}{R_{11}^2} + \frac{1}{R_{22}^2} - \frac{1}{R_{33}^2} \right)$$

$$L = \frac{3}{2R_{23}^2}, M = \frac{3}{2R_{31}^2}, N = \frac{3}{2R_{12}^2}$$

with

$$R_{11} = \frac{Y_1}{Y_a}, R_{22} = \frac{Y_2}{Y_a}, R_{33} = \frac{Y_3}{Y_a}$$

$$R_{12} = \frac{\sqrt{3}T_{12}}{Y_a}, R_{23} = \frac{\sqrt{3}T_{23}}{Y_a}, R_{31} = \frac{\sqrt{3}T_{31}}{Y_a}$$

where  $Y_1$ ,  $Y_2$ , and  $Y_3$  are the tensile yield stresses measured in material directions x, y and z, respectively;  $T_{12}$ ,  $T_{23}$ , and  $T_{31}$  are the shear yield stresses in pure shear; and  $Y_a$  is the reference yield stress which should be an average yield stress in all directions.

In practical applications, however, the initial yield stress cannot be measured in all directions. The plastic anisotropy is pronounced in the sheet metal due to prior rolling process, for which the plastic anisotropy is customarily characterized by r-values defined by strain ratio measured in the uniaxial tension, i.e.,

$$r_a = \frac{\varepsilon_w}{\varepsilon_t} = \frac{\ln(w_0/w)}{\ln(t_0/t)} = \frac{H + (2N - F - G - 4H)\sin^2\theta \cos^2\theta}{F \sin^2\theta + G \cos^2\theta}$$

where  $t$  and  $w$  denote thickness and width, respectively; and  $\theta$  denotes the angle of orientation (usually measured from the rolling direction). Assuming that the anisotropy parameters stay constant throughout the deformation, F, G, H and N can be determined by r-values from tensile specimen cut at 0, 45 and 90 degrees to the rolling direction:

$$\frac{H}{G} = r_0 \quad , \quad \frac{H}{F} = r_{90}$$

$$\frac{N}{G} = \left( r_{45} + \frac{1}{2} \right) \left( 1 + \frac{r_0}{r_{90}} \right)$$

The orthotropic plasticity parameters should be calculated from the r-values and the initial yield stress either in 0 or 90 degree direction ( $Y_0$  or  $Y_{90}$ ) from the experiment. The yield stress in the thickness direction can be written as

$$Y_{th} = Y_0 \sqrt{\frac{r_{90}(1+r_0)}{r_0+r_{90}}} = Y_{90} \sqrt{\frac{r_0(1+r_{90})}{r_0+r_{90}}}$$

Similarly, yield stresses in shear may be evaluated by

$$T_{12} = Y_{th} \sqrt{\frac{1}{2r_{45} + 1}}$$

and

$$T_{23} = T_{31} = \frac{Y_a}{\sqrt{3}}$$

in which the transverse direction is assumed isotropic.

8. The pressure-dependent yielding, based on Drucker-Prager yield criterion, contains three options for frictional materials such as rocks and concrete. The generalized Mohr-Coulomb criterion introduces linear and parabolic models, developed by Drucker and Prager. The linear Mohr-Coulomb model assumes a linear function of hydrostatic stress for a yield function, i.e.,

$$aI_1 + \sqrt{J_2} - \frac{\bar{\sigma}}{\sqrt{3}} = 0 \quad \text{or} \quad \bar{\sigma} = \sqrt{3}\alpha I_1 + \sqrt{3J_2}$$

where

$$I_1 = \sigma_x + \sigma_y + \sigma_z$$

and

$$J_2 = \frac{1}{6} [(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2]$$

The parameters  $\alpha$  and  $\bar{\sigma}$  (effective stress coinciding with the yield stress) can be related to material constants  $c$  (cohesion) and  $\phi$  (frictional angle) by

$$c = \frac{\bar{\sigma}}{3\sqrt{(1 - 12\alpha^2)}}$$

and

$$\sin \phi = \frac{3\alpha}{\sqrt{1 - 3\alpha^2}}$$

The parabolic Mohr-Coulomb model allows a yield envelope to be parabolic in the plane strain case, for which the yield function is expressed as

$$\sqrt{3J_2} + \sqrt{3}\beta\bar{\sigma}I_1 - \bar{\sigma} = 0$$

in which parameters are related to the material constants by

$$\bar{\sigma}^2 = 3\left(c^2 - \frac{\alpha^2}{3}\right)$$

and

$$\beta = \frac{\alpha}{\sqrt{3(3c^2 - \alpha^2)}}$$

9. The keywords may appear in any order. However, aniso and press, are mutually exclusive, and cannot coexist.
10. All the alphanumeric fields are recognizable by the first four letters.
11. In SOL 400, MATEP is only supported for nonlinear elements with property extensions. This implies that for such elements, PBARL, PBEAML, PCOMP / PCOMPG, PROD, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PBARN1, PBEMN1, PSHLN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Also, linear 2D triangular elements specified on PSHLN2 and 3D tetrahedral elements specified on PSLDN1 should be associated with an incompressible formulation (IPS for 2D plane strain, IAX for 2D axisymmetric and ISOL for 3D tetrahedral). If the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data. See remark 9. under the NLMOPTS
12. RYIELD = LINMOHR, PBLMOHR and WKHARD = CHABOCHE and JHCOOK are only applicable to isotropic materials (MAT1).
13. MATEP can be used to define optional plasticity properties in conjunction with explicit or implicit creep that has been defined through the MATVP card.

- a. For explicit creep, supported yield criteria include RYIELD = VMISES, HILL, BARLAT, LINMOHR and PBLMOHR. All conventional data defined through fields like Y0, WKHARD, etc. are used to define the plasticity properties. Note that in this case, the plasticity is treated implicitly whereas the creep is treated explicitly.
- b. For implicit creep, plasticity properties are defined through special options of the MATEP card - RYIELD field has to be set to IMPCREEP field and the actual yield stress has to be set on the VMISES field under the IMPCREEP option. In this case, both creep and plasticity are treated implicitly. Note - in this case, only Von Mises yield criterion is satisfied. The creep happens immediately whereas the plasticity happens only after the equivalent stress exceeds the VMISES value.

MATEP

Elasto-Plastic Material Properties - SOL 600

Specifies elasto-plastic material properties to be used for large deformation analysis. Used in SOL 600 only.

Format (Note that the primary entry is required. All other continuation lines are required only for certain options and only one such option may be entered):

MATEP	100	table		20		HILL	ADDRAD		
	ANISO		1.1	0.9		1.02			

Describer	Meaning
MID	Identification number of MAT1, MAT2, MATORT or MAT9 entry. (Integer > 0).
FORM	Selects a form of stress-plastic strain function to be specified (Character):
	SLOPE for defining non-zero H. (Default)
	TABLE for defining the function in TABLES1or TABL3Di units of table are unspecified
	PERFECT for defining perfectly plastic material. (H is zero or blank)

Describer	Meaning
Y0	Initial yield stress $Y_0$ or hydrostatic stress for Mohr-Coulomb materials. See Remark 2. (Real > 0 or blank)
FID	Identification number of TABLES1 or TABL3Di entry. (Integer > 0 or blank)
RYIELD	Enter one of the following yield criteria rules. (Character, Default = vMises if there are no continuation lines. Otherwise, the default will be adjusted to agree with information on the continuation lines. For example, if the second line has PRESS in field 2 and LIN in field 3, the default for RYIELD will be LinMohr.)
ELASTIC	for purely elastic material (implies von Mises for multi-directional stresses). Vmises for von Mises yield criteria.
VMISES	von Mises yield criteria
HILL	for Hill's 1948 yield criteria.
BARLAT	for Barlat's 1991 yield criteria
LINMOHR	for Linear Mohr-Coulomb yield criteria. (See SOL 600 Notes/ Remarks regarding this entry in combination with MATS1. This entry overrides.)
PBLMOHR	for parabolic Mohr-Coulomb yield criteria. (See SOL 600 Notes/Remarks regarding this entry in combination with MATS1. This entry overrides.)
BUYUK	for the Buyukozturk concrete model.
ORNL	for one of the ORNL types. (see "Ornl" below)
GENPLAS	for Generalized Plasticity model
VISCPLAS	for Viscoplastic model using user subroutine UVSCPL
RIGID	for Rigid-Plastic material (no elasticity, von Mises yield)
IMPCREEP	for implicit creep model combining both plasticity and creep, von Mises yield criteria.
WKHARD	Selects a hardening rule defined by various work-hardening rules (Character):
ISOTROP	for isotropic hardening. (Default)
KINEM	for kinematic hardening.
COMBINE	for combination between kinematic and isotropic hardening
CHABOCHE	for Chaboche formulation - like combined (see Marc Vol C documentation for details for this model)
PWRLAW	for Power Law formulation (see Marc Vol C documentation for details of this model, for superplastic forming, this is the only available option)

Describer	Meaning
	<p><b>RPWRLAW</b> for Rate Power Law formulation (see Marc Vol C documentation for details of this model)</p> <p><b>JHCOOK</b> for Johnson-Cook formulation (see Marc Vol C documentation for details of this model)</p> <p><b>KUMAR</b> for Kumar formulation - (see Marc Vol C documentation for details of this model). See Remark 4.</p>
METHOD	Selects a material processing method. See Remark 12. (Character):
	<p><b>ADDMEAN</b> for large strain additive decomposition using the mean normal process. (Default)</p> <p><b>ADDRAD</b> for large strain additive decomposition using the radial return process. (SOL 600 only)</p> <p><b>MULTRAD</b> for multiplicative decomposition (FeFp) using the radial return process</p> <p><b>MULTPLN</b> for plane stress or strain FeFp multiplicative decomposition. (SOL 600)</p> <p><b>SMLMEAN</b> for small strain additive decomposition using the mean normal process. (SOL 600 only)</p> <p><b>SMLRAD</b> for small strain additive decomposition using the radial return process. (SOL 600 only)</p>
H	plasticity modulus, ignored if FID field is specified. H has the same meaning as H in Remark 2 of the MATS1 entry. (Real $\geq 0$ ; Default = 0.0)
“Reffect”	A keyword signifying that the following data pertains to the rate-dependent material properties (do not enter if rate-dependent effects are not to be included).
OPTION	Selects an option for strain-rate dependent yield stress (Character):
	<p><b>TABLE</b> for TABLES1 input. (Default)</p> <p><b>COWPER</b> for Cowper and Symonds model. See Remark 6.</p>
RTID	TABLES1 ID for strain-rate effects on yield stress, i.e., the table defines yield stress as a function of strain-rate starting from zero strain-rate. The yield stresses in this table should comprise the initial yield stress specified on Y0 or FID field at zero strain-rate.
C	Specifies the constant C for Cowper and Symonds model. (Real; Default = 1)
P	Specifies the constant P for Cowper and Symonds model. (Real; Default = 1)
“Aniso”	A keyword signifying that the following data (Rij) pertain to the Hill’s (Rij) or Barlat’s (M, Ci) yield criteria. See Remark 8. and Marc Vol A and C documentation (enter only RYIELD = HILL or BARLAT).
Rij	Stress ratios of initial yield stresses in various material directions to the reference yield stress from FID/Y0 field. (Real $> 0$ ; Default = 1.0 for R11, R22, R33, R12, R23, R31, respectively for Hill), or

Describer	Meaning
M	Barlat M coefficient (see Marc Vol A and C documentation)
C1	Barlat C1 coefficient (see Marc Vol A and C documentation)
C2	Barlat C2 coefficient (see Marc Vol A and C documentation)
C3	Barlat C3 coefficient (see Marc Vol A and C documentation)
C6	Barlat C6 coefficient (see Marc Vol A and C documentation)
“ORNL”	A keyword signifying that the following data pertains to the ORNL’s yield criteria. Only enter if RYIELD = ORNL. See Remark 7.
OPTION	Selects an option for ORNL yield criteria (Character): NORM                           for normal ORNL model for stainless steel. (Default) CRMO                           for ORNL 2-1/4 Cr-Mo steel model. REVP                           for ORNL reversed plasticity model. ARST                           for ORNL full alpha reset model.
Yc10	Equivalent 10th cycle tensile yield stress. (Real > 0)
TID	Identification number of TABLES1 entry for normalized 10th cycle stress-plastic strain curve. (Integer; Default = 0)
“Press”	A keyword signifying that the following data pertain to the pressure-dependent yield criteria. Enter only if Ryield=LinMohr, PblMohr or concrete cracking is to be simulated. See Remarks and 9.
OPTION	Selects an option for pressure-dependent yield criteria. (Character): LIN                               for linear Mohr-Coulomb model. (Default) PBL                               for parabolic Mohr-Coulomb model. CONC                           for Buyukozturk concrete model.
ALPHA	Specifies a parameter alpha for linear Mohr-Coulomb model or concrete model. (Real > 0 or blank)
BETA	Specifies a parameter beta for parabolic Mohr-Coulomb model or Buyukozturk concrete model (not used for linear Mohr-Coulomb model). (Real > 0 or blank)
CRACKS	Critical cracking stress for Buyukozturk concrete model. (Real > 0 or blank)
SOFTEN	Tension-softening modulus for Buyukozturk concrete model. (Real ≥ 0; Default = 0)
CRUSHS	Strain at which material crushes. (Real > 0; Default = 1.E10)
SRFAC	Shear retention factor defining shear stress carrying capacity when crack closes for Buyukozturk concrete model. (0 ≤ Real < 1; Default = 0)
“Gurson”	A keyword signifying that the following data pertain to the modified Gurson model for porous metal plasticity with damage effects. Enter only if the Gurson damage model is to be used. See Remark 9.
Q1	First coefficient for the Gurson yield function. (Real ≥ 0; Default = 1.5)

Describer	Meaning
Q2	Second coefficient for the Gurson yield function. (Real $\geq 0$ ; Default = 1)
INITIAL	Initial void volume fraction. ( $0 \leq \text{Real} < 1$ ; Default = 0)
CRITICAL	Critical void volume fraction at which void coalescence starts. ( $0 < \text{Real} < 1$ ; Default = 0.2)
FAILURE	Failure void volume fraction at which the material loses strength. ( $1./q1 < \text{Real} < 1$ ; Default = 0.733)
NUCL	Select a method of void nucleation (character, Default = strain): NONE for no nucleation. STRAIN for plastic strain controlled nucleation. STRESS for stress controlled nucleation. See Remark 9.
MEAN	Mean strain or stress for void nucleation. (Real $> 0$ ; Default = 0.3)
SDEV	Standard deviation in the assumed normal distribution of nucleation strain or stress. (Real $> 0$ ; Default = 0.01)
NFRAC	Volume fraction of nucleating particles for void nucleation. ( $0 < \text{Real} < 0.5$ ; Default = 0.04)
“Chaboche”	A keyword specifying the following data pertains to the Chaboche model (Enter only if Wkhard=Chaboche)
R0	R0 for isotropic hardening. (Real)
Rinf	Rinfinity for isotropic hardening (Q0 in case of using plastic-strain-range memorization). (Real)
B	b coefficient for isotropic hardening. (Real)
C	C coefficient for kinematic hardening (Real)
Gam	Gamma coefficient for kinematic hardening (Real)
Kap	Kappa value for viscosity model. (Real)
N	n coefficient for viscosity model. (Real)
Qm	Qm coefficient for isotropic hardening. (Real)
$\mu$	coefficient for isotropic hardening. (Real)
$\eta$	coefficient to introduce progressive memory. (Real)
“PwrLaw”	A keyword specifying the following data pertains to the Power Law or Rate Power Law model (see Marc Vol C , ISOTROPIC option for more details. Enter only if WKHARD =PWRLAW or RPWRLAW).
A	Coefficient A. (Real)
M	Coefficient m. (Real)
B	Coefficient B. (Real)

Describer	Meaning						
N	Exponent n. (Real)						
$\sigma_0 \epsilon_0$	Enter $\sigma_0$ for rate power law or $\epsilon_0$ for the power law model (Real) See Marc Vol C, ISOTROPIC option if this field is left blank or set to 0.0						
“Kumar”	A keyword specifying the following data pertains to the Kumar model (see Marc Vol C , ISOTROPIC option for more details. Enter only if Wkhard =Kumar).						
B0	Coefficient B0. (Real)						
A	Coefficient A. (Real) If A=0.0, B1,B2, and B3 are used						
B1	Coefficient B1. (Real)						
B2	Coefficient B2. (Real)						
B3	Coefficient B3. (Real)						
T(B0)	TABLEM1 ID for coefficient B0. (Integer)						
T(A)	TABLEM1 ID for coefficient A. (Integer)						
N	Exponent n. (Real) If N=0.0, B4, B5 and B6 are used						
B4	Coefficient B4. (Real)						
B5	Coefficient B5. (Real)						
B6	Coefficient B6. (Real)						
T(N)	TABLEM1 ID for exponent n						
“JhCook”	A keyword specifying the following data pertains to the Johnson-Cook model (see Marc Vol C , ISOTROPIC option for more details. Enter only if WKHARD =JHCOOK).						
A	Coefficient A. (Real)						
B	Coefficient B. (Real)						
N	Exponent n. (Real)						
C	Coefficient C. (Real)						
M	Exponent m. (Real)						
Tmelt	Melting temperature. (Real)						
Troom	Ambient temperature. (Real)						
$\epsilon_0$ Dot	Reference strain rate. (Real)						
“YldOpt”	A keyword specifying one of the following yield models will be used.						
OPTION	Select a yield option from the list below:						
	<table style="width: 100%; border: none;"> <tr> <td style="width: 30%;">GENPL</td> <td>General plasticity viscoplastic model using user subroutine UVSCPL</td> </tr> <tr> <td>RIGID</td> <td>Rigid-plastic material, no elasticity, vonMises yield</td> </tr> <tr> <td>IMCREEP</td> <td>Implicit creep model, both plasticity and creep with vonMises yield criteria</td> </tr> </table>	GENPL	General plasticity viscoplastic model using user subroutine UVSCPL	RIGID	Rigid-plastic material, no elasticity, vonMises yield	IMCREEP	Implicit creep model, both plasticity and creep with vonMises yield criteria
GENPL	General plasticity viscoplastic model using user subroutine UVSCPL						
RIGID	Rigid-plastic material, no elasticity, vonMises yield						
IMCREEP	Implicit creep model, both plasticity and creep with vonMises yield criteria						

Describer	Meaning
“Units”	A keyword specifying if data is read from a database and if so, the units to be used if data is read from a database. (Enter only if necessary).
4	Read from Marc database for flow stress (default units)
5	Use MATILDA database (default units)
6	Data read from input file in SI-mm units
7	Data read from input file in SI-m units
8	Data read from input file in US units
“VParam”	A keyword specifying that the number of viscoplastic parameters. Up to two viscoelastic parameters are to be entered (used when RYIELD=ViscPlas)
Nvp	Number of viscoplastic parameters. (Integer must be 0, 1, or 2)
Vp1-1	First Viscoplastic parameter for Nvp=1. (Real; Default = 0.0)
Vp2-1	Second viscoplastic parameter for Nvp=1. (Real; Default = 0.0)
Vp1-2	First Viscoplastic parameter for Nvp=2. (Real; Default = 0.0, leave blank if Nvp=0 or Nvp=1)
Vp2-2	Second viscoplastic parameter for Nvp=2. (Real; Default = 0.0, leave blank if Nvp=0 or Nvp=1)
“ImpCreep”	A keyword specifying that the equivalent (von Mises) tensile yield stress will be entered in the next field (used when RYIELD=ImpCreep).
VMISES	Equivalent (von Mises) tensile yield stress. Overrides any similar entry made for this material elsewhere. (Real, no Default)

Remarks:

1. Unless continuation entry is present specifying various material models, von Mises yield criterion is used as default.
2. If  $Y_0$  is not specified, FID field referring to a stress-plastic strain curve must be provided. If  $Y_0$  is specified without FID field, the material is assumed perfectly plastic or has one slope, H. If both  $Y_0$  and FID fields are specified, FID supersedes the  $Y_0$  field and the first data point in TABLES1 represents  $Y_0$ .

The initial yield point corresponds to the first data point in the function specified on the FID field.

$$Y(\overline{\varepsilon}^p) = Y_0(1 + b \overline{\varepsilon}^p)^n$$

where  $Y_0$  is an initial yield stress, b and n are parameters characterizing the stress-strain relationship.

In case of an anisotropic material, the initial yield point corresponds to the reference yield stress ( $Y_a$  in Remark 7.)

3. For SOL 600, the form of the stress-strain curve is determined by parameters MRTABLS1 and MRTABLS2.
4. The plastic deformation starts when the effective stress ( $\bar{\sigma}$ ) exceeds the yield stress.

The yield stress is initially defined by the initial yield point, which is subsequently modified by the hardening rule to account for strain hardening. Under the isotropic hardening rule, the size of the yield surface expands as a function of effective plastic strain ( $\bar{\epsilon}^p$ ). Under the kinematic hardening rule, the center of the yield surface moves in stress space while keeping the same size and shape. Ziegler's law is used to define the translation of the yield surface. Under the combined hardening, the initial hardening is assumed to be entirely isotropic, but the elastic range attains a constant value (i.e., behaving like kinematic hardening) after some plastic straining. The effective stress for von Mises is expressed as

with

$$\bar{\sigma} = \sqrt{\frac{1}{2}[(\sigma_x - \sigma_y)^2 + (\sigma_y - \sigma_z)^2 + (\sigma_z - \sigma_x)^2] + 3(\tau_{xy}^2 + \tau_{yz}^2 + \tau_{zx}^2)}$$

where the stress components are measured from the center of yield surface.

$$R_{11} = \frac{Y_1}{Y_a}, R_{22} = \frac{Y_2}{Y_a}, R_{33} = \frac{Y_3}{Y_a}$$

$$R_{12} = \frac{\sqrt{3}T_{12}}{Y_a}, R_{23} = \frac{\sqrt{3}T_{23}}{Y_a}, R_{31} = \frac{\sqrt{3}T_{31}}{Y_a}$$

where  $Y_1$ ,  $Y_2$ , and  $Y_3$  are the initial tensile yield stresses measured in material directions 1, 2 and 3, respectively;  $T_{12}$ ,  $T_{23}$ , and  $T_{31}$  are the shear yield stresses in pure shear; and  $Y_a$  is the reference yield stress which should be an average yield stress in all directions.

In practical applications, however, the initial yield stress cannot be measured in all directions. The plastic anisotropy is pronounced in the sheet metal due to prior rolling process, for which the plastic anisotropy is customarily characterized by r-values defined by strain ratio measured in the uniaxial tension, i.e.,

$$r_a = \frac{\epsilon_w}{\epsilon_t} = \frac{l_n(w_o/w)}{l_n(t_o/t)} = \frac{H + (2N - F - G - 4H)\sin^2\alpha \cos^2\alpha}{F \sin^2\alpha + G \cos^2\alpha}$$

where  $t$  and  $w$  denote thickness and width, respectively; and  $\alpha$  denotes the angle of orientation (usually measured from the rolling direction). Assuming that the anisotropy parameters stay constant throughout the deformation, F, G, H and N can be determined by r-values from tensile specimen cut at 0, 45 and 90 degrees to the rolling direction:

$$\frac{H}{G} = r_0 \quad , \quad \frac{H}{F} = r_{90}$$

$$\frac{N}{G} = \left( r_{45} + \frac{1}{2} \right) \left( 1 + \frac{r_0}{r_{90}} \right)$$

The orthotropic plasticity parameters should be calculated from the r-values and the initial yield stress either in 0 or 90 degree direction ( $Y_0$  or  $Y_{90}$ ) from the experiment. The yield stress in the thickness direction can be written as

$$Y_{th} = Y_0 \sqrt{\frac{r_{90}(1+r_0)}{r_0+r_{90}}} = Y_{90} \sqrt{\frac{r_0(1+r_{90})}{r_0+r_{90}}}$$

Similarly, yield stresses in shear may be evaluated by

$$T_{12} = Y_{th} \sqrt{\frac{1}{2r_{45}+1}}$$

and

$$T_{23} = T_{31} = \frac{Y_a}{\sqrt{3}}$$

in which the transverse direction is assumed isotropic.

5. The Cowper and Symonds model scales the initial yield stress as a function of strain-rate, i.e.,

$$Y(\dot{\varepsilon}) = Y_0 \left[ 1 + \left( \frac{\dot{\varepsilon}}{C} \right)^{1/P} \right]$$

6. Hill's anisotropic model introduces orthotropic plastic material. This option can only be combined with orthotropic or anisotropic elastic material (i.e., with MAT2, MATORT or MAT9). The plastic anisotropy proposed by Hill introduces six parameters to the von Mises yield function, from which an effective stress may be derived as

$$\bar{\sigma} = \sqrt{F(\sigma_2 - \sigma_3)^2 + G(\sigma_3 - \sigma_1)^2 + H(\sigma_1 - \sigma_2)^2 + 2L\tau_{23}^2 + 2M\tau_{31}^2 + 2N\tau_{12}^2}$$

in which the material parameters can be related to the yield stress ratios by

$$F = \frac{1}{2} \left( \frac{1}{R_{22}^2} + \frac{1}{R_{33}^2} - \frac{1}{R_{11}^2} \right)$$

$$G = \frac{1}{2} \left( \frac{1}{R_{33}^2} + \frac{1}{R_{11}^2} - \frac{1}{R_{22}^2} \right)$$

$$H = \frac{1}{2} \left( \frac{1}{R_{11}^2} + \frac{1}{R_{22}^2} - \frac{1}{R_{33}^2} \right)$$

$$L = \frac{3}{2R_{23}^2}, M = \frac{3}{2R_{31}^2}, N = \frac{3}{2R_{12}^2}$$

with

$$R_{11} = \frac{Y_1}{Y_a}, R_{22} = \frac{Y_2}{Y_a}, R_{33} = \frac{Y_3}{Y_a}$$

$$R_{12} = \frac{\sqrt{3}T_{12}}{Y_a}, R_{23} = \frac{\sqrt{3}T_{23}}{Y_a}, R_{31} = \frac{\sqrt{3}T_{31}}{Y_a}$$

where  $Y_1$ ,  $Y_2$ , and  $Y_3$  are the initial tensile yield stresses measured in material directions 1, 2 and 3, respectively;  $T_{12}$ ,  $T_{23}$ , and  $T_{31}$  are the shear yield stresses in pure shear; and  $Y_a$  is the reference yield stress which should be an average yield stress in all directions.

In practical applications, however, the initial yield stress cannot be measured in all directions. The plastic anisotropy is pronounced in the sheet metal due to prior rolling process, for which the plastic anisotropy is customarily characterized by  $r$ -values defined by strain ratio measured in the uniaxial tension, i.e.,

$$r_a = \frac{\epsilon_w}{\epsilon_t} = \frac{l_n(w_o/w)}{l_n(t_o/t)} = \frac{H + (2N - F - G - 4H)\sin^2\alpha \cos^2\alpha}{F \sin^2\alpha + G \cos^2\alpha}$$

where  $t$  and  $w$  denote thickness and width, respectively; and  $\alpha$  denotes the angle of orientation (usually measured from the rolling direction). Assuming that the anisotropy parameters stay constant throughout the deformation,  $F$ ,  $G$ ,  $H$  and  $N$  can be determined by  $r$ -values from tensile specimen cut at 0, 45 and 90 degrees to the rolling direction:

$$\frac{H}{G} = r_0 \quad , \quad \frac{H}{F} = r_{90}$$

$$\frac{N}{G} = \left( r_{45} + \frac{1}{2} \right) \left( 1 + \frac{r_0}{r_{90}} \right)$$

The orthotropic plasticity parameters should be calculated from the r-values and the initial yield stress either in 0 or 90 degree direction ( $Y_0$  or  $Y_{90}$ ) from the experiment. The yield stress in the thickness direction can be written as

$$Y_{th} = Y_0 \sqrt{\frac{r_{90}(1+r_0)}{r_0+r_{90}}} = Y_{90} \sqrt{\frac{r_0(1+r_{90})}{r_0+r_{90}}}$$

Similarly, yield stresses in shear may be evaluated by

$$T_{12} = Y_{th} \sqrt{\frac{1}{2r_{45}+1}}$$

and

$$T_{23} = T_{31} = \frac{Y_a}{\sqrt{3}}$$

in which the transverse direction is assumed isotropic.

7. The elasticity constants must be isotropic for ORNL plasticity except for normal ORNL model for stainless steel. The 10th cycle stress-plastic strain curve in TID field should be a normalized function so that the yield stress at zero plastic strain is unity.

The pressure-dependent yielding, based on Drucker-Prager yield criterion, contains three options for frictional materials such as rocks and concrete. The generalized Mohr-Coulomb criterion introduces linear and parabolic models, developed by Drucker and Prager. The linear Mohr-Coulomb model assumes a linear function of hydrostatic stress for a yield function, i.e.,

$$\alpha I_1 + \sqrt{J_2} - \frac{\bar{\sigma}}{\sqrt{3}} = 0 \quad \text{or} \quad \bar{\sigma} = \sqrt{3}\alpha I_1 + \sqrt{3J_2}$$

where

$$I_1 = \sigma_x + \sigma_y + \sigma_z$$

and

$$J_2 = \frac{1}{6}[(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2]$$

The parameters  $\alpha$  and  $\bar{\sigma}$  (effective stress coinciding with the yield stress) can be related to material constants  $c$  (cohesion) and  $\phi$  (frictional angle) by

$$c = \frac{\bar{\sigma}}{3\sqrt{(1-12\alpha^2)}}$$

and

$$\sin \phi = \frac{3\alpha}{\sqrt{1 - 3\alpha^2}}$$

The parabolic Mohr-Coulomb model allows a yield envelope to be parabolic in the plane strain case, for which the yield function is expressed as

$$\sqrt{3J_2 + \sqrt{3}\beta\bar{\sigma}I_1} - \bar{\sigma} = 0$$

in which parameters are related to the material constants by

$$\bar{\sigma}^2 = 3\left(c^2 - \frac{\alpha^2}{3}\right)$$

and

$$\beta = \frac{\alpha}{\sqrt{3(3c^2 - \alpha^2)}}$$

8. The Drucker-Prager plasticity models can only be combined with isotropic elasticity. The Buyukozturk concrete plasticity model is a particular form of the generalized Drucker-Prager plasticity model, which is developed specifically for plane stress cases by Buyukozturk. The Buyukozturk yield function is expressed as

$$\beta\sqrt{3}Y I_1 + \gamma I_1^2 + 3J_2 - Y^2 = 0$$

where  $\beta$  is a user-specified constant,  $\gamma$  is an internal parameter (set to 0.2) with no user's access, and  $Y$  is the yield stress.

The Buyukozturk concrete plasticity model is coupled with crack and crush capability, which is designed for a low-tension material. The low-tension material develops a crack in the perpendicular direction to the maximum principal stress when it exceeds a critical value. The tension softening modulus can be specified (in absolute value) by the user to process the cracking process gradually. The default value (0.) is intended for a sudden cracking with a complete loss of the stiffness upon cracking. After the initial crack, a second crack can initiate in the perpendicular direction to the first crack. Likewise, the third crack can be formed in 3D solid elements. The loading may reverse the direction after the crack is formed. In this case, the crack will close and some load carrying capacity is resumed. The compression capability is fully resumed and the shear stresses may be transmitted over the crack surface with a reduced stiffness by a factor specified as shear retention factor. The material may fail in compression by crushing. The input value for the crush strain is positive, which implies an absolute value of a compressive strain. The material loses its integrity for good upon crushing. The reinforcement bars may be simulated by adding REBAR elements.

9. The Gurson model for porous metal plasticity may be used only with isotropic hardening rule. All other hardening rules will be ignored if Gurson model is selected. The Gurson model modified by Tvergaard and Needleman is designed for porous metal plasticity with damage effects in the ductile material. The material is assumed to form voids under loading, which grow, coalesce, then leads to crack formation and eventually failure. This process is a function of hydrostatic stress and the void volume fraction  $f_v$ . The yield function is established as follows:

$$\frac{3J_2}{Y^2} + 2q_1 f_v^* \cosh\left(\frac{q_2 I_1}{2Y}\right) - [1 - (q_1 f_v^*)^2] = 0$$

in which  $Y$  denotes a yield stress of the fully dense matrix material,  $I_1$  denotes the first invariant of stresses, and the modified void volume fraction  $f_v^*$  is computed by

$$f_v^* = f_v \quad \text{if } f_v \leq f_v^c$$

$$f_v^* = f_v^c + \left( \frac{f_v^u - f_v^c}{f_v^f - f_v^c} \right) (f_v - f_v^c) \quad \text{if } f_v > f_v^c$$

where  $f_v^c$  is the critical void volume fraction,  $f_v^f$  is the void volume at failure and  $f_v^u = 1/q_1$ . The solid loses all stress carrying capability when the void volume fraction reaches  $f_v^f$ .

The evolution of damage as measured by void volume fraction is due to void nucleation and void growth. Void nucleation occurs by debonding of the second phase particles. The strain for nucleation depends on the particle sizes. Assuming a normal distribution of particle sizes, the void nucleation itself is modeled as a normal distribution in strains if nucleation is strain-controlled. If the void nucleation is assumed to be stress controlled in the matrix, a normal distribution is assumed in stresses. The void volume fraction changes due to the growth of existing voids and nucleation of new voids, i.e.,

$$\dot{f}_v = \dot{f}_{growth} + \dot{f}_{nucleation}$$

in which the void growth can be determined based on the compressibility of the material

$$\dot{f}_{growth} = (1 - f_v) \dot{\epsilon}_{kk}^p$$

and the nucleation can be defined either as strain or stress-controlled with a normal distribution about the mean value. In case of strain-controlled nucleation, the rate is expressed as

$$\dot{f}_{nucleation} = \frac{f_v^n}{S \sqrt{2\pi}} \text{Exp} \left[ -\frac{1}{2} \left( \frac{\bar{\epsilon}_m^p - \epsilon_n}{S} \right)^2 \right] \dot{\epsilon}_m^p$$

where  $f_v^n$  is the volume fraction of void forming particles,  $\bar{\epsilon}_m^p$  denotes the effective plastic strain in the matrix material, and the void nucleation strain is assumed normally distributed with a mean value of  $\epsilon_n$  and a standard deviation of  $S$ . In case of stress-controlled nucleation, the rate is expressed as

$$\dot{f}_{nucleation} = \frac{f_v^n}{S \sqrt{2\pi}} \text{Exp} \left[ -\frac{1}{2} \left( \frac{\bar{\sigma} + \frac{1}{3} \sigma_{kk} - \sigma_n}{S} \right)^2 \right] \left( \dot{\sigma} + \frac{1}{3} \dot{\sigma}_{kk} \right)$$

If the size of the second phase particles are widely dispersed, the standard deviation would be larger than more uniform cases. A typical values for an engineering alloy as suggested by numerical experiments are set as default values for  $\epsilon_n$ ,  $S$ , and  $f_v^n$ .

10. The keywords may appear in any order. However, aniso, ORNL, press, and Gurson are mutually exclusive, and cannot coexist.
11. All the alphanumeric fields are recognizable by the first four letters.
12. For SOL 600, METHOD (first line, field 8) corresponds to Marc's PLASTICITY options as follows. METHOD must be the same for all MATEP entries in the SOL 600 input but this is not enforced. The value of METHOD on MATEP with the smallest MID governs who the PLASTICITY option is set. If METHOD is left blank, it may alternatively be set by PARAM,MARCPLAS.

Name	Marc PLASTICITY parameter value
Addmean	3
Addrad	4
Multrad	5
Multpln	6
Smlmean	1
Smlrad	2

13. The Bulk Data fields denoted by N/A are different from blank fields. Those fields with N/A are not used currently, but the space is reserved in case of future additions. On the other hand, the blank fields which have no specifications are neither used nor reserved (any memory space) for future use. The Method field determines the options under Marc parameter PLASTICITY.

The initial yield stress should be extracted from the table provided in the FID field. The yield stress-plastic strain function specified in TABLES1 under FID field is not a normalized function.

The anisotropic material parameters  $R_{ij}$  are equivalent to Marc input data as follows:

R11 = YRDIR1  
 R22 = YRDIR2  
 R33 = YRDIR3  
 R12 = YRSHR1  
 R23 = YRSHR2  
 R31 = YRSHR3

The crack/crush capability in Marc may be combined with other isotropic material options.

14. The strain effect on the yield stress (Reffect) is specified under the model definition option STRAIN RATE in Marc.
15. This Bulk Data entry accommodates Marc's input data under the model definition options ISOTROPIC, ORTHOTROPIC, ANISOTROPIC, RATE EFFECTS, WORK HARD, DAMAGE and CRACK DATA as well as the parameter PLASTICITY.
16. The fields without default values can be left blank only if they are specifically permitted to be blank.
17. RYIELD equates to Marc's ISOTROPIC (3,2) field.
18. WKHARD equates to Marc's ISOTROPIC (3,3) field.
19. RYIELD = LINMOHR, PBLMOHR and WKHARD = CHABOCHE, PWRLAW, RPWRLAW, JHCOOK, and KUMAR are only applicable to isotropic materials (MAT1).

MATEP

Elasto-Plastic Material - SOL 700

Elasto-plastic material properties for SOL 700 only.

Format:

Note that the primary entry is required. All other continuation lines are required only for certain options and only one such option may be entered.

	"Reffect"	COWPER		2.0	4.0				

Describer	Meaning
MID	Identification number of MAT1 or MATORT entry. MATORT is only acceptable for RYIELD=ORTHOOCR and MAT1 is acceptable for all other yield criteria except ORTHOOCR. (Integer > 0; required.)
FORM	Selects a form of stress-plastic strain function to be specified for RYIELD=VMISES. (Character; default=SLOPE):
	SLOPE Defines non-zero H.
	TABLE Defines the function using TABLED1 entry. Units of table are unspecified.
	PERFECT Defines perfectly plastic material (H is zero or blank and FID is blank).

Describer	Meaning
Y0	Initial yield stress for RYIELD=VMISES and ORTHOCR. (Real > 0.0; default=blank)
FID	Identification number of TABLED1 for RYIELD=VMISES. (Integer > 0; default=blank)
RYIELD	Enter on of the following yield criteria rules. (Character; Default = VMISES)
VMISES	von Mises yield criteria. It supports “Reffect” option. See Remarks 1.-8.
JHCOOK	For Johnson-Cook formulation. It supports “JhCook” option. See Remarks 9. and 10.
RPWRLAW	Rate power law. It supports “PwrLaw” option. See Remark 11.
POLY	Polynomial Yield Model. It supports “Poly” option. See Remark 12.
TMMODEL	Tanimura-Mimura Yield Model. It supports “TMmodel” option. See Remark 13.
ZAMODEL	Zerilli-Armstrong Yield Model. It supports “ZAmodeL” option. See Remarks 14.
ORTHOCR	Orthotropic Crushable Model. It supports “OrthoCr” option. It is only available for solid elements with MATORT. See Remarks 15.-18.
SOIL	Elastoplastic Crushable Model. It supports “Soil” option. It is only available for solid elements. See Remarks 19.-22.
TYPE	The type of stress and strain defined in FID. (Character; default=TRUE)
ENG	Engineering stress and strain.
TRUE	True stress and strain.
PLAST	True stress and plastic strain.
PMOD	Plastic modulus and true stress.
H	Plasticity modulus. (Real > 0; Default = 0).
“Reffect”	A keyword signifying that the following data pertains to the rate-dependent material properties (do not enter rate-dependent effects if they are not to be included). If TABLED1 is entered and one of the independent variables is strain rate, this field and its options should not be specified.
OPTION1	Selects an option for strain-rate dependent yield stress (Character; default=TABLE):
TABLE	Specifies that RTID input used to define rate dependency.
COWPER	Specifies the Cowper and Symonds rate-dependency model.
RTID	TABLED1 ID for strain-rate effects on yield stress, i.e., the table defines yield stress as a function of strain-rate starting from zero strain-rate. The yield stresses in this table should comprise the initial yield stress specified on Y0 or FID field at zero strain-rate.

Describer	Meaning
C	Specifies the constant C for Cowper and Symonds model. (Real; Default = 1.0)
P	Specifies the constant P for Cowper and Symonds model. (Real; Default = 1.0)
“Jhcook”	Johnson-Cook yield model where the yield stress is a function of effective plastic strain, strain rate, and temperature.
A	Static yield stress. (Real > 0.0; required.)
B	Hardening parameter. (Real; default=0.0)
N	Hardening exponent. (Real; default=1.0)
C	Strain-rate parameter. (Real; default=0.0)
M	Temperature exponent. (Real; default=1.0)
TMELT	Melt temperature. (Real; default=1.E20)
TROOM	Room temperature. (Real; default=293.0)
ε0DOT	Reference strain rate. (Real > 0.0; default=1.0)
CP	Specific heat. (Real; default=1.E20)
“PwrLaw”	Rate power law
A	Hardening parameter. (Real; default=0.0)
M	Hardening exponent. (Real; default=1.0)
B	Initial yield parameter. (Real > 0.0; required)
N	Strain rate exponent. (Real; default=1.0)
C	Minimum yield stress. (Real; default=1.E20)
“Poly”	Polynomial Yield Model
A	Initial yield parameter. (Real > 0.0; required)
B	Coefficient B. (Real; default=0.0)
C	Coefficient C. (Real; default=0.0)
D	Coefficient D. (Real; default=0.0)
E	Coefficient E. (Real; default=0.0)
F	Coefficient F. (Real; default=0.0)
YMAX	Maximum yield stress. (Real; default=1.E20)
“SGmodel”	Steinberg-Guinan Yield Model
A1-A4	Yield parameters. (Real > 0.0; required.)
H, B	Yield parameters. (Real; default=0.0)
TMELT	Melt temperature. (Real; default=1.E20)
TROOM	Room temperature. (Real; default=293.0)
CP	Specific heat. (Real; default=1.E20)

Describer	Meaning
“TMmodel”	Tanimura-Mimura Yield Model
A	Static yield parameter. (Real > 0.0; Required)
B	Hardening parameter. (Real; default=0.0)
C	Strain rate parameter. (Real; default=0.0)
D	Strain rate parameter. (Real; default=0.0)
M	Temperature exponent. (Real; default=1.0)
$\epsilon SM$	Quasi-static strain rate. (Real > 0.0; default=1.0)
TMELT	Melt temperature. (Real; default=1.E20)
TROOM	Room temperature. (Real; default=293.0)
YCR	Critical yield stress. (Real > 0.0; default=1.E20)
E	Strain rate parameter. (Real; default=0.0)
K	Strain rate exponent. (Real; default=1.0)
$\epsilon 0DOT$	Reference strain rate. (Real > 0.0; default=1.0)
CP	Specific heat. (Real; default=1.E20)
“ZAModel”	Zerilli-Armstrong Yield Model.
A	Static yield parameter. (Real > 0.0; required)
B	Hardening parameter. (Real > 0 0; default=0.0)
N	Hardening exponent. (Real > 0.0; default=1.0)
C	Strain rate parameter. (Real; default=0.0)
M	Temperature exponent. (Real; default=1.0)
$\epsilon 0DOT$	Reference strain rate. (Real > 0.0; default=1.0)
D	Bcc parameter. (Real; default=0.0)
	= 0            Fcc metal
	≠ 0           Bcc metal
CP	Specific heat. (Real; default=1.E20)
“OrthoCr”	Orthotropic Crushable Model.
E	Young’s modulus for the fully compacted material. (Real > 0.0; required)
NU	Poisson’s ratio for the fully compacted material. (-1.0 < Real < 0.5; required)
RELV	Relative volume at which the material is fully compacted. (0.0 < Real < 1.0; required)
TYPE	The type of data defined as the x-value in TIDXX~TIDSR. (Character; default=CRUSH)
	CRUSH                    Crush factor (1-relative volume)

Describer	Meaning
	RELVOL                      Relative volume $V/V_0$
TIDXX	TABLED1 ID defining the variation of the (local) xx-stress (y-value) with relative volume or crush (x-value). (Integer > 0; required)
TIDYY	TABLED1 ID defining the variation of the (local) yy-stress (y-value) with relative volume or crush (x-value). (Integer > 0; required)
TIDZZ	TABLED1 ID defining the variation of the (local) zz-stress (y-value) with relative volume or crush (x-value). (Integer > 0; required)
TIDXY	TABLED1 ID defining the variation of the (local) xy-shear stress (y-value) with relative volume or crush (x-value). (Integer > 0; required)
TIDYZ	TABLED1 ID defining the variation of the (local) yz-shear stress (y-value) with relative volume or crush (x-value). (Integer > 0; required)
TIDZX	TABLED1 ID defining the variation of the (local) zx-shear stress (y-value) with relative volume or crush (x-value). (Integer > 0; required)
TIDSR	TABLED1 ID defining the variation of a yield factor (y-value) with the deviatoric strain rate (x-value). (Integer > 0; default=not used)
“Soil”	Elastoplastic Crushable Model.
TABLE	TABLED1 ID defining the variation of pressure (y-value) with crush factor or volumetric strain (x- value). (Integer > 0; required)
TYPE	The type of data defined as the x-value in the table. (Real > 0.0; default=1.0)
	1.0                      Crush factor. (= 1-relative volume)
	2.0                      Volumetric (true) strain
VALUE	The value for cut-off stress. (Real < 0.0; See Remark 20.)
CUTOFF	Cut-off stress. See Remark 21. (Real > 0.0; default=2.0)
	1.0                      Pressure for total tensile failure
	2.0                      Pressure for tensile failure
	3.0                      Minimum pressure
A0, A1, A2	Yield function constants. (Real; default=0.0)
YIELD	Surface description. See Remark 22. (Real > 0.0; default=1.0)
	1.0                      The yield surface is defined as a function of p and $J_2$ .
	2.0                      The yield surface is defined as a function of p and $s_y$ .
YSTYP	Type of YSURF Yield Surface description. See Remark 22. (Real > 0.0; default=1.0)
	1.0                      DYNA definition
	2.0                      Dytran additional definition

Remarks:

1. A bilinear stress-strain characteristic is used by specifying FORM=SLOPE, Y0 and H:

where the equivalent stress is given by 
$$\sigma = \sigma_0 + \frac{E \cdot E_h}{E - E_h} \epsilon_p$$

where

$\sigma_0$	= yield stress specified in the Y0 field
$E$	= Young's modulus
$E_h$	= hardening modulus specified in the H field
$\epsilon_p$	= equivalent plastic strain
$\sigma$	= equivalent stress

2. A piecewise linear, stress-strain characteristic is used by specifying FID and TYPE (beams and shells only)

$$\sigma = [(\sigma_i - \sigma_{i-1})(\epsilon - \epsilon_{i-1}) / (\epsilon_i - \epsilon_{i-1})] + \sigma_{i-1}$$

The stress-strain characteristic used internally in Nastran SOL700 is in terms of true stress and equivalent plastic strain. However, for convenience, the stress-strain characteristic can be input in any of the following ways:

True stress/true strain	(TYPE = TRUE)
Engineering stress/engineering strain	(TYPE = ENG)
True stress/plastic strain	(TYPE = PLAST)
Plastic modulus/true stress	(TYPE = PMOD)

3. With solid elements, only an elastic perfectly plastic yield model is currently used. Only the Y0 field is used.
4. If FID is blank or zero, a bilinear stress-strain curve is assumed. If FID has a value, it refers to a TABLED1 entry giving the stress-strain curve for the material.
5. If FID is defined, the value of YIELD is left blank, since it is determined from the stress-strain curve.
6. If RTID is blank or zero and C and P are blank or zero, the yield stress does not vary with strain rate. If RTID has a value, then it references a TABLED1 entry, which gives the variation of the scale factor applied to the yield stress with strain rate. (C and P must be blank or zero.)

If RTID is blank or zero and C and P are defined, the enhancement of the yield stress with strain rate

is calculated as 
$$\frac{\sigma_d}{\sigma_y} = 1 + \left(\frac{\dot{\epsilon}_p}{C}\right)^{1/p}$$

where  $\sigma_d$  is the dynamic stress,  $\sigma_y$  is the static yield stress, and  $\dot{\epsilon}_p$  is the equivalent plastic strain rate.

7. If TYPE is PLAST or PMOD, Young's modulus must be defined. If TYPE is ENG or TRUE and Young's modulus is defined, it overrides the value calculated from the stress-strain curve.
8. Note that for values exceeding the maximum x-value of either of the TABLED1 entries (see FID and RTID fields), linear extrapolation is used based upon the last two points specified in the TABLED1.
9. The Johnson Cook yield stress is computed from

$$\sigma_y = (A + B\epsilon_p^N) \left[ 1 + C \ln\left(\frac{\dot{\epsilon}}{\dot{\epsilon}_0}\right) \right] (1 - T^{*M})$$

where

$\epsilon_p$	= effective plastic strain
--------------	----------------------------

$$T^* = \frac{T - TROOM}{TMELT - TROOM}$$

$\dot{\epsilon}$   
 $\dot{\epsilon}_0$  = reference strain rate

$\epsilon_0$  = reference strain rate

T = temperature

TROOM = room temperature

TMELT = melt temperature

A, B, N, C, and M are input constants.

10. The reference strain rate for Johnson Cook yield model is per unit time.
11. The rate power law yield stress is computed from

$$\sigma_y = MAX(C, B + A\epsilon_p^{M \cdot N} \dot{\epsilon})$$

where

$\epsilon_p$	= effective plastic strain
--------------	----------------------------

$\dot{\epsilon}$  = reference strain rate

A, B, M, N and C are constants.

12. The polynomial yield stress is computed from

$$\sigma_y = \text{MIN}(YMAX, A + B\varepsilon_p + C\varepsilon_p^2 + D\varepsilon_p^3 + E\varepsilon_p^4 + F\varepsilon_p^5)$$

where

$\varepsilon_p$	= effective plastic strain
-----------------	----------------------------

YMAX = maximum yield stress

A, B, C, D, E and F are constants.

13. The Tanimura-Mimura yield stress is computed from

$$\sigma_y = \left[ A + B\varepsilon_p + (C + D\varepsilon_p) \left( 1 - \frac{A + B\varepsilon_p}{\sigma_{cr}} \right) \ln \left( \frac{\dot{\varepsilon}}{\dot{\varepsilon}_s} \right) \right] (1 - T^{*M}) + E \left( \frac{\dot{\varepsilon}}{\dot{\varepsilon}_0} \right)^K$$

where

$\varepsilon_p$	= effective plastic strain
-----------------	----------------------------

$\sigma_{cr}$  = critical yield stress

$\dot{\varepsilon}$  = effective strain rate

$\dot{\varepsilon}_s$  = quasi-static strain rate

$\dot{\varepsilon}_0$  = reference strain rate

$$T^* = \frac{T - TROOM}{TMELT - TROOM}$$

T = temperature

TROOM = room temperature

TMELT = melt temperature

A, B, D, M, E and K are constants

14. The Zerilli-Armstrong yield stress is computed from

$$\sigma_y = \begin{cases} (A + B\varepsilon_p^N)e^{\left[-MT + CT \ln\left(\frac{\dot{\varepsilon}}{\dot{\varepsilon}_0}\right)\right]} & \text{For FCC Metals} \\ (A + B\varepsilon_p^N) + De^{\left[-MT + CT \ln\left(\frac{\dot{\varepsilon}}{\dot{\varepsilon}_0}\right)\right]} & \text{For BCC Metals} \end{cases}$$

where

$\varepsilon_p$	= effective plastic strain
$\dot{\varepsilon}$	= effective strain rate
$\dot{\varepsilon}_0$	= reference strain rate

$T$  = temperature

A, B, N,C,M and D are constants.

- If the initial Poisson's ratios in MATORT are not supplied, the default is set to zero. Therefore, the behavior of the material during compaction is uncoupled. This means that straining in the (local) x-direction produces stresses only in the (local) x-direction, and not in the (local) y- or z-direction. The tables define the variation of the stress in a particular direction with the relative volume or the crush. The relative volume is defined as (current volume)/(initial volume) and varies from 1.0 (uncompressed) to 0.0 (zero volume). Crush is defined as one minus the relative volume and varies from 0.0 to 1.0. Since the tables should be defined with increasing x-values, it is convenient to use the default value for type, which is CRUSH. When defining the curves, care should be taken that the extrapolated values do not lead to negative yield stresses.
- The elastic moduli (and the initial Poisson's ratios only if they are supplied) in MATORT vary linearly with the relative volume from their initial uncompact values to the fully compacted ones.
- When the material is fully compacted, its behavior becomes isotropic with an elastic perfectly plastic material characteristic.
- If the TIDSR option is used, you can supply a table including strain-rate effects. Strain rate is defined here as the Euclidean norm of the deviatoric strain-rate tensor; i.e.,  $\dot{\varepsilon} = \sqrt{\varepsilon_{ij}^{dev} \cdot \varepsilon_{ij}^{dev}}$   
 The y values in this table are factors with which the stresses in the other tables are multiplied to incorporate strain-rate effects.

19. The pressure-volume characteristic can either be defined in terms of the amount of crush, which is minus the engineering strain and is defined as  $(1 - \frac{V}{V_0})$ , with  $\frac{V}{V_0}$  as the relative volume; or in terms of the volumetric (true) strain which is defined as:  $\int_{t_0}^t \frac{dV}{V}$  or  $\ln\left(\frac{V}{V_0}\right)$

The crush factor must be between 0 and 1. The volumetric strain must always be negative.

20. If the field for the value of CUTOFF is left blank, then this value is calculated from the yield function defined by the constants A0, A1, and A2. In case of a Mohr-Coulomb yield model, the cut-off pressure is calculated as the root of the pressure-yield stress curve. If the YIELD=1.0 is used, the cut-off pressure is calculated as the intersection point of the yield surface with the hydrostat (if only A0 is nonzero, then the cut-off pressure is set to -100K, where K is the bulk modulus). The cut-off pressure must be negative.
21. Either a minimum pressure (CUTOFF=3.0) or a failure pressure (CUTOFF=1.0 or 2.0) can be specified. In the first case, this corresponds to a tensile cutoff, where the pressure cannot fall below the minimum value. In the second case, if the pressure falls below the failure pressure the element fails and cannot carry tensile loading for the remainder of the analysis. Thus, the pressure can never become negative again. If CUTOFF=1.0 is used, the elements can physically fail, which means that the stresses are set to zero, but also the failure flag is used as in normal MATF models. If CUTOFF=2.0 is used, only the stresses are set to zero.
22. If YIELD=1.0 is used, the yield stress is determined by a Mohr-Coulomb model:  $\sigma_y = \text{MIN}(A_0 + A_1 p, A_2)$

If YIELD=2.0 is used, the yield surface in three-dimensional space is defined by  $\phi_s=0$  here

$$\Phi_s = \frac{1}{2} S_{ij} S_{ij} - (B_0 + B_1 p + B_2 p^2) = J_2 - (B_0 + B_1 p + B_2 p^2)$$

where  $s_{ij}$  are the deviatoric stresses and  $J_2$  is the second invariant of the stress deviation. The coefficients  $B_0$ ,  $B_1$  and  $B_2$  can be related to the coefficients  $A_0$ ,  $A_1$  and  $A_2$ . The relation between the coefficients depends on the YSTYP field as shown below.

If YSTYP=2.0, then

$$B_0 = A_0$$

$$B_1 = A_1$$

$$B_2 = A_2$$

Thus, the yield stress is defined as  $\sigma_y = \sqrt{3(A_0 + A_1 p + A_2 p^2)}$

$$B_0 = \frac{1}{3}A_0^2$$

If  $Y_{STYP}=1.0$ , then  $B_1 = \frac{2}{3}A_0A_1$

$$B_2 = \frac{1}{3}A_1^2$$

and  $A_2$  is ignored.

Thus, the yield stress is defined as  $\sigma_y = A_0 + A_1 p$

**MATF**

**Material Failure Model**

Specifies failure model properties for linear elastic materials to be used for static, quasi static or transient dynamic analysis. Up to three criteria may be specified for each material. For progressive failure (ITYPE=2) only the first criterion will contribute to failure. The other two, if specified, will only provide output of failure index. SOL 400 (only with extended property entries), and all linear solution sequences between SOL101 and SOL112 (only with CPYRAM or CHEXA/PCOMPLS) are supported.

	4500.	4500.	4500.						

(Note: The 4th and 6th lines cannot be entirely blank and the last line of the 3rd criteria has been omitted.)

Describer	Meaning
MID	Identification number of a MAT1, MAT2, MAT8, MATORT or MAT9 entry. See Remarks 1. and 2. (Integer > 0; no Default)
ITYPE	Flag to invoke progressive failure. (Integer; Default = 0) 0 No progressive failure, compute failure indices only. 2 Gradual selective stiffness degradation. 3 Immediate selective stiffness degradation.
“CRI”	Enter the character string “CRI” to start input data for a failure criterion.
CRI67	Used with the alternate format only. (Integer; no Default; Required) It is highly recommended that only one criterion be used. However, up to three criteria from the list under Criteria below can be specified in a packed list as follows: $1000000*ITYPE+10000*C3+100*C2+C1$ where C1, C2, C3 are integer values for the various Criteria listed.
Criterion	Select an integer corresponding to the failure criterion to be applied. (Integer; no Default) Up to three failure criteria may be specified for each MID. 1 For maximum stress criterion. (See Remark 3.) 2 For maximum strain criterion. (See Remark 4.) 3 For Hill failure criterion. (See Remark 5.) 4 For Hoffman failure criterion. (See Remark 6.) 5 Tsai-Wu failure criterion. (See Remark 7.) 7 Hashin failure criterion. (See Remark 8.) 8 Puck failure criterion. (See Remark 9.) 10 Hashin-Tape (See Remark ) 11 Hashin-Fabric (See Remark ) 13 User-defined criterion with user subroutine UFAIL See Remark 11.
$V_i^j$	See the respective remark for the meaning of material data. Stress limit $i$ for criterion $j$ . See Remarks for meaning and default.
$W_i^j$	Strain limit $i$ for criterion $j$ . See Remarks for meaning and default.

Describer	Meaning
Find <sup>j</sup>	Failure index scale factor for criterion j. Used for criteria 3, 4, and 5. (Real > 0.0, or blank, Default = 1.0)
"PF"	Enter the character string "PF" to start progressive failure input data if ITYPE is 2 or 3. If the defaults are to be taken, the PF line may be omitted. Only the first criterion uses the PF line. (Character; no Default)
A1	Residual stiffness fraction. For ITYPE=2, the stiffness is not reduced beyond this fraction of the initial stiffness. For ITYPE=3, this is the fraction of initial stiffness upon failure. (Real > 0.0, Default = 0.01)
A2	<p>Leave blank except for Criterion values listed below.</p> <p>Criterion=7 (Hashin) A2 is the factor for E2 reduction due to matrix compression failure. Takes values between 0.0 and 1.0 and defaults to 0.0 where E2 is reduced in the same way as for matrix tension. A value of 1.0 leads to no E2 reduction due to matrix compression failure.</p> <p>Criterion=8 (Puck) - Same as for Criterion=7</p> <p>Criterion=10 (Hashin Tape) - Same as for Criterion=7</p>
A3	<p>Leave blank except for the Criterion values listed below.</p> <p>Criterion=7 (Hashin) A3 is the factor for G12 reduction relative to E2 reduction. It takes values between 0.0 and 1.0 and defaults to 0.0 where G12 is reduced in the same way as E2. A value of 1.0 leads to no G12 reduction.</p> <p>Criterion=8 (Puck) - Same as for Criterion=7</p> <p>Criterion=10 (Hashin Tape) - Same as for Criterion=7</p>
A4	<p>Leave blank except for the Criterion values listed below</p> <p>Criterion=7 (Hashin) A4 is the factor for E3 reduction due to fiber failure. It takes values between 0.0 and 1.0 and defaults to 0.0 where E3 is reduced in the same way as E1. A value of 1.0 leads to an E3 reduction due to E2 only. Values between 0.0 and 1.0 lead to a mixture of degradation from matrix and fiber failure.</p> <p>Criterion=8 (Puck) - Same as for Criterion=7</p> <p>Criterion=10 (Hashin Tape)- Same as for Criterion=7.</p>
A5	<p>Leave blank except for the Criterion values listed below</p> <p>Criterion=7 (Hashin) A5 is the factor for G12 reduction from fiber failure and takes values between 0.0 and 1.0, It defaults to 0.0 where G12 reduces to matrix failure. A value of 1.0 leads to G12 reduction due to only fiber failure. Values between 0.0 and 1.0 lead to a mixture of degradation from matrix and fiber failure.</p> <p>Criterion=8 (Puck) - Same as for Criterion=7</p> <p>Criterion=10 (Hashin Tape) - Same as for Criterion=7</p>

Remarks:

1. The MATF Bulk Data entry contains supplementary data for failure index calculation and failure prediction of the elastic materials with the same MID. If this capability is used in nonlinear analysis, MATF can activate a progressive failure process.
2. Progressive failure behavior for various materials can be simulated using the MATF Bulk Data entry. Failure occurs when any one of the specified failure criterion is satisfied; that is, the calculated failure index exceeds 1.0. Upon failure, the elastic moduli are reduced. This is done differently depending on failure criterion. The behavior up to the failure point is linear elastic. After failure the behavior is still elastic but with a different stiffness. The option should not be combined with other material nonlinearities like plasticity.
3. According to the Maximum Stress Criterion, six failure indices  $F_1$  are calculated as follows:

$$F_1 = \begin{cases} \frac{\sigma_x}{V_1} & \text{for } \sigma_x > 0 \\ \frac{-\sigma_x}{V_2} & \text{for } \sigma_x < 0 \end{cases}$$

$$F_2 = \begin{cases} \frac{\sigma_y}{V_3} & \text{for } \sigma_y > 0 \\ \frac{-\sigma_y}{V_4} & \text{for } \sigma_y < 0 \end{cases}$$

$$F_3 = \begin{cases} \frac{\sigma_z}{V_5} & \text{for } \sigma_z > 0 \\ \frac{-\sigma_z}{V_6} & \text{for } \sigma_z < 0 \end{cases}$$

$$F_4 = \frac{\tau_{xy}}{V_7}$$

$$F_5 = \frac{\tau_{yz}}{V_8}$$

$$F_6 = \frac{\tau_{zx}}{V_9}$$

where the indices (x, y, z) denote material coordinate direction.

$V_1$  : maximum allowable stress in the x-direction in tension. Real > 0.0, no Default.

$V_2$  : maximum allowable stress in the x-direction in compression. Real > 0.0 or blank; Default  $V_1$

$V_3$  : maximum allowable stress in the y-direction in tension. Real > 0.0, no Default.

$V_4$  : maximum allowable stress in the y-direction in compression. Real > 0.0 or blank; Default  $V_3$

$V_5$  : maximum allowable stress in the z-direction in tension. Real > 0.0; no Default

$V_6$  : maximum allowable stress in the z-direction in compression. Real > 0.0 or blank; Default  $V_5$

$V_7$  : maximum allowable in-plane shear stress. Real > 0.0 no Default

$V_8$  : maximum allowable yz shear stress. Real > 0.0 or blank; Default  $V_7$

$V_9$  : maximum allowable zx shear stress. Real > 0.0 or blank; Default  $V_7$

4. According to the Maximum Strain Criterion, 6 failure indices  $F_i$  are calculated as follows:

$$F_1 = \begin{cases} \frac{\varepsilon_x}{W_1} & \text{for } \varepsilon_x > 0 \\ \frac{-\varepsilon_x}{W_2} & \text{for } \varepsilon_x < 0 \end{cases}$$

$$F_2 = \begin{cases} \frac{\varepsilon_y}{W_3} & \text{for } \varepsilon_y > 0 \\ \frac{-\varepsilon_y}{W_4} & \text{for } \varepsilon_y < 0 \end{cases}$$

$$F_3 = \begin{cases} \frac{\varepsilon_z}{W_5} & \text{for } \varepsilon_z > 0 \\ \frac{-\varepsilon_z}{W_6} & \text{for } \varepsilon_z < 0 \end{cases}$$

$$F_4 = \frac{\varepsilon_{xy}}{W_7}$$

$$F_5 = \frac{\varepsilon_{yz}}{W_8}$$

$$F_6 = \frac{\varepsilon_{zx}}{W_9}$$

where the indices (x, y, z) denote material coordinate direction.

$W_1$  : maximum allowable strain in the x-direction in tension. Real > 0.0, no Default.

$W_2$  : maximum allowable strain in the x-direction in compression. Real > 0.0 or blank; Default  $W_1$

$W_3$  : maximum allowable strain in the y-direction in tension. Real > 0.0, no Default.

$W_4$  : maximum allowable strain in the y-direction in compression. Real > 0.0 or blank; Default  $W_3$

$W_5$  : maximum allowable strain in the z-direction in tension. Real > 0.0; no Default

$W_6$  : maximum allowable strain in the z-direction in compression. Real > 0.0 or blank; Default  $W_5$

$W_7$  : maximum allowable shear strain in the xy plane. Real > 0.0 no Default

$W_8$  : maximum allowable shear strain in the yz plane. Real > 0.0 or blank; Default  $W_7$

$W_9$  : maximum allowable shear strain in the zx plane. Real > 0.0 or blank; Default  $W_7$

5. According to the Hill Failure Criterion, there is no distinction between tensile and compressive behavior. A single failure index is calculated as:

$$F = \left[ \frac{\sigma_x^2}{V_1^2} + \frac{\sigma_y^2}{V_3^2} + \frac{\sigma_z^2}{V_5^2} - \left( \frac{1}{V_1^2} + \frac{1}{V_3^2} - \frac{1}{V_5^2} \right) \sigma_x \sigma_y - \left( \frac{1}{V_2^2} + \frac{1}{V_5^2} - \frac{1}{V_3^2} \right) \sigma_x \sigma_z - \left( \frac{1}{V_3^2} + \frac{1}{V_5^2} - \frac{1}{V_1^2} \right) \sigma_y \sigma_z + \frac{\tau_{xy}^2}{V_7^2} + \frac{\tau_{yz}^2}{V_8^2} + \frac{\tau_{zx}^2}{V_9^2} \right] / \text{Find}$$

where the indices (x, y, z) denote material coordinate direction.

$V_1$  : maximum allowable stress in the x-direction in tension. Real > 0.0, no Default.

$V_3$  : maximum allowable stress in the y-direction in tension. Real > 0.0, no Default.

$V_5$  : maximum allowable stress in the z-direction in tension. Real > 0.0; no Default

$V_7$  : maximum allowable in-plane shear stress. Real > 0.0 no Default

$V_8$  : maximum allowable yz shear stress. Real > 0.0 or blank; Default  $V_7$

$V_9$  : maximum allowable zx shear stress. Real > 0.0 or blank; Default  $V_7$

6. The Hoffman Failure Criterion introduces distinction between tensile and compressive stresses to generalize the Hill Failure Criterion. A single failure index F is calculated as:

$$F = \left( C_x(\sigma_x - \sigma_y)^2 + C_y(\sigma_y - \sigma_z)^2 + C_z(\sigma_z - \sigma_x)^2 + \left( \frac{1}{V_1} - \frac{1}{V_2} \right) \sigma_x + \left( \frac{1}{V_3} - \frac{1}{V_4} \right) \sigma_y + \left( \frac{1}{V_5} - \frac{1}{V_6} \right) \sigma_z + \frac{\tau_{xy}^2}{V_7^2} + \frac{\tau_{yz}^2}{V_8^2} + \frac{\tau_{zx}^2}{V_9^2} \right) / \text{Find}$$

with

$$C_x = \frac{1}{2} \left( \frac{1}{V_1 V_2} + \frac{1}{V_3 V_4} - \frac{1}{V_5 V_6} \right)$$

$$C_y = \frac{1}{2} \left( \frac{1}{V_3 V_4} + \frac{1}{V_5 V_6} - \frac{1}{V_1 V_2} \right)$$

$$C_z = \frac{1}{2} \left( \frac{1}{V_5 V_6} + \frac{1}{V_1 V_2} - \frac{1}{V_3 V_4} \right)$$

where the indices (x, y, z) denote material coordinate direction.

- $V_1$  : maximum allowable stress in the x-direction in tension (Real > 0.0, no Default).
- $V_2$  : maximum allowable stress in the x-direction in compression (Real > 0.0 or blank; Default  $V_1$  )
- $V_3$  : maximum allowable stress in the y-direction in tension (Real > 0.0, no Default).
- $V_4$  : maximum allowable stress in the y-direction in compression (Real > 0.0 or blank; Default  $V_3$  )
- $V_5$  : maximum allowable stress in the z-direction in tension (Real > 0.0, no Default).
- $V_6$  : maximum allowable stress in the z-direction in compression (Real > 0.0 or blank; Default  $V_5$  )
- $V_7$  : maximum allowable in-plane shear stress (Real > 0.0, no Default).
- $V_8$  : maximum allowable yz shear stress (Real > 0.0, no Default  $V_7$ ).
- $V_9$  : maximum allowable zx shear stress (Real > 0.0, no Default  $V_7$ ).

7. The Tsai-Wu Failure Criterion is another generalization of the Hill Failure Criterion. A single failure index F is calculated as:

$$F = \left[ \left( \frac{1}{V_1} - \frac{1}{V_2} \right) \sigma_x + \left( \frac{1}{V_3} - \frac{1}{V_4} \right) \sigma_y + \left( \frac{1}{V_5} - \frac{1}{V_6} \right) \sigma_z + \frac{\sigma_x^2}{V_1 V_2} + \frac{\sigma_y^2}{V_3 V_4} + \frac{\sigma_z^2}{V_5 V_6} + \frac{\tau_{xy}^2}{V_7^2} + \frac{\tau_{yz}^2}{V_8^2} + \frac{\tau_{zx}^2}{V_9^2} + 2V_{10} \sigma_x \sigma_y + 2V_{11} \sigma_y \sigma_z + 2V_{12} \sigma_x \sigma_z \right] / \text{Find}^j$$

where the indices (x, y, z) denote material coordinate direction.

- $V_1$  : maximum allowable stress in the x-direction in tension. Real > 0.0, no Default.
- $V_2$  : maximum allowable stress in the x-direction in compression. Real > 0.0 or blank; Default  $V_1$
- $V_3$  : maximum allowable stress in the y-direction in tension. Real > 0.0, no Default.
- $V_4$  : maximum allowable stress in the y-direction in compression. Real > 0.0 or blank; Default  $V_3$
- $V_5$  : maximum allowable stress in the z-direction in tension. Real > 0.0; no Default
- $V_6$  : maximum allowable stress in the z-direction in compression. Real > 0.0 or blank; Default  $V_5$
- $V_7$  : maximum allowable in-plane shear stress. Real > 0.0 no Default
- $V_8$  : maximum allowable yz shear stress. Real > 0.0 or blank; Default  $V_7$

$V_9$  : maximum allowable zx shear stress. Real > 0.0 or blank; Default  $V_7$

$V_{10}$  : interactive strength constant for the xy plane. Real; no Default

$V_{11}$  : interactive strength constant for the yz plane. Real; no Default

$V_{12}$  : interactive strength constant for the zx plane. Real; no Default

The following restrictions apply to  $V_{10}$ ,  $V_{11}$  and  $V_{12}$  :

$$V_{10}^2 < \frac{1}{V_1 V_2 V_3 V_4} \quad V_{11}^2 < \frac{1}{V_3 V_4 V_5 V_6} \quad V_{12}^2 < \frac{1}{V_1 V_2 V_5 V_6}$$

8. For the Hashin criterion four failure indices are calculated:

$$F_1 = \begin{cases} \left(\frac{\sigma_x}{V_1}\right)^2 + \frac{1}{V_{10}^2}(\tau_{xy}^2 + \tau_{xz}^2) & \sigma_x > 0 \\ 0 & \sigma_x \leq 0 \end{cases}$$

$$F_2 = \begin{cases} \frac{|\sigma_x|}{V_2} & \sigma_x < 0 \\ 0 & \sigma_x \geq 0 \end{cases}$$

$$F_3 = \begin{cases} \frac{1}{V_3^2}(\sigma_y + \sigma_z)^2 + \frac{1}{V_{11}^2}(\sigma_{yz}^2 - \sigma_y \sigma_z) + \frac{1}{V_{10}^2}(\sigma_{xy}^2 + \sigma_{xz}^2) & \sigma_y + \sigma_z > 0 \\ 0 & \sigma_y + \sigma_z \leq 0 \end{cases}$$

$$F_4 = \begin{cases} \left(\frac{1}{V_4} \left( \left( \frac{V_4}{2V_{11}} \right)^2 - 1 \right) (\sigma_y + \sigma_z) + \frac{1}{4V_{11}^2} (\sigma_y + \sigma_z)^2 + \frac{1}{V_{11}^2} (\sigma_{yz}^2 - \sigma_y \sigma_z) + \frac{1}{V_{10}^2} (\sigma_{xy}^2 + \sigma_{xz}^2) \right) & \sigma_y + \sigma_z < 0 \\ 0 & \sigma_y + \sigma_z \geq 0 \end{cases}$$

where the indices (x, y, z) denote material coordinate direction.

$V_1$  : maximum fiber tensile stress. Real > 0.0, no Default.

$V_2$  : maximum fiber compressive stress. Real > 0.0 or blank; Default  $V_1$

$V_3$  : maximum matrix tensile stress. Real > 0.0, no Default.

$V_4$  : maximum matrix compressive stress. Real > 0.0 or blank; Default  $V_3$  .

$V_{10}$  : maximum in plane shear stress. Real > 0.0 no Default

$V_{11}$  : maximum transverse shear stress; Default  $V_{10}$

9. For the Puck failure criterion five failure indices are calculated for the plane stress case and four for the general 3-D case.

The first two failure indices are related to fiber failure and apply to both plane stress and 3-D case:

Tensile fiber mode, for  $\sigma_x > 0$

$$F_1 = \frac{\sigma_x}{V_1}$$

Compressive fiber mode, for  $\sigma_x < 0$

$$F_2 = \frac{|\sigma_x|}{V_1}$$

For plane stress case, the next three failure indices are related to the matrix failure and are given as follows:

$$F_3 = \sqrt{\left(\frac{\sigma_{xy}}{V_{10}}\right)^2 + \left(1 - W_2 \frac{V_3}{V_{10}}\right)^2 \left(\frac{\sigma_y}{V_3}\right)^2} + W_2 \frac{\sigma_y}{V_{10}} \quad \text{for } \sigma_y > 0$$

$$F_4 = \frac{1}{V_{10}} \left( \sqrt{\sigma_{xy}^2 + (W_1 \sigma_y)^2} + W_1 \sigma_y \right) \quad \text{for } \sigma_y < 0 \text{ and } \left( 0 \leq \left| \frac{\sigma_y}{\sigma_{xy}} \right| \leq \frac{R_1}{R_2} \right)$$

$$F_5 = \left( \frac{\sigma_{xy}}{2(1 + W_3 V_{10})} \right)^2 + \left( \frac{\sigma_y}{V_4} \right)^2 \frac{V_4}{|\sigma_y|} \quad \text{for } \sigma_y < 0 \text{ and } \left( 0 \leq \left| \frac{\sigma_{xy}}{\sigma_y} \right| \leq \frac{R_2}{R_1} \right)$$

where the parameters,  $R_1$  and  $R_2$  are as follows:

$$R_1 = \frac{V_{10}}{2(1 + W_1)} \left( \sqrt{1 + 2W_1 \frac{V_4}{V_{10}}} - 1 \right)$$

$$R_2 = V_{10} \sqrt{1 + 2W_3}$$

Failure index for 3-D case is calculated based on stress,  $\sigma_n(\theta)$ ,  $\sigma_{nt}(\theta)$  and  $\sigma_{n1}(\theta)$  on an arbitrary plane with inclination angle  $\theta$ . The stresses are given by:

$$\sigma_n = \sigma_y \cos^2 \theta + \sigma_z \sin^2 \theta + 2\sigma_{yz} \sin \theta \cos \theta$$

$$\sigma_{nt} = (\sigma_z - \sigma_y) \sin \theta \cos \theta + \sigma_{yz} (\cos^2 \theta - \sin^2 \theta)$$

$$\sigma_{n1} = \sigma_{zx} \sin \theta + \sigma_{xy} \cos \theta$$

For 3-D case, the next two failure indices related to matrix failure are given by:

$$F_3 = \sqrt{\left(\frac{1}{V_3} - P_1\right)^2 \sigma_n^2 + \left(\frac{\sigma_{nt}}{R_1}\right)^2 + \left(\frac{\sigma_{n1}}{V_{10}}\right)^2} + P_1 \sigma_n \quad \text{for } \sigma_n \geq 0$$

$$F_4 = \sqrt{\left(\frac{\sigma_{nt}}{R_1}\right)^2 + \left(\frac{\sigma_{n1}}{V_{10}}\right)^2 + (P_2 \sigma_n)^2} + P_2 \sigma_n \quad \text{for } \sigma_n \geq 0$$

where  $P_1$  and  $P_2$  are given as:

$$P_1 = \left(\frac{W_4}{R_1}\right) \frac{\sigma_{nt}^2}{\sigma_{nt}^2 + \sigma_{n1}^2} + \left(\frac{W_2}{V_{10}}\right) \frac{\sigma_{n1}^2}{\sigma_{nt}^2 + \sigma_{n1}^2}$$

$$P_2 = \left(\frac{W_3}{R_1}\right) \frac{\sigma_{nt}^2}{\sigma_{nt}^2 + \sigma_{n1}^2} + \left(\frac{W_1}{V_{10}}\right) \frac{\sigma_{n1}^2}{\sigma_{nt}^2 + \sigma_{n1}^2}$$

The following material parameters are used:

$V_1$  = Maximum fiber tensile stress (Real > 0.0; no Default)

$V_2$  = Maximum fiber compressive stress (Real > 0.0 or blank; Default  $V_1$ )

$V_3$  = Maximum matrix tensile stress (Real > 0.0; no Default)

$V_4$  = Maximum matrix compressive stress (Real > 0.0 or blank; Default  $V_3$ )

$V_{10}$  = Maximum in-plane shear stress. (Real > 0.0; no Default)

$W_1$  = p12c, slope 1 of failure envelope (Real > 0.0; no Default)

$W_2$  = p12t, slope 2 of failure envelope (Real > 0.0; Default  $W_1$ )

$W_3$  = p23c, slope 3 of failure envelope (Real > 0.0 or blank; Default; calculated internally; this is recommended for plane stress)

$W_4$  = p23t, slope 4 of failure envelope (Real > 0.0; Default  $W_3$ , not used for plane stress)

The Hashin-Tape criterion is a variant of the Hashin criterion adapted for tape type of materials. Four failure indices are calculated:

$$F_1 = \begin{cases} \left(\frac{\sigma_x}{V_1}\right)^2 + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{xz}}{V_{12}}\right)^2 & \sigma_x > 0 \\ 0 & \sigma_x \leq 0 \end{cases}$$

$$F_2 = \begin{cases} \left(\frac{\sigma_x}{V_2}\right)^2 + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{xz}}{V_{12}}\right)^2 & \sigma_x < 0 \\ 0 & \sigma_x \geq 0 \end{cases}$$

$$F_3 = \begin{cases} \frac{1}{V_3^2}(\sigma_y + \sigma_z)^2 - \frac{\sigma_y \sigma_z}{V_{11}^2} + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{xz}}{V_{12}}\right)^2 + \left(\frac{\tau_{yz}}{V_{11}}\right)^2 & \sigma_y + \sigma_z > 0 \\ 0 & \sigma_y + \sigma_z \geq 0 \end{cases}$$

$$F_4 = \begin{cases} \left( \left( \frac{V_4}{2V_{11}} \right)^2 - 1 \right) \frac{(\sigma_y + \sigma_z)}{V_4} + \frac{1}{4V_{11}^2} (\sigma_y + \sigma_z)^2 - \frac{\sigma_y \sigma_z}{V_{11}^2} + \left( \left( \frac{\tau_{xy}}{V_{10}} \right)^2 + \left( \frac{\tau_{xz}}{V_{12}} \right)^2 + \left( \frac{\tau_{yz}}{V_{11}} \right)^2 + V_5 \left( \frac{\sigma_x}{V_6} \right)^2 \right) & (\sigma_y + \sigma_z < 0) \\ 0 & \sigma_y + \sigma_z \geq 0 \end{cases}$$

$V_1$  = Maximum tape fiber tensile stress (Real > 0.0; no Default)

$V_2$  = Maximum tape fiber compressive stress (Real > 0.0 or blank; Default  $V_1$ )

$V_3$  = Maximum tape cross-fiber tensile stress (Real > 0.0; no Default)

$V_4$  = Maximum tape cross-fiber compressive stress (Real > 0.0 or blank; Default  $V_3$ )

$V_{10}$  = Maximum in-plane shear stress. (Real > 0.0; no Default)

$V_{11}$  = Maximum transverse shear stress. (Real > 0.0 or blank; Default  $V_{10}$ )

$V_{12}$  = Maximum z-x transverse shear stress. (Real > 0.0 or blank; Default  $V_{11}$ )

$V_5$  = Maximum fiber tensile stress for matrix compression (Real > 0.0 or blank; required if

$V_6 = 1.0$ , otherwise not used)

$V_6$  = Contribution factor for  $V_5$  (Real 0.0 or 1.0; Default = 0.0)

The Hashin-Fabric criterion is a variant of the Hashin criterion adapted for fabric type of materials. Six failure indices are calculated:

$$F_1 = \begin{cases} \left(\frac{\sigma_x}{V_1}\right)^2 + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{xz}}{V_{12}}\right)^2 & \sigma_x > 0 \\ 0 & \sigma_x \leq 0 \end{cases}$$

$$F_2 = \begin{cases} \left(\frac{\sigma_x}{V_2}\right)^2 + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{xz}}{V_{12}}\right)^2 & \sigma_x < 0 \\ 0 & \sigma_x \geq 0 \end{cases}$$

$$F_3 = \begin{cases} \left(\frac{\sigma_y}{V_3}\right)^2 + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{yz}}{V_{11}}\right)^2 & \sigma_y < 0 \\ 0 & \sigma_y \geq 0 \end{cases}$$

$$F_4 = \begin{cases} \left(\frac{\sigma_y}{V_4}\right)^2 + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{yz}}{V_{12}}\right)^2 & \sigma_y < 0 \\ 0 & \sigma_y \geq 0 \end{cases}$$

$$F_5 = \begin{cases} \left(\frac{\sigma_z}{V_5}\right)^2 + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{xz}}{V_{12}}\right)^2 + \left(\frac{\tau_{yz}}{V_{11}}\right)^2 & \sigma_z < 0 \\ 0 & \sigma_z \geq 0 \end{cases}$$

$$F_6 = \begin{cases} \left(\frac{\sigma_z}{V_6}\right)^2 + \left(\frac{\tau_{xy}}{V_{10}}\right)^2 + \left(\frac{\tau_{xz}}{V_{12}}\right)^2 + \left(\frac{\tau_{yz}}{V_{11}}\right)^2 & \sigma_z < 0 \\ 0 & \sigma_z \geq 0 \end{cases}$$

- $V_1$  = Maximum first fiber tensile stress (Real > 0.0; no Default)
- $V_2$  = Maximum first fiber compressive stress (Real > 0.0 or blank; Default  $V_1$ )
- $V_3$  = Maximum second cross-fiber tensile stress (Real > 0.0; no Default)
- $V_4$  = Maximum second cross-fiber compressive stress (Real > 0.0 or blank; Default  $V_3$ )
- $V_5$  = Maximum thickness tensile stress (Real > 0.0; no Default)
- $V_6$  = Maximum thickness compressive stress ((Real > 0.0 or blank; Default =  $V_5$ )
- $V_{10}$  = Maximum in-plane shear stress. (Real > 0.0; no Default)
- $V_{11}$  = Maximum transverse shear stress. (Real > 0.0 or blank; Default  $V_{10}$ )
- $V_{12}$  = Maximum z-x transverse shear stress. (Real > 0.0 or blank; Default  $V_{11}$ )

10. A MATTF entry with the same MID as MATF may be used to specify the temperature variation of the failure criterion values.
11. User subroutine UFAIL is used along with option MATUDS.
12. In SOL 400, MATF is only supported for elements with property extensions. This implies that for such elements, PBAR / PBARL, PBEAM / PBEAML, PCOMP / PCOMPG, PROD, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PBARN1, PBEMN1, PSHLN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Note that, prior to MD Nastran 2010, if the property extensions were missing, then the MATF data was not considered in the element's formulation. If the property extensions are missing, they are automatically added with default settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.  
For non-composite material with MATF, only the first failure criteria is calculated and its failure index is outputted in NLOUT.
13. For the primary format, if only one criterion is needed and no data is required on the 3rd line, it can be omitted. If more than one criterion is needed, all 3 lines are required except for the last one. If the third line of the last one is not required, it may be omitted.
14. Stress limits such as ST, SC, SS,  $X_t$ ,  $X_c$ ,  $Y_t$ ,  $Y_c$  in the MAT1, MAT2 and MAT8 entries are not used in SOL 400.
15. Stress and/or strain allowables in all directions should be defined if the default is not appropriate. Be sure not to set some of these values to low numbers.
16. If MAT8 with Hashin is used in SOL 400 run with PSLDN1 then Hashin FT will be ignored with an appropriate warning message to include MATF instead.

**MATF**

**Material Failure Model - SOL 600**

Specifies failure model properties for linear elastic materials to be used for static, quasi static or transient dynamic analysis in SOL 600. Up to three criterion may be specified for each material if failure indices are desired (ITYPE=0). For progressive failure (ITYPE=2) only one criterion should normally be specified. Even if failure indices (no progressive failure) is the objective of the analysis, it is recommended that only one criterion per material be specified to simplify post processing.

	4500.	4500.	4500.						

Describer	Meaning
MID	Identification number of a MAT1, MAT2, MAT8, MATORT or MAT9 entry. See Remarks 1. and 2. (Integer > 0; no Default)
ITYPE	Flag to invoke progressive failure. (Integer; Default = 0)
	0 No progressive failure compute failure indices only. (Default)
	1 Standard (original) Marc method.
	2 Gradual selective stiffness degradation. (MSC Nastran 2005 and subsequent releases)
	3 Immediate selective stiffness degradation. (MSC Nastran 2005 and subsequent releases)
SB	Allowable shear stress of bonding material between layers (composites only). To use SB in the stiffness formulation of composites, include PARAM,MINCLDSB,1 in the bulk data. (Real, no Default)
UFAIL	Enter the string "UFAIL" if the ufail.f user subroutine is to be used to define your own failure conditions. If UFAIL is entered, leave fields 3 and 4 blank and do not enter any continuation lines. UFAIL is not available using the alternate format. (Character; Default is blank,). The file ufail.f must be in the same directory as the Nastran input file and must be in lower case.
"CRI"	For the primary failure model, warning may lead to slow convergence.

Descriptor	Meaning
CRI67	Used with the alternate format only. (Integer; no Default; Required) It is highly recommended that only one criterion be used. However, up to three criteria from the list under Criteria below can be specified in a packed list as follows: 1000000*ITYPE+10000*C3+100*C2+C1 where C1, C2, C3 are integer values for the various Criteria are listed.
Criteria	Select an integer corresponding to the failure criterion to be applied. (Integer; no Default) Up to three failure criterion may be specified for each MID for SOL 600.
	1 for maximum stress criterion. (See Remark 3.)
	2 for maximum strain criterion. (See Remark 4.)
	3 for Hill failure criterion. (See Remark 5.)
	4 for Hoffman failure criterion. (See Remark a.)
	5 Tsai-Wu failure criterion. (See Remark b.)
	7 Hashin failure criterion. (See Remark 8.)
	8 Puck failure criterion (See Remark 9.)
	9 User-defined failure criterion. (See Remark 8.)
	10 Hashin-Tape (See Remark )
	11 Hashin-Fabric (See Remark )
	For Hashin models or Puck model, see Remarks 9, 8, , for meaning of material data.
$V_1 = X_t$	Maximum tensile stress in x-direction. (Real, 0.0, or blank, no Default)
$V_2 = X_c$	Maximum compressive stress (absolute value) in x-direction (Real, 0.0, or blank, Default = $X_t$ )
$V_3 = Y_t$	Maximum tensile stress in y-direction. (Real, 0.0, or blank, no Default)
$V_4 = Y_c$	Maximum compressive stress (absolute value) in y-direction. (Real, 0.0, or blank, Default = $Y_t$ )
$V_5 = Z_t$	Maximum tensile stress in z-direction. (Real, 0.0, or blank, no Default)
$V_6 = Z_c$	Maximum compressive stress (absolute value) in z-direction. (Real, 0.0, or blank, Default = $Z_t$ )
$V_7 = S_{xy}$	Maximum shear stress in xy-plane. (Real, 0.0, or blank, no Default)
$V_8 = S_{yz}$	Maximum shear stress in yz-plane. (Real, 0.0, or blank, Default = $S_{xy}$ for criterion 5)
$V_9 = S_{zx}$	Maximum shear stress in zx-plane (Real, 0.0, or blank, Default = $S_{xy}$ for criterion 5)
Find	Failure index. See Remarks 5.-a. (Real, 0.0, or blank, Default = 1.0)
$V_{10} = F_{xy}$	Interactive strength constant for xy-plane. (Real, 0.0, or blank, Default = $-\frac{1}{2}\sqrt{\frac{1}{X_t X_c} \frac{1}{Y_t Y_c}}$ for criterion 5)

Describer	Meaning
$V_{11} = F_{yz}$	Interactive strength constant for yz-plane. (Real, 0.0, or blank, Default = $-\frac{1}{2}\sqrt{\frac{1}{Y_t Y_c} \frac{1}{Z_t Z_c}}$ for criteria 5)
$V_{12} = F_{zx}$	Interactive strength constant for zx-plane. (Real, 0.0, or blank, Default = $-\frac{1}{2}\sqrt{\frac{1}{Z_t Z_c} \frac{1}{X_t X_c}}$ for criterion 5).
Ext	Maximum tensile strain in x-direction. (Real, 0.0, or blank, no Default)
Exc	Maximum compressive strain (absolute value) in x-direction. (Real, 0.0, or blank, Default = Ext for criterion 2)
Eyt	Maximum tensile strain in y-direction. (Real, 0.0, or blank, Default = Ext for criterion 2)
Eyc	Maximum compressive strain (absolute value) in y-direction. (Real, 0.0, or blank, Default = Eyt for criterion 2)
Ezt	Maximum tensile strain in z-direction. (Real, 0.0, or blank, Default = Ext for criterion 2)
Ezc	Maximum compressive strain (absolute value) in z-direction. (Real, 0.0, or blank, Default = Ezt for criteria 2)
Gxy	Maximum shear strain in xy-plane. (Real, 0.0, or blank, no Default)
Gyz	Maximum shear strain in yz-plane. (Real, 0.0, or blank, Default = Gxy for criterion 2)
Gzx	Maximum shear strain in zx-plane. (Real, 0.0, or blank, Default = Gxy for criterion 2)
“PF”	Enter the character string “PF” to start progressive failure input data if ITYPE is 2 or 3. If the defaults are to be taken, the PF line and the line following the PF line may be omitted (Character, no Default)
A1	Residual stiffness fraction. For Criteria=3, this is the fraction of initial stiffness upon failure. For Criteria=2, the stiffness is not reduced more than this fraction (Real, Default = 0.01)
A2	Must be 0.0 or blank except for the Criteria values listed below
Criteria=7 (Hashin)	A2 is the factor for E2 reduction due to matrix compression failure. Takes values between 0.0 and 1.0 and defaults to 0.0 where E2 is reduced in the same way as for matrix tension. A value of 1.0 leads to no E2 reduction due to matrix compression failure.
Criteria=10 (Hashin Tape)	Same as for Criteria=7
Criteria=8 (Puck)	Same as for Criteria=7

Describer	Meaning
A3	<p>Must be 0.0 or blank except for the Criteria values listed below</p> <p>Criteria=7 (Hashin)      A3 is the factor for G12 reduction relative to E2 reduction. It takes values between 0.0 and 1.0 and defaults to 0.0 where G12 is reduced in the same way as E2. A value of 1.0 leads to no G12 reduction</p> <p>Criteria=10 (Hashin Tape)      Same as for Criteria=7</p> <p>Criteria=8 (Puck)      Same as for Criteria=7</p>
A4	<p>Must be 0.0 or blank except for the Criteria values listed below</p> <p>Criteria=7 (Hashin)      A4 is the factor for E3 reduction due to fiber failure. It takes values between 0.0 and 1.0 and defaults to 0.0 where E3 is reduced in the same way as E1. A value of 1.0 leads to an E3 reduction due to E2 only. Values between 0.0 and 1.0 lead to a mixture of degradation from matrix and fiber failure.</p> <p>Criteria=10 (Hashin Tape)      Factor for E3 reduction due to fiber failure. It takes values between 0.0 and 1.0 and defaults to 0.0 where E3 is reduced in the same way as E1. A value of 1.0 leads to an E3 reduction due to E2 only. Values between 0.0 and 1.0 lead to a mixture of degradation from matrix and fiber failure.</p> <p>Criteria=8 (Puck)      Same as for Criteria=7</p>
A5	<p>Must be 0.0 or blank except for the Criteria values listed below</p> <p>Criteria=7 (Hashin)      A5 is the factor for G12 reduction from fiber failure and takes values between 0.0 and 1.0. It defaults to 0.0 where G12 reduces to matrix failure. A value of 1.0 leads to G12 reduction due to only fiber failure. Values between 0.0 and 1.0 lead to a mixture of degradation from matrix and fiber failure</p> <p>Criteria=10 (Hashin Tape)      Same as for Criteria=7</p> <p>Criteria=8 (Puck)      Same as for Criteria=7</p>
IC1	<p>For all Criteria values except those listed below, IC1 is set to 1 if failure in the positive x-direction is critical (leads to element deactivation).</p> <p>Criteria=7 (Hashin)      Set IC1=1 if fiber tension is critical (leads to element deactivation).</p> <p>Criteria=10 (Hashin Tape)      Same as for Criteria=7</p> <p>Criteria=8 (Puck)      Same as for Criteria=7</p> <p>(Integer, Default = 0)</p>

Describer	Meaning
IC2	<p>For all Criteria values except those listed below, IC2 is set to 1 if failure in the negative x-direction is critical</p> <p>Criteria=7 (Hashin)                      Set IC2=1 if fiber compression is critical</p> <p>Criteria=10 (Hashin Tape)              Same as for Criteria=7</p> <p>Criteria=8 (Puck)                         Same as for Criteria=7</p> <p>(Integer, Default = 0)</p>
IC3	<p>For all Criteria values except those listed below, IC3 is set to 1 if failure in the positive y-direction is critical</p> <p>Criteria=7 (Hashin)                      Set IC3=1 if matrix tension is critical</p> <p>Criteria=10 (Hashin Tape)              Same as for Criteria=7</p> <p>Criteria=8 (Puck)                         Same as for Criteria=7</p> <p>(Integer, Default = 0)</p>
IC4	<p>For all Criteria values except those listed below, IC4 is set to 1 if failure in the negative y--direction is critical</p> <p>Criteria=7 (Hashin)                      Set IC4=1 if matrix compression is critical</p> <p>Criteria=10 (Hashin Tape)              Same as for Criteria=7</p> <p>Criteria=8 (Puck)                         Set IC4=1 if matrix compression mode B is critical</p> <p>(Integer, Default = 0)</p>
IC5	<p>For all Criteria values except those listed below, IC5 is set to 1 if failure in the positive z-direction is critical</p> <p>Criteria=7 (Hashin)                      Not used, leave blank</p> <p>Criteria=10 (Hashin Tape)              Not used leave blank</p> <p>Criteria=8 (Puck)                         Set IC5=1 if matrix compression mode C is critical</p> <p>(Integer, Default = 0)</p>
IC6	<p>For all Criteria values except those listed below, IC6 is set to 1 if failure in the negative z--direction is critical</p> <p>Criteria=7 (Hashin)                      Not used, leave blank</p> <p>Criteria=10 (Hashin Tape)              Not used leave blank</p> <p>Criteria=8 (Puck)                         Not used leave blank</p> <p>(Integer, Default = 0)</p>

Describer	Meaning
IC7	<p>For all Criteria values except those listed below, IC7 is set to 1 if failure in the xy plane is critical</p> <p>Criteria=7 (Hashin)            Not used, leave blank</p> <p>Criteria=10 (Hashin Tape)    Not used leave blank</p> <p>Criteria=8 (Puck)              Not used leave blank</p> <p>(Integer, Default = 0)</p>

Remarks:

1. The MATF Bulk Data entry contains supplementary data for failure prediction of the elastic materials with the same MID. If this capability is used in nonlinear analysis, MATF can activate progressive failure process.
2. Progressive failure behavior for various materials can be simulated using the MATF Bulk Data entry. Failure occurs when any one of the specified failure criterion is satisfied. Upon failure, the elastic modulus reduces to 10% of the original modulus if there is only one value of modulus as in isotropic material or in a beam or truss element. If it pertains to an orthotropic material, all of the material moduli at the integration point are reduced to the lowest modulus specified. The behavior up to the failure point is linear elastic even if an elasto-plastic material is specified, which is followed by a nonlinear behavior for the post-failure analysis. If the initial yield stress is less than the allowable maximum stress, the failure criterion will be ignored.
3. According to the Maximum Stress Criterion, the material fails when any of the stress components (9 components including 6 normal stress components in tension and compression, and three shear stress components) exceeds the maximum allowable stress:

$$|\sigma_{ij}| > Xt, Xc, Yt, \dots, S_{xy}, \dots \text{etc.}$$

where the indices (x, y, z or i, j) denote material coordinate direction.

4. According to the Maximum Strain Criterion, the material fails when any of the strain components (9 components including 6 normal strain components in tension and compression, and three shear strain components) exceeds the maximum allowable strain:

$$|\varepsilon_{ij}| > Ext, Exc, Ext, \dots, Gxy, \dots \text{etc.}$$

where the indices (x, y, z or i, j) denote material coordinate direction.

5. According to the Hill Failure Criterion, there is no distinction between tensile and compressive behavior. The failure is determined based on

$$\frac{\sigma_x^2}{X^2} + \frac{\sigma_y^2}{Y^2} + \frac{\sigma_z^2}{Z^2} - \left(\frac{1}{X^2} + \frac{1}{Y^2} - \frac{1}{Z^2}\right)\sigma_x\sigma_y - \left(\frac{1}{Y^2} + \frac{1}{Z^2} - \frac{1}{X^2}\right)\sigma_y\sigma_z - \left(\frac{1}{Z^2} + \frac{1}{X^2} - \frac{1}{Y^2}\right)\sigma_z\sigma_x + \frac{\tau_{xy}^2}{S_{xy}^2} + \frac{\tau_{yz}^2}{S_{yz}^2} + \frac{\tau_{zx}^2}{S_{zx}^2} > F_{ind}$$

in which  $X, Y, Z, S_{xy}, S_{yz}, S_{zx}$  are maximum allowable stresses and  $F_{ind}$  is the failure index prescribed by the user.

- a. The Hoffman Failure Criterion introduces distinction between tensile and compressive stresses to generalize the Hill Failure Criterion, i.e.,

$$C_x(\sigma_x - \sigma_y)^2 + C_y(\sigma_y - \sigma_z)^2 + C_z(\sigma_z - \sigma_x)^2 + \left(\frac{1}{X_t} - \frac{1}{X_c}\right)\sigma_x + \left(\frac{1}{Y_t} - \frac{1}{Y_c}\right)\sigma_y + \left(\frac{1}{Z_t} - \frac{1}{Z_c}\right)\sigma_z + \frac{\tau_{xy}^2}{S_{xy}^2} + \frac{\tau_{yz}^2}{S_{yz}^2} + \frac{\tau_{zx}^2}{S_{zx}^2} > F_{ind}$$

with

$$C_x = \frac{1}{2} \left( \frac{1}{X_t X_c} + \frac{1}{Y_t Y_c} - \frac{1}{Z_t Z_c} \right)$$

$$C_y = \frac{1}{2} \left( \frac{1}{Y_t Y_c} + \frac{1}{Z_t Z_c} - \frac{1}{X_t X_c} \right)$$

$$C_z = \frac{1}{2} \left( \frac{1}{Z_t Z_c} + \frac{1}{X_t X_c} - \frac{1}{Y_t Y_c} \right)$$

in which  $X_t, X_c, Y_t, Y_c, Z_t, Z_c, S_{xy}, S_{yz}, S_{zx}$  are maximum allowable stresses and  $F_{ind}$  is the failure index, prescribed by the user.

- b. The Tsai-Wu Failure Criterion is another generalization of the Hill Failure Criterion:

$$\begin{aligned} & \left(\frac{1}{X_t} - \frac{1}{X_c}\right)\sigma_x + \left(\frac{1}{Y_t} - \frac{1}{Y_c}\right)\sigma_y + \left(\frac{1}{Z_t} - \frac{1}{Z_c}\right)\sigma_z + \frac{\sigma_x^2}{X_t X_c} + \frac{\sigma_y^2}{Y_t Y_c} + \frac{\sigma_z^2}{Z_t Z_c} \\ & + \frac{\tau_{xy}^2}{S_{xy}^2} + \frac{\tau_{yz}^2}{S_{yz}^2} + \frac{\tau_{zx}^2}{S_{zx}^2} + 2F_{xy}\sigma_x\sigma_y + 2F_{yz}\sigma_y\sigma_z + 2F_{zx}\sigma_x\sigma_z > F_{ind} \end{aligned}$$

in which  $X_t, X_c, Y_t, Y_c, Z_t, Z_c, S_{xy}, S_{yz}, S_{zx}$  are maximum allowable stresses,  $F_{xy}, F_{yz}, F_{zx}$  are interactive strength constants, and  $F_{ind}$  is the failure index, prescribed by the user.

6. For the Hashin criterion the inputs are used:

$V_1$  = Maximum fiber tensile stress  
 $V_2$  = Maximum fiber compressive stress  
 $V_3$  = Maximum matrix tensile stress  
 $V_4$  = Maximum matrix compressive stress  
 $V_7$  = Maximum in-plane shear stress  
 $V_8$  = Maximum transverse shear stress  
 All other variables should be set to zero

7. For the Puck failure criterion the following inputs are used:

$V_1$  = Maximum fiber tensile stress  
 $V_2$  = Maximum fiber compressive stress  
 $V_3$  = Maximum matrix tensile stress  
 $V_4$  = Maximum matrix compressive stress  
 $V_7$  = Maximum in-plane shear stress  
 Ext = p12c, slope 1 of failure envelope  
 Exc = p12t, slope 2 of failure envelope  
 Eyt = p23c, slope 3 of failure envelope  
 Eyc = p23t, slope 4 of failure envelope

8. For the user-defined failure criterion, leave all fields blank except fields 1-3 of the primary entry (continuation entries are not required).  
 9. For the Hashin-Tape criterion the following inputs are used:

- $V_1$  = Maximum tape fiber tensile stress
- $V_2$  = Maximum tape fiber compressive stress
- $V_3$  = Maximum tape cross-fiber tensile stress
- $V_4$  = Maximum tape cross-fiber compressive stress
- $V_7$  = Maximum in-plane shear stress
- $V_8$  = Maximum transverse shear stress
- $V_9$  = Maximum z-x transverse shear stress
- $V_5$  = Maximum fiber tensile stress for matrix compression
- $V_6$  = Contribution factor for  $Z_t$  (Real 0.0 or 1.0; Default = 0.0)

All other variables should be set to zero

For the Hashin-Fabric criterion the following inputs are used:

- $V_1$  = Maximum first fiber tensile stress
- $V_2$  = Maximum first fiber compressive stress
- $V_3$  = Maximum second cross-fiber tensile stress
- $V_4$  = Maximum second cross-fiber compressive stress
- $V_5$  = Maximum thickness tensile stress
- $V_6$  = Maximum thickness compressive stress
- $V_7$  = Maximum in-plane shear stress
- $V_8$  = Maximum transverse shear stress
- $V_9$  = Maximum z-x transverse shear stress

All other variables should be set to zero

10. A MATTF entry with the same MID as MATF may be used to specify the temperature variation of the failure criterion values.

**Notes:**

1. This Bulk Data entry accommodates Marc's input data under the model definition option FAIL DATA.
2. For the primary format, if only one criterion is needed and no data is required on the 3rd line, it can be omitted. If more than one criterion is needed, all 3 lines are required except for the last one. If the third line of the last one is not required, it may be omitted.
3. For the alternate format the third line may be omitted if no data is needed.

4. For Nastran versions prior to MSC 2007, the alternate format was the only available option. These older versions used ITYPE=1 and a packed list for CRI67 with the format  $100*C3+10*C2+C1$ . ITYPE=1 was an older progressive failure method that is no longer recommended. If these jobs are re-run using MSC 2007, the CRI67 field should be changed as described above or the new primary format used.
5. Stress limits such as ST, SC, SS,  $X_t$ ,  $X_c$ ,  $Y_t$ ,  $Y_c$  in the MAT1, MAT2 and MAT8 entries are not used in SOL 600.

**MATF**

**Material Failure Model - SOL 700**

Specifies failure model properties. Use SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATF	MID								
	“CRI”	Criterion (=101)	MES	DT					
	“CRI”	Criterion (=102)	D1	D2	D3	D4	D5	ε0DOT	
			TROOM	TMELT	CP	MTH			
	“CRI”	Criterion (=103)	MPS	MPS-C	VOLF	DT			
	“CRI”	Criterion (=104)	PRS						
	“CRI”	Criterion (=105)	ALPHA	THETA	GAMMA	BETA	R	D	
			W	X0	CBAR	N	TYPE	ITER	
			TOFF						

Example:

MATF	7								
	CRI	101	2.0	1.0E20					

Describer	Meaning
MID	Identification number of MAT1 or MATORT entry. (Integer > 0; required.)
“CRI”	Enter the character string “CRI” to start input data for a failure criterion.
Criterion	Select an integer corresponding to the failure criterion to be applied. Only one failure criterion is allowed. (Integer; no Default)
101	Maximum Equivalent Stress Failure Model. It is only available for solid elements.
102	Johnson-Cook Failure Model. It is only available for solid elements. See Remarks 1.
103	Maximum Plastic Strain Failure Model. It is only available for Hugh-Liu beams, shells and solid elements.
104	Maximum Pressure Failure Model. It is only available for solid elements.
105	CAP Failure Model. It is only acceptable for solid elements. See Remark 2.-4.

Describer	Meaning
MES	Maximum equivalent stress that causes failure on the deviatoric part of the stress tensor. (Real > 0.0; required)
DT	Minimum time step that causes total failure. (Real > 0.0; default=not used.)
D1-D5	Damage coefficients. (Real; default=0.0)
ε0DOT	Reference plastic strain rate. (Real; default=1.0)
TROOM	Room temperature. (Real; default=0.0)
TMELT	Melt temperature. (Real; default=1.0E20)
CP	Heat capacity. (Real; default=1.0E20)
MTH	Specifies how failure is applied. (Character; default=CONT) CONT      Continuous failure DISC      Discrete failure
MPS	Maximum plastic strain that causes failure. (Real > 0.0; required)
MPS-C	Maximum plastic strain when material is under compression that causes failure. (Real > 0.0; default=MPS-C)
VOLF	Minimum volumetric failure criteria. It is only available for solid elements. (Real > 0.0; default=1.0E-12)
DT	Minimum time step that causes total failure. This option is only acceptable in solid elements. (Real > 0.0; default=not used)
PRS	Maximum pressure that causes failure. (Real > 0.0; required)
ALPHA	Failure envelope parameters. (Real ≥ 0.0; required)
THETA	Failure envelope linear coefficient. (Real ≥ 0.0; required)
GAMMA	Failure envelope exponential coefficient. See Remark 2. (Real ≥ 0.0; required)
BETA	Failure envelope exponent. (Real ≥ 0.0; required)
R	Cap surface axis ratio. (Real ≥ 0.0; required)
D	Hardening law exponent. (Real ≥ 0.0; required)
W	Hardening law coefficient. (Real ≥ 0.0; required)
X0	Hardening law exponent. (Real ≥ 0.0; default=0.0)
CBAR	Kinematic hardening coefficient. (Real ≥ 0.0; default=0.0)
N	Kinematic hardening parameter. (Real ≥ 0.0; default=0.0)
TYPE	Formulation type. (Character; default=SOIL) SOIL      Soil or concrete (cap surface may contract) ROCK      Rock (cap surface does not contract)
ITER	Iteration scheme. (Character; default=VEC) VEC      Fixed number of iterations (vectorized)

Describer	Meaning
	FULL Fully iterative
TOFF	Tension cut off (positive in compression). See Remark 3. (Real < 0.0; default=blank)

**Remarks:**

1. Defines the properties of a failure model where failure is determined by a damage model. The damage model is given by:

$$D = \sum_{time} \frac{\Delta \epsilon_p}{\epsilon^{frac}}$$

$$\epsilon^{frac} = (D_1 + D_2 \exp(D_3 \sigma^*)) \left( 1 + D_4 \ln \frac{\dot{\epsilon}_{pl}}{\dot{\epsilon}_{pl}^0} \right) (1 + D_5 T^*)$$

$$T = SIE / CP$$

$$T^* = \frac{T - T_{room}}{T_{melt} - T_{room}}$$

$$\sigma^* = \frac{\sigma_m}{\bar{\sigma}}$$

The summation is performed over all past time increments. The variable D measures the damage; T is the temperature,  $\sigma_m$  is the mean stress,  $\bar{\sigma}$  is the von Mises equivalent stress, and  $\epsilon^{frac}$  is the fracture strain.

The fracture strain depends on a nondimensional plastic strain rate,  $\dot{\epsilon}_{pl} / \dot{\epsilon}_{pl}^0$ . If D exceeds one it set equal to one.

There are two methods to determine when elements fail:

- Continuous failure: The yield stress is reduced by a factor (1-D). When D exceeds 1 the yield stress equals zero and the element fails.
- Discrete failure: the element fails when D equals one.

This failure model applies to high-strain rate deformation of metals. It is less suitable for quasi-static problems.

2. For a physically meaningful model, the value of the failure envelope exponential coefficient should be less than the failure envelope parameter (ALPHA < GAMMA).
3. The tension cut off value (TOFF) can be defined on the entry and must be less than zero. If the tension cut off is left blank, Nastran SOL700 calculates the tension cut off as the intersection point of the failure envelope surface with the J1-axis as described in Remark 4.

4. The cap material model can be used for geomechanical problems with materials like soil, concrete and rock.

The cap model is characterized by the following constitutive equations:

$$\begin{aligned}\varepsilon &= \varepsilon^e + \varepsilon^p \\ \sigma &= C(\varepsilon - \varepsilon^p)\end{aligned}$$

where  $\varepsilon$ ,  $\varepsilon^e$ , and  $\varepsilon^p$  are the total, elastic and plastic strain tensor,  $C$  is the elasticity matrix and  $\sigma$

is the stress tensor. The flow rule is given by:

$$\dot{\varepsilon}^p = \sum_{k=1}^e \dot{\lambda}_k \frac{\partial f_k}{\partial \sigma}$$

where the sum is over the active yield surfaces  $f^k$ , i.e., the failure envelope ( $k=1$ ), the hardening cap surface ( $k=2$ ), and the fixed tension cutoff surface ( $k=3$ ). The yield conditions are defined by:

$$\begin{aligned}f_1(\sigma) &\leq 0 \\ f_2(\sigma, \kappa) &\leq 0 \\ f_3(\sigma) &\leq 0\end{aligned}$$

The hardening parameter,  $\kappa$ , for the cap model is related to the plastic volume change by a hardening law.

The cap model is a plasticity model described by a yield surface that is defined by means of a failure envelope, a hardening cap and a tension cut off. Figure 1 shows the typical yield surfaces in a cap model.

The failure envelope surface is denoted by  $f_1 = \sqrt{J_{2D}} - \text{MIN}(F_e(J_1), T_{mises})$

and the cap by  $f_2 = \sqrt{J_{2D}} - F_c(J_1, \kappa)$  for  $L(\kappa) \geq J_1 \geq X(\kappa)$

where  $J_1$  is the first invariant (trace) of the stress tensor,  $J_{2D}$  is the second invariant of the stress deviator,  $\kappa$  is an internal state variable that measures hardening as a function of the history of plastic volumetric strain and  $L(\kappa)$  and  $X(\kappa)$  define the range of the cap. Note that  $J_1$  is chosen as negative in tension.

Figure 9-97 Typical Yield Surfaces in a Cap Model

The functions  $F_e$  and  $F_c$  are given by (see References 1. and 2.):

$$F_e(J_1) = a - \gamma \exp(-\beta J_1) + \theta J_1$$

$$F_c(J_1, \kappa) = \frac{1}{R} \sqrt{[X(\kappa) - L(\kappa)]^2 - [J_1 - L(\kappa)]^2}$$

The von Mises type transition failure surface is defined by the

following:  $T_{mises} = \frac{1}{R} |X(\kappa) - L(\kappa)|$

The intersection of the cap with the (hydrostatic)  $J_1$  axis is given by:  $X(\kappa) = \kappa + R F_e(\kappa)$

and  $L(\kappa)$  is defined by:  $L(\kappa) = \kappa = \begin{cases} \kappa & \text{if } \kappa > 0 \\ 0 & \text{if } \kappa \leq 0 \end{cases}$

The hardening parameter,  $\kappa$ , is related to the actual plastic volume

change:  $\epsilon_v^p(X) = W \{ 1 - \exp[-D(X(\kappa) - X_0)] \}$

The tension cut off surface is given by the function:  $f_3 = T - J_1$

where  $T$  is the maximum hydrostatic tension sustainable by the material.

Kinematic work hardening for the failure envelope surface is based on the approach of Isenberg et. Al. [1978]. It is switched on by specifying  $N$ . The failure envelope surface is replaced by a family of envelope surfaces that are bounded by an initial yield surface and by a limiting failure envelope surface. Which member of the family is taken, is implemented by replacing in all yield relations the stress tensor  $\sigma$  by  $\sigma - \zeta$  where  $\zeta$  is a deviatoric tensor that accumulates in time. This tensor  $\zeta$  is called

the “back stress tensor” and is defined by  $\frac{d\zeta}{dt} = \bar{c}\bar{F}(\sigma, \zeta)\frac{d\varepsilon^P}{dt}$

$$F = \text{MAX}\left(0, 1 - \frac{(\sigma - \zeta) \cdot \zeta}{2NF_e(J_1)}\right)$$

Here  $\varepsilon^P$  is the deviatoric plastic strain tensor,  $N$  denotes the size of the yield surface and represents the radial distance between the outside of the initial yield surface and the inside of the limit surface. After each increment of  $\zeta$ , it is checked whether its second invariant exceeds  $N$ . In that case,  $\zeta$  is scaled by a scalar such that its second invariant equals  $N$ . For consistency between the limit surface of the kinematic hardening cap model and the failure envelope of the standard cap model, the parameter  $\alpha$  is placed by  $\alpha - N$ .

## MATF1 Frequency Dependent Isotropic Material Definition

Defines the frequency dependent properties for an isotropic poroelastic material.

Format:

1	2	3	4	5	6	7	8	9	10
MATF1	MID	T(E)	T(G)	T(NU)	T(RHO)	T(A)		T(GE)	
	T(ST)	T(SC)	T(SS)						

Example:

MATF1	1	30			130				
-------	---	----	--	--	-----	--	--	--	--

Describer	Meaning
MID	Material property identification number that matches the identification number on MAT1 entry. (Integer>0; Required)
T(E)	Identification number of a TABLEMi entry for the Young's modulus. (Integer≥0 or Blank)
T(G)	Identification number of a TABLEMi entry for the shear modulus. (Integer≥0 or Blank)
T(NU)	Identification number of a TABLEMi entry for the Poisson's ratio. (Integer≥0 or Blank)
T(RHO)	Identification number of a TABLEMi entry for the mass density. (Integer≥0 or Blank)
T(A)	Identification number of a TABLEMi entry for the thermal expansion coefficient. (Integer≥0 or Blank)
T(GE)	Identification number of a TABLEMi entry for the damping coefficient. (Integer≥0 or Blank)
T(ST)	Identification number of a TABLEMi entry for the tension stress limit. (Integer≥0 or Blank)
T(SC)	Identification number of a TABLEMi entry for the compression stress limit. (Integer≥0 or Blank)
T(SS)	Identification number of a TABLEMi entry for the shear stress limit. (Integer≥0 or Blank)

Remarks:

1. Remarks 1 to 4 under [MATT1](#) are applicable with MATF1..
2. MATF1 must reside under Case Control 'BEGIN BULK TRMC' and is applicable to that trim component only. It may only be referenced by MATPE1 entry for a poroelastic element.

**MATFAB**

**Woven Fabric Material- SOL700**

Defines the properties of a bi-directional woven fabric material for shell elements. Used in SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATFAB	MID	RHO	ECOAT	NUCOAT	GCOAT	DAMPCOAT	COMPCOAT	PERC	
+	E1L	E1Q		THETA1	XWARP	YWARP	ZWARP		
+	E2L	E2Q		THETA2	XWEFT	YWEFT	ZWEFT		
+	SCOF	G12	DAMPFIB	COMPFIB	LOCKA NG1	LOCKANG2			

Example:

MATFAB	3	850	5.52E6	0.33					
+	21.6E7				1.0	0.0	0.0		
+	21.6E7				0.0	1.0	0.0		

Describer	Meaning
MID	Unique material number. (Integer > 0; required)
RHO	Density. (Real > 0.0; required)
ECOAT	Young's modulus of coating material. See Remark 1. (Real > 0.0; default=blank)
NUCOAT	Poisson's ratio of coating material. See Remark 1. (Real > 0.0; default=blank)
GCOAT	Shear modulus of coating material. See Remark 1. (Real > 0.0; default=blank)
DAMPCOAT	Damping is applied to the coating stresses. See Remark 2. (Real > 0.0; default=0.1)
	$d\sigma_{ij} = DAMPCOAT \cdot ECOAT \cdot \varepsilon_{ij} dt_{elm}$
COMPCOAT	Scale factor for coating compression stresses. See Remark 3. (0.0? Real?1.0; default=1.0)
PERC	Thickness percentage of coating material. (0.0? Real?100.0; default=0.0=no coating)
E1L	Young's modulus of fabric in warp direction, linear coefficient. (Real > 0.0; required)
E1Q	Young's modulus of fabric in warp direction, quadratic coefficient. (Real > 0.0; default=0.0)
THETA1	Orientation angle between the element coordinate system and the warp ends. See Remark 4. (Real; default=blank)
XWARP	X component of vector indicating the warp direction of the fabric material. The vector is with respect to the basic coordinate system. See Remark 4. (Real; default=1.0)
YWARP	Y component of vector indicating the warp direction of the fabric material. The vector is with respect to the basic coordinate system. See Remark 4. (Real; default=0.0)

Describer	Meaning
ZWARP	Z component of vector indicating the warp direction of the fabric material. The vector is with respect to the basic coordinate system. See Remark 4. (Real; default=0.0)
E2L	Young's modulus of fabric in weft direction, linear coefficient. (Real > 0.0; required)
E2Q	Young's modulus of fabric in weft direction, quadratic coefficient. (Real ? 0.0; default=0.0)
THETA2	Orientation angle between the element coordinate system and the weft ends. See Remark 4. (Real; default=blank)
XWEFT	X component of vector indicating the weft direction of the fabric material. The vector is with respect to the basic coordinate system. See Remark 4. (Real; default=0.0)
YWEFT	Y component of vector indicating the weft direction of the fabric material. The vector is with respect to the basic coordinate system. See Remark 4. (Real; default=1.0)
ZWEFT	Z component of vector indicating the weft direction of the fabric material. The vector is with respect to the basic coordinate system. See Remark 4. (Real; default=0.0)
SCOF	Shear coefficient of friction. See Remark 6. (Real; default=0.0)
G12	Shear modulus of fabric material. See Remark 7. (Real; default=blank)
DAMPFIB	Damping is applied to the fiber stresses. See Remark 2. (Real ≥ 0.0; default=0.1)
	$d\sigma_{ij} = DAMPCOA \bullet E\varepsilon_{ij}dt_{elm}$
COMPFIB	Scale factor for fiber compression stresses. See Remark 3. (0.0 ≤ Real ≤ 1.0; default=1.0)
LOCKANG1	Locking angle 1 for change in fiber cross-over angle. See Remark 10. (Real ≥ 0.0; default=10.0)
LOCKANG2	Locking angle 2 for change in fiber cross-over angle. See Remark 10. (Real ≥ 0.0; default=15.0)

#### Remarks:

1. When a coating is defined (PERC>0), two out of three values need to be specified for ECOAT, NUCOAT, and GCOAT.
2. For air bag modeling the following values of DAMPCOAT and DAMPFIB are suggested:  
DAMPCOAT= 0.05  
DAMPFIB= 0.05
3. The compressive stresses in the fibers are scaled with the value of COMPFIB. Putting COMPFIB = 0.0 results in a tension only fiber model.

The compressive stresses in the coating are scaled with the value of COMPCOAT. Putting COMPCOAT = 0.0 results in a tension only coating model.

The compressive stresses are scaled in the direction of the principal stresses.

When PERC = 100%, and the coating of this fabric model is used to simulate an isotropic air bag material, it is best to scale down the compressive stresses of the coating. A suggested value is COMPCOAT = 0.1

4. Since this is a model which tracks warp and weft directions and uses total warp/weft strain as a state variable, the initial warp and weft directions must be specified. There are two ways to indicate the initial warp and weft directions:
  - a. THETA1 and THETA2  
Orientation angles between the element coordinate system and the warp/weft ends. If no orientation angle is specified, vectors will be used to indicate the warp/weft directions of the fabric material with respect to the basic coordinate system.
  - b. XWARP, YWARP, ZWARP and XWEFT, YWEFT, ZWEFT  
Vectors indicating the warp/weft directions of the fabric material with respect to the basic coordinate system. The projection of these vectors on the surface of each element is used to determine the angle between the element and the material coordinate system. If the orientation angles are defined, these vectors are ignored.
5. For shell element properties (PSHELL1), when the material is MATFAB, the material angle THETA is ignored. The orientation of the fabric fibers is defined completely on the MATFAB entry.  
For layered composite element properties (PCOMP), when the material of a ply is MATFAB, the angle THETA<sub>i</sub> is ignored. The orientation of the fabric fibers is defined completely on the MATFAB entry.
6. The maximum shear stress is given by a friction coefficient of the fabric (SCOF) times the RMS value of the direct fiber stresses.
7. If the field G12 is left blank, the shear modulus is computed from the RMS value of the two linear stiffness coefficients.
8. When MATFAB material is referenced by shell elements, the Spin Rate method (SPIN) is applied automatically when no stress-rotation correction is specified on SPINCOR option. See PSHELL1 entry for the details on SPINCOR option.
9. There are a number of specific output sublayer variables useful for this material:
  - Q1AF Direction cosines/sines between the element coordinate
  - Q2AFIB System and the warp ends
  - Q1BFIB Direction cosines/sines between the element coordinate
  - Q2BFIB System and the weft picks
  - SGMA Direct stress in fabric parallel to the warp ends
  - SGMB Direct stress in fabric parallel to the weft picks
  - SGFRIC Stress due only to shear in the weave of the fabric
  - EPSFA Strain in fabric parallel to the warp ends
  - EPSFB Strain in fabric parallel to the weft picks
  - ANGLE Crossover angle between warp ends and weft picks

10. When a fabric is being sheared, the angle between the fibers changes. At a certain moment, the fibers will reach a locking angle, after which a further change in the fiber angle is no longer possible.

The simulation models this behavior as follows:

- a.  $\text{Change in Fiber Crossover Angle} < \text{LockAng1}$

The shear stress between the fibers is cut off based on the friction coefficient SCOF

- b.  $\text{LockAng1} < \text{Change in Fiber Crossover Angle} < \text{LockAng2}$

The shear stress between the fibers is linearly increased.

- c.  $\text{Change in Fiber Crossover Angle} > \text{LockAng2}$

The shear stress between the fibers is no longer cut off.

This situation is equal to an infinite friction coefficient SCOF.

**MATFTG**

**Fatigue Material Properties**

Defines fatigue material properties for time domain based SOLs 101, 103, 112 and frequency domain based SOLs 108 and 111.

Format (SOL 101, 103, 112):

1	2	3	4	5	6	7	8	9	10

Describer	Meaning
MID	Unique material ID that matches the identification of a MAT1 entry unless the MATID line is supplied (Integer>0). See Remark 1.
CNVRT	Conversion factor. See Remark 2. regarding units.
MATOUT	SOL 108, 111 only. This is a debug option for writing the fully derived material curve to a file (Integer 0 or 1; Default = 0).
STATIC	Required flag indicating that yield and/or ultimate tensile strengths and other common parameters are supplied (Character=STATIC). See Remark 3. and 4.
YS	Yield strength (Valid range equivalent in MPa: $50.0 \leq \text{Real} \leq 3000$ ). See Remark 2. regarding units.
UTS	Ultimate tensile strength (Valid range equivalent in MPa: $100.0 \leq \text{Real} \leq 4000$ ). See Remark 2. regarding units.
CODE	SOL 101, 103, 112 only. Material code used in automatically generating S-N or $\epsilon$ -N data curves and for surface finish correction. See Remark 3.
TYPE	SOL 101, 103, 112: Specification of the type of S-N curves defined using the TABLE or BASTEN flag (no Default). See Remark 4.
	SOL 108, 111: Specification as to whether material definitions are specified as RANGE or AMPLitude. See Remark 4.
RR	SOL 101, 103, 112 only. R-ratio of test used to create S-N or $\epsilon$ -N curve. ( $-1.0e30 \leq \text{Real} \leq 1.0$ , Default=-1.0, fully reversed loading).
SE	SOL 101, 103, 112 only. Standard Error of Log(N). ( $0.0 \leq \text{Real} \leq 10.0$ , Default=0.1).
mp	SOL 101, 103, 112 only. Plastic Poisson's Ratio. ( $0.45 \leq \text{Real} \leq 0.55$ , Default=0.5).

Describer	Meaning
RA	<b>SOL 101, 103, 112</b> only. Percentage reduction in area used for deriving $\epsilon$ -N data for metals of type “other” (TYPE field = 200-207 or >300). (0.0<Real≤100.0; no Default).
SN SNS1/SNS2 SNBR1/SNBR0	Flag indicating the definition of an S-N curve(s) follow (Character = SN, optional). See Remark 5. and 7. and 8.
SRI1	Stress range intercept. (Valid range equivalent in MPa: $1.0 \leq \text{Real} \leq 2.5e4$ , no Default). See Remark 2 regarding units.
b1	First fatigue strength exponent. ( $-1.0 < \text{Real} < -0.02$ , no Default)
Nc1	In 1-segment S-N curve, the cycles limit of endurance. In 2-segment S-N curve, this is the fatigue transition point. Both are defined in cycles. ( $1.0 \leq \text{Real} \leq 1.0E25$ ; no Default).
b2	Second fatigue strength exponent. It is zero when defining 1-segment S-N curve; ( $-0.5 < \text{Real} \leq 0.0$ , Default=0.0).
Nfc	Fatigue cutoff. ( $1.e-9 \leq \text{Real} \leq 1.0e30$ ; Default=1.0e30).
SE	<b>SOL 101, 103, 112</b> only. Standard Error of Log(N). ( $0.0 \leq \text{Real} \leq 10.0$ , Default=0.1). SE from “STATIC” line will be used if left blank.
BTHRESH	<b>SOL 101, 103, 112</b> only. Threshold value of the bending (r) ratio used in interpolation between “stiff” and “flexible” SN curves for fatigue analysis of seam welds. ( $0.0 \leq \text{Real} \leq 0.999$ ; Default=0.5)
M1 - M4	<b>SOL 101, 103, 112</b> only. Mean stress slope parameters M1 through M4 representing sensitivity to mean stress in four (4) regimes of R-ratio as plotted on a constant life Haigh diagram and used in FKM mean stress correction. ( $-0.99 \leq \text{Real} \leq 0.0$ ; Default = blank). See Remark 6.
MSS	<b>SOL 101, 103, 112</b> only. Mean stress sensitivity factor, used only for fatigue analysis of spot welds with CORR=SIMPLE on the FTGPARM entry. ( $0.0 \leq \text{Real} \leq 1.0$ , Default=blank). This mean stress correction method is a simplified version of the FKM method where $M1=M2=M3=M4=-MSS$ .
RTHICK	<b>SOL 101, 103, 112</b> only. Reference thickness/threshold (in consistent model length units) for sheet thickness correction used in fatigue analysis of seam welds. Ignored if THICK=0 on the FTGPARM entry for “SEAMW”. Must be supplied if THICK=1. ( $\text{Real} \geq 1.0e-9$ ; Default=1.0)
nTHICK	<b>SOL 101, 103, 112</b> only. Sheet thickness correction exponent used in the fatigue analysis of seam welds. Ignored if THICK=0 on the FTGPARM entry for “SEAMW”. Must be supplied if THICK=1. (Real; Default=0.16667)
SF-FXY SF-MXY SF-FZ SF-MZ	<b>SOL 101, 103, 112</b> only. Scale factor for stress due to FX or FY (shear forces), MX or MY (bending moments), FZ (axial force), and MZ (torsion), respectively (Real, Default = blank) used in fatigue analysis of spot welds only. See Remark 9.

Describer	Meaning
DE-FXY DE-MXY DE-FZ DE-MZ	<b>SOL 101, 103, 112</b> only. Diameter exponent for stress due to FX or FY (shear forces), MX or MY (bending moments), FZ (axial force), and MZ (torsion), respectively (Real, Default = blank) used in fatigue analysis of spot welds only. See Remark 9.
TE-FXY TE-MXY TE-FZ TE-MZ	<b>SOL 101, 103, 112</b> only. Thickness exponent for stress due to FX or FY (shear forces), MX or MY (bending moments), FZ (axial force), and MZ (torsion), respectively (Real, Default = blank) used in fatigue analysis of spot welds only. See Remark 9.
TABLE	Flag indicating the definition of S-N curves as a number of tables follows (Character=TABLE; optional). See Remark 5.
VALUEi	<b>SOL 101, 103, 112:</b> The constant mean stress, R-ratio, or life (in cycles) of this particular S-N curve. (Real; no Default). See Remark 2 regarding units.  <b>SOL 108, 111:</b> This should be specified as 1.0 as only one curve is supported and should be defined as zero mean.
TIDi	<b>SOL 101, 103, 112:</b> A TABLEM1 ID defining the S-N curve of stress range (y) vs. life (x) (in cycles) for this particular S-N curve, or mean stress (x) vs. stress amplitude (y) for constant life (Haigh diagram) curves (Integer>0). See Remark 2. regarding units.  <b>SOL 108, 111:</b> A TABLEM1 (may cause unintended recalculation of eigenvalues if used in RESTART job) or TABRND1 ID defining the S-N curve of stress (y) vs. life (x) (in cycles). Only one curve is allowed and should be defined at zero mean. See Remark 2. regarding units.
MMPDS	<b>SOL 108, 111</b> only. Flag indicating the definition of an S-N curve based on the MMPDS S-N approach (Character=MMPDS; optional). See Remark 5.
A1 A2 A3 A4	Coefficients or exponent of the standard MMPDS-01 material equation (must be defined in units-KSI based on amplitude). (Real; typical ranges $5 \leq A1 \leq 110$ ; $-47 \leq A2 \leq -1.0$ , $0.1 \leq A3 \leq 1.0$ ; $0.0 \leq A4 \leq 114$ ; no Default). CNVRT is not applied to these values at all - it is ignored!
BASTEN	<b>SOL 101, 103, 112</b> only. Flag indicating the definition of an S-N curve based on the Bastenaire S-N approach (Character=BASTEN; optional). See Remark 5.
A	Bastenaire coefficient - a parameter positioning the curve along the life axis. (Valid range equivalent in MPa: $1.0e4 \leq \text{Real} \leq 1.0e10$ ). See Remark 2. regarding units.
B	Scale Factor parameter. (Valid range equivalent in MPa: $1.0 \leq \text{Real} \leq 1.0e10$ ). See Remark 2. regarding units.
c	Bastenaire exponent. ( $0.01 \leq \text{Real} \leq 1.0e10$ )
Eb	Bastenaire fatigue limit (Valid range equivalent in MPa: $1.0 \leq \text{Real} \leq 1.0e10$ ). See Remark 2 regarding units.

Describer	Meaning
Sd	Bastenaire scatter factor. (Valid range equivalent in MPa: $0.0 \leq \text{Real} \leq 1.0e25$ ). See Remark 2 regarding units.
EN	Flag indicating the definition of an $\varepsilon$ -N curve is to follow. (Character=EN; optional). See Remark 5..
Sf	Fatigue strength coefficient (Valid range equivalent in MPa: $50.0 \leq \text{Real} \leq 4000.0$ ; no Default). See Remark 2. regarding units.
b	Fatigue strength exponent ( $-0.5 \leq \text{Real} \leq -2.0e-3$ ; no Default).
c	Fatigue ductility exponent. ( $-1.2 \leq \text{Real} \leq -0.15$ ; no Default).
Ef	Fatigue ductility coefficient, ( $0.001 \leq \text{Real} \leq 10.0$ ; no Default).
n'	Cyclic strain-hardening exponent, ( $5.0e-3 \leq \text{Real} \leq 0.5$ ; no Default).
K'	Cyclic strength coefficient, (Valid range equivalent in MPa: $50 \leq \text{Real} \leq 1.2e4$ ; no Default). See Remark 5. regarding units.
Nc	<b>SOL 101, 103, 112</b> only. Cut-off (reversals), ( $1.0e5 \leq \text{Real} \leq 1.0e24$ ; Default=2.0e8).
GAMMA	<b>SOL 108, 111</b> only. Additional coefficient needed for the Walker equation, ( $0.0 \leq \text{Real} \leq 1.0$ ; Default=0.0).
SEe	<b>SOL 101, 103, 112</b> only. Standard Error of Log(e) (elastic), ( $0.0 \leq \text{Real} \leq 10.0$ ; Default=0.0).
SEp	<b>SOL 101, 103, 112</b> only. Standard Error of Log(e) (plastic), ( $0.0 \leq \text{Real} \leq 10.0$ ; Default=0.0 ).
SEc	<b>SOL 101, 103, 112</b> only. Standard Error of Log(e) (cyclic), ( $0.0 \leq \text{Real} \leq 10.0$ ; Default=0.0).
Ne	<b>SOL 101, 103, 112</b> only. Endurance Limit (Reversals), ( $1.0 e-9 \leq \text{Real} \leq 1.0e25$ ; Default=2.0e8).
FSN	<b>SOL 101, 103, 112</b> only. Fatemi-Socie Parameter, ( $0.0 \leq \text{Real} \leq 10.0$ ; Default=0.6)
S	<b>SOL 101, 103, 112</b> only. Wang Brown Parameter, ( $-10.0 \leq \text{Real} \leq 10.0$ ; Default=1.0)
TOLER	<b>SOL 108, 111</b> only. Parameter used for frequency based strain life analysis with Neuber notch correction in vibration fatigue only. ( $\text{Real} \geq 1e-10$ , Default = 1e-5)
MATID	Flag indicating that a list of MAT1 IDs is to follow. See Remark 1.
E	Young's modulus, (Valid range equivalent in MPa: $\text{Real} > 0.0$ , no Default).
NU	Elastic Poisson's ratio. ( $0.25 \leq \text{Real} \leq 0.35$ , Default = 0.3)
MIDi	IDs of existing MAT1 entries to which this MATFTG entry will be linked. At least one ID must be supplied. The "THRU" keyword is supported.

Remarks:

1. Element properties must reference MAT1 entries in order to be linked to a MATFTG entry as only metal fatigue analysis of isotropic materials is supported. The MID must match that of an existing MAT1 entry called out by the property entry (e.g. PSHELL) unless the "MATID" line is provided, in which case all the MIDi referenced on the "MATID" line are then linked to the MATFTG entry. When the "MATID" line is used, E (required) and NU (optional) must be provided on this line as the code has no way of knowing from which referenced MAT1 this data should be extracted. Young's Modulus (E) and elastic Poisson's ratio (NU) are extracted from the corresponding MAT1 entry of the same ID when no "MATID" line is present. Usage of E and NU in the fatigue analysis itself is dependent on the type of fatigue analysis requested and fatigue material properties provided. Young's Modulus (E) is mainly used for deriving S-N or  $\epsilon$ -N data when none is provided. If the "MATID" line is used, and a MAT1 of the same ID also exists, that MAT1 ID must be in the MIDi list or it will be ignored in the analysis. In other words, when the "MATID" line is used, only the supplied MIDi IDs are used in the fatigue analysis.
2. The CNVRT field is only used if fatigue material stress based parameters are directly input using the "STATIC," "SN," "EN," "TABLE," or "BASTEN" methods. It is used to allow the user to input the fatigue material stress related parameters, (YS, UTS, SRI1, VALUEi, TIDi, A, B, Eb, K) in different units other than the model's consistent units. Example: model is producing stresses in PSI units, fatigue material parameters input in MPa, the CNVRT factor should be 145.0377 to convert MPa to PSI. Note that the y-values of any referenced TABLEM1 entries are also converted for the S-N method or both the x- and y-values when TYPE=LIFE (Haigh curves). It is also necessary to use the DTI,UNITS for defining the model's stress units. See DTI,UNITS. (Real; Default=1.0)
3. For SOLs 101, 103, and 112, if only STATIC is supplied, then for standard S-N or  $\epsilon$ -N analysis, the S-N or  $\epsilon$ -N curve is derived using the UTS and a material CODE. For fatigue analysis of spot or seam welds, a standard material set is used based on CODE, and UTS can be set to any valid number as the UTS from the standard material set will be used instead (only ferrous and aluminum codes are valid for spot/seam welds). Valid codes are listed in Table 9-22 below. At a minimum UTS must be supplied along with the material CODE and E on MAT1, or an error will be issued. If either flag (SN or EN) is present, then the automatic generation is suppressed if all the data necessary to define S-N or  $\epsilon$ -N curves are given. For SN, these fields are SRI1, b1, Nc1. For EN, these fields are Sf, b, c, Ef, n', K'. Either all of them are present, in which case they are used directly, or all of them are omitted, in which case the parameters are derived as mentioned above. The determination as to whether S-N or  $\epsilon$ -N curves are generated is determined by the TYPE field set on the FTGPARAM entry. If surface finish corrections are to be applied, CODE is also required (see PFTG entry). When curves are derived, the specified CODE gets internally converted to a generic code *ferrous*=99 for CODE<100, *aluminum*=100 for 100 ≤ CODE < 200, *other*=0 for 200 ≤ CODE < 300, or *titanium*=300 for 300 ≤ CODE < 400. When SN or EN flags exist, the generic code is set to *other*, but the CODE is used as given.

For SOLs 108, and 111, if only STATIC is supplied, see Remark 5.

4. For SOLs 101, 103, and 111: TYPE can be set to AMPL, RANGE, or MAX for amplitude, range, or maximum stress, respectively, when using the "BASTEN" flag. Or TYPE can be set to MEAN (or AMEAN), RRATIO (or ARRATIO), or LIFE (or ALIFE) for constant mean, R-ratio, or life (Haigh diagrams), respectively, when using the "TABLE" flag. When using multiple S-N curves for mean

stress correction, CORR=INTERP on FTGPARM must be used. In this case, for RRATIO, a curve at  $R=-1$  is required and for MEAN, a curve at zero (0) mean is required. AMPL, RANGE, and MAX are used to define stress types of Bastenaire models. MEAN vs. AMEAN, or RRATIO vs. ARRATIO, or LIFE vs. ALIFE indicates the stress type of the curves is range or amplitude, respectively.

**For SOLs 108 and 111:** TYPE can be set to AMPL or RANGE to indicate that the S-N curve is defined as amplitude or range and is applicable for the SN and TABLE lines.

- For SOLs 101, 103, and 111:** If an S-N analysis is specified (TYPE field on FTGPARM entry) but no S-N curve is supplied, an error will be issued. If an  $\varepsilon$ -N analysis is specified but no  $\varepsilon$ -N curve is supplied, an error will be issued. The STATIC data is required if SN or EN flags are specified on the MATFTG entry. The SN, BASTEN, and TABLE flags are generally mutually exclusive. When both SN and TABLE lines are defined, if TYPE is set, the SN parameters (SRI1, b1, Nc1, b2) will be ignored. EN flag may be present with SN, BASTEN, or TABLE flags, but one or the other will be ignored based on the type of analysis as set using the TYPE field on the FTGPARM entry. See Remark 7. and 8. for other “SNS1/SNS2/SNBR1/SNBR2” definitions.

**For SOLs 108 and 111:** The STATIC line is required and at least one of SN, TABLE, MMPDS, or EN lines. If no SN, TABLE, MMPDS, or EN lines are present, then the fatigue analysis is skipped and only the random vibration analysis is performed<sup>1</sup>. The use of the TYPE field in the FTGPARM entry has limited affect. Please note: If only SN data is present, it is used by default. If only EN data is present, it is used by default. The SN, TABLE, and MMPDS entries are mutually exclusive and if more are present for any particular MID, then the following hierarchical rule is implement to choose which to use: MMPDS, TABLE, SN. If both SN and EN are defined for a particular MID, EN is selected by default unless TYPE on the FTGPARM is set, in which case the corresponding SN or EN definition is used. However, TYPE is ignored if the corresponding material definition is not present, and the material definition used is then based on the hierarchy just defined.

- For SOLs 101, 103, and 111:** Mean stress sensitivity: M1 for  $R>1$ ; M2 for  $-\infty < R < 0$ ; M3 for  $0 < R < 0.5$ ; M4 for  $0.5 < R < 1$ . If  $M_{1-4}$  are undefined, and the material type (CODE) is given, all the parameters will be estimated using empirically defined rules for the FKM mean stress correction method. If only  $M_2$  is defined, then  $M_1$  and  $M_4$  will be set to zero and  $M_3$  to  $M_2/3$ .
- For SOLs 101, 103, and 111:** The “SN” line is used for the definition of standard SN parameters for any SN analysis. In the case of fatigue analysis of spot welds, “SNS1” and “SNS2” are used to define the SN curves of the top and bottom sheets to which the spot weld is connected and “SN” is used to define the SN curve of the weld nugget. If no “SN”, “SNS1”, or “SNS2” flags are present, generic SN parameters are used for steel or aluminum per the material CODE supplied. See Table 9-23 for default values used in this case. If CODE is blank, steel is assumed. If only one of the flags is provided, then “SN” = “SNS1” = “SNS2”. If “SNS1” or “SNS2” is missing but the other is present, then “SNS1” = “SNS2”. If “SNS1” and “SNS2” are defined, but not “SN”, then “SN” = “SNS1”.
- For SOLs 101, 103, and 111:** The “SN” line is used for the definition of standard SN parameters for any SN analysis. In the case of fatigue analysis of seam welds, “SNBR1” and “SNBR0” are used to define the flexible (bending ratio=1.0) and stiff (bending ratio=0.0) SN curves. If no “SN”, “SNBR1”, or “SNBR0” flags are present, generic SN parameters are used for steel or aluminum per the material

<sup>1</sup>If the EN line is supplied with only n’ and K’ defined, then the Neuber notch correction is also applied in the random only analysis affecting the resultant output stress PSD.

CODE supplied. See [Table 9-23](#) for default values used in this case. If CODE is blank, steel is assumed. If only “SN” is supplied, then the “SN” parameters are used for both “SNBR1” and SNBR0”. If “SNBR1” or “SNBR0” is missing but the other is present, then “SNBR1” = “SNBR0”. The 3rd and 4th lines of data for these keywords should not be entered as they are applicable to fatigue analysis of spot welds only, and not for seam welds.

9. For SOLs 101, 103, and 111: If SF, DE, & TE values are not supplied, default values are used based on material CODE for steel or aluminum. See [Table 9-24](#) and [Table 9-25](#). These should only be entered for fatigue analysis of spot welds and not for anything else.

Table 9-22 Table of Material CODEs

CODE	Description
1	Flake cast iron (FCI)
2	Ferritic cast iron with compacted graphite (FCICG)
3	Pearlitic cast iron with compacted graphite (PCICG)
4	Bainitic cast iron with compacted graphite (BCICG)
5	Ferritic cast iron with spheroidal graphite (FCISG)
6	Ferrite/pearlite cast iron with spheroidal graphite (FPCISG)
7	Pearlitic cast iron with spheroidal graphite (PCISG)
8	Bainitic cast iron with spheroidal graphite (BCISG)
9	Cast steel with less than 0.2% carbon (CSL2C)
10	Normalized cast steel with 0.2-0.4% carbon (NCS24C)
11	Quenched & tempered cast steel with 0.2-0.4% carbon (QTCS24)
12	Normalized cast steel with 0.4-0.7% carbon (NCS47)
13	Plain carbon wrought steel with < 0.2% carbon (PCWS)
14	Hot rolled/normalized plain carbon wrought steel, 0.2-0.4% carbon (HNPCWS24)
15	Quenched & tempered cast steel with 0.4-0.7% carbon (QTCS47)
16	Quenched & tempered plain carbon wrought steel, 0.2-0.4% carbon (QTPCWS24)
17	Hot rolled/normalized plain carbon wrought steel, 0.4-0.7% carbon (HNPCWS47)
18	Quenched & tempered plain carbon wrought steel, 0.4-0.7% carbon (QTPCWS47)
19	Normalized low alloy wrought steel (NLAWS)
20	Quenched & tempered low alloy wrought steel (QTHSLAWS)
21	Normalized Ni/Cr/Mo wrought steel (NNCMWS)
22	Quenched & tempered Ni/Cr/Mo wrought steel (QTNCMWS)
23	Austenitic stainless steel (ASS)
24	Ferritic stainless steel (FSS)
25	Martensitic stainless steel (MSS)
26	Annealed plain carbon wrought steel, 0.2-0.4% carbon (APCWS24)
27	Annealed plain carbon wrought steel, 0.4-0.7% carbon (APCWS47)
28	Normalized carbon/manganese steel (MCMS)
29	Quenched and tempered carbon/manganese steel (QTCMS)
30	Hardened chromium steel (HCS)
31	Quenched and tempered chromium steel (QTCS)

CODE	Description
99	Steel of unknown heat treatment (STEEL)
100	Wrought aluminum (WA)
101	Wrought aluminum-copper alloy (WACA)
102	Wrought aluminum-manganese alloy (WAMNA)
103	Wrought aluminum-magnesium alloy (WAMGA)
104	Wrought aluminum-magnesium-silicon alloy (WAMGSA)
105	Wrought aluminum-zinc alloy (WAZA)
106	Cast aluminum alloy (CAA)
107	Wrought complex special purpose aluminum alloys (WCSPAA)
200	Wrought copper (WCU)
201	Wrought brass (WBR)
202	Wrought aluminum bronze (WABR)
203	Cupronickel (CUPNI)
204	Nickel silver (NIAG)
205	Wrought phosphor bronze (WPHBR)
206	Wrought copper beryllium (WCUBE)
207	Cast copper alloys (CCUA)
300	Titanium alloy (TA)
400	Wrought magnesium alloys (WMGA)
401	Cast magnesium alloys (CMGA)
500	Fusible alloys, solders (FUSSOL)
600	Cast zinc alloys (CZINCA)
700	Wrought nickel alloys (WNIA)
701	Cast nickel alloys (CNIA)
800	Precious metals (PRECMET)
900	Clad materials (CLADMAT)
1000	Thermoplastics (THERPLAS)
1001	Thermosetting plastics (TSETPLAS)

MZ	SF-MZ = 0.0	DE-MZ = 0.0	TE-MZ = 0.0

## MATG

## Gasket Material Properties

Specifies gasket material properties to be used in SOL 600 and SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
MATG	MID	IDMEM	BEHAV	TABLD	TABLU1	TABLU2	TABLU3	TABLU4	
	TABLU5	TABLU6	TABLU7	TABLU8	TABLU9	TABLU10	YPRS	EPL	
	GPL	GAP	TABYPRS	TABEPL	TABGPL	TABGAP	N/A	N/A	

Example:

MATG	100	10	0	1001	1002	1003			
							100.	2500.	
	950.	0.0							

Descriptor	Meaning
MID	Material ID number. (Integer)
IDMEM	ID of MAT1 providing material behavior for membrane behavior. See Remarks. (Integer)
BEHAV	Behavior type (presently only type 0 is supported). (Integer)
TABLD	ID of a TABLES1 table providing loading path of the gasket (pressure versus displacement). See Remarks 1. and 3. (Integer)
TABLUi	ID of TABLES1 table providing unloading path(s) of the gasket (pressure versus displacement) can range from 1 to 10. If there is no unloading, no unloading tables need be entered. Leave fields blank for tables that are not required. See Remarks. (Integer)
YPRESS	Yield pressure. See Remark 4. (Real)
EPL	Tensile modulus (pressure per unit length). (Real)
GPL	Transverse shear modulus (force per unit area). (Real)
GAP	Initial gap (if present). (Real)
TABYPRS	ID of TABLES1 table associated with yield pressure (not presently used). (Integer)
TABEPL	ID of TABLES1 table associated with tensile modulus (not presently used). (Integer)
TABGPL	ID of TABLES1 table associated with transverse shear modulus (not presently used). (Integer)
TABGAP	ID of TABLES1 table associated with initial gap (not presently used). (Integer)

Remarks:

1. MATG defines nonlinear properties in the thickness direction for compression only, designed for gasket-like materials. MATG has anisotropy only in the thickness direction, which is called normal anisotropy.
2. The MATG option can only be used with continuum composite elements, use PLCOMP.
3. The MATG entry defines the compressive behavior in thickness. The thickness direction is the principal direction (3) in 3-dimensional solids and (2) for 2-dimensional solids (plane strain and axisymmetric elements). Since MATG material allows only normal anisotropy, linear properties in MAT1 are required for in-plane behavior.
4. The initial yield pressure should match a point in table TABLD.
5. The loading path for the gasket is always in compression. However, it starts from the origin to initial yield pressure (nonlinear elastic range) and continues with strain hardening slope into the plastic region. All the data points are specified in the first quadrant.
6. As many as 10 unloading paths may be defined in the thickness direction using TABLS1 in pressure vs. gasket closure distance as in the loading path. All the unloading paths must start from zero pressure and end at the loading path in the plastic region. Unloading behavior at undefined paths will be interpolated between two adjacent unloading paths. The last point of the last specified unloading path signifies full compression, which does not allow any further closure beyond the point.

Element Thickness Direction for MATG	Runs Parallel from Face	To Face
Element T direction	G1-G2-G3-G4	G5-G6-G7-G8

7. If creep analysis is required, Bulk Data entry, MPCREEP, must also be entered to activate Marc's CREEP parameter.

Figure 9-98 Pressure-closure Relation of a Gasket

8. See associated MATTG entry for temperature variation of these properties.
9. All continuation cards must be entered.
10. MID, IDMEM, BEHAV, TABLD, TABLU1, YPRS, EPL and GPL must be non-zero.
11. Each unloading curve must begin with gasket pressure of 0.0. Subsequent unloading curves must start with larger closure distances (when gasket pressure is 0.0) than previous unloading curves.
12. Points on loading and unloading curves must be defined in order of increasing gasket pressure.
13. MATG may be referenced by “solid” composite elements only, via PCOMPLS linked to PSOLID and PSHLN2 linked to PLPLANE.
14. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
15. Result data recovery is not supported in SOL 400 when ANALSYS=MODES, MFREQ or DFREQ.

**MATHE**

**Hyperelastic Material Properties**

Specifies hyperelastic (rubber-like) material properties for nonlinear (large strain and large rotation) analysis in SOL 600 and SOL 400 only.

Format 1 (Default): Generalized Mooney-Rivlin Model (Model = Mooney). The first two lines are required, the others may be omitted depending on how many terms are desired.)

1	2	3	4	5	6	7	8	9	10
MATHE	MID	Model		K	RHO	Texp	Tref	GE

-------	---	-------	--	----------	---------	----------	------	-------	--

Describer	Meaning
MID	Identification number of a MATHE entry. (Integer > 0; no Default)
Model	Select hyperelastic material model from (Character; Default = Mooney):
Mooney	for generalized Mooney-Rivlin hyperelastic model. See Remark 1.
Ogden	for Ogden hyperelastic model. See Remark 2.
Foam	for foam model. See Remark 3.
Aboyce	for Arruda-Boyce strain energy model. See Remarks 4. and 17.
Gent	for Gent strain energy model. See Remarks 5. and 17.
GHEM1	Invariant-base user subroutine (foam models only) $W = W(I_1, I_2, I_3)$
GHEM2	Principal-stretch based user subroutine (foam models only) $W = W(\lambda_1, \lambda_2, \lambda_3)$
GHEM3	Invariant-based with volumetric and deviatoric split user subroutine (foam models only) $W = W_{dev}(I_1, I_2) + U(J)$
GHEM4	Principal-stretch based with volumetric and deviatoric split user subroutine (foam models only) $W = W_{dev}(\bar{\lambda}_1, \bar{\lambda}_2, \bar{\lambda}_3) + U(J)$
GHEM5	Invariant-based with deviatoric part only (rubber models only) $W = W_{dev}(I_1, I_2)$

Describer	Meaning
GHEM6	<p>Principal-stretch based with deviatoric part only (rubber models only)  <math>W = W_{dev}(\bar{\lambda}_1, \bar{\lambda}_2, \bar{\lambda}_3)</math></p> <p>where <math>I_1, I_2, I_3</math> (<math>\lambda_1, \lambda_2,</math> and <math>\lambda_3</math>) are strain invariants (principal stretches), and <math>\bar{I}_1</math> and <math>\bar{I}_2</math> (<math>\bar{\lambda}_1, \bar{\lambda}_2,</math> and <math>\bar{\lambda}_3</math>) are their deviatoric parts, defined by <math>\bar{I}_1 = J^{-2/3} I_1</math> and <math>\bar{I}_2 = J^{-4/3} I_2, \bar{\lambda}_i = J^{-1/3} \lambda_i</math> (<math>i = 1, 2, 3</math>); <math>J</math> is the determinant of the deformation gradient.            For GHEMi models, see Remarks 13., 14., and 15.</p>
NOT	Number of terms to be used in Ogden and Foam model. ( $0 < \text{Integer} \leq 5$ ; Default = 1)
K	Specifies a bulk modulus. See Remarks 7. and 16. (Real > 0 or -1.0; Default = automatically set for nearly incompressible condition. Enter -1.0 if nonlinear volumetric strain energy function defined by Di will be used.
RHO	Mass density in original configuration. (Real; Default = 0.0)
Texp	Coefficient of thermal expansion. See Remark 8. (Real; Default = 0.0)
Tref	Reference temperature at which the thermal expansion coefficient is measured. Tref is used only if the thermal expansion coefficient is temperature-dependent. (Real; Default = 0.0)
GE	<p>If GE is real it represents the structural damping coefficient. See Remark 12. (Real; Default = 0.0).            For SOL 600 only, if GE is integer, it represents the form of the user subroutine uelastomer.f as follows:</p> <ol style="list-style-type: none"> <li>1 Foam Material - Invariant-based model  <math>W = W(I_1, I_2, I_3)</math></li> <li>2 Foam Material - Principal stretch based  <math>W = W(\lambda_1, \lambda_2, \lambda_3)</math></li> <li>3 Foam Material -Invariant-based with volumetric and deviatoric split  <math>W = W_{dev}(\bar{I}_1, \bar{I}_2) + U(J)</math></li> <li>4 Foam Material - Principal stretch with volumetric and deviatoric split  <math>W = W_{dev}(\bar{\lambda}_1, \bar{\lambda}_2, \bar{\lambda}_3) + U(J)</math></li> <li>5 Rubber Material (Mooney, Arruda-Boyce or Gent) - Invariant based  <math>W = W_{dev}(\bar{I}_1, \bar{I}_2)</math></li> <li>6 Rubber Material (Ogden) - Principal stretch based)  <math>W = W_{dev}(\bar{\lambda}_1, \bar{\lambda}_2, \bar{\lambda}_3)</math></li> </ol>

Describer	Meaning
	<p>where <math>I_1, I_2,</math> and <math>I_3</math> (<math>\lambda_1, \lambda_2,</math> and <math>\lambda_3</math>) are strain invariants (principal stretches), and <math>\bar{I}_1</math> and <math>\bar{I}_2</math> (<math>\bar{\lambda}_1, \bar{\lambda}_2,</math> and <math>\bar{\lambda}_3</math>) are their deviatoric parts, defined by <math>\bar{I}_1 = J^{-2/3} I_1</math> and <math>\bar{I}_2 = J^{-4/3} I_2, \bar{\lambda}_i = J^{-1/3} \lambda_i</math> (<math>i = 1, 2, 3</math>); <math>J</math> is the determinant of the deformation gradient. If GE is integer, Bulk Data entry USRSUB6 is also required (see <i>Marc Volume D</i> for more details.)</p>
NA	Order of the distortional strain energy polynomial function. See Remark 6. ( $0 < \text{Integer} < \text{or} = 5$ ; Default = 2; Default = 5 for SOL 600)
ND	Order of the Volumetric strain energy polynomial function. See Remark 6. ( $0 < \text{Integer} < \text{or} = 5$ ; Default = 1; Default = 5 for SOL 600)
Cij	Material constants related to distortional deformation for generalized Mooney-Rivlin model. (Real; Default = 0.0) SOL 600 uses only five constants (C10, C01, C20, C11, and C30) and ignores others.
Di	Material constants related to volumetric deformation. (Real $\geq 0.0$ ) Needed only if $K = -1.0$ . Not used for foam model. See Remark 7. For SOL 600, only Mooney model supports nonlinear volumetric strain energy function.
TAB1	Table identification number of a TABLES1 entry that contains simple tension-compression data to be used in the estimation of the material constants Cij. The x-values in the TABLES1 entry must be stretch ratios $l/l_0$ and y-values must be values of the engineering stress $F/A_0$ . $l_0$ is the initial length and $A_0$ is the initial cross-sectional area. See Remark 9. (Integer $> 0$ or blank)
TAB2	Table identification number of a TABLES1 entry that contains equibiaxial tension data to be used in the estimation of the material constants Cij. The x-values in the TABLES1 entry must be stretch ratios $l/l_0$ and y-values must be values of the engineering stress $F/A_0$ . $l_0$ is the initial length and $A_0$ is the initial cross-sectional area. See Remark 9. (Integer $> 0$ or blank)
TAB3	Table identification number of a TABLES1 entry that contains simple shear data to be used in the estimation of the material constants Cij. The x-values in the TABLES1 entry must be values of the shear strain and y-values must be values of the engineering shear stress. (Integer $> 0$ or blank)
TAB4	Table identification number of a TABLES1 entry that contains pure shear data to be used in the estimation of the material constants Cij. The x and y values in the TABLES1 entry must be stretch ratios $\lambda_1 = l/l_0$ and the values of the nominal stress $F/A_0$ . $l_0$ and $A_0$ are the initial length and cross-sectional area, respectively, in the l-direction. See Remark 9. (Integer $> 0$ or blank)

Describer	Meaning
TABD	Table identification number of a TABLES1 entry that contains pure volumetric compression data to be used in the estimation of the material constant Di. The x-values in the TABLES1 entry must be values of the volume ration $J = \lambda^3$ where $\lambda = l/l_0$ is the stretch ratio in all three directions; y-values must be values of the pressure, assumed positive in compression. See Remark 9. (Integer > 0 or blank)
Muk	Coefficients $\mu_k$ of the strain energy function for Ogden or foam material. See Remarks 2. and 3. (Real; Default = 0)
Alphak	Coefficients $\alpha_k$ of the strain energy function for Ogden or foam material. See Remarks 2. and 3. (Real; Default = 0)
Betak	Coefficients $\beta_k$ of the strain energy function for foam material. These fields should be left blank for Ogden mode. See Remarks 2. and 3. (Real; Default = 0)
NTK	Material constant for Arruda-Boyce strain energy model. (Real > 0; Default = 1)
N/E	Material constant representing the number (N) of statistical links of the chain for Arruda-Boyce model; or tensile modulus (E) for Gent strain energy model. (Real > 0; Default = 1)
Im	Maximum first invariant for Gent strain energy model. (Real > 0; Default = 0)

Remarks:

- The generalized Mooney-Rivlin strain energy function may be expressed as follows:

$$W(J, \bar{I}_1, \bar{I}_2) = \sum_{i+j=1}^3 C_{ij}(\bar{I}_1 - 3)^i (\bar{I}_2 - 3)^j + 4.5K(J^{1/3} - 1)^2$$

with

$$\bar{I}_1 = \bar{\lambda}_1^2 + \bar{\lambda}_2^2 + \bar{\lambda}_3^2$$

$$\bar{I}_2 = \bar{\lambda}_1^2 \bar{\lambda}_2^2 + \bar{\lambda}_2^2 \bar{\lambda}_3^2 + \bar{\lambda}_3^2 \bar{\lambda}_1^2$$

where  $K$  and  $J$  are bulk modulus and volume ratio, respectively.

For small strains, the shear modulus  $G$  is related to the Mooney-Rivlin constants by

$$G = 2(C_{10} + C_{01}) \text{ with } C_{01} \approx 0.25 C_{10}$$

The model reduces to a Mooney-Rivlin material with only two constants ( $C_{10}$  and  $C_{01}$ ), and to a Neo-Hookean material with one constant ( $C_{10}$ ). The third order Mooney-Rivlin model in SOL 600 uses only five distortional constants ( $C_{10}$ ,  $C_{01}$ ,  $C_{11}$ ,  $C_{20}$ ,  $C_{30}$ ) and the bulk modulus  $K$  for volumetric deformation. Instead of MATHE, the hyperelastic material can be specified using MATHP Bulk Data entry in SOLs 106, 129, and 600.

2. For the Ogden material model, the strain energy function is

$$W = \sum_{k=1}^5 \frac{\mu_k}{\alpha_k} (\bar{\lambda}_1^{\alpha_k} + \bar{\lambda}_2^{\alpha_k} + \bar{\lambda}_3^{\alpha_k} - 3) + 4.5K(J^{1/3} - 1)^2$$

where  $\alpha_k$  and  $\mu_k$  are the moduli and exponent constants, while  $\bar{\lambda}_i$  is the deviatoric stretch ratio defined as:

$$\bar{\lambda}_i = J^{-\frac{1}{3}} \lambda_i$$

and  $J$  and  $K$  are the determinant of the deformation gradient and the bulk modulus, respectively. A two-term Ogden model is equivalent to a simple Mooney-Rivlin model

$$\begin{aligned} \mu_1 &= 2C_{10} \quad \text{and} \quad \mu_2 = 2C_{01} \\ \text{with} \quad \alpha_1 &= 2. \quad \text{and} \quad \alpha_2 = 2. \end{aligned}$$

3. For foam material model, the distortional strain energy function is the same as Ogden. The volumetric energy function of foam model is defined by a polynomial function with coefficients  $\beta_i$
4. For the Arruda-Boyce model, the strain energy function is

$$W = N_{KT} \left[ \frac{1}{2} (\bar{I}_1 - 3) + \frac{1}{20N} (\bar{I}_1^2 - 9) + \frac{1}{1050N^2} (\bar{I}_1^3 - 27) + \frac{19}{7000N} (\bar{I}_1^4 - 81) + \frac{519}{67375N^4} (\bar{I}_1^5 - 243) \right] + 4.5K(J^{1/3} - 1)^2$$

$$\text{with } \bar{I}_1 = \bar{\lambda}_1^2 + \bar{\lambda}_2^2 + \bar{\lambda}_3^2$$

where  $N_{KT}$  is a material constant and  $N$  is a material parameter representing the number of statistical links of the material chain.

If the material test data are available from multiple experiments such as uniaxial and equi-biaxial tests, the Ogden model is more accurate in fitting experimental results. If only uniaxial tension data is available, the Arruda-Boyce model provides more accurate data fitting for multiple modes of deformation.

5. For the Gent model, the strain energy function is

$$W = -\frac{1}{6}EI_m \log \left[ \frac{I_m}{I_m - \bar{I}_1 + 3} \right]$$

where  $E$  and  $I_m$  are tensile modulus and maximum first invariant, respectively.

6. The curve fitting is activated if any of the TAB1, TAB2, TAB3, TAB4 and/or TABD are specified. The NA and ND fields are used in case of the curve fitting for Mooney from the experimental data.
7. Although the conventional Mooney-Rivlin and Neo-Hookean materials are fully incompressible, SOL 600 provides a compressible rubber model. Nearly incompressible material may be simulated with a large value of  $K$ . The default value for the Mooney-Rivlin model represents a nearly incompressible condition, which is  $K = 10^4 (C10 + C01)$ . In case of Ogden model, the default is  $2500 \cdot \sum \mu_k \alpha_k$ . If any of the  $D_i$  are non-zero, then the entered value of the Bulk Modulus must be -1.0 and the nonlinear volumetric strain energy function will be used. See Remark 16.
8. The thermal expansion coefficient is a secant value measured with respect to a temperature,  $T_{ref}$ .

$$\text{The thermal strain is computed by } \varepsilon_{th} = \bar{\alpha}(T - T_0)$$

where  $T_0$  is an initial temperature. The secant coefficient of thermal expansion is related to the instantaneous coefficient of thermal expansion by

$$\alpha = \frac{d\varepsilon_{th}}{dT} = \bar{\alpha} + \frac{d\bar{\alpha}}{dT}(T - T_0)$$

The choice of secant or instantaneous coefficient (CTE) of thermal expansion is determined by PARAM, MARALPHA in SOL 600. All CTE's in SOL 600 models must be either secant or instantaneous.

9. All the material constants may be obtained from least squares fitting of experimental data. One or more of four experiments (TAB1 to TAB4) may be used to obtain constants for distortional properties. The bulk modulus  $K$  may be obtained from pure volumetric compression data (TABD). If all TAB1 through TAB4 fields are blank, the material constants must be specified by the user. Parameter estimation, specified through any of the TABLES1 entries, supersedes the manual input of the parameters. It is recommended that the GUI be used to determine the materials constants, so one can visualize the correlation between the numerical representation and the experimental data. It is recommended that the experimental data span the range of anticipated strains to reduce the chances of adverse numerical calculations.
10. All the alphanumeric fields are recognizable by the first four letters.
11. Enter NKT and N/E for Aboyce (leave  $I_m$  blank). Enter N/E and  $I_m$  for Gent (leave NKT blank).
12. For SOL 600, Bulk Data entry USRSUB6 is also required.

13. The GHEMi models using the user subroutine are only available if the updated Lagrange formulation is used for the hyperelastic material. The user subroutine MD UELASTOMER defined with the GHEMi must be used along with the Bulk Data entry MATUDS.
14. The GHEMi are not available for plane stress, shell, membrane, and beam elements.
15. For the GHEM3 and GHEM4 models, the user subroutine is called twice, once with either a 3 or 4 to evaluate the deviatoric strain energy and once with a 7 to evaluate the volumetric strain energy.
16. The series representation of the volumetric strain energy is only available for the updated Lagrange formulation.
17. The Gent and Arruda-Boyce models are not available for plane stress, shell, membrane, and beam elements.
18. The Ogden, Foam, Arruda-Boyce and Gent models are not available in SOLs 106 and 129.
19. In SOL 400, MATHE is only supported for nonlinear elements with property extensions. This implies that for such elements, PBEAM / PBEAML, PCOMP / PCOMPG, PROD, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PBEMN1, PSHLN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Also, for incompressible rubber models, linear 2D triangular elements specified on PSHLN2 and 3D tetrahedral elements specified on PSLDN1 should be associated with an incompressible formulation (IPS for 2D plane strain, IAX for 2D axisymmetric and ISOL for 3D tetrahedral). Note that only PSOLID with PSLDN1 should be used for 3D solid nonlinear elements and PLSOLID cannot be used for MATHE. Note also that, prior to MD Nastran 2010, if the property extensions were missing, then the analysis would stop with an error. From MD Nastran 2010 onwards, if the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.
20. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.

#### Notes (SOL 600 only):

1. The structural damping constant GE is specified in Marc under the option DAMPING as a numerical damping  $\gamma$ , i.e.,

$$C = \alpha M + \left( \beta + \frac{2\gamma}{\omega} \right) K$$

in which  $2\gamma$  is equivalent to GE;  $\alpha$  and  $\beta$  are equivalent to user parameters ALPHA1 and ALPHA2.

2. Material curve-fitting from experimental data is not supported in SOL 400. Direct material property input is required.
3. This Bulk Data entry accommodates Marc's input data under the model definition options MOONEY, OGDEN, and FOAM as well as the parameter ELASTICITY. It also accommodates MATHP input data in Nastran.

**MATHE** Hyperelastic Material Properties - SOL 700

Specifies hyperelastic (rubber-like) material properties for nonlinear analysis. Use SOL700 only.

**Format 1 (default): Mooney-Rivlin Model (Model=Mooney1)**

1	2	3	4	5	6	7	8	9	10

Descriptor	Contents
MID	Material identification number. (Integer > 0; required.)
Model	Select hyperelastic material model from (Character; Default = Mooney1) Mooney1 Mooney-Rivlin hyperelastic model. It is only available for solid elements. See Remark 1. Ogden1 Ogden hyperelastic model. It is only available for solid elements. See Remark 2. FOAM1 Isotropic elastic foam material. It is only available for solid elements. See Remarks 3.-8.
RHO	Density. (Real > 0; required)
A	Strain-energy density function constant. (Real; required)
B	Strain-energy density function constant. (Real; required)
NU	Poisson's ratio. ( $0.0 \leq R < 0.5$ ; required)
MU1-MU8	Strain energy density function coefficients. MU1 is required. (Real; default=0.0)
ALPHA1-ALPHA8	Strain energy density function coefficients. ALPHA1 is required. (Real; default=0.0)
TYPE	The type of data defined as the x-value in the table. (Real > 0.0; default=1.0) 1.0 Crush factor. (= 1-relative volume) 2.0 True strain
VALUE	The value for cut-off stress. (Real $\leq$ 0.0; default=-0.1 $\times$ Young's modulus)
CUTOFF	Cut-off stress. (Real > 0.0; default=3.0) 1.0 Stress for tensile failure 2.0 Minimum stress 3.0 Not used
TABLE	TABLED1 ID defining the variation of stress (y-value) with crush factor or true strain (x- value). (Integer > 0; required)
TABY	TABLED1 ID giving the variation of the scale factor for the stress (y-value) with the strain rate (x-value). (Integer > 0; default=not used)
ALPHA	Energy dissipation factor. ( $0.0 \leq \text{Real} \leq 1.0$ ; default=0.0)
UNLOAD	Unloading option. (Real > 0.0; default=3.0) 1.0 Unloading via exponential curve 2.0 Unloading via piecewise linear curve 3.0 Unloading via quadratic curve

Remarks:

1. The Mooney-Rivlin constitutive behavior of this material is defined as a total stress/total strain relationship. The nonlinear elastic material response is formulated by a strain-energy density function for large strain components rather than by Hooke's law.

The strain-energy density function is formulated according to the Mooney-Rivlin model and is

$$\text{defined as } W(I_1, I_2, I_3) = A(I_1 - 3) + B(I_2 - 3) + C\left(\frac{1}{I_3} - 1\right) + D(I_3 - 1)^2$$

$$C = \frac{1}{2}A + B$$

The constants C and D are defined as:

$$D = \frac{A(5\nu - 2) + B(11\nu - 5)}{2(1 - 2\nu)}$$

where  $A$ ,  $B$  and  $\nu$  are input parameters.

$I_1$ ,  $I_2$  and  $I_3$  are strain invariants in terms of stretches.

For a rubber-like material, the shear modulus  $G$  is much less than the bulk modulus  $K$ . As a result, Poisson's ratio is nearly equal to one half.

2. The constitutive behavior of this material is defined as a total stress/total strain relationship. The nonlinear elastic material response is formulated by a strain-energy density function for large strain components using Ogden function.

The strain-energy density function is formulated according to the Ogden model and is defined as

$$W = \sum_{i=1}^3 \sum_{j=1}^8 \frac{\mu_j}{\alpha_j} (\bar{\lambda}_i^{\alpha_j} - 1) + \frac{1}{2}K(J - 1)^2$$

The over bar (-) indicates that the volumetric effects have been eliminated from the principal stretches.

3. Poisson's ratio for FOAM1 model is effectively zero. Therefore, the shear and elastic moduli are calculated from  $K$ , the bulk modulus.
4. For this model, the stress-strain curve is independent of the experimental test performed to obtain the material data (uniaxial, shear, or volumetric). The most common test is the uniaxial compression test where the stress-strain characteristic can either be defined in terms of the amount of crush, which is minus the engineering strain, or in terms of the true strain. Since Poisson's ratio is effectively zero, the

amount of crush is defined as  $\left(1 - \frac{V}{V_0}\right)$ , with  $\left(\frac{V}{V_0}\right)$  as the relative volume, and the true strain is

$$\text{defined as } \int_{t_0}^t \frac{dV}{V} \text{ or } \ln\left(\frac{V}{V_0}\right)$$

The crush factor must be between 0 and 1. The true strain must always be negative and the stress positive (absolute value).

5. The yield surface in three-dimensional space is a sphere in principal stresses, and is defined by

$$\tau_{11}^2 + \tau_{22}^2 + \tau_{33}^2 = R_s^2$$

where the radius of the sphere,  $R_s$ , depends on the strains and strain rates as follows:

$$R_s = f_1(R_e)f_2(R_r)$$

$$\text{with } R_e = \varepsilon_{11}^2 + \varepsilon_{22}^2 + \varepsilon_{33}^2$$

$$\text{and } R_r = \dot{\varepsilon}_{11}^2 + \dot{\varepsilon}_{22}^2 + \dot{\varepsilon}_{33}^2$$

and  $f_1$  is the function supplied in the stress-strain table and  $f_2$  (if defined) is the function supplied in the factor-strain rate table.

6. A minimum (CUTOFF=2.0) or failure (CUTOFF=1.0) tensile stress can be defined. In the first case this corresponds to a tensile cut-off where the stress cannot fall below the minimum value. In the second case, if the stress falls below the failure stress the element fails and cannot carry tensile loading for the remainder of the analysis. Thus the stress can never become negative again.
7. The unloading behavior is piecewise linear (UNLOAD=2.0), quadratic (UNLOAD=3.0) or exponential (UNLOAD=1.0). The unloading curve is constructed such that the ratio of the dissipated energy (area between compressive loading and unloading curve) to total energy (area under the loading curve) is equal to the energy dissipation factor alpha. In the case of piecewise linear unloading, Nastran SOL700 constructs an unloading curve whose segments are parallel to the supplied compression table, except for the first and last segments, which pass respectively through the origin and the point P on the compression curve where the unloading starts. In the case of quadratic unloading, Nastran SOL700 constructs a quadratic curve starting in the origin and ending in point P. If the quadratic unloading curve falls below the strain axis, then the unloading stress is set to zero. In the case of exponential unloading, the unloading curve is constructed in a similarly to quadratic unloading except for the shape of the curve, which is created from an exponential function instead of a quadratic polynomial.
8. Not default values for taby, alpha, unload options are allowed only when cutoff is set to 1.0 or 2.0.

**MATHED****Damage Model Properties for Hyperelastic Materials - SOL 600**

Specifies damage model properties for hyperelastic materials to be used for static, quasi static or transient dynamic analysis in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATHED	MID	method	Scale1	Relax1	Prop1	Scale2	Relax2	Prop2	
	Dinf	N/A	Scalem1	Relaxm1	N/A	Scalem2	Relaxm2		

Example:

MATHED	100		1.	0.3	0.5	0.8	0.4	1.0	
--------	-----	--	----	-----	-----	-----	-----	-----	--

Describer	Meaning
MID	Identification number of MATHE entry. See Remark 1. (Integer > 0)
Method	Select a method for damage calculation (Character) from: <b>Multip</b> for multiplicative decomposition. (Default) <b>Additiv</b> for additive decomposition. See Remarks 2. and 3.
Scale1,2	Scaling factor $d_n$ for n=1 or 2 in Kachanov factor $K(\alpha, \beta)$ described in Remark 3. (Real $\geq 0.0$ ; < 1.0; Default = 0.0)
Relax1,2	Relaxation rate $\eta_n$ for n=1 or 2 in Kachanov factor $K(\alpha, \beta)$ described in Remark 3. (Real $\geq 0$ or blank)
Prop1,2	Proportionality factor $\delta_n$ for n=1 or 2 in Kachanov factor $K(\alpha, \beta)$ described in Remark 3. See Remark 4. (Real > 0.0; Default = 1.0)
Dinf	$d^\infty$ described in the equations of Remark 3. If Blank, the program will compute it; however even if set, the program usually calculates it. In most cases $d^\infty = 1.0$ -scale1-scale2. (Real > 0.0 or blank)
Scalem1,2	Scaling factor $d_m$ for m=1 or 2 in Kachanov factor $K(\alpha, \beta)$ described in Remark 3. (Real $\geq 0.0$ ; Default = 0.0)
Relaxm1,2	Relaxation rate $\lambda_m$ for m=1 or 2 in Kachanov factor $K(\alpha, \beta)$ described in Remark 3. (Real > 0.0 or blank)

Remarks:

- The MATHE Bulk Data entry with the same MID must exist for MATHED to be effective.  
The damage capability is available for all the elastomeric materials (Mooney-Rivlin, Ogden, Gent, Arruda-Boyce).

2. Under repeated application of loads, elastomers undergo damage by mechanisms involving chain breakage, multi-chain damage, micro-void formation, and micro-structural degradation due to detachment of filler particles from the network entanglement. The damage model for elastomeric materials is based on the undamaged strain energy function  $W_0$ , multiplied by a Kachanov damage factor,  $K$ , i.e.,

$$W = K(\alpha, \beta)W_0$$

where  $\alpha$  and  $\beta$  are parameters for discontinuous and continuous damage models, respectively. Two types of phenomenological models, discontinuous and continuous, exist to simulate the damage. The discontinuous damage model simulates the “Mullins’ effect,” which involves a loss of stiffness (represented by a parameter  $\alpha$ ) below the previously attained maximum strain. The higher the maximum attained strain the larger the loss of stiffness is. There is a progressive stiffness loss with increasing maximum strain amplitude. Most of the stiffness loss takes place in the first few cycles provided the maximum strain level is not increased. This phenomenon is observed in both filled as well as natural rubber although the higher level of carbon black particles increases the hysteresis and the loss of stiffness. The continuous damage model (Miehe’s formulation) can simulate the damage accumulation for strain cycles for which the values of effective energy is below the maximum attained value of the past history. The evolution of continuous damage parameter is governed by the arc-length of the effective strain energy, represented by a parameter  $\beta$ .

Discontinuous Damage

Continuous Damage

3. Both the continuous damage as well as the discontinuous damage can be modeled by a cumulative Kachanov factor in multiplicative or additive decomposition form.

For multiplicative decomposition

$$K(\alpha, \beta) = d^\infty + \sum_{n=1}^2 d_n \exp\left(-\frac{\alpha + \delta_n \beta}{\eta_n}\right)$$

For additive decomposition

$$K(\alpha, \beta) = d^\infty + \sum_{n=1}^2 d_n^\alpha \exp\left(-\frac{\alpha}{\eta_n}\right) + \sum_{m=1}^2 d_m^\beta \exp\left(-\frac{\beta}{\lambda_m}\right)$$

where  $d_n$ ,  $\delta_n$ ,  $\eta_n$ ,  $d_m$ , and  $\lambda_m$  are constants specified by the user, and  $d^\infty$  is calculated by the program such that the Kachanov factor assumes a value of unity at zero damage if left blank.

4. The proportionality factor is not used by additive decomposition which requires the continuation fields to include the continuous damage model.
5. User subroutines must be called out using PARAM,MARCUSUB,CHAR where CHAR is a character variable such as UDAMAG.

**Note:**

1. This Bulk Data entry accommodates Marc's input data under the model definition option DAMAGE.

## MATHP

## Hyperelastic Material Properties

Specifies material properties for use in fully nonlinear (i.e., large strain and large rotation) hyperelastic analysis of rubber-like materials (elastomers).

Format:

1	2	3	4	5	6	7	8	9	10
MATHP	MID	A10	A01	D1	RHO	AV	TREF	GE	
		NA	ND						
	A20	A11	A02	D2					
	A30	A21	A12	A03	D3				
	A40	A31	A22	A13	A04	D4			
	A50	A41	A32	A23	A14	A05	D5		
	TAB1	TAB2	TAB3	TAB4				TABD	

Example:

MATHP	2	80.	20						
		1	1						

Describer	Meaning
MID	Identification number of a MATHP entry. (Integer > 0; No Default)
Aij	Material constants related to distortional deformation. (Real; Default = 0.0)
Di	Material constants related to volumetric deformation. (Real ≥ 0; Default for D1 is $10^3 \cdot (A10 + A01)$ ; Default for D2 through D5 is 0.0.)
RHO	Mass density in original configuration. (Real; Default = 0.0)
AV	Coefficient of volumetric thermal expansion. (Real; Default = 0.0)
TREF	Reference temperature. See <a href="#">MATBV, 2172</a> . (Real; Default = 0.0)
GE	Structural damping element coefficient. (Real; Default = 0.0)
NA	Order of the distortional strain energy polynomial function. (0 < Integer ≤ 5; Default = 1)
ND	Order of the volumetric strain energy polynomial function. (0 < Integer ≤ 5; Default = 1)
TAB1	Table identification number of a TABLES1 entry that contains simple tension/compression data to be used in the estimation of the material constants Aij. xi values in the TABLES1 entry must be stretch ratios $l/l_0$ and yi values must be values of the engineering stress $F/A_0$ . Stresses are negative for compression and positive for tension. (Integer > 0 or blank)

Describer	Meaning
TAB2	Table identification number of a TABLES1 entry that contains equibiaxial tension data to be used in the estimation of the material constants $A_{ij}$ . $x_i$ values in the TABLES1 entry must be stretch ratios $l/l_0$ . $y_i$ values must be values of the engineering stress $F/A_0$ . $l$ is the current length, $F$ is the current force, $l_0$ is the initial length and $A_0$ is the cross-sectional area. In the case of pressure of a spherical membrane, the engineering stress is given by $Pr_0\lambda^2/2t_0$ where $P$ = current value of the pressure and $r_0, t_0$ = initial radius and thickness. (Integer > 0 or blank)
TAB3	Table identification number of a TABLES1 entry that contains simple shear data to be used in the estimation of the material constants $A_{ij}$ . $x_i$ values in the TABLES1 entry must be values of the shear tangent $\gamma$ and $y_i$ values must be values of the engineering shear stress $F/A_0$ . (Integer > 0 or blank)
TAB4	Table identification number of a TABLES1 entry that contains pure shear data to be used in the estimation of the material constants $A_{ij}$ . $x_i$ and $y_i$ values in the TABLES1 entry must be stretch ratios $\lambda_1 = l/l_0$ and values of the nominal stress $F/A_0$ . $l$ is the current length, $F$ is the current force, $l_0$ and $A_0$ are the initial length and cross-sectional area, respectively in the 1-direction. (Integer > 0 or blank)
TABD	Table identification number of a TABLES1 entry that contains pure volumetric compression data to be used in the estimation of the material constants $D_i$ . $x_i$ values in the TABLES1 entry must be values of the volume ratio $J = \lambda^3$ where $\lambda = l/l_0$ is the stretch ratio in all three directions; $y_i$ values must be values of the pressure, assumed positive in compression. (Integer > 0 or blank)

Remarks:

1. The generalized Mooney-Rivlin strain energy function may be expressed as follows:

$$U(J, \bar{I}_1, \bar{I}_2) = \sum_{i+j=1}^{NA} A_{ij}(\bar{I}_1 - 3)^i(\bar{I}_2 - 3)^j + \sum_{i=1}^{ND} D_i(J - 1 - AV(T - T_0))^{2i}$$

$$A_{00} = 0$$

where  $\bar{I}_1$  and  $\bar{I}_2$  are the first and second distortional strain invariants, respectively;  $J = \det F$  is the determinant of the deformation gradient; For small strains, the bulk modulus  $K$  and the shear modulus  $G$  are related to the Mooney-Rivlin Material.

$2D1 = K$  and  $2(A10 + A01) = G$  at small strains, in which  $K$  is the bulk modulus and  $G$  is the shear modulus. The model reduces to a Mooney-Rivlin material if  $NA=1$  and to a Neo-Hookean material if  $NA = 1$  and  $A01 = 0.0$ . See Remark 2. For Neo-Hookean or Mooney-Rivlin materials no continuation entry is required.  $T$  is the current temperature and  $T_0$  is the initial temperature.

2. Conventional Mooney-Rivlin and Neo-Hookean materials are fully incompressible. Full incompressibility is not presently available but may be simulated with a large enough value of D1. Note that a value of D1 lower than  $10^3 \cdot (A10 + A01)$  is, however, not recommended.
3. The material constants  $A_{ij}$  and  $D_i$  are obtained from least squares fitting of experimental data. One or more of four experiments (TAB1 to TAB4) may be used to obtain constants for distortional properties  $A_{ij}$ .  $D_i$  may be obtained from pure volumetric compression data (TABD). If all TAB1 through TAB4 are blank,  $A_{ij}$  must be specified by the user. Parameter estimation, specified through any of the TABLES1 entries, supercedes the manual input of the parameters.
4. IF ND=1 and a nonzero value of D1 is provided or obtained from experimental data in TABD, then the parameter estimation of the material constants  $A_{ij}$  takes compressibility into account in the cases of simple tension/compression, equibiaxial tension, and general biaxial deformation. Otherwise, full incompressibility is assumed in estimating the material constants.
5. See Chapters [Hyperelastic Elements](#), [Hyperelastic Material](#) and [Hyperelastic Material](#) in the *MSC Nastran Reference Guide* for further details.
6. In SOL400, MATHP is supported for 2 sets of elements:
  - a. Incompressible conventional 2D (plane strain and axisymmetric) elements and 3D (continuum) elements without property extensions. They are prescribed through PLPLANE and PLSOLID, respectively. The original element formulations that are also available in SOL106 are used in these cases.
  - b. Incompressible elements that are supported through property extensions. For such elements, PBAR / PBARL, PBEAM / PBEAML, PCOMP / PCOMPG, PROD, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PBARN1, PBEMN1, PSHLN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Also, for incompressible rubber models, 2D 3-node triangular elements and 3D 4-node tetrahedral elements should be associated with an incompressible formulation by specifying IPS for 2D plane strain and IAX for 2D axisymmetric elements in PSHLN2, as well ISOL for 3D tetrahedral element in PSLDN1.
7. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.

**Note:**

1. PLSOLID is only used with the elements in (a) and only PSOLID with PSLDN1 can be used for 3D solid nonlinear elements in (b).
2. Prior to MD Nastran 2010, if the property extensions were missing, the analysis would stop with an error. From MD Nastran 2010 onwards, if the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.

## MATNLE

## Advanced NLELAST Options - SOL 600

The MATNLEx entries specify advanced forms of nonlinear elastic materials. The simple NLELAST option uses MAT1, MATS1, TALBES1 in the same manner as data is entered for SOL 106 or SOL 129.

## Format 1: Standard Nastran NLELAST Model

Use NLELAST on MATS1 entry.

## Format 2: Invariant-based Material Model

TCLIM	ID of TABL3Di entry for CLIM vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
KIND	Tension/compression usage flag. (Integer; Default = 1) 1 = Both tension and compression data will be used 2 = Only tension data will be used
TYPE	Poisson ratio/Bulk Modulus flag. (Integer; Default = 1) 1 = Constant Poisson's ratio will be used 2 = Constant bulk modulus will be used
LIM	Stress limit flag. (Integer; Default = 0) 0 = Material has no tension or compression limits 1 = Material has tension limits 2 = Material has compression limits 3 = Material has both tension and compression limits
GE	Structural damping coefficient. (Real; Default = 0.0)
NAME	Material name. (Character; no Default) Optional name of the material, may be blank or as long as 16 characters.
EC	Young's modulus in compression. (Real; no Default)
PRC	Poisson's ratio in compression. (Real; no Default)
TEC	ID of TABL3Di entry for EC vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TPRC	ID of TABL3Di entry for PRC vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
E11	Orthotropic modulus E11. (Real; no Default)
E22	Orthotropic modulus E22. (Real; no Default)
E33	Orthotropic modulus E33. (Real; no Default)

Describer	Meaning
PR12	Orthotropic Poisson's ratio in 12 direction. (Real; no Default)
PR23	Orthotropic Poisson's ratio in 23 direction. (Real; no Default)
PR31	Orthotropic Poisson's ratio in 31 direction. (Real; no Default)
TE11	ID of TABL3Di entry for E11 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TE22	ID of TABL3Di entry for E22 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TE33	ID of TABL3Di entry for E33 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TPR12	ID of TABL3Di entry for PR12 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TPR23	ID of TABL3Di entry for PR23 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TPR31	ID of TABL3Di entry for PR31 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
G12	Orthotropic shear modulus G12. (Real; no Default)
G23	Orthotropic shear modulus G23. (Real; no Default)
G31	Orthotropic shear modulus G31. (Real; no Default)
A11	Orthotropic coefficient of thermal expansion in 1 direction. (Real; no Default)
A22	Orthotropic coefficient of thermal expansion in 2 direction. (Real; no Default)
A33	Orthotropic coefficient of thermal expansion in 3 direction. (Real; no Default)
TG12	ID of TABL3Di entry for G12 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TG23	ID of TABL3Di entry for G23 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TG31	ID of TABL3Di entry for G31 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TA11	ID of TABL3Di entry for A11 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TA22	ID of TABL3Di entry for A22 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)
TA33	ID of TABL3Di entry for A33 vs up to 4 variables such as strain, temperature, strain rate, ... (Integer; no Default; leave blank if table is not required)

Remarks:

1. The structural damping constant GE is specified in MARC under the option DAMPING as a numerical damping  $\gamma$ ,

$$C = \alpha M + \left( \beta + \frac{2\gamma}{\omega} \right) K$$

in which  $2\gamma$  is equivalent to GE;  $\alpha$  and  $\beta$  are equivalent to user parameters ALPHA1 and ALPHA2.

2. This Bulk Data entry accommodates MARC's input data under the model definition option NLELAST for material model types 2-6.
3. 3D tables associated with this entry should normally select independent variable 69 (equivalent mechanical strain) or 73 (any strain component) to define the stress-strain curve. Normally the only other independent 3D table variables used with this entry are 12 (temperature) or 16 (equivalent strain rate).
4. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.

## MATORT

## 3D Orthotropic Material Properties

Specifies orthotropic material properties. Parameters for both isotropic and anisotropic yield conditions can also be specified along with elastic material properties. Can be specified for all 3-D and 2-D continuum elements and shells in SOL400/600/700. Can also be specified with solid composite, solid shell composite and pyramid elements in all linear solution sequences between SOL101 and SOL112, and analysis only for SOL200.

Format:

1	2	3	4	5	6	7	8	9	10
MATORT	MID	E1	E2	E3	NU12	NU23	NU31	RHO	
	G12	G23	G31	A1	A2	A3	TREF	GE	
	IYLD	IHARD	SY		R11 or m	R22 or C1	R33 or C2	N/A	
	R12 or C3	R23 or C6	R31	N/A	N/A	N/A	N/A	N/A	
	OPTION	FILE	X1	Y1	Z1	X2	Y2	Z2	

Example:

MATORT	100	3.e6	2.8e7	1.5e5	0.25				
--------	-----	------	-------	-------	------	--	--	--	--

Describer	Meaning
MID	Identification number of a MATORT entry. (Integer > 0; No Default)
E1	Modulus of elasticity in longitudinal or 1-direction. See Remark 1. (Real > 0)
E2	Modulus of elasticity in lateral direction or 2-direction. (Real > 0; no Default; must be entered)
E3	Modulus of elasticity in thickness direction or 3-direction. (Real > 0; no Default; must be entered)
NU12	Poisson's ratio $\varepsilon_2/\varepsilon_1$ for uniaxial loading in 1-direction. See Remark 2. (Real; no Default; must be entered)
NU23	Poisson's ratio $\varepsilon_3/\varepsilon_2$ for uniaxial loading in 2-direction. (Real; no Default; must be entered)
NU31	Poisson's ratio $\varepsilon_1/\varepsilon_3$ for uniaxial loading in 3-direction. (Real; Default = NU23)
RHO	Mass density. (Real; Default = 0.0)
G12	Shear modulus in plane 1-2. See Remark 3. (Real > 0; no Default; must be entered)
G23	Shear modulus in plane 2-3. (Real > 0.; no Default; must be entered)
G31	Shear modulus in plane 3-1. (Real > 0; no Default; must be entered)
Ai	Coefficient of thermal expansion in i-direction (Real; Default = 0.0).

Describer	Meaning
TREF	Reference temperature at which the thermal expansion coefficient is measured. TREF is used only if the thermal expansion coefficient is temperature-dependent. (Real; Default = 0.0)
GE	Structural damping coefficient. (Real; Default = 0.0).
IYLD	Integer pertaining to one of the following yield criterion: (Integer)  -1 = Elastic 1 = von Mises (Default) 2 = Hill (1948) yield 3 = Barlat (1991) yield 4 = Viscoplasticity through user subroutine UVSCPL
IHARD	Integer pertaining to one of the following work hardening rules: (Integer) 1 = Isotropic (Default) 2 = Kinematic 3 = Combined Isotropic/Kinematic
SY	Equivalent (von Mises) tensile yield stress. (Real > 0 or blank; Default=10 <sup>20</sup> )
Rij	Stress ratios of initial yield stresses in various material directions to the reference yield stress. (Real > 0.0 or blank; Default = 1.0 for R11, R22, R33, R12, R23 and R31). See Hill's yield function in <i>MSC Nastran Nonlinear User's Guide</i> (SOL 400) for details.
m	Barlat exponent (Real > 0.0 or blank; Default = 2.0).
Ci	Barlat material coefficient (Real > 0.0 or blank; Default = 1.0 for C1, C2, C3 and C6). See Balart's yield function in <i>MSC Nastran Nonlinear User's Guide</i> (SOL 400) for details.

Describer	Meaning
-----------	---------

OPTION Material axes option used to determine how the local material axis system is defined. See Remark 7. (Character; default=ELEM)

VECT

Globally orthotropic with the material axes defined by two vectors V1 and V2, specified using the fields X1, Y1, Z1 and X2, Y2, Z2. The a-axis is defined by the first vector. The b- and c-axes are then defined as:

ELEM

Globally orthotropic material with the material axes defined by element topology. Grid point 1 defines the origin, grid point 5 lies on the c-axis, and grid point 2 lies in the a-c plane. The a, b, and c axes are defined as follows:

ELMAT

Orthotropic material properties and the material coordinate system is defined by the element. The material properties are read from a formatted file. The filename is specified in the FILE field adjacent to OPTION.

Format of material properties file:

```
Record#
EID, DENSITY, DUMMY, DUMMY, DUMMY,
E1, E2, E3, G12, G23, G31,
NU12, NU13, NU23, NU21, NU31, NU32
```

ELPROP

Globally orthotropic material with the material axes defined by element topology (see also ELEM). The elasticity matrix is available per element.

Describer	Meaning
FILE	Material file name (OPTION=ELMAT only). See Remark 8.  (Character; default=blank)
X1, Y1, Z1	Components of the vector V1 in the basic coordinate system. See Remark 8. (Real; default=0.0)
X2, Y2, Z2	Components of the vector V2 in the basic coordinate system. See Remark 8. (Real; default=0.0)

### Remarks:

1. All the material constants are specified in the orthotropic material coordinates in 1, 2, and 3 direction.
2. In general,  $v_{12}$  is not the same as  $v_{21}$ , but they are related by  $v_{ij}/E_i = v_{ji}/E_j$ . Furthermore, material stability requires that

$$E_i > v_{ij}^2 E_j$$

$$\text{and } 1 - v_{12}v_{21} - v_{23}v_{32} - v_{31}v_{13} - 2v_{21}v_{32}v_{13} > 0.$$

3. It may be difficult to find all nine orthotropic constants. In some practical problems, the material properties may be reduced to normal anisotropy in which the material is isotropic in a plane, e.g., in plane 1-2 and has different properties in the direction normal to the plane 1-2. In the plane of isotropy, the properties are reduced to

$$E_1 = E_2 = E_p$$

$$v_{31} = v_{32} = v_{np}$$

$$v_{13} = v_{23} = v_{pn}$$

$$G_{13} = G_{23} = G_n$$

$$\text{with } v_{np}/E_n = v_{pn}/E_p \quad \text{and } G_p = \frac{E_p}{2(1 + \nu_p)}.$$

There are five independent material constants for normal anisotropy (e.g.,  $E_p$ ,  $E_n$ ,  $\nu_p$ ,  $\nu_{np}$ ,  $G_n$ ).

In case the material has a planar anisotropy, in which the material is orthotropic only in a plane, the elastic constants are reduced to seven, e.g.,  $E_1$ ,  $E_2$ ,  $E_3$ ,  $\nu_{12}$ ,  $G_{12}$ ,  $G_{23}$ ,  $G_{31}$ .

4. Do not enter values for SY, Rij, m and Ci unless plasticity is to be taken into account.
5. For elastoplastic case, MATORT only support perfect plasticity.
6. MATEP option is the recommended approach for elastoplastic materials.

7. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
8. OPTION, FILE, X1, Y1, Z1, X2, Y2 and Z2 fields are only supported by new SOL700.
9. New SOL700 based on Dytran does not support A1, A2, A3, TREF, GE, IYLD, IHARD, SY, Rij, m and Ci fields.

#### Notes:

1. The structural damping constant GE is specified as a numerical damping  $\gamma$ , i.e.,

$$C = \alpha M + \left( \beta + \frac{2\gamma}{\omega} \right) K$$

in which  $2\gamma$  is equivalent to GE.

2. This Bulk Data entry accommodates Marc's input data under the model definition option ORTHOTROPIC.

## MATPE1 Isotropic Poroelastic Material Property definition

Defines the material properties for an isotropic poroelastic material.

Format:

1	2	3	4	5	6	7	8	9	10
MATPE1	MID	MAT1	MAT10	BIOT	POROPT	SRHO			
	VISC	GAMMA	PRANDTL	POR	TOR	AFR	VLE	TLE	

Example:

MATPE1	101	1	10						
	1.84-8	1.4	7.13-1	9.5-1	1.4	2.5-5	9.32-2	9.32-2	

Describer	Meaning
MID	Material identification number, referenced by PSOLID entry. (Integer>0)
MAT1	Identification number of MAT1 (and MATF1 if it is frequency-dependent) entry for the skeleton (solid-phase) of porous material. (Integer>0, Required)
MAT10	Identification number of MAT10 entry for the fluid-phase of porous material. (Integer>0, Required)
BIOT	Biot factor. (Real>0.0, Default=1.0)
POROPT	Simplified porous options: LUMPED, RIGID, MIKI or DELANY
SRHO	Solid density for POROPT=LUMPED (Real≥0.0)
VISC	Fluid dynamic viscosity. See Remark 4. (Real>0.0, Required except for POROPT = "DELANY" or "MIKI")
GAMMA	Fluid ratio of specific heats. See Remark 5. (Real>0.0, Default=1.402)
PRANDTL	Fluid Prandtl number, Pr. See Remark 6. (Real>0.0, Default=0.71)
POR	Porosity of porous material. (Real>0.0, Required except for POROPT = "DELANY" or "MIKI")
TOR	Tortuosity of porous material. (Real>0.0, Default=1.0)
AFR	Air flow resistivity. (Real>0.0, Required)
VLE	Viscous characteristic length. (Real≥0.0, Default=0.0)
TLE	Thermal characteristic length. (Real≥0.0, Default=0.0)

### Remarks:

1. MATPE1 entry is referenced by PSOLID cards when FCTN=PORO. It is used to define the isotropic poroelastic material properties for both solid and fluid phases of a poroelastic medium.
2. MATPE1 entry must be put under BEGIN BULK TRMC.

3. For a frequency-dependent skeleton material, MATF1 specifies the material properties at frequencies on matching MAT1 fields.
4. Fluid dynamic viscosity, VISC, is temperature dependent. At 15°C (Celsius), its value is  $1.82 \times 10^{-6}$  N.s/m<sup>2</sup> in the SI units.
5. GAMMA is defined as  $C_p/C_v$ , where  $C_p$  is the specific heat at constant pressure and  $C_v$  the specific heat at constant volume. Its default value is 1.402 for the air at ambient temperature.
6. PRANDTL number, Pr, is defined as  $\mu C_p/k$  where  $\mu$  is the fluid dynamic viscosity (VISC) and  $k$  the thermal conductivity. For the dry air at ambient temperature, its value is around 0.7-0.8.
7. Porosity,  $\Omega$ , is defined as  $V_f/V_t$  where  $V_f$  is the volume of fluid and  $V_t$  is the total volume of the poroelastic material. Hence, porosity is dimensionless.
8. Tortuosity measures the complexity of the path an air particle must follow to process from one point to another point. It is a dimensionless parameter.
9. Resistivity measures the resistance of poroelastic material against the flow of fluid. In SI unit, it is measured in N.s/m<sup>4</sup>.
10. The density of poroelastic material is defined as  $\rho_{pem} = \Omega\rho_f + (1 - \Omega)\rho_s$  where  $\rho_f$  is the fluid density from MAT10 and  $\rho_s$  is the solid density from MAT1.
11. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
12. Assumptions for simplified BIOT porous material model are as follows:
 

LUMPED	the material skeleton can be assumed as extremely soft (E=0)
RIGID	the material skeleton can be assumed as rigid
MIKI or DELANY	Semi-empirical numerical mode; assuming porosity=1
13. MAT1 field should be left blank for POROPT=RIGID, MIKI or DELANY.
14. For POROPT=LUMPED, solid density can be provided either from MAT1 ID in MAT1 field or directly from SRHO field of MATPE1.

## MATRIG

## Rigid Material

Defines the properties of a rigid material in SOL 700.

Format:

1	2	3	4	5	6	7	8	9	10
MATRIG	MID	RHO	E	NU	MASS	XC	YC	ZC	
	IXX	IXY	IXZ	IYY	IYZ	IZZ	CID		
	VX	VY	VZ	WX	WY	WZ			
	XC-LOCAL	YC-LOCAL	ZC-LOCAL						

Example:

MATRIG	7	7850.	210.E9	0.3	750	0.0	7.0	-3.0	
	17.0	13.2	14.3	20.9	15.7	10.0	12		
			13.3						

Describer	Meaning	Type	Default
MID	Unique material number.	$I > 0$	Required
RHO	Density	$R > 0$	1.0
E	Young's modulus	$R > 0$	1.0
NU	Poisson's ratio	$0.0 < R < 0.5$	0.2
MASS	Mass of the rigid body.	$R > 0.0$	See Remark 2.
XC, YC, ZC	x, y, and z coordinates of the center of gravity.	R	See Remark 6.
IXX, IXY, IXZ, IYY, IYZ, IZZ	Inertia tensor of the rigid body about the center of gravity.	R	See Remark 6.
CID	Number of a coordinate system in which the inertia tensor and the center of gravity are defined.	$I > 0$	See Remarks 7. and 8.
VX, VY, VZ	Initial translational velocity of the center of gravity in the basic coordinate system.	R	0.0
WX, WY, WZ	Initial rotational velocities of the rigid body about the center of gravity in the basic coordinate system.	R	0.0
XC-LOCAL YC-LOCAL ZC-LOCAL	x, y, and z local coordinates of the center of gravity	R	See Remark 8.

Remarks:

1. All coordinates are defined in the basic coordinate system.

2. If MASS is blank or zero, the mass will be calculated from the density and the geometry of the mesh defining the rigid body.
3. The continuation lines are not required.
4. The MATRIG definition is used instead of a material definition and is referenced by properties PSOLIDn, PSHELLn, PBAR, and PBEAMn. Different properties can refer to the same MATRIG entry forming one rigid body.
5. If the fields VX, VY, VZ, WX, WY, and WZ are blank, then the initial conditions of the rigid body are calculated from the initial velocities on the TIC and TIC1 entries referring to grid points attached to the rigid body. The net initial conditions are the average of those for all the grid points attached to the rigid body.  
If the initial conditions are set using the VX, VY, VZ, WX, WY, and WZ fields, the TIC and TIC1 entries referring to grid points attached to the rigid body are ignored.
6. If the inertia tensor or the coordinates of the center of gravity are undefined, then they will be computed from the density or mass and the geometry of the mesh defining the rigid body.
7. The inertia tensor can only be defined in a local rectangular coordinate system. If the entry for a local coordinate system is left blank, then the inertia tensor is defined in the global coordinate system.
8. The center of gravity can be defined in a local rectangular coordinate system (CID). However, XC YC ZC (x, y, and z coordinates of the center of gravity in the basic coordinate system) should be left blank when XC-LOCAL YC-LOCAL ZC-LOCAL (x, y, and z coordinates of the center of gravity in a local coordinate system) defined.

## MATS1 Material Stress Dependence

Specifies stress-dependent material properties for use in applications involving nonlinear materials. This entry is used if a MAT1 entry is specified with the same MID in a nonlinear solution sequence (SOLs 106, 129 and 400). For SOL 400 the MATEP option is the recommended approach for elastic-plastic materials.

Format:

1	2	3	4	5	6	7	8	9	10
MATS1	MID	TID	TYPE	H	YF	HR	LIMIT1	LIMIT2	

Example:

MATS1	17	28	PLASTIC	0.0	1	1	2.+4		
-------	----	----	---------	-----	---	---	------	--	--

Describer	Meaning
MID	Identification number of a MAT1 entry. (Integer > 0)
TID	Identification number of a TABLES1 or TABLEST entry. If H is given, then this field must be blank. See Remark 3. (Integer ≥ 0 or blank)
TYPE	Type of material nonlinearity. See Remarks. (Character: “NLELAST” for nonlinear elastic or “PLASTIC” for elastoplastic.)
H	Work hardening slope (slope of stress versus plastic strain) in units of stress. For elastic-perfectly plastic cases, H = 0.0. For more than a single slope in the plastic range, the stress-strain data must be supplied on a TABLES1 entry referenced by TID, and this field must be blank. See Remark 2. (Real)
YF	Yield function criterion, selected by one of the following values (Integer): <ul style="list-style-type: none"> <li>1 von Mises (Default)</li> <li>2 Tresca</li> <li>3 Mohr-Coulomb</li> <li>4 Drucker-Prager</li> </ul>
HR	Hardening Rule, selected by one of the following values (Integer): <ul style="list-style-type: none"> <li>1 Isotropic (Default)</li> <li>2 Kinematic</li> <li>3 Combined isotropic and kinematic hardening</li> </ul>
LIMIT1	Initial yield point. See Table 9-26. (Real)
LIMIT2	Internal friction angle, measured in degrees, for the Mohr-Coulomb and Drucker-Prager yield criterion. See Table 9-26. (0.0 ≤ Real < 45.0)

Table 9-26 Yield Functions Versus LIMIT1 and LIMIT2

Yield Function (YF)	LIMIT1	LIMIT2
von Mises (1) or Tresca (2)	Initial Yield Stress in Tension, $Y_1$	Not used
Mohr-Coulomb (3) or Drucker-Prager (4)	2* Cohesion, $2c$ (in units of stress)	Angle of Internal Friction $\phi$ (in degrees)

Remarks:

1. If TYPE = “NLELAST”, then MID may refer to a MAT1 entry only. Also, the stress-strain data given in the TABLES1 entry will be used to determine the stress for a given value of strain. The values H, YF, HR, LIMIT1, and LIMIT2 will not be used in this case.

Thermoelastic analysis with temperature-dependent material properties is available for linear and nonlinear elastic isotropic materials (TYPE = “NLELAST”) and linear elastic anisotropic materials. Four options of constitutive relations exist. The relations appear in Table 19 along with the required Bulk Data entries.

Table 19 Constitutive Relations and Required Material Property Entries

Constitutive Relation	Required Bulk Data Entries
$\{\sigma\} = [G_e(T)]\{\varepsilon\}$	MAT1 and MATT1
$\{\sigma\} = \frac{\bar{E}(\sigma, \varepsilon)}{E} [G_e(T)]\{\varepsilon\}$	MAT1, MATT1, MATS1, and TABLES1
$\{\sigma\} = \frac{\bar{E}(T, \sigma, \varepsilon)}{E} [G_e]\{\varepsilon\}$	MAT1, MATS1, TABLEST, and TABLES1
$\{\sigma\} = \frac{\bar{E}(T, \sigma, \varepsilon)}{E} [G_e(T)]\{\varepsilon\}$	MAT1, MATT1, MATS1, TABLEST, and TABLES1

In Table 19  $\{\sigma\}$  and  $\{\varepsilon\}$  are the stress and strain vectors,  $[G_e]$  the elasticity matrix,  $\bar{E}$  the effective elasticity modulus, and  $E$  the reference elasticity modulus.

2. If TYPE = “PLASTIC”, the elastic stress-strain matrix is computed from MAT1 entry, and then the isotropic plasticity theory is used to perform the plastic analysis. In this case, either the table identification TID or the work hardening slope H may be specified, but not both. If the TID is omitted, the work hardening slope H must be specified unless the material is perfectly plastic. The plasticity modulus ( $H$ ) is related to the tangential modulus ( $E_T$ ) by

$$H = \frac{E_T}{1 - \frac{E_T}{E}}$$

where  $E$  is the elastic modulus and  $E_T = dY/d\varepsilon$  is the slope of the uniaxial stress-strain curve in the plastic region. See Figure 9-99.

Figure 9-99 Stress-Strain Curve Definition When H Is Specified in Field 5

3. If TID is given, TABLES1 entries ( $X_i, Y_i$ ) of stress-strain data ( $\varepsilon_k, Y_k$ ) must conform to the following rules (see Figure 9-100):
  - If TYPE = "PLASTIC", the stress-total strain curve (i.e., TYPE in TABLES1 must be 1) must be defined in the first quadrant. The first point must be at the origin ( $X_1 = 0, Y_1 = 0$ ) and the second point ( $X_2, Y_2$ ) must be at the initial yield point ( $Y_1$  or  $2c$ ) specified on the MATS1 entry. The slope of the line joining the origin to the yield stress must be equal to the value of  $E$ . Also, TID may not reference a TABLEST entry.

The stress-total strain curve has 2 different definitions

- For conventional element, small strain formulation in terms of engineering strain and stress is used. Therefore, engineering stress-strain curve should be used here.
- For advanced nonlinear element, large strain formulation in terms of logarithmic strain and true stress is adopted. Then true stress-logarithmic strain curve should be used.

Note that SOL 106 and SOL 129 supports conventional element only. SOL 400 supports both of the conventional and advanced elements.

For TYPE = "PLASTIC", it should be noted that for conventional elements, strains should be below .05 to small strain formulation. Within this strain range, difference between logarithmic strain and engineering strain may be negligible. If the element strains exceed .05, then it is recommended to use the MATEP entry which will automatically switch to a large strain formulation in SOL 400

For SOL 600, if use of the MATS1 entry is desired, then it should be used in conjunction with PARAM,MRTABLS1,value.

- If TYPE = "NLELAST", the full stress-strain curve ( $-\infty < x < \infty$ ) may be defined in the first and the third quadrant to accommodate different uniaxial compression data. If the curve is defined only in the first quadrant, then the curve must start at the origin (X1 = 0.0, Y = 0.0) and the compression properties will be assumed identical to tension properties.

Figure 9-100 Stress-Strain Curve Definition When TID Is Specified in Field 3

4. In SOL 400, MATS1 is supported for 2 sets of elements:

- a. Elements with no property extensions that are prescribed through PROD, PBEAML, PSHELL and PSOLID. The original small-strain element formulations that are also available in SOL106 are used in these cases.
- b. Large-strain elements that are supported through property extensions. For such elements, PBAR / PBARL, PBEAM / PBEAML, PCOMP / PCOMPG, PROD, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PBARN1, PBEMN1, PSHLN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Also, for TYPE = PLASTIC, linear 2D triangular elements specified on PSHLN2 and 3D tetrahedral elements specified on PSLDN1 should be associated with an incompressible formulation (IPS for 2D plane strain, IAX for 2D axisymmetric and ISOL for 3D tetrahedral. Note also that, prior to MD Nastran 2010, if the property extensions were missing, then for supported elements (i.e., PROD, PBEAML, PSHELL or PSOLID), the analysis would use the element formulations in (a), or ignore the MATS1 data for unsupported elements. From MD Nastran 2010 onwards, if the property extensions are missing, then they are automatically added with appropriate settings by the program unless the element belongs to group (a) or the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.

**MATS3**      Advanced Orthotropic, Nonlinear Elastic Materials for Axisymmetric Elements

Specifies NLELAST option for advanced orthotropic, nonlinear elastic materials at axisymmetric conditions in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
MATS3	MID	TEX	TETH	TEZ	TNUXTH	TNUTHZ	TNUZX	TRHO	
			TGZX	TAX	TATH	TAZ			

Example:

MATS3	33	56			67				
			12						

Describer	Meaning
MID	Identification number of a MAT3 entry. (Integer > 0; no Default)
TEX	ID of TABL3Di entry for EX. (Integer; no Default; leave blank if table is not required)
TETH	ID of TABL3Di entry for ETH. (Integer; no Default; leave blank if table is not required)
TEZ	ID of TABL3Di entry for EZ. (Integer; no Default; leave blank if table is not required)
TNUXTH	ID of TABL3Di entry for NUXTH. (Integer; no Default; leave blank if table is not required)
TNUTHZ	ID of TABL3Di entry for NUTHZ. (Integer; no Default; leave blank if table is not required)
TNUZX	ID of TABL3Di entry for NUZX. (Integer; no Default; leave blank if table is not required)
TRHO	ID of TABL3Di entry for RHO. (Integer; no Default; leave blank if table is not required)
TGZX	ID of TABL3Di entry for GZX. (Integer; no Default; leave blank if table is not required)
TAX	ID of TABL3Di entry for AX. (Integer; no Default; leave blank if table is not required)
TATH	ID of TABL3Di entry for ATH. (Integer; no Default; leave blank if table is not required)
TAZ	ID of TABL3Di entry for AZ. (Integer; no Default; leave blank if table is not required)

Remarks:

1. TABL3Di is a table where an entry can be a function of up to 4 variables such as strain, temperature, strain rate, etc.

2. In SOL 400, MATS3 is used in conjunction with MAT3 and is only supported for axisymmetric elements with property extensions. This implies that for such elements, PLPLANE should be associated with PSHLN2. Note that, prior to MD Nastran 2010, if the property extensions were missing, then the MATS3 data was not considered in the element's formulation. From MD Nastran 2010 onwards, if the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.

## MATS8 Advanced Orthotropic, Nonlinear Elastic Material for Shell Elements

Specifies NLELAST option for advanced orthotropic, nonlinear elastic material for plane stress and shell elements in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
MATS8	MID	TE1	TE2	TNU12	TG12	TG1Z	TG2Z	TRHO	
	TA1	TA2							

Example:

MATS8	34	12							
	1								

Describer	Meaning
MID	Identification number of a MAT8 entry. (Integer > 0; no Default)
TE1	ID of TABL3Di entry for E1. (Integer; no Default; leave blank if table is not required)
TE2	ID of TABL3Di entry for E2. (Integer; no Default; leave blank if table is not required)
TNU12	ID of TABL3Di entry for NU12. (Integer; no Default; leave blank if table is not required)
TG12	ID of TABL3Di entry for G12. (Integer; no Default; leave blank if table is not required)
TG1Z	ID of TABL3Di entry for G1Z. (Integer; no Default; leave blank if table is not required)
TG2Z	ID of TABL3Di entry for G2Z. (Integer; no Default; leave blank if table is not required)
TRHO	ID of TABL3Di entry for RHO. (Integer; no Default; leave blank if table is not required)
TA1	ID of TABL3Di entry for A1. (Integer; no Default; leave blank if table is not required)
TA2	ID of TABL3Di entry for A2. (Integer; no Default; leave blank if table is not required)

Remarks:

1. TABL3Di is a table where an entry can be a function of up to 4 variables such as strain, temperature, strain rate, etc. As an example, say the analysis required TE1 to be a function of strain. Then the corresponding TABL3D0 entry is TABL3D0, KIND=73 to specify *local strain component* as the independent variable. The dependent variable is *E1*.
2. In SOL 400, MATS8 is used in conjunction with MAT8 and is only supported for shell elements with property extensions. This implies that for such elements, PSHELL should be associated with PSHLN1. Note that, prior to MD Nastran 2010, if the property extensions were missing, then the MATS8 data was not considered in the element's formulation. From MD Nastran 2010 onwards, if the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.

## MATSMA Material Properties for Shape Memory Alloys

For SOL 600 and SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATSMA	MID	MODEL	$T_0$	L					
	$E_a$	$\nu_a$	$\alpha_a$	$\sigma_a$	$\rho_a$	$\sigma_s^A$	$\sigma_f^{AS}$	$C_a$	
	$E_m$	$\nu_m$	$\alpha_m$	$\sigma_m$	$\rho_m$	$\sigma_s^S$	$\sigma_f^{SA}$	$C_m$	
	$\nu^T$	$M_{frac}$	$\sigma_{eff}^g$	$\sigma_{max}^g$					
	$g_0$	$g_a$	$g_b$	$g_c$	$g_d$	$g_e$	$g_f$	$g_{max}$	

Example:

MATSMA	1	2	77.	0.05					
	50000.	0.33	0.00001	1.0E+20		520.	600.	8.66	
	50000.	0.33	0.00001	1.0e+20		300	200.	6.66	
	0.0	0.0	100.	1.0e+20					
	300.	-4.	2.	0.	0.	0.	3.0	1.0	

Describer	Meaning
MID	Material ID. (Integer > 0)
MODEL	Flag to indicate the model being used. (Integer > 0; see Remark 1.): = 1 (Mechanical: Aruchhio's model) = 2 (Thermo-Mechanical: Asaro-Sayeedvafa model)
$T_0$	Reference temperature used to measure stresses. (Real > 0)
L	For the mechanical model, the parameter L represents maximum deformation, obtainable by detwinning of multiple-variant martensite. (Real > 0; for the thermo-mechanical model, see Remark 2.) (typically 0.06-0.104)
Austenite Properties (all Real):	
$E_a$	Young's modulus of elasticity (typically 60-83 GPa).
$\nu_a$	Poisson's ratio (typically 0.33).
$\alpha_a$	Coefficient of thermal expansion (typically $3.67 \times 10^{-6}/^{\circ}\text{F}$ ).
$\sigma_a$	Equivalent von Mises stress (not used in mechanical model) (typically 195-690 MPa).

Describer	Meaning
$\rho_a$	Mass density.
$\sigma_s^{AS}$	Material parameter representing start of Austenite to Martensite transformation. For thermo-mechanical model, the program calculates the Austenite start temperature in the stress-free configuration ( $A_s^0$ ) related to $\sigma_s^{AS}$ from relations shown in <a href="#">Table 9-27</a> .
$\sigma_f^{AS}$	Material parameter representing finish of Austenite to Martensite transformation. For thermo-mechanical model, the program calculates the Austenite finish temperature in the stress-free configuration ( $A_f^0$ ) related to $\sigma_f^{AS}$ from relations shown in <a href="#">Table 9-27</a> .
$C_a$	Slope of the stress-dependence of austenite start finish and start temperatures (typically 6-8 MPa).
Martensite Properties (all Real):	
$E_m$	Young's modulus of elasticity
$\nu_m$	Poisson's ratio
$\alpha_m$	Coefficient of thermal expansion
$\sigma_m$	Equivalent von Mises stress (not used in mechanical model)
$\rho_m$	Density
$\sigma_s^{SA}$	Material parameter representing start of Martensite to Austenite transformation. For thermo-mechanical model, the program calculates the Martensite start temperature in the stress-free configuration ( $M_s^0$ ) related to $\sigma_s^{SA}$ from relations shown in <a href="#">Table 9-27</a> .
$\sigma_f^{SA}$	Material parameter representing finish of Martensite to Austenite transformation. For thermo-mechanical model, the program calculates the Martensite finish temperature in the stress-free configuration ( $M_f^0$ ) related to $\sigma_f^{SA}$ from relations shown in <a href="#">Table 9-27</a> .
$C_m$	Slope of the stress-dependence of austenite start finish and start temperatures. (typically 5-6 MPa)
The following quantities are applicable to only thermo-mechanical model (all Real):	
$\nu^T$	Equivalent volumetric transformation strain. (typically 0.0-0.003)
$M_{frac}$	Initial martensite volume fraction. (0.0-1.0)
$\sigma_{eff}^g$	Twinning stress (see Remark 2.). (typically 100-150 MPa)

Describer	Meaning
$\sigma_{\max}^g$	Stress at which the maximum value of $g = g_{\max}$ is reached if a cut-off value is needed (normalized with $g_0$ ).
$g_0$	Stress level used to nondimensionalizing the stress in the function. ( $2.0-10.0 * \sigma_{\text{eff}}^g$ )
$g_a$	g function coefficient (typically $g_a < 0.0$ )
$g_b$	g function exponent (typically $g_b = 2.0$ )
$g_c$	g function coefficient (typically $g_c \geq 0.0$ )
$g_d$	g function exponent (typically $g_d = 2.25 \sim 2.75$ )
$g_e$	g function coefficient (typically $g_e \leq 0.0$ )
$g_f$	g function exponent (typically $g_f = 3.0$ )
$g_{\max}$	Maximum value of function g if a cut-off value is needed (typically $g_{\max} = 1.0$ ).

Remarks:

1. The mechanical (Auricchio's) model can be obtained from the thermo-mechanical model by ignoring the last two rows in the input.
2. Twinning becomes active when the equivalent stress reaches twinning stress. For thermo-mechanical model, the “unstressed transformation temperatures” for Martensite and Austenite,  $M_s^0, M_f^0, A_s^0, A_f^0$  are calculated from the reference temperature, the material parameters representing the start and finish of the Austenite and Martensite transformations, i.e.,  $\sigma_s^{SA}, \sigma_f^{SA}, \sigma_s^{AS}, \sigma_f^{AS}$  as well as the coefficients,  $C_m, C_a$  that provide the stress dependence of the transformation temperatures as shown in [Table 9-27](#).

Table 9-27

The Relationship between Mechanical Model and Thermo-Mechanical Model
$\sigma_s^{AS} = (T_o - M_s^0)C_m$
$\sigma_f^{AS} = (T_o - M_f^0)C_m$
$\sigma_s^{SA} = (T_o - A_s^0)C_a$
$\sigma_f^{SA} = (T_o - A_f^0)C_a$

Figure 9-101

3. For the thermo-mechanical model, the equivalent deviatoric strain, (typically 0.05 - 0.085) is automatically calculated by the program as  $\epsilon^T = \sqrt{2/3} * L$  (since it is assumed that the input to this model is an extension of the mechanical model and conversion is done wherever applicable as in Table 9-27. However, in the case where the thermal-mechanical model input parameters are directly used then one must enter a value of  $\sqrt{2/3} * \epsilon_q$  so that a correct value of  $\epsilon_q$  is used in the calculations.
4. The Mechanical (Auricchio's) model is not available for 1-D or plane stress conditions. The thermo-mechanical model must be used.
5. In SOL 400, MATSMA is only supported for nonlinear elements with property extensions, PBARN1, PBEMN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Note that, prior to MSC Nastran 2010, if the property extensions were missing, then the analysis would stop with an error. From MSC Nastran 2010 onwards, if the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.
6. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
7. In SOL 400; remark 4. implies that the Mechanical model may not be used with PBAR, PBARL, PBEAM, PBEAML, PROD, PSHEAR, PSHELL, PCOMP(G). It can only be used with PLPLANE/PSHLN2 (without BEH=PSTRS) and PSOLID/PSLDN1.

## MATSORT      Advanced Orthotropic, Nonlinear Elastic Material for Shell Elements

Specifies NLELAST option for advanced 3D orthotropic, nonlinear elastic materials in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
MATSORT	MID	TE1	TE2	TE3	TNU12	TNU23	TNU31	TRHO	
	TG12	TG23	TG31	TA1	TA2	TA3			

Example:

MATSORT	689	77	77	77					
				89	89	89			

Describer	Meaning
MID	Identification number of a MATORT entry. (Integer > 0; no Default)
TE1	ID of TABL3Di entry for E1. (Integer; no Default; leave blank if table is not required)
TE2	ID of TABL3Di entry for E2. (Integer; no Default; leave blank if table is not required)
TE3	ID of TABL3Di entry for E3. (Integer; no Default; leave blank if table is not required)
TNU12	ID of TABL3Di entry for NU12. (Integer; no Default; leave blank if table is not required)
TNU23	ID of TABL3Di entry for NU23. (Integer; no Default; leave blank if table is not required)
TNU31	ID of TABL3Di entry for NU31. (Integer; no Default; leave blank if table is not required)
TRHO	ID of TABL3Di entry for RHO. (Integer; no Default; leave blank if table is not required)
TG12	ID of TABL3Di entry for G12. (Integer; no Default; leave blank if table is not required)
TG23	ID of TABL3Di entry for G23. (Integer; no Default; leave blank if table is not required)
TG31	ID of TABL3Di entry for G31. (Integer; no Default; leave blank if table is not required)
TA1	ID of TABL3Di entry for A1. (Integer; no Default; leave blank if table is not required)
TA2	ID of TABL3Di entry for A2. (Integer; no Default; leave blank if table is not required)
TA3	ID of TABL3Di entry for A3. (Integer; no Default; leave blank if table is not required)

Remarks:

1. TABL3Di is a table where an entry can be a function of up to 4 variables such as strain, temperature, strain rate, etc. If one of the independent variables is temperatures then you should not use MATTORT.

2. In SOL 400, MATSORT is used in conjunction with MATORT and is only supported for 2D and 3D elements with property extensions. This implies that for such elements, PCOMP / PCOMP, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PSHLN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Note that, prior to MD Nastran 2010, if the property extensions were missing, then the analysis would stop with an error. From MD Nastran 2010 onwards, if the property extensions are missing, they are automatically added with default settings by the program unless the user has set NLMOPTS,SPROP,MAP,-1 in the bulk data.

## MATT1 Isotropic Material Temperature Dependence

Specifies temperature-dependent material properties on MAT1 entry fields via TABLEMi entries.

Format:

1	2	3	4	5	6	7	8	9	10
MATT1	MID	T(E)	T(G)	T(NU)	T(RHO)	T(A)		T(GE)	
	T(ST)	T(SC)	T(SS)						

Example:

MATT1	17	32	65	84		15			
	52								

Describer	Meaning
MID	Material property identification number that matches the identification number on MAT1 entry. (Integer > 0)
T(E)	Identification number of a TABLEMi entry for the Young's modulus. (Integer $\geq 0$ or blank)
T(G)	Identification number of a TABLEMi entry for the shear modulus. (Integer $\geq 0$ or blank)
T(NU)	Identification number of a TABLEMi entry for the Poisson's ratio. (Integer $\geq 0$ or blank)
T(RHO)	Identification number of a TABLEMi entry for the mass density. (Integer $\geq 0$ or blank)
T(A)	Identification number of a TABLEMi entry for the thermal expansion coefficient. See Remark 4. (Positive or negative integer, 0 or blank)
T(GE)	Identification number of a TABLEMi entry for the damping coefficient. (Integer $\geq 0$ or blank)
T(ST)	Identification number of a TABLEMi entry for the tension stress limit. (Integer $\geq 0$ or blank)
T(SC)	Identification number of a TABLEMi entry for the compression limit. (Integer $\geq 0$ or blank)
T(SS)	Identification number of a TABLEMi entry for the shear limit. (Integer $\geq 0$ or blank)

## Remarks:

1. Fields 3, 4, etc., of this entry correspond, field-by-field, to fields 3, 4, etc., of the MAT1 entry referenced in field 2. The value in a particular field of the MAT1 entry is replaced or modified by the table referenced in the corresponding field of this entry. In the example shown, E is modified by TABLEMi 32, G is modified by TABLEMi 65, NU is modified by TABLEMi 84, A is modified by TABLEMi 15, and ST is modified by TABLEMi 52. Blank or zero entries mean that there is no temperature dependence of the fields on the MAT1 entry.
2. Any quantity modified by this entry must have a value on the MAT1 entry. Initial values of E, G, or NU may be supplied according to Remark 3 on the MAT1 entry.
3. Table references must be present for each item that is temperature dependent. If any one of Young's modulus, shear modulus or Poisson's ratio is temperature dependent, then T(E), T(G) and T(NU) should be specified together to get accurate results.
4. The T(A) table value can be either a positive or negative integer. For a nonlinear static analysis of a composite element with the PARAM,COMP MATT,YES, if the TABLEMi ID for the coefficient of thermal expansion is negative, the TABLEMi ordinate values will be interpreted as the thermal strain  $\varepsilon(T)$  rather than the coefficient of thermal expansion ordinate values  $\alpha(T)$ . Internally to Nastran, a negative  $ID_{T(A)}$  value will be changed to  $|ID_{T(A)}| + 100000000$ .
5. The continuation entry is not used by SOL 600. For SOL 600, see MATTEP.
6. T(G), T(RHO) and T(GE) are not used by SOL 600. T(E) and T(NU) should be used instead of T(E) and T(G).
7. This entry is not used by SOL 700.

## MATT2 Anisotropic Material Temperature Dependence

Specifies temperature-dependent material properties on MAT2 entry fields via TABLEMj entries.

Format:

1	2	3	4	5	6	7	8	9	10
MATT2	MID	T(G11)	T(G12)	T(G13)	T(G22)	T(G23)	T(G33)	T(RHO)	
	T(A1)	T(A2)	T(A3)		T(GE)	T(ST)	T(SC)	T(SS)	
		T(GE11)	T(GE12)	T(GE13)	T(GE22)	T(GE23)	T(GE33)		

Example:

MATT2	17	32					15		
	62								

Describer	Meaning
MID	Material property identification number that matches the identification number on a MAT2 entry. (Integer > 0)
T(Gij)	Identification number of a TABLEMk entry for the terms in the material property matrix. (Integer ≥ 0 or blank)
T(RHO)	Identification number of a TABLEMk entry for the mass density. (Integer ≥ 0 or blank)
T(Ai)	Identification number of a TABLEMk entry for the thermal expansion coefficient. See Remark 3. (Positive or negative integer, 0 or blank)
T(GE)	Identification number of a TABLEMk entry for the damping coefficient. (Integer ≥ 0 or blank)
T(ST)	Identification number of a TABLEMk entry for the tension stress limit. (Integer ≥ 0 or blank)
T(SC)	Identification number of a TABLEMk entry for the tension compression limit. (Integer ≥ 0 or blank)
T(SS)	Identification number of a TABLEMk entry for the tension shear limit. (Integer ≥ 0 or blank)
T(GEij)	Identification number of a TABLEMk entry for the terms in the material structural damping property matrix. (Integer > 0 or blank)

Remarks:

- Fields 3, 4, etc., of this entry correspond, field by field, to fields 3, 4, etc., of the MAT2 entry referenced in field 2. The value in a particular field of the MAT2 entry is replaced or modified by the table referenced in the corresponding field of this entry. In the example shown, G11 is modified by TABLEMk 32, G33 is modified by TABLEMk 15, and A1 is modified by TABLEMk 62. If Ri is zero or blank, then there is no temperature dependence of the field on the MAT2 entry.

2. Any quantity modified by this entry must have a value on the MAT2 entry.
3. Any of the T(A) table value can be either a positive or negative integer. For a nonlinear static analysis of a composite element with the PARAM,COMPMMATT,YES, if the TABLEMk ID for the coefficient of thermal expansion is negative, the TABLEMk ordinate values will be interpreted as the thermal strain  $\epsilon(T)$  rather than the coefficient of thermal expansion ordinate values  $\alpha(T)$ . Internally to Nastran, a negative  $ID_{T(A)}$  value will be changed to  $|ID_{T(A)}| + 100000000$

## MATT3 MAT3 Material Temperature Dependence

Specifies temperature-dependent material properties on MAT3 entry fields via TABLEMi entries that are temperature dependent.

Format:

1	2	3	4	5	6	7	8	9	10
MATT3	MID	T(EX)	T(ETH)	T(EZ)	T(NUXTH)	T(NUTHZ)	T(NUZX)	T(RHO)	
			T(GZX)	T(AX)	T(ATH)	T(AZ)		T(GE)	

Example:

MATT3	23	32		15					
			62						

Describer	Meaning
MID	Material property identification number that matches the identification number on MAT3 entry. (Integer > 0)
T(EX) T(ETH) T(EZ)	Identification number of a TABLEMi entry for the Young's modulus in the $x$ , $\theta$ , and $z$ directions. (Integer $\geq 0$ or blank)
T(GZX)	Identification number of a TABLEMi entry for the shear modulus. (Integer $\geq 0$ or blank)
T(NUXTH) T(NUTHZ) T(NUZX)	Identification number of a TABLEMi entry for the Poisson's ratio in the $x\theta$ , $\theta z$ , and $zx$ directions. (Integer $\geq 0$ or blank)
T(RHO)	Identification number of a TABLEMi entry for the mass density. (Integer $\geq 0$ or blank)
T(AX) T(ATH) T(AZ)	Identification number of a TABLEMi entry for the thermal expansion coefficients in the $x$ , $\theta$ , and $z$ directions. (Integer $\geq 0$ or blank)
T(GE)	Identification number of a TABLEMi entry for the damping coefficient. (Integer $\geq 0$ or blank)

Remarks:

- Fields 3, 4, etc., of this entry correspond, field by field, to fields 3, 4, etc., of the MAT3 entry referenced in field 2. The value recorded in a particular field of the MAT3 entry is replaced or modified by the table referenced in the corresponding field of this entry. In the example shown, EX is modified by TABLEMi 32, EZ is modified by TABLEMi 15, and GZX is modified by TABLEMi 62. If Ri is zero or blank, then there is no temperature dependence of the field on the MAT3 entry.
- Any quantity modified by this entry must have a value on the MAT3 entry.

## MATT4 Thermal Material Temperature Dependence

Specifies table references for temperature-dependent MAT4 material properties.

Format:

1	2	3	4	5	6	7	8	9	10
MATT4	MID	T(K)	T(CP)		T(H)	T( $\mu$ )	T(HGEN)		

Example:

MATT4	17	102	103			105			
-------	----	-----	-----	--	--	-----	--	--	--

Describer	Meaning
MID	Identification number of a MAT4 entry that is temperature dependent. (Integer > 0)
T(K)	Identification number of a TABLEMj entry that gives the temperature dependence of the thermal conductivity. (Integer $\geq$ 0 or blank)
T(CP)	Identification number of a TABLEMj entry that gives the temperature dependence of the thermal heat capacity. (Integer $\geq$ 0 or blank)
T(H)	Identification number of a TABLEMj entry that gives the temperature dependence of the free convection heat transfer coefficient. (Integer $\geq$ 0 or blank)
T( $\mu$ )	Identification number of a TABLEMj entry that gives the temperature dependence of the dynamic viscosity. (Integer $\geq$ 0 or blank)
T(HGEN)	Identification number of a TABLEMj entry that gives the temperature dependence of the internal heat generation property for QVOL. (Integer $\geq$ 0 or blank)

Remarks:

1. The basic quantities on the MAT4 entry are always multiplied by the corresponding tabular function referenced by the MATT4 entry.
2. If the fields are blank or zero, then there is no temperature dependence of the referenced quantity on the MAT4 entry.

## MATT5 Thermal Anisotropic Material Temperature Dependence

Specifies temperature-dependent material properties on MAT5 entry fields via TABLEMi entries.

Format:

1	2	3	4	5	6	7	8	9	10
MATT5	MID	T(KXX)	T(KXY)	T(KXZ)	T(KYY)	T(KYZ)	T(KZZ)	T(CP)	
		T(HGEN)							

Example:

MATT5	24	73							
-------	----	----	--	--	--	--	--	--	--

Describer	Meaning
MID	Identification number of a MAT5 entry that is to be temperature dependent. (Integer > 0)
T(Kij)	Identification number of a TABLEMi entry. The TABLEMi entry specifies temperature dependence of the matrix term. (Integer ≥ 0 or blank)
T(CP)	Identification number of a TABLEMi entry that specifies the temperature dependence of the thermal heat capacity. (Integer ≥ 0 or blank)
T(HGEN)	Identification number of a TABLEMi entry that gives the temperature dependence of the internal heat generation property for the QVOL entry. (Integer ≥ 0 or blank)

Remarks:

1. The basic quantities on the MAT5 entry are always multiplied by the tabular function referenced by the MATT5 entry.
2. If the fields are blank or zero, then there is no temperature dependence of the referenced quantity on the basic MAT5 entry.

## MATT8 Shell Orthotropic Material Temperature Dependence

Specifies temperature-dependent material properties on MAT8 entry fields via TABLEMi entries.

Format:

1	2	3	4	5	6	7	8	9	10
MATT8	MID	T(E1)	T(E2)	T(NU12)	T(G12)	T(G1Z)	T(G2Z)	T(RHO)	
	T(A1)	T(A2)		T(Xt)	T(Xc)	T(Yt)	T(Yc)	T(S)	
	T(GE)	T(F12)							

Example:

MATT8	17	32							
	15			52					

Describer	Meaning
MAT	Material property identification number that matches the identification number on MAT1 entry. (Integer > 0)
T(E1)	Identification number of a TABLEMi entry for the Young's modulus 1. (Integer ≥ 0 or blank)
T(E2)	Identification number of a TABLEMi entry for the Young's modulus 2. (Integer ≥ 0 or blank)
T(NU12)	Identification number of a TABLEMi entry for Poisson's ratio 12. (Integer ≥ 0 or blank)
T(G12)	Identification number of a TABLEMi entry for shear modulus 12. (Integer ≥ 0 or blank)
T(G1Z)	Identification number of a TABLEMi entry for transverse shear modulus 1Z. (Integer ≥ 0 or blank)
T(G2Z)	Identification number of a TABLEMi entry for transverse shear modulus 2Z. (Integer ≥ 0 or blank)
T(RHO)	Identification number of a TABLEMi entry for mass density. (Integer ≥ 0 or blank)
T(Ai)	Identification number of a TABLEMi entry for thermal expansion coefficient 1. See Remark 3. (Positive or negative integer, 0 or blank)
T(A2)	Identification number of a TABLEMi entry for thermal expansion coefficient 2. See Remark 3. (Integer or blank)
T(Xt)	Identification number of a TABLEMi entry for tension stress/strain limit 1. (Integer ≥ 0 or blank)
T(Xc)	Identification number of a TABLEMi entry for compression stress/strain limit 1. (Integer ≥ 0 or blank)

Describer	Meaning
T(Yt)	Identification number of a TABLEMi entry for tension stress/strain limit 2. (Integer $\geq 0$ or blank)
T(Yc)	Identification number of a TABLEMi entry for compression stress/strain limit 2. (Integer $\geq 0$ or blank)
T(S)	Identification number of a TABLEMi entry for shear stress/strain limit. (Integer $\geq 0$ or blank)
T(GE)	Identification number of a TABLEMi entry for structural damping coefficient. (Integer $\geq 0$ or blank)
T(F12)	Identification number of a TABLEMi entry for Tsai-Wu interaction term. (Integer $\geq 0$ or blank)

**Remarks:**

- Fields 3, 4, etc., of this entry correspond, field-by-field, to fields 3, 4, etc., of the MAT8 entry referenced in field 2. The value in a particular field of the MAT8 entry is replaced or modified by the table referenced in the corresponding field of this entry. In the example shown, E1 is modified by TABLEMi 32, A1 is modified by TABLEMi 15, and Xt is modified by TABLEMi 52. Blank or zero entries mean that there is no temperature dependence of the fields on the MAT8 entry.
- Any quantity modified by this entry must have a value on the MAT8 entry.
- Any of the T(Ai) table value can be either a positive or negative integer. For a nonlinear static analysis of a composite element with the PARAM,COMP MATT,YES, if the TABLEMi ID for the coefficient of thermal expansion is negative, the TABLEMi ordinate values will be interpreted as the thermal strain  $\epsilon(T)$  rather than the coefficient of thermal expansion ordinate values  $\alpha(T)$ . Internally to Nastran, a negative  $ID_{T(A)}$  value will be changed to  $|ID_{T(A)}| + 100000000$ .

## MATT9 Solid Element Anisotropic Material Temperature Dependence

Specifies temperature-dependent material properties on MAT9 entry fields via TABLEMk entries.

Format:

1	2	3	4	5	6	7	8	9	10
MATT9	MID	T(G11)	T(G12)	T(G13)	T(G14)	T(G15)	T(G16)	T(G22)	
	T(G23)	T(G24)	T(G25)	T(G26)	T(G33)	T(G34)	T(G35)	T(G36)	
	T(G44)	T(G45)	T(G46)	T(G55)	T(G56)	T(G66)	T(RHO)	T(A1)	
	T(A2)	T(A3)	T(A4)	T(A5)	T(A6)		T(GE)		
	T(GE11)	T(GE12)	T(GE13)	T(GE14)	T(GE15)	T(GE16)	T(GE22)	T(GE23)	
	T(GE24)	T(GE25)	T(GE26)	T(GE33)	T(GE34)	T(GE35)	T(GE36)	T(GE44)	
	T(GE45)	T(GE46)	T(GE55)	T(GE56)	T(GE66)				

Example:

MATT9	17	32			18			17	
				12					
				5			10		

Describer	Meaning
MID	Material property identification number that matches the identification number on MAT9 entry. (Integer > 0)
T(Gij)	Identification number of a TABLEMk entry for the terms in the material property matrix. (Integer ≥ 0 or blank)
T(RHO)	Identification number of a TABLEMk entry for the mass density. (Integer ≥ 0 or blank)
T(Ai)	Identification number of a TABLEMk entry for the thermal expansion coefficients. (Integer ≥ 0 or blank)
T(GE)	Identification number of a TABLEMk entry for the damping coefficient. (Integer ≥ 0 or blank)
T(GEij)	Identification number of a TABLEMk entry for the terms in the material structural damping property matrix. (Integer > 0 or blank).

Remarks:

- Fields 3, 4, etc., of this entry correspond, field by field, to fields 3, 4, etc., of the MAT9 entry referenced in field 2. The value recorded in a particular field of the MAT9 entry is replaced or modified by the table referenced in the corresponding field of this entry. In the example shown, G11 is modified by TABLEMj 32, G14 is modified by TABLEMj 18, etc. If the fields are zero or blank, then there is no temperature dependence of the fields on the MAT9 entry.
- Any quantity modified by this entry must have a value on the MAT9 entry.
- The continuation entries are optional.

**MATTEP**

**Thermo-Elastic-Plastic Material Properties - SOL 400**

Specifies temperature-dependent elasto-plastic material properties to be used for static, quasi static or transient dynamic analysis in SOL 400 only.

Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
MATTEP	MID		T(Y0)	T(FID)				T(H)	
	N/A			N/A					
	“Chaboche”	R0	Rinf	B	C	Gam	Kap	N	
		Qm	$\mu$	$\eta$					

Example:

MATTEP	100		20						
--------	-----	--	----	--	--	--	--	--	--

Describer	Meaning
MID	Identification number of MATEP entry. See Remark 1. (Integer > 0)
T(Y0)	Identification number of TABLEMi entry for thermo-elasto-plastic material. See Remarks 2. (Integer > 0 or blank)
T(FID)	Identification number of TABLEST entry for temperature-dependent stress-strain curves (Integer > 0 or blank). See Remark 4.
T(H)	Identification number of TABLEMi entry for temperature-dependent plasticity moduli in thermo-elasto-plastic material. See Remarks 3. (Integer > 0 or blank)
“Chaboche”	A keyword specifying the following data pertains to the Chaboche model.
R0	Identification number of TABLEMi entry for temperature dependent R0 for isotropic hardening (Integer > 0).
Rinf	Identification number of TABLEMi entry for temperature dependent Rinfinity for isotropic hardening (Integer > 0).
B	Identification number of TABLEMi entry for temperature dependent coefficient B for isotropic hardening (Integer > 0).
C	Identification number of TABLEMi entry for temperature dependent coefficient C for kinematic hardening (Integer > 0).
Kap	Identification number of TABLEMi entry for temperature dependent Kappa value for viscosity model (Integer > 0).
N	Identification number of TABLEMi entry for temperature dependent coefficient n for viscosity model (Integer).
Qm	Identification number of TABLEMi entry for temperature dependent coefficient Qm for isotropic hardening (Integer > 0)

Describer	Meaning
$\mu$	Identification number of TABLEMi entry for temperature dependent coefficient $\mu$ for isotropic hardening (Integer > 0).
$\eta$	Identification number of TABLEMi entry for temperature dependent coefficient $\eta$ to introduce progressive memory (Integer > 0).

#### Remarks:

1. The MATEP Bulk Data entry with the same MID must exist for MATTEP to be effective. All the fields defined in MATTEP correspond to the same fields of MATEP. The value in a particular field of the MATEP entry is replaced or modified by the table referenced in the corresponding field of this entry.
2. The table represents yield stresses as a function of temperature. Therefore, the curve should comprise the initial stress from Y0 or FID field on MATEP (most likely at room temperature). T(Y0) field accommodates FID field in case FID field defines the initial yield stress instead of Y0 field. In this case, the yield stresses at any plastic strain will be scaled by the same ratio as the initial yield stress at the same temperature.
3. The table represents a normalized plasticity moduli (work hardening slope) as a function of temperature.
4. Temperature dependent stress-strain curves may be entered in a general manner using the T(FID) option. The integer value entered in this field represents the ID of a TABLEST entry which provides IDs of TABLES1 stress-plastic strain curves vs. temperature. All such curves must be entered as stress vs. plastic strain. No curves should be referenced on the MATS1 entry. For this option T(Y0) and T(H) should be left blank and if entered, SOL 400 will re-set them to blank if T(FID) is a positive integer.
5. This entry must be used in conjunction with MAT1, MATEP and MATT1 all with the same MID. The MATT1 entry must have at least one non-blank entry in fields 3-7 of the primary MATT1 entry.

## MATTEP

## Thermo-Elastic-Plastic Material Properties - SOL 600

Specifies temperature-dependent elasto-plastic material properties to be used for static, quasi static or transient dynamic analysis in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATTEP	MID		T(Y0)	T(FID)				T(H)	
	N/A		T(yc10)	N/A					
	“Chaboche”	R0	Rinf	B	C	Gam	Kap	N	
		Qm	$\mu$	$\eta$					
	“PwrLaw”	A	M	B	N	$\sigma_0 \epsilon_0$			

Example:

MATTEP	100		20						
--------	-----	--	----	--	--	--	--	--	--

Describer	Meaning
MID	Identification number of MATEP entry. See Remark 1. (Integer > 0)
T(Y0)	Identification number of TABLEMi entry for thermo-elasto-plastic material. See Remarks 2. (Integer > 0 or blank)
T(FID)	Identification number of TABLEST entry for temperature-dependent stress-strain curves (Integer > 0 or blank). See Remark 4.
T(H)	Identification number of TABLEMi entry for temperature-dependent plasticity moduli in thermo-elasto-plastic material. See Remarks 3. (Integer > 0 or blank)
T(yc10)	Identification number of TABLEMi entry for equivalent 10th cycle tensile yield stress specified in the Yc10 field of MATEP entry. (Integer > 0 or blank).
“Chaboche”	A keyword specifying the following data pertains to the Chaboche model.
R0	Table for R0 for isotropic hardening. (Integer > 0)
Rinf	Table for Rinfinity for isotropic hardening (Integer > 0)
B	Table for b coefficient for isotropic hardening. (Integer > 0)
C	Table for C coefficient for kinematic hardening. (Integer > 0)
Kap	Table for Kappa value for viscosity model. (Integer > 0)
N	Table for n coefficient for viscosity model. (Integer > 0)
Qm	Table for Qm coefficient for isotropic hardening. (Integer > 0)
$\mu$	Table for $\mu$ coefficient for isotropic hardening. (Integer > 0)
$\eta$	Table for $\eta$ coefficient to introduce progressive memory. (Integer > 0)

Describer	Meaning
“PwrLaw”	A keyword specifying the following data pertains to the Power Law or Rate Power Law model (see Marc Vol C , ISOTROPIC option for more details).
A	Table for coefficient A. (Integer > 0)
M	Table for coefficient m. (Integer > 0)
B	Table for coefficient B. (Integer > 0)
N	Table for exponent n. (Integer > 0)
$\sigma_0 \epsilon_0$	Table for $\sigma_0 \epsilon_0$ . (Integer > 0)

#### Remarks:

1. The MATEP Bulk Data entry with the same MID must exist for MATTEP to be effective. All the fields defined in MATTEP correspond to the same fields of MATEP. The value in a particular field of the MATEP entry is replaced or modified by the table referenced in the corresponding field of this entry.
2. The table represents yield stresses as a function of temperature. Therefore, the curve should comprise the initial stress from Y0 or FID field on MATEP (most likely at room temperature). T(Y0) field accommodates FID field in case FID field defines the initial yield stress instead of Y0 field. In this case, the yield stresses at any plastic strain will be scaled by the same ratio as the initial yield stress at the same temperature.
3. The table represents a normalized plasticity moduli (work hardening slope) as a function of temperature.
4. Temperature dependent stress-strain curves may be entered in a general manner using the T(FID) option. The integer value entered in this field represents the ID of a TABLEST entry which provides IDs of TABLES1 stress-plastic strain curves vs. temperature. All such curves must be entered as stress vs. plastic strain. No curves should be referenced on the MATS1 entry. For this option T(Y0) and T(H) should be left blank and if entered, MSC Nastran will re-set them to blank if T(FID) is a positive integer.
5. This entry must be used in conjunction with MAT1, MATEP and MATT1 all with the same MID. The MATT1 entry must have at least one non-blank entry in fields 3-7 of the primary MATT1 entry.

#### Note:

This Bulk Data entry accommodates Marc’s input data under the model definition options TEMPERATURE EFFECTS.

## MATTF Material Failure Model Temperature Variation

Describes the temperature, strain rate, or other type of variation of material failure properties used in conjunction with MATF in SOL 600 and SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
MATTF	MID		T(SB)						
	KIND	Criteria	T(Xt)	T(Xc)	T(Yt)	T(Yc)	T(Zt)	T(Zc)	1st
	T(Sxy)	T(Syz)	T(Szx)	T(Find)	T(Fxy)	T(Fyz)	T(Fzx)	T(Ext)	
	T(Exc)	T(Eyt)	T(Eyc)	T(Ezt)	T(Ezc)	T(Gxy)	T(Gyz)	T(Gzx)	
	KIND	Criteria	T(Xt)	T(Xc)	T(Yt)	T(Yc)	T(Zt)	T(Zc)	2nd
	T(Sxy)	T(Syz)	T(Szx)	F(Find)	F(Fxy)	T(Fyz)	T(Fzx)	T(Ext)	
	T(Exc)	T(Eyt)	T(Eyc)	T(Ezt)	T(Ezc)	T(Gxy)	T(Gyz)	T(Gzx)	
	KIND	Criteria	T(Xt)	T(Xc)	T(Yt)	T(Yc)	T(Zt)	T(Zc)	3rd
	T(Sxy)	T(Syz)	T(Szx)	T(Find)	T(Fxy)	T(Fyz)	T(Fzx)	T(Ext)	
	T(Exc)	T(Eyt)	T(Eyc)	T(Ezt)	T(Ezc)	T(Gxy)	T(Gyz)	T(Gzx)	

Example:

MATTF	100								
	12	1	51	52	53	54	55	56	
	61	62	63						
	12	2							2nd
	71	72	73	74	75	76	77	78	
	12	4	81	82	83	84	85	86	3rd
	91	92	93	94					

(Note: The 4th and 6th lines cannot be entirely blank and the last line of the 3rd criterion has been omitted.)

Describer	Meaning
MID	Identification number of a matching MATF entry. (Integer > 0; no Default; Required)
T(SB)	Identification of a TABLEMi entry providing the variation of the allowable shear stress of the bonding material between layers (composites only) (Integer; Default = 0 meaning no variation).
KIND	Enter the type of variation of the failure properties using the values listed below. (Integer; no Default) 12 Temperature

Describer	Meaning
Criteria	Enter same value as used by MATF (reference only). (Integer) If more than one KIND is required, enter the three lines for each KIND and Criteria as many times are required. (Integer; must be same as used by companion MATF, reference only)
T(SB)	Identification of a TABLEMi entry providing the variation of the allowable shear stress of the bonding material between layers (composites only) (Integer; Default = 0 meaning no variation)
T(Xt)	Identification of a TABLEMi entry providing the variation of the maximum tensile stress in x-direction (Integer; Default = 0 meaning no variation)
T(Xc)	Identification of a TABLEMi entry providing the variation of the maximum compressive stress (absolute value) in x-direction (Integer; Default = 0 meaning no variation)
T(Yt)	Identification of a TABLEMi entry providing the variation of the maximum tensile stress in y-direction (Integer; Default = 0 meaning no variation)
T(Yc)	Identification of a TABLEMi entry providing the variation of the maximum compressive stress (absolute value) in y-direction (Integer or blank)
T(Zt)	Identification of a TABLEMi entry providing the variation of the maximum tensile stress in z-direction (Integer; Default = 0 meaning no variation)
T(Zc)	Identification of a TABLEMi entry providing the variation of the maximum compressive stress (absolute value) in z-direction (Integer; Default = 0 meaning no variation)
T(Sxy)	Identification of a TABLEMi entry providing the variation of the maximum shear stress in xy-plane (Integer; Default = 0 meaning no variation)
T(Syz)	Identification of a TABLEMi entry providing the variation of the maximum shear stress in yz-plane (Integer; Default = 0 meaning no variation)
T(Szx)	Identification of a TABLEMi entry providing the variation of the maximum shear stress in zx-plane (Integer; Default = 0 meaning no variation)
T(Find)	Identification of a TABLEMi entry providing the variation of the Failure index (Real > 0., (Integer; Default = 0 meaning no variation)
T(Fxy)	Identification of a TABLEMi entry providing the variation of the interactive strength constant for xy-plane (Integer; Default = 0 meaning no variation)
T(Fyz)	Identification of a TABLEMi entry providing the variation of the interactive strength constant for yz-plane (Integer; Default = 0 meaning no variation)
T(Fzx)	Identification of a TABLEMi entry providing the variation of the interactive strength constant for zx-plane (Integer; Default = 0 meaning no variation)
T(Ext)	Identification of a TABLEMi entry providing the variation of the maximum tensile strain in x-direction (Integer; Default = 0 meaning no variation)

Describer	Meaning
T(Exc)	Identification of a TABLEMi entry providing the variation of the maximum compressive strain (absolute value) in x-direction (Integer; Default = 0 meaning no variation)
T(Yet)	Identification of a TABLEMi entry providing the variation of the maximum tensile strain in y-direction (Integer; Default = 0 meaning no variation)
T(Eyc)	Identification of a TABLEMi entry providing the variation of the maximum compressive strain (absolute value) in y-direction (Integer; Default = 0 meaning no variation)
T(Ezt)	Identification of a TABLEMi entry providing the variation of the maximum tensile strain in z-direction (Integer; Default = 0 meaning no variation)
T(Ezc)	Identification of a TABLEMi entry providing the variation of the maximum compressive strain (absolute value) in z-direction (Integer; Default = 0 meaning no variation)
T(Gxy)	Identification of a TABLEMi entry providing the variation of the maximum shear strain in xy-plane (Integer; Default = 0 meaning no variation)
T(Gyz)	Identification of a TABLEMi entry providing the variation of the maximum shear strain in yz-plane (Integer; Default = 0 meaning no variation)
T(Gzx)	Identification of a TABLEMi entry providing the variation of the maximum shear strain in zx-plane (Integer; Default = 0 meaning no variation)

Remarks:

1. See the MATF entry for a complete description of the meaning of each of the variables for the various failure criterion.
2. If there is no variation of a particular entry, leave the field blank or enter zero.
3. Continuation entries except the last line are required. The last line is optional.

**MATTG**

Temperature Variation of Interlaminar Materials

Specifies gasket material property temperature variation to be used in SOL 600 and SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
MATTG	MID	IDYM	IDVM	IDDM	IDLD	IDU1	IDU2	IDU3	
	IDU4	IDU5	IDU6	IDU7	IDU8	IDU9	IDU10	IDYPR	
	IDEPL	IDGPL	IDGAP	N/A	N/A	N/A	N/A	N/A	

Example:

MATTG	100	10	20	1001	1002	1003			
								1010	
	1020	1030							

Describer	Meaning
MID	Material ID number that matches the material ID of a corresponding MATG material. (Integer > 0; Required)
IDYM	ID of TABLEMi entry that gives the temperature variation of Young’s modulus for the membrane behavior of the material. (Integer ≥ 0 or blank)
IDVM	ID of TABLEMi entry that gives the temperature variation of Poisson’s ratio for the membrane behavior of the material. (Integer ≥ 0 or blank)
IDDM	ID of TABLEMi entry that gives the temperature variation of the mass density for the membrane behavior of the material. (Integer ≥ 0 or blank)
IDLD	ID of TABLEMi entry that gives the temperature variation of the loading curve of the material. (Integer ≥ 0 or blank)
IDUi	ID of TABLEMi entry that gives the temperature variation of the unloading curve of the material. There can be up to 10 unloading curves and each can have a different temperature variation. If there is no unloading, there does not need to be any unloading curves. (Integer ≥ 0 or blank)
IDYPR	ID of TABLEMi entry that gives the temperature variation of the yield pressure for the out-of-plane behavior of the material. (Integer ≥ 0 or blank)
IDEPL	ID of TABLEMi entry that gives the temperature variation of the tensile modulus for the out-of-plane behavior of the material. (Integer ≥ 0 or blank)
IDGPL	ID of TABLEMi entry that gives the temperature variation of the transverse shear modulus for the out-of-plane behavior of the material. (Integer ≥ 0 or blank)
IDGAP	ID of TABLEMi entry that gives the temperature variation of the initial gap for the out-of-plane behavior of the material. (Integer ≥ 0 or blank)

**MATTHE**

**Hyperelastic Material - Temperature Dependence**

Specifies temperature-dependent properties of hyperelastic (rubber-like) materials (elastomers) for nonlinear (large strain and large rotation) analysis in SOLs 106, 129, 600 and SOL 400 only.

Format 1 (Default): Generalized Mooney-Rivlin model (Model=Mooney). The first two lines are required, the others may be omitted depending on how many terms are desired.)

1	2	3	4	5	6	7	8	9	10
MATTHE	MID	Model		T(K)	T(RHO)	T(Texp)		T(GE)	
	T(C10)	T(C01)	T(D1)						
	T(C20)	T(C11)	T(C02)	T(D2)					
	T(C30)	T(C21)	T(C12)	T(C03)	T(D3)				
	T(C40)	T(C31)	T(C22)	T(C13)	T(C04)	T(D4)			
	T(C50)	T(C41)	T(C32)	T(C23)	T(C14)	T(C05)	T(D5)		

Format 2: Ogden Model

1	2	3	4	5	6	7	8	9	10
MATTHE	MID	Model		T(K)	T(RHO)	T(Texp)		T(GE)	
	T(D1)	T(D2)	T(D3)	T(D4)	T(D5)				

Format 3: Arruda-Boyce model or Gent Model (Model = Aboyce or Gent)

1	2	3	4	5	6	7	8	9	10
MATTHE	MID	Model		T(K)	T(RHO)	T(Texp)		T(GE)	
	T(NKT)	T(N/E)	T(Im)						
	T(D1)	T(D2)	T(D3)	T(D4)	T(D5)				

Example - Format 1:

MATTHE	1	Monney							
	10	1	100						
	20	11	2	200					
	30	21	12	3	300				
	40	31	22	13	4	400			
	50	41	32	23	14	5	500		

Example - Format 2:

MATTHE	1	Ogden							
	100	200	300	400	500				

Example - Format 3:

MATTHE	1	Aboyce							
	1	2							
	100	200	300	400	500				

Describer	Meaning
MID	Identification number of a MATHE entry. See Remark 1. (Integer > 0; no Default)
Model	Select hyperelastic material model form. (Character; Default = Mooney)
	Mooney For generalized Mooney-Rivlin hyperelastic model
	Ogden For Ogden hyperelastic model
	Foam For Foam model
	Aboyce For Arruda-Boyce strain energy model
	Gent For Gent strain energy model
T(Value)	Identification number of a TABLEMi entry for the temperature variation of the matching value from the MATHE entry - see the MATHE entry for the definition of each coefficient value. (Integer; Default = 0 which means no table variation for that particular value)

Remarks:

1. The MATTHE entry must have the same ID as the corresponding MATHE entry. Each table ID on the MATTHE entry corresponds to a parameter on the MATHE entry.
2. If the thermal expansion coefficient is temperature-dependent, the thermal strain is computed as

$$\varepsilon_{th} = \bar{\alpha}(T - T_{ref}) - \bar{\alpha}_0(T_0 - T_{ref})$$

where  $T_{ref}$  is the reference temperature at which measurement of the thermal expansion coefficient is based,  $T_0$  is an initial temperature, and  $\bar{\alpha}_0$  is the thermal expansion coefficient at the initial temperature  $T_0$ . If the thermal expansion is not temperature-dependent, the thermal strain expression is reduced to the usual expression:

$$\varepsilon_{th} = \bar{\alpha}(T - T_0)$$

3. If experimental data is provided, it is expected that the user has the data for multiple tests of the same type at different temperatures. The use of TABLEST's for this entry is not presently available. If experimental data is used to define the constants, use a GUI to define the constants at each temperature, enter the baseline values on the MATHE entry and the variation of each coefficient using TABLEMi.

## MATTORT

## Thermoelastic Orthotropic Material

Specifies temperature-dependent properties of elastic orthotropic materials for linear and nonlinear analyses used in SOL 600 and SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
MATTORT	MID	T(E1)	T(E2)	T(E3)	T(NU12)	T(NU23)	T(NU31)	N/A	
	T(G12)	T(G23)	T(G31)	T(A1)	T(A2)	T(A3)	T(SY)	T(WHS)	

Example:

MATTORT	100	5	6	7					
---------	-----	---	---	---	--	--	--	--	--

Describer	Meaning
MID	Identification number of a MATORT entry. See Remark 1. (Integer > 0; no Default)
T(Ei)	Identification number of a TABLEMi entry for the Young's modulus as a function of temperature in each respective direction. Remark 2. (Integer > 0 or blank)
T(Nuij)	Identification number of a TABLEMi entry for the Poisson's ratio as a function of temperature in each respective direction. (Integer > 0 or blank)
T(Gij)	Identification number of a TABLEMi entry for the shear modulus as a function of temperature in each respective direction. (Integer > 0 or blank)
T(Ai)	Identification number of a TABLEMi entry for the coefficient of thermal expansion as a function of temperature. (Integer > 0 or blank)
T(SY)	Identification number of a TABLEMi entry for the yield stress as a function of temperature. (Integer > 0 or blank)
T(WHS)	Identification number of a TABLEMi entry for the work hardening slope as a function of temperature. (Integer > 0 or blank)

Remarks:

1. The MATTORT entry must have the same ID as the corresponding MATORT entry. Each table ID on the MATTORT entry corresponds to a parameter on the MATORT entry.
2. The table represents material constants as a function of temperature. Therefore, the curve should comprise the original value specified in the MATORT entry (most likely at room temperature).
3. For SOL 600, the continuation line is required for versions prior to MD Nastran 2010 and MSC Nastran 2009.

## MATTUSR Specifies Table Variation of User Defined Generic Materials

Specifies table variation of user defined generic materials in SOL 600 and SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATTUSR	MID			T(RHO)	T(A1)	T(A2)	T(A3)		
	T(GE)	T(ST)	T(SC)	T(SS)					

Example:

MATTUSR	20			51	52				
---------	----	--	--	----	----	--	--	--	--

Describer	Meaning
MID	Identification number of MATUSR. (Integer > 0; no Default)
T(RHO)	Table ID of a TABLEM1 or TABL3Di for the mass density for structural analysis. (Integer, no Default)
T(Ai)	Table ID of a TABLEM1 or TABL3Di for the coefficient of thermal expansion. (Integer) If T(A1) is not zero and T(A2) and T(A3) are zero, then T(A1)=T(A2)=T(A3).
T(GE)	Identification number of a TABLEMk entry for the damping coefficient. (Integer ≥ 0 or blank)
T(ST)	Identification number of a TABLEMk entry for the tension stress limit. (Integer ≥ 0 or blank)
T(SC)	Identification number of a TABLEMk entry for the compression limit. (Integer ≥ 0 or blank)
T(SS)	Identification number of a TABLEMk entry for the tension shear limit. (Integer ≥ 0 or blank)

**MATVE**

Thermo-Visco-Elastic Material Properties

Specifies temperature-dependent visco-elastic material properties in terms of Thermo-Rheologically Simple behavior to be used for quasi-static or transient dynamic analysis in SOL 600 and SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATVE	MID	function	RT	ENER	FRACT	TDIF	TREF	NP	
	A1	A2							
	C0	C1	C2	C3	C4	etc.			
	W0	W1	W2	W3	W4	etc.			
	T0	T1	T2	T3	T4	etc.			
	IFICT								

Example:

MATVE	100	WLF	100.						
	0.8	1.2

MATVE	103	USER	345.					8	

Describer	Meaning
MID	Identification number. See Remark 1. (Integer > 0)
Function	Name of the shift function. See Remarks 2. and 3. (Character)
	W Williams-Landell-Ferry form, Requires A1 and A2. (Default)
	LF

Describer	Meaning
	P power series form
	O
	W
	E
	R
	N Narayanaswamy model
	A
	R
	A
	U specify the shift function with a user subroutine
	SE
	R
RT	Enter the reference or glass transition temperature. (Real; Default = 0.)
ENER	Used for NARA model only, enter the activation energy divided by the gas constant Q/R. (Real; no Default)
FRACT	Used for NARA only, enter the fraction parameter. (Real; no Default)
TDIF	Used for NARA only, enter the temperature shift between your temperature and absolute temperature for calculating fictitive temperatures. (Real; no Default)
TREF	Used for NARA only, enter the reference temperature for structural relaxation. (Real; no Default)
NP	For POWER, enter the number of coefficients in the power series representation. For NARA, NP is the member of terms in the Proxy series.
A1, A2	For WLF model enter the constants A1 and A2. For other models, enter 0.0 for A1 and A2. Do not enter a blank line as it will be stripped out. (Real; no Default)
Ci	Coefficients of the shift function, enter NP values for POWER only. Do not enter Ci for NARA. (Real; no Defaults)
Wi	For NARA model only, enter the weighting factors in increasing order of subscript. Enter NP values. For WLF and POWER, skip these values. (Real; no Defaults)
Ti	For the NARA model only, enter the relaxation time values in increasing order of subscript. Enter NP values. For WLF and POWER, skip these values. (Real; no Defaults)
IFICT	For NARA model only, enter initial fictive temperature (Integer > 0)
	1= Initial temperature
	2= Structural relaxation reference temperature
	3= 0.0 (default)

## Remarks:

1. The MATVE Bulk Data entry with the same MID must exist for MATTVE to be effective.

- The viscoelastic behavior is especially noticeable in the organic high polymers. There are many different kinds of such materials including various plastics, natural and synthetic rubbers. Their mechanical properties depend strongly on temperature, and these properties change drastically in the vicinity of a critical temperature called the glass-transition temperature  $T_g$ . The polymer well below  $T_g$  is an organic glass with a relatively high modulus. The viscoelastic behavior predominates in the transition range around  $T_g$ . The polymer above the transition region (but below the melting point) becomes a rubbery solid with a low modulus.

Polymers are broadly classified as amorphous polymers and polycrystalline polymers. Under stress-relaxation at a constant strain in the glass-transition region temperature, the amorphous polymer exhibits a phase change over time from the glassy state to the rubbery state. The response is manifested in the shear modulus as a function of time, in which initially high shear modulus changes into low shear modulus. The relaxation curve of the modulus in a log-log scale plot appears as a flat plateau of glassy modulus  $G_g$  shifting down to the equilibrium modulus  $G_e$  at the rubbery plateau. Such a relaxation behavior of the amorphous polymer is observed even when the temperature is well below  $T_g$  for a prolonged period of time in a very slow process. A similar behavior is found in the rubbery elastic region, but the process is faster.

Fortunately, the mechanical properties of amorphous polymers obey a time-temperature superposition principle, which allows the use of data obtained at different temperatures to extend the time scale at any given temperature. For such a behavior, the amorphous polymer is characterized as thermo-rheologically simple (TRS). Since the relaxation process extends several decades on the logarithmic time scale at lower temperatures, it is not feasible to determine the whole curve by a constant strain test at one temperature. Instead, the relaxation characteristics are measured at elevated temperatures in reduced time scale. Then the polymers exhibit a translational shift of all the characteristic responses with a change of temperature along the logarithmic time axis. This shift occurs parallel to the time axis without a change in properties: glassy and rubbery moduli. The modulus curve shifts towards shorter time with an increased temperature.

- The reduced ( $\xi$ ), or pseudo, time is related to the actual time ( $t$ ) through a shift function which is a function of temperature, i.e.,

$$\xi(t) = \int_0^t \frac{ds}{A(T(s))}$$

where  $A(T)$  is a shift function in terms of temperature  $T$  at time  $t$ . The shift function is a material property and must be determined experimentally. A shift function approximated by Williams-Landell-Ferry, known as WLF equation, has the form:

$$\log A = h(T) = -\frac{A_1(T - T_0)}{A_2 + (T - T_0)}$$

where  $T_0$  is the reference temperature at which relaxation data are given and  $A_1, A_2$  are calibration constants obtained at this temperature. Notice that  $A = 1$  if the reduced time is the same as the actual time. If  $T \leq T_0 - A_2$ , the deformation will be elastic.

Another form of the shift function is available as a power series in  $(T - T_0)$ , i.e.,

$$\log A = h(T) = \sum_{i=0}^{10} C_i (T - T_0)^i$$

4. The WLF shift function requires A1 and A2. The power series can have a maximum 11 coefficients C0 through C10.

**Note:**

1. This entry matches the three options for SHIFT FUNCTION in Marc: William-Landell-Ferry, Power Series and Narayanaswamy models.
2. The user subroutine is TRSFAC in SOL 600; this is not supported in SOL 400.

## MATUDS

## Material User Defined Service or Subroutine

Allows the user to provide material routines for use with enhanced material models in SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
MATUD S	MID	MTYPE	GROUP	UNAME					
	“INT”	IDATA1	IDATA2	IDATA3	IDATA4	IDATA5	IDATA6	IDATA7	
		IDATA8	IDATA9	...	...	IDATA <sub>n</sub>			
	“REAL”	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	
		RDATA8	RDATA9	...	...	RDATA <sub>n</sub>			
	“CHAR”	CDATA1	CDATA2	...	...	CDATA <sub>n</sub>			

Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE MATERIAL 'SCA.MDSolver.Util.Ums '
```

*In Bulk Data:*

MATUDS	17	MATEP	MATERIAL	UELASTOM					
MATUDS	17	MATUSR	MATERIAL	HYPELA2					
	REAL	.00134	1.467+4	.03					
	INT	8	3						

Describer	Meaning
MID	Identification number of a MAT1, MAT2, MAT3, MAT8, MAT9, MATHE, MATHP, MATORT, MATUSR, MCOHE, or MATD* entries.
MTYPE	The name of the material entry. MAT1, MATEP, MATE, MATHE, MATORT, MATUSR, MATVE, or MATVP. (Character; no Default).
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default)
UNAME	User subroutine name associated with the entry. See Remark 6.and 7.(Character).
“INT”	Keyword indicating that the following data is integer. (Character)
IDATA <sub>i</sub>	Additional user supplied Integer data not already existing on the specified MAT entry. (Integer; no Default)
“REAL”	Keyword indicating that the following data is real. (Character)
RDATA <sub>i</sub>	Additional user supplied Real data not already existing on the specified MAT entry. (Real; no Default)

- “CHAR” Keyword indicating that the following data is Character. (Character)
- CDATAi Additional user supplied Character data not already existing on the specified MAT entry. (Character; no Default)

#### Remarks:

1. This entry triggers the call to a user material subroutine for advanced nonlinear materials. The GROUP must match the GROUP field of the CONNECT SERVICE FMS statement.
2. On the FMS CONNECT statement, only the CONNECT SERVICE can be used with this entry.
3. The MID must match an existing MID.
4. A CDATAi entry cannot be the Character “REAL”, “INT”, or “CHAR”
5. Certain user subroutines, such as MATHE, require integer or real data input as specified in the User Defined Services document.
6. UNAME must be truncated to 8 characters in the bulk data field.
7. The following user subroutines are currently available for user convenience. See the User Defined Services document for details.

MTYPE	UNAME	SOL 400
MATHE	uelastomer	X
MATUSR	hypela2	X
MAT1	crplaw	X
MATF	ufail	X
MATF	uprogfail	X
MATORT	orient	X
MATUSR	umat	X
MCOHE	ucohes	X

8. In SOL 400, MATUDS is only supported for elements with property extensions. This implies that for such elements, PBAR / PBARL, PBEAM / PBEAML, PCOMP / PCOMPG, PROD, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PBARN1, PBEMN1, PSHLN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. If the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.
9. The UMAT and UCOHES user subroutines support user defined state variables, see UDSESV entry.
10. For hyper-elastic(or plastic) materials. the deformation gradient is available for bricks and shells in the user-defined material subroutines, the variable IHYPER on the material card should be set to 1. The deformation gradient components  $F_{11}$ ,  $F_{21}$ ,  $F_{31}$ ,  $F_{12}$ ,  $F_{22}$ ,  $F_{32}$ ,  $F_{13}$ ,  $F_{23}$  and  $F_{33}$  can be found in the history variables array in positions IDATA2+1 to IDATA2+9, the positions coming right after the requested number of history variables. For shell elements, the components of the deformation

gradient are with respect to the co-rotational system for the element currently used. In this case the third row of the deformation gradient, the components  $F_{31}$ ,  $F_{32}$  and  $F_{33}$  will not be properly updated when entering the user-defined material routine. These components depend on the thickness strain increment which in turn must be determined so that the normal stress in the shell vanishes. For a given thickness strain increment  $d3$ , these three components,  $f31$ ,  $f32$  and  $f33$ , can be determined by calling the subroutine. For hyper-elastic materials there are push forward operations that can be called from within the user defined subroutines too. If the local coordinate system option is invoked ( $IDATA3=1$ ), then the deformation gradient is transformed to this local system prior to entering the user-defined material routine according to:

$$\overline{F}_{ij} = Q_{ki}^s F_{kj}$$

where  $Q_{ki}^s$  refers to a transformation between the current global and material frames. For  $IDATA$  equal to 3 one can choose to put  $IHYPER$  equal to -1 which results in that the deformation gradient is transformed according to:

$$\overline{F}_{ij} = F_{ik} Q_{kj}^r$$

where  $Q_{kj}^r$  is the transformation between the reference global and material and frames. For this latter option the spatial frame remains the global one so the stresses should be expressed in this frame of reference upon exiting the user defined routines. The suitable choice of  $IHYPER$  depends on the formulation of the material model. For shells, there is also the option of setting  $IHYPER=3$  which will make the deformation gradient computed from the nodal coordinates and in the global coordinate system. With this option the user must compute the stress in the local system of interest, whence a transformation matrix between the global and this local system is passed to the user material routines. The columns in this matrix correspond to local basis vectors expressed in global coordinates, and this is the system that stress needs to be computed in. The user must be aware that since the deformation gradient is calculated directly from the element deformation it may not be consistent with the theory of the element that is used for the material. Also, the thickness used in the calculations is constant and there is currently no thickness change treatment for this option. In the following, a Neo-Hookean material is used as an example of the usage of the deformation gradient in user-defined materials. With  $\lambda$  and  $\mu$  being the Lamé parameters in the linearized theory, the strain energy density for this material is given by:

$$\psi = \frac{1}{2} \lambda [\ln(\det F)]^2 - \mu [\ln(\det F)] + \frac{1}{2} \mu [\text{tr}(F^T F) - 3]$$

meaning that the Cauchy stress can be expressed as:

$$\sigma = \frac{1}{\det F} [\lambda \ln(\det F) I + \mu (F^T F - 1)]$$

**MATUDS****Material User Defined Service or Subroutine - SOL 600**

Allows the user to provide material routines for use with enhanced material models in SOL 600.

**Format:**

1	2	3	4	5	6	7	8	9	10
MATUDS	MID	MTYPE		UNAME	IOPT				
	“INT”	IDATA1	IDATA2	IDATA3	IDATA4	IDATA5	IDATA6	IDATA7	
		IDATA8	IDATA9	...	...	IDATA <sub>n</sub>			
	“REAL”	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	
		RDATA8	RDATA9	...	...	RDATA <sub>n</sub>			
	“CHAR”	CDATA1	CDATA2	...	...	CDATA <sub>n</sub>			

**Examples:**

MATUDS	17	MATEP		uelastomer	2				
MATUDS	33	MATHYP		hypela2	13				
	REAL	1.0E-4	2.0E-6	4.8E-6	38.6		1.2E-4		
	INT	1	3	51	52	53	54		
		55	56						

Describer	Meaning
MID	Material property identification number that matches the identification number on a MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, or MATHE, primary material entry or a MATVE, MATVP, MATEP, MATF, associated material entry for structural analysis. MAT4 and MAT5 material entries for heat analysis. COHESIV for Cohesive zone modeling. (Integer > 0)
MTYPE	The name of the material entry. MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, MATHE, MATG, MATVE, MATVP, MATEP, MATF, MATS1, MATS3, MATS8, MAT4, MAT5, COHESIV. (Character; no Default)
UNAME	A primary or secondary name to identify the user subroutine. See Remark 6. (Character; no Default)
IOPT	A user subroutine option flag. See Remark 9. (Character; Default blank)
“INT”	Keyword indicating that the following data is integer. (Character)
IDATA <sub>i</sub>	Additional user supplied Integer data not already existing on the specified MAT entry. (Integer; no Default)
“REAL”	Keyword indicating that the following data is real. (Character)
RDATA <sub>i</sub>	Additional user supplied Real data not already existing on the specified MAT entry. (Real; no Default)

“CHAR” Keyword indicating that the following data is Character. (Character)  
 CDATAi Additional user supplied Character data not already existing on the specified MAT entry. (Character; no Default)

Remarks:

1. This entry triggers the call to a user material subroutine for advanced nonlinear materials.
2. If the matching material entry is not present, the RDATA and IDATA fields may be used to construct the applicable material entry in which case the real and integer field values are in the order shown for the material entry (MATxxx and MATTxxx). The applicable material entries will be internally constructed from the MID, RDATA and IDATA fields.
3. Certain user subroutines, such as MATHE, require integer or real data input as specified in the User Defined Services document.
4. This entry triggers a call to a user subroutine.
5. The following user subroutines are currently available for user convenience. See the User Defined Services document for details.

MTYPE	EVAL	SOL 600
MATHE	uelastomer	X
MATVP	crplaw	X
	vswell	X
	crpvis	X
	ucrplw	X
	uvscpl	X

Material-related structural and heat transfer user subroutines documented in Marc Volume D “User Subroutines and Special Routines” may be entered using MATUDS in addition to those tabulated above. They may alternatively be entered using Bulk Data entry [USRSUB6](#).

6. If IDATAi values are defined they are stored in common block /userii-mid/ ival(1000) Up to 1000 integer values may be specified. The userii common block would then be placed in the user subroutine along with other coding.
7. If RDATAi values are defined they are stored in common block /userr8-mid/ rvals(1000) Up to 1000 real\*8 values may be specified. The userr8 common block would then be placed in the user subroutine along with other coding.
8. The MATUDS entry may be used instead of the USRSUB6 entry. Both entries should not be used in the same run. When USERSUB is used, flags such as IUSER on the MATVP entry or parameters that are needed will be filled in automatically although they may also be entered if desired. EVAL will be stored as a character\*16 name in common block /userch/
9. This name identifies the user subroutine name to be called.

10. IOPT is a user subroutine option flag required by certain MAT<sub>xxx</sub> entries. See the applicable MAT<sub>xxx</sub> entry for values IOPT may use.

**MATUSR**

## Defines Generic Material Properties for Hypoelastic or User Material Model

Specifies user-defined, generic material properties for hypoelastic material models in SOL 600 and user defined material models in SOL 400 only. This entry is used in conjunction with the MATUDS option to activate user subroutine md\_hypela2 (SOL 400) or hypela2 (SOL 600) for planar, shell or solid elements. For nonintegrated beam elements it is used in conjunction with user subroutine ubeam (SOL 600).

Format:

1	2	3	4	5	6	7	8	9	10
MATUSR	MID	IPREF	IKINEM	RHO	A1	A2	A3	TREF	
	GE	ST	SC	SS					

Example:

MATUSR	20	1	2	1.0E-4	2.0E-6				
--------	----	---	---	--------	--------	--	--	--	--

Describer	Meaning
MID	Identification number. (Integer > 0; no Default)
IPREF	Flag to indicate that user defined material is given with respect to user defined coordinate system. (Integer; Default = 0; see Remark 14.) 0 User stress-strain law is isotropic (Default) 1 User stress strain is with respect to user defined coordinate system
IKINEM	Flag to indicate which additional kinematic quantity is passed into user subroutine. Incremental and total strains are always passed into user subroutine. (Integer; Default = 0, see Remark 3.) 0 Pass in incremental strain $\Delta\epsilon$ only. 1 Pass in $\Delta\epsilon$ , deformation gradient (F) and rotation (R) 2 Pass in $\Delta\epsilon$ , deformation gradient (F) and stretch ratios ( $\dot{\lambda}$ ) 3 Pass in $\Delta\epsilon$ , F, R and $\dot{\lambda}$ 13 Pass in $\Delta\epsilon$ , F, R and $\dot{\lambda}$ . Kinematic quantities are calculated at the mid increment if large strain is requested resulting in logarithmic strains. 23 Pass in $\Delta\epsilon$ , F, R and $\dot{\lambda}$ . Kinematic quantities are calculated at the end of the increment if large strain is requested.
RHO	Mass density for structural analysis (Real $\geq 0$ ; no Default)
Ai	Coefficient of thermal expansion. (Real; no Default)
TREF	Reference temperature for the calculation of thermal loads, or a temperature-dependent thermal coefficient. See Remarks 6, 8, and 15. (Real; Default = 0.0)

Describer	Meaning
GE	Structural element damping coefficient. See Remarks 7, 8, 9. and 15.
ST,SC,SS	Stress limits for tension, compression and shear are optionally supplied ( these are used only to compute margins of safety in certain elements) and have no effect on the computational procedures. See Remark 15. (Real; Default = 0.0)

#### Remarks:

1. This option is used together with MATUDS to define a generic material model. MATUDS is not required for SOL 600.
2. Only enter those fields necessary for the analysis being performed.
3. For SOL 400, IKINEM should be greater than 0 and user subroutine HYPELA2 is used. For SOL 600, if IKINEM=0, then subroutine HYPELA is used, else HYPELA2.
4. The generic material model is able to represent a nonlinear material behavior. For this constitutive theory, it is assumed that

$$\dot{\sigma}_{ij} = L_{ijkl} \dot{\epsilon}_{kl} + g_{ij}$$

where  $L$  is a function of the mechanical strain and  $g$  is a function of the temperature.

The stress and strains are true stresses and logarithmic strains, respectively, when used in conjunction with large strain requests.

When used in conjunction with PARAM,LGDISP,1 (without large strain) the above equation is expressed as

$$\dot{S}_{ij} = L_{ijkl} \dot{E}_{kl} + g_{ij}$$

where  $E$  and  $S$  are the Green-Lagrange strain and second Piola-Kirchhoff stress, respectively.

5. For the MD\_HYPELA2 user subroutine, in order to provide an accurate solution, a tangent stiffness should be evaluated at each iteration. In addition, the total stress should be defined as its exact value at the end of the increment. This allows the residual load correction to work effectively. In MD\_HYPELA2, additional information is available regarding the kinematics of deformation. In particular, the deformation gradient (F), rotation tensor (R), and the eigenvalues ( $\dot{\lambda}$ ) and eigenvectors (N) to form the stretch tensor (U) are also provided. This information is available only for the continuum elements namely: plane strain, generalized plane strain (SOL 600 only), plane stress, axisymmetric, axisymmetric with twist, and three-dimensional cases.
6. TREF is used as the reference temperature for the calculation of the thermal loads. TEMPERATURE (INITIAL) may be used for this purpose, in which case TREF should be blank
7. Note that the structural damping will change with time, to obtain the damping coefficient, multiply the critical damping ratio  $C/C_0$  by 2.
8. TREF and GE are ignored if this entry is referenced by a PCOMP or a PCOMPG entry.
9. If PARAM,W4 is not specified, GE is ignored in a transient analysis. See [Parameter Descriptions](#).

10. This material model should not be used with the PSHELL option or with PBARN1, PBEAMN1 or PCOMP(G) and smeared section integration.
11. For SOL 400 the user subroutines md\_hypela2 or md\_ubeam are used. For SOL 600 user subroutine hypela or hypela2 and ubeam are used, unless a MATUDS option is also included.
12. For SOL 400 this option automatically invokes the PSHLN1, PSHLN2, PSLDN1 element formulation
13. In a thermal-mechanically coupled simulation, MAT4 or MAT5 should be used to define the material behavior.
14. For SOL 600, IPREF = 0 means user subroutines ANEXP and ORIENT are not called. IPREF = 1 means the two routines are called.
15. TREF, GE, ST, SC and SS are ignored in SOL 600.
16. If A1 is given and A2, A 3 are not then isotropic thermal expansion and  $A1 = A2 = A3$ .
17. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MAT9, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.

**MATVE**

**Visco-Elastic Material Properties**

Specifies visco-elastic material properties to be used for quasi-static or dynamic analysis in SOL 600 and SOL 400.

Format for Model = Iso:

1	2	3	4	5	6	7	8	9	10

1	2	3	4	5	6	7	8	9	10
MATVE	1	ISO1							
	3030	0.98							

Describer	Meaning
MID	Identification number of primary material (MAT1 or MAT3 or MAT8 or MATROT or MATHE) entry. (Integer > 0). See Remark 2.
Model	Selects a visco-elastic model defining time-dependent deformation behavior (Character): ISO1 for isotropic materials referenced by MAT1 (Default) (an alternate name is Linear). ORTHO if referenced by MAT3, MAT8 and MATORT. MOONEY1 for Mooney-Rivlin model if referenced by MATHE. OGDEN1 for Ogden model if referenced by MATHE. FOAM1 for foam model if referenced by MATHE (SOL 400 only). See Remarks 2., 3., 4., 6. and 8.
Alphas	Solid coefficient of thermal expansion (Real; Default = 0). See Remark 6.
Alphal	Liquid coefficient of thermal expansion (Real; Default = 0). See Remark 6.
Gi	Shear modulus for $i^{\text{th}}$ term in Prony series (Real > 0.; Default = 0).
Ki	Bulk modulus for $i^{\text{th}}$ term in Prony series (Real > 0.; Default = 0).
Wdi	Multiplier (scale factor) for $i^{\text{th}}$ term deviatoric behavior in Prony series (Real $\geq$ 0.; Default = 0). for Hyperelastic Material.
Wvi	Multiplier (scale factor) for $i^{\text{th}}$ term volumetric behavior in Prony series (Real $\geq$ 0.; Default = 0.). See Remark 7.
Tdi	Defines time constants for deviatoric behavior in Prony series (Real $\geq$ 0.; Default = 0). See Remark 7.
Tvi	Defines time constants for volumetric behavior in Prony series (Real $\geq$ 0.; Default = 0). See Remark 7.

Remarks:

1. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MAT9, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
2. The time-dependent behavior in the viscoelastic material is modeled by a Prony series expression for both small and large strain problems. The stress relaxation behavior can be modeled by relaxation functions of the shear modulus and bulk modulus and total strain energy in terms of a series of exponential decay terms, which is known as the Prony series. This is equivalent to the generalized Maxwell model, which consists of many Maxwell models connected in parallel along with an elastic spring representing a long-term behavior. The constitutive behavior of viscoelasticity depends not only on the current state of stress and strain, but also on the entire history of the development of these states. Such a behavior is most readily expressed by hereditary or Duhamel integral. The Prony series is a discrete form of this hereditary integral.
3. ISO1 supports both volumetric and deviatoric viscoelastic behavior by allowing deviatoric terms (Gi and Tdi) and volumetric terms (Ki and Tvi) in the Prony series. The shear and bulk moduli for isotropic material (ISO1) can be expressed in a Prony series as

$$G(t) = G^\infty + \sum_{i=1} G_i e^{-t/T_{di}}$$

$$K(t) = K^\infty + \sum_{i=1} K_i e^{-t/T_{di}}$$

where instantaneous values are given by:

$$G^0 = G^\infty + \sum_{i=1} G_i$$

$$K^0 = K^\infty + \sum_{i=1} K_i$$

In terms of instantaneous values, the shear and the bulk modulus relaxation can also be written as.

$$G(t) = G^0 - \sum_{i=1} G_i (1 - e^{-t/T_{di}})$$

$$K(t) = K^0 - \sum_{i=1} K_i (1 - e^{-t/T_{di}})$$

If a Prony series is selected, at least one set of modulus and time constant must be provided i.e., (G1, Td1) and /or (K1, Tv1).

4. ORTHO supports only deviatoric viscoelastic behavior by allowing deviatoric terms (Gij and Tdi) in the Prony series. For orthotropic material behavior, the relaxation coefficients are applied to the shear modulus as

$$G_{ij}(t) = G_{ij}^0 - \sum_{n=1} G_{ij}^n (1 - e^{-t/T_{di}})$$

where  $G_{ij}^n$  is the shear modulus for  $n^{\text{th}}$  term is Prony series (Real > 0; Default = 0) for Orthotropic Material. (Here  $G_{ij}$  imply  $G_{xy}$ ,  $G_{yz}$  and  $G_{zx}$  as mentioned in ORTHO table).

5. In case of a viscous hyperelastic material, total strain energy be expressed as a Prony series expansion in terms of energy functional

$$\Psi = \Psi^\infty + \sum_{n=1} \Psi_n e^{-t/T_{di}}$$

Above equation can also be expressed as a function of the elastic strain energy density for instantaneous deformations  $\Psi^\infty$ .

$$\psi = \psi^{\infty} + \sum_{n=1} W_i \psi^0 e^{-t/T_i}$$

where  $W_i$  are weighting factors  $\psi_i/\psi^0$  and  $T_i$  are time constants. Two Prony series can be formed

based on deviatoric ( $\psi^d$ ) and volumetric strain energy ( $\psi^v$ ). If a viscous hyperelastic Prony series is selected, at least one pair of weighting factor and time constant must be provided: ( $W_{d1}$ ,  $T_{d1}$ ) and /or ( $W_{v1}$ ,  $T_{v1}$ ). OGDEN support both deviatoric ( $W_{di}$ ,  $T_{di}$ ) and volumetric strain energy ( $W_{vi}$ ,  $T_{vi}$ ) Prony series. However, Mooney supports only deviatoric strain energy ( $W_{di}$ ,  $T_{di}$ ) Prony series. Foam is defined in total strain energy density function and specified through  $W_i$  and  $T_i$ .

6. If ALPHAS or ALPHAL is specified, the thermal expansion coefficient specified in MAT1, MATT1, MATHE, MATTHE, MATORT or MATTORT will be ignored. Use of ALPHAS or ALPHAL requires the MATTVE Narayanaswami model.
7. If the weighting factor is left blank, the relaxation function corresponding to that coefficient is omitted.
8. In SOL 400, MATVE is used only supported for elements with property extensions. This implies that for such elements, PBAR / PBARL, PBEAM / PBEAML, PCOMP / PCOMPG, PROD, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PBARN1, PBEMN1, PSHLN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Note that, prior to MSC Nastran 2010, if the property extensions were missing, then the MATVE data was not considered in the element's formulation. If the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS,SPROPMAP,-1 in the bulk data.
9. FOAM (FOAM1) no difference between deviatoric and volumetric multipliers and relaxation time. Program will use deviatoric input to apply on entire strain energy function.

#### Notes:

1. The Prony series uses values of  $G_i$  or  $K_i$  for Isotropic and Orthotropic materials. It uses weighting ( $W_i$ ) functions for Mooney, Ogden and Foam materials.
2. The instantaneous material properties are specified on primary material entries (i.e., for MAT1 or MAT3 or MAT8 or MATORT or MATHE)
3. In the MATVE entries, material properties with the Prony series parameters are specified.
4. MATVE with "ISO", "MOONEY", "OGDEN", "FOAM" models are similar to the corresponding "ISO1", "MOONEY1", "OGDEN1", "FOAM1" models with the only exception being that the former models are limited to 5 terms in the Prony series. With the latter models, there is no limit to the number of terms in the Prony series.

**MATVE**

Visco-Elastic Material Properties- SOL700

Specifies isotropic visco-elastic material properties to be used for quasi-static or dynamic analysis in SOL 700. Used in SOL 700 only.

Format (for types Iso, Mooney, Ogden and Foam):

1	2	3	4	5	6	7	8	9	10
MATVE	MID	Model			G0	GI	BETA	VISC	

Example:

MATVE	1	ISOLIN			8.E7	1.E7	0.1		
-------	---	--------	--	--	------	------	-----	--	--

Describer	Meaning
MID	Identification number of MAT1 or MATHE entry (Integer > 0; required).
Model	Selects a visco-elastic model defining time-dependent deformation behavior (Character): <b>ISOLIN</b> for linear isotropic materials referenced by MAT1
G0	Short-time shear modulus. (Real; default=0.0)
GI	Long-time shear modulus. (Real; default=0.0)
BETA	Decay constant. (Real; default=0.0)
VISC	Shear viscosity constant. (Real; default=0.0)

Remarks:

1. The spring-damper analog of this model is:

2. The deviatoric stress is given by

$$\sigma'_{ij}(t) = 2G_I \varepsilon'_{ij}(t) + 2 \int_0^t G(t-\tau) \frac{\partial \varepsilon'_{ij}(\tau)}{\partial \tau} d\tau + 2\eta_0 \frac{\partial \varepsilon'_{ij}(t)}{\partial t}$$

$$G(t - \tau) = G(G_0 - G_I)e^{-\beta(t - \tau)}$$

The above equation for the deviatoric stress is the integral form of the differential equation

$$\dot{\sigma}'_{ij} + \beta\sigma'_{ij} = 2\eta_0\ddot{\varepsilon}'_{ij} + (2\eta_0\beta + 2G_0)\dot{\varepsilon}'_{ij} + 2G_I\beta\varepsilon'_{ij}$$

A special case is for which is often written  $\eta_0 = G_I = 0$

$$\dot{\varepsilon}'_{ij} = \dot{\varepsilon}'_{ijelastic} + \dot{\varepsilon}'_{ijviscous} = \frac{\dot{\sigma}'_{ij}}{2G_0} + \frac{\beta}{2G_0}\sigma'_{ij}$$

## MATVP

## Viscoplastic or Creep Material Properties - SOL600

Specifies viscoplastic or creep material properties to be used for quasi-static analysis.

Primary Format: PARAM, MARCMATT, 1 required

1	2	3	4	5	6	7	8	9	10
MATVP	MID	A	IT3D	M	N	P	Q	IUSER	

Alternate Format: PARAM, MARCMATT, -1 required

1	2	3	4	5	6	7	8	9	10
MATVP	MID	FORM	COEFF	STRESS	STRAIN	TEMP	TIME	IUSER	

Example 1: TABL3D used to specify computation of A.

MATVP	101	1.0	20	1.5	1.1	1.0	1.0		
-------	-----	-----	----	-----	-----	-----	-----	--	--

Example 2: Coefficient A provided with exponents for stress, strain, temperature, and time.

MATVP	102	.00375		1.5	1.1	1.0	1.0		
-------	-----	--------	--	-----	-----	-----	-----	--	--

Example 3: Primary format user subroutine **crplaw.f** and **vswell.f** are used.

MATVP	100							12	
-------	-----	--	--	--	--	--	--	----	--

Example 4: Alternate format with four table inputs

MATVP	10	TABLE	3.5-15	101	102	103	104		
-------	----	-------	--------	-----	-----	-----	-----	--	--

Example 5: Alternate User subroutine **ucrplw.f** is used

MATVP	75	USER						4	
-------	----	------	--	--	--	--	--	---	--

Descriptor	Meaning
MID	Identification number of MAT1, MAT2, MATORT or MAT9 entry. See Remark 1. (Integer > 0)
<b>Power-Law Creep Model</b>	
A	Enter the coefficient A in for the equations of Remark 2. (this value could alternatively be built into the table referenced using IT3D in which case A should be set to 1.0. If A=0.0, user subroutine(s) designated by the flag in field 9 may be used to define the creep law and fields 4-8 will be ignored if entered. (Real; no Default)
IT3D	ID of a TABL3Di entry that defines the variation with respect to stress, strain, temperature and/or time per the equations discussed in Remark 2. The exponents are provided in the next 4 fields. (Integer > 0; Default = 0)
M	Exponent m for stress in equation in Remark 2. (Real; Default = 0.0)

Describer	Meaning
N	Exponent n for strain in equation in Remark 2. (Real; Default = 0.0)
P	Exponent p for temperature in equation in Remark 2. (Real; Default = 0.0)
Q	Exponent q for time in equation in Remark 2. (Real; Default = 0.0)
IUSER	Packed list designating which user subroutines (if any) apply to this analysis. The user must confirm that the selected user subroutines are appropriate for the current analysis and are consistent with other entries in the model. (Integer; Default = 0)
	1            crplaw.f
	2            vswell.f
	3            crpvis.f
	4            ucrplw.f
	5            uvscpl.f
	(examples, if crplaw.f is used, enter 1 if both crplaw.f and vswell.f are required, enter 12).

**Power-Law Creep Model Alternate Format**

FORM	Selects a creep data input form defining creep strain rate from the options listed below. (Character; no Default):
	“POWER”    for exponent input in power law form
	“TABLE”    for piece-wise linear curve input in TABLEM1 entry.
	“USER”     user subroutine crplaw.f will be used instead of the values/table ID’s on the entry (if this form is used, fields 4-8 should be ignored if entered).
	See Remark 2.
COEFF	Specifies the coefficient value, A in equation. (Real > 0)
STRESS	Identification number of TABLEM1 (Integer > 0) for the function f or exponent m (Real > 0.) for an effective stress function, depending on the Form field.
STRAIN	Identification number of TABLEM1 (Integer > 0) for the function g or exponent n (Real; Default = 0.) for an equivalent creep strain function, depending on the Form field.
TEMP	Identification number of TABLEM1 (Integer > 0) for the function h or exponent p (Real; Default = 0) for a temperature function, depending on the Form field.
TIME	Identification number of TABLEM1 (Integer > 0) for the function K or exponent q (Real > 0; Default = 1) for a time function, depending on the Form field.

## Remarks:

1. The MATVP entry is activated if a MAT1, MAT2, MATORT, or MAT9 entry with the same MID is specified in an implicit nonlinear analysis. This creep capability is available for isotropic, orthotropic, and anisotropic elasticity, which can be coupled with plasticity using MATEP entry. Coupling with plasticity is allowed only for selected plasticity models, which include von Mises, Hill's anisotropy (creep stays isotropic), and Mohr-Coulomb models. However, viscoelasticity (MATVE) cannot be combined with viscoplasticity (MATVP).
2. The creep behavior of the material is expressed in terms of creep strain rate as a product of a number of terms (functions of effective stress, equivalent creep strain, temperature, and time) in either exponential form or piecewise linear curves, i.e.,

$$\dot{\bar{\varepsilon}}^c = A \bar{\sigma}^{-m} (\bar{\varepsilon}^c)^n T^p (qt^{q-1}) \text{ or}$$

$$\dot{\bar{\varepsilon}}^c = Af(\bar{\sigma})g(\bar{\varepsilon}^c)h(T)\frac{dK(t)}{dt}$$

Power-Law creep (exponential form) can be used with either explicit or implicit creep methods. The choice of explicit or implicit creep is made via the NLMOPTS option.

- a. Explicit creep can be combined with other plasticity options defined through the MATEP card. The supported plasticity models include Von Mises, Hill's Anisotropy (creep remains isotropic) and Mohr-Coulomb models. The creep and plastic strains are treated separately with the algorithm handling the creep in an explicit manner and handling the plasticity in an implicit manner.
- b. Implicit power law creep can be combined with the Von Mises yield criterion defined through the MATEP card. Both the creep and plasticity are handled simultaneously through an implicit viscoplasticity algorithm and a combined inelastic strain is computed.
- c. Note that for the explicit creep strain-rate evaluation, N should only be specified if some creep strain is already present in the model. Otherwise, N should be zero (blank), or implicit creep should be selected in CREEP of NLMOPTS.
- d. The dependence of time (Q) is specified as function of total equivalent creep strain i.e.,  $\dot{\bar{\varepsilon}}^c = At^q \bar{\varepsilon}^c = Aqt^{q-1}$ .

The functions  $f$ ,  $g$ ,  $h$  and  $K$  are specified as piece-wise linear functions in a tabular form using TABLEM1 entry, if the Table Form is selected. Notice that the last term in time shows function  $K$  for the equivalent creep strain in terms of time, instead of creep strain rate.

The creep strain from the creep material is a permanent strain unlike the creep strain for materials using the CREEP Bulk Data entry. As such, this creep material may be classified as viscoplastic material. This creep capability is provided for the primary and the secondary creep behavior, because the tertiary creep involves material instability such as necking.

3. See associated Bulk Data entry, MPCREEP.
4. The alternate format is determined by field 3 with a character string POWER, TABLE, or USER.
5. There must be a non-blank entry in field 3 for either format.

6. MATVP is used in conjunction with NLPARM with no restrictions on the value of the total time ( $NINC * DT$ ). NLAUTO may be added to specify under stress, strain or other criteria and/or for advanced convergence controls not available on the first line of NLPARM. Additional convergence and solver controls are available using NLSTRAT.

## MATVP

## Viscoplastic or Creep Material Properties - SOL400

Specifies viscoplastic or creep material properties to be used for quasi-static analysis.

Format: Power-Law Creep Model

1	2	3	4	5	6	7	8	9	10
MATVP	MID	A	IT3D	M	N	P	Q	IUSER

	1787.02	3.73	15.09						

Describer	Meaning
MID	Identification number of MAT1, MAT2, MATORT or MAT9 entry. See Remark 1. (Integer > 0)
<b>Power-Law Creep Model</b>	
A	Enter the coefficient A in for the equations of Remark 2. (this value could alternatively be built into the table referenced using IT3D in which case A should be set to 1.0. If A=0.0, user subroutine(s) designated by the flag in field 9 may be used to define the creep law and fields 4-8 will be ignored if entered. (Real; no Default)
IT3D	ID of a TABL3Di entry that defines the variation with respect to stress, strain, temperature and/or time per the equations discussed in Remark 2. The exponents are provided in the next 4 fields. (Integer > 0; Default = 0)

Describer	Meaning
M	Exponent m for stress in equation in Remark 2. (Real; Default = 0.0)
N	Exponent n for strain in equation in Remark 2. (Real; Default = 0.0)
P	Exponent p for temperature in equation in Remark 2. (Real; Default = 0.0)
Q	Exponent q for time in equation in Remark 2. (Real; Default = 0.0)
IUSER	IUSER=1 if user subroutine crplaw.f is desired. (Integer; Default = 0)

### Anand Solar Creep Model

ANAND	A keyword specifying the Anand solder creep model. The Anand solder creep model consists of a simple set of constitutive equations for large, isotropic, viscoplastic problems. If this key word is used, next 9 fields for parameters of Material properties must be filled with values. Please note that Anand solder creep model is only for isotropic materials. See Remark 6, 7, and 8.
PREXF	Pre-exponential factor, $A(s^{-1})$ .
ACTEN	Activation Energy, $Q (J/mol)$ .
MULST	Multiplier of stress, $\xi$ .
STNRT	Strain rate sensitivity of stress, m.
SATCO	Deformation resistance saturation coefficient, $\hat{s}$ (MPa).
STNSA	Strain rate sensitivity of saturation, n.
HRCN	Hardening constant, $h_0$ (MPa).
STNHR	Strain rate sensitivity of hardening, a.
DEFRS	Initial value of deformation resistance, $s_0$ (MPa).

### Remarks:

1. This MATVP entry is activated if a MAT1, MAT2, MATORT, or MAT9 entry with the same MID is specified in an implicit nonlinear analysis. This creep capability is available for isotropic, orthotropic, and anisotropic elasticity, which can be coupled with plasticity using MATEP entry. Coupling with plasticity is allowed only for selected plasticity models, which include von Mises, Hill's anisotropy (creep stays isotropic), and Mohr-Coulomb models. However, viscoelasticity (MATVE) cannot be combined with viscoplasticity (MATVP).

Note that ANAND solder creep model may be associated with isotropic material, i.e., MAT1, only.

2. The creep behavior of the material is expressed in terms of creep strain rate as a product of a number of terms (functions of effective stress, equivalent creep strain, temperature, and time) in exponential form, i.e.,

$$\dot{\epsilon}^c = A \bar{\sigma}^{-m} (\bar{\epsilon}^c)^n T^p (qt^q - 1)$$

Power-Law creep (exponential form) can be used with either explicit or implicit creep methods. The choice of explicit or implicit creep is made via the NLMOPTS option.

- a. Explicit creep can be combined with other plasticity options defined through the MATEP card. The supported plasticity models include Von Mises, Hill's Anisotropy (creep remains isotropic) and Mohr-Coulomb models. The creep and plastic strains are treated separately with the algorithm handling the creep in an explicit manner and handling the plasticity in an implicit manner.
- b. Implicit power law creep can be combined with the Von Mises yield criterion defined through the MATEP card. Both the creep and plasticity are handled simultaneously through an implicit viscoplasticity algorithm and a combined inelastic strain is computed.
- c. The dependence of time (Q) is specified as function of total equivalent creep strain i.e.,  

$$\dot{\varepsilon}^c = A t^q.$$

Note that the creep strain rate is internally computed as:

$$\dot{\varepsilon}^c = A t^q$$

The creep strain from the creep material is a permanent strain unlike the creep strain for materials using the CREEP Bulk Data entry. As such, this creep material may be classified as viscoplastic material. This creep capability is provided for the primary and the secondary creep behavior, because the tertiary creep involves material instability such as necking.

3. See associated Bulk Data entry, NLMOPTS
4. For NLSTEP adaptive stepping, use of TABSCTL to specify user criteria on creep strains and stresses is also recommended. MATVP is used only supported for elements with property extensions. This implies that for such elements, PBAR / PBARL, PBEAM / PBEAML, PCOMP / PCOMPG, PROD, PSHEAR, PSHELL, PLPLANE and PSOLID should be associated with PBARN1, PBEMN1, PSHLN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 respectively. Note that, prior to MD Nastran 2010, if the property extensions were missing, then the MATVP data was not considered in the element's formulation. From MD Nastran 2010 onwards, if the property extensions are missing, they are automatically added with appropriate settings by the program unless the user has set NLMOPTS, SPROPMAP, -1 in the bulk data.
5. When used with PBAR, PBEAM, PBEAML, PCOMP, PCOMPG, PROD, PSHEAR, PSHELL or PLPLANE (with BEH=PSTRS) the explicit formulation must be used, set VALC3=0 on NLMOPTS.
6. Flow equation for Anand Solder model is given by:

$$\dot{\varepsilon}_p = A \exp\left(-\frac{Q}{RT}\right) \left[ \sinh\left(\xi \frac{\sigma}{s}\right) \right]^{1/m}$$

where A is the pre-exponential factor; Q is the activation energy; m is the strain rate sensitivity;  $\xi$  is the multiplier of stress, R is the gas constant (8.314 J/mol/K); T is the absolute temperature; s is deformation resistance with an initial value  $s_0$ . The evolution of deformation resistance is given by

$$\frac{ds}{dt} = \left\{ h_0 |B|^a \frac{B}{|B|} \right\} \frac{d\varepsilon_p}{dt}$$

where;

$$B = 1 - \frac{s}{s''}$$

and

$$s'' = \hat{s} \left[ \frac{1}{A} \frac{d\varepsilon_p}{dt} \exp\left(\frac{Q}{RT}\right) \right]^n$$

where  $h_0$  is hardening constant;  $a$  is the strain rate sensitivity of hardening;  $\hat{s}$  is the deformation resistance saturation coefficient,  $n$  is the strain rate sensitivity of saturation.

7. To activating creep analysis with ANAND creep model, the following parameters are mandatory:
  - a. In Bulk Data Card NLMOPTS: keyword “CREEP” and “LRGSTRN” must be selected with value:
    - “LRGSTRN” with value 1 for updated Lagrange formulation, Hypo-elasticity and additive plasticity with mean normal value.
    - “CREEP” with valc3=1, Implicit Creep on; and valc4=0/1/2, for elastic tangent as default (Blank or 0), 1 for secant tangent, and 2 for Radial Return, respectively.
  - b. In Bulk Data Card NLSTEP: CREEP in “GENERAL” is required for ANAND creep model.
  - c. In Bulk Data Card MATVP: material parameters of ANAND creep model are defined in MATVP card with keyword “ANAND” in the 3<sup>rd</sup> field and following 9 fields.
8. NLSTRESS in Case Control will output the equivalent creep strain on grid point. To output the component of the creep strain, NLOUT in NLSTRESS Case Control command must be set and request Creep output in Bulk Data Card.

In case control section:

```
NLSTRESS (NLOUT=num) = ALL
```

In bulk data section:

```
NLOUT, num, TOTTEMP, CCRPSTRN
```

## MAUXCMD Auxiliary Command to Spawn one Nastran Process from Another - SOL 600

Defines auxiliary command to spawn on Nastran process from another Nastran process in SOL 600.

Format:

1	2	3	4	5	6	7	8	9	10
MAUXCMD	Command	Cont	Cont	Cont	Cont	Cont	Cont	Cont	

Example:

MAUXCMD	/mscinst/nast2008/bin/mdnast2008	
---------	----------------------------------	--

Describer	Meaning
Command	Enter the command you normally use to execute Nastran from the command line (Character; no default; limit of 64 characters)

Remark:

1. At present, this entry may only be used for CINTC when PARAM,MBLADCMD,10 is set.

**MBOLT** Defines a Bolt For Use in SOL 600 in Countries Outside the USA

Defines a bolt for use in SOL 600 in countries outside the USA. Used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MBOLT	ID	GRIDC	V1	V2	V3				
	GRIDS	G1	G2	G3	G4	G5	G6	G7	
		G8	G9	Etc.					
	ELEMS	E1	E2	E3	E4	E5	E6	E7	
		E8	E9	Etc.					

Example:

MBOLT	100	1025	0.0	1.0	0.0				
	GRIDS	101	102	103	104	105			
	ELEMS	1	2	3	4	5	6	7	
		10							

Describer	Meaning
ID	Element ID of the bolt. (Integer; Required; no Default)
GRIDC	Control GRID ID where forces or displacements are applied. (Integer; no Default; Required)
V1	First component of vector normal to the bolt cross section in basic coordinate system. (Real; Default = 0.0)
V2	Second component of vector normal to the bolt cross section in basic coordinate system. (Real; Default = 0.0)
V3	Third component of vector normal to the bolt cross section in basic coordinate system. (Real; Default = 0.0)
GRIDS	Enter the character string GRIDS to define the start of the entry that defines all of the grids at the bolt intersection cross section (do not enter the ID for GRIDC). (Integer; no Default)
G1, G2, etc.	Grid IDs of the grid points at the bolt intersection. (Integer; no Default)
ELEMS	Enter the character string ELEMS to define the start of the entry that defines all of the elements at the bolt intersection cross section lying on the side of the cross section corresponding to the negative normal direction. (Integer; no Default)
E1, E2, etc.	Element IDs of the grid points at the bolt intersection. (Integer; no Default)

**Remarks:**

1. Enter as many GRIDS and ELEMS lines as necessary to define all the grid and element IDs in the cross section.
2. All GRIDS must precede all ELEMS.
3. The bolt itself is not actually modeled, just the intersecting surfaces. The nodes and elements where the bolt goes through the intersecting surfaces are described by this entry.
4. Specify a different MBOLT entry for each individual bolt.
5. This entry can only be used with Marc 2003 or later outside the USA.
6. For more information, please consult the Marc Theoretical Manual (Volume A of the Marc documentation).
7. This entry maps to Marc's CROSS SECTION entry.
8. GRIDC must already exist. It is not generated by the MBOLT entry. It typically would not be used by any other element, MPC, etc.

## MBOLTUS

### Defines a Bolt for Use in SOL 600 in the USA

Defines a bolt for use only in SOL 600 and only in the USA.

Format:

1	2	3	4	5	6	7	8	9	10
MBOLTUS	ID	GRIDC							
	TOP	GT1	GT2	GT3	GT4	GT5	GT6	GT7	
		GT8	GT9	Etc.					
	BOTTOM	GB1	BG2	BG3	BG4	GB5	GB6	GB7	
		GB8	GB9	Etc.					

Example:

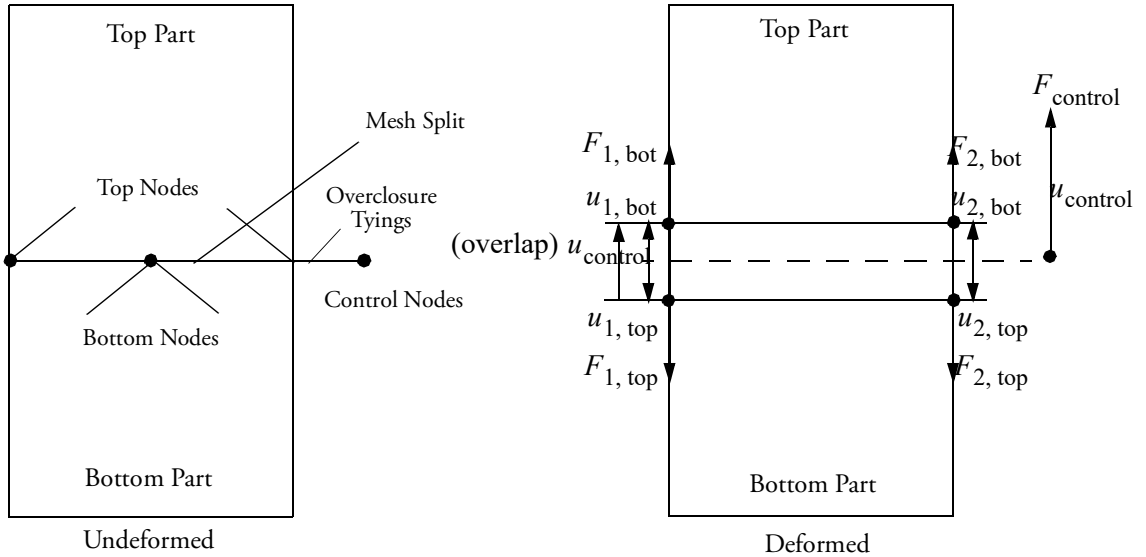

MBOLTUS	100	1025		1.0					
	TOP	101	102	103	104	105			
	BOTTOM	1	2	3	4	5			

Describer	Meaning
ID	Element ID of the bolt. (Integer; Required; no Default)
GRIDC	Control GRID ID where forces or displacements are applied. (Integer; no Default; Required)
TOP	Enter the character string TOP to define the start of the entry that defines all of the grids at the “top” of the bolt intersection with the structure (do not enter the ID for GRIDC). (Integer; no Default)
GT1, GT2, etc.	Grid IDs of the grid points at the top of the bolt intersection. (Integer; no Default)
BOTTOM	Enter the character string BOTTOM to define the start of the entry that defines all of the grids at the “bottom” of the bolt intersection with the structure (do not enter the ID for GRIDC) (Integer; no Default)
GB1, GB2, etc.	Grid IDs of the grid points at the bottom of the bolt intersection (Integer; no Default)

Remarks:

1. Enter as many GRIDS as necessary (up to the limit of 999 top grids and 999 bottom grids) to define all the grids at the “top” and “bottom” of the bolt intersection with the structure.
2. The bolt itself is not actually modeled, just the intersecting surfaces. The nodes and elements where the bolt goes through the intersection surfaces are described by the entry.
3. Specify a different MBOLTUS entry for each individual bolt.
4. This entry can only be used with Marc 2003 or later.

5. For more information, please consult the Marc Theoretical Manual (Volume A of the Marc documentation)
6. This entry maps to Marc's TYING type 69.
7. GRIDC must already exist. It is not generated by the MBOLTUS entry. It typically would not be used by any other element, MPC, etc.
8. The following figure indicates the required modeling and data input.

## MCHSTAT      Option to Change State Variables for SOL 600

This option provides various ways of changing state variables throughout the model. It is required if Bulk Data entry, MTCREEP is used. It may also be used to enter temperatures calculated from a previous heat transfer analysis and saved on a t16 or t19 file in which case MINSTAT is used to define the initial stress-free temperatures and MCHSTAT is used to define the temperatures that cause thermal strains.

Format:

1	2	3	4	5	6	7	8	9	10
MCHSTAT	ID	IDV	IOPT		INCR	NSET	IFORM	IPRT	
		NPST							
	"FILE"	Name							
	"ELEM"	ELE1	ELE2	INT1	INT2	LAY1	LAY2	VAL	
	"STATE"	NS	IS1	IS2	IS4	IS5	IS6		
		IS7	IS8	IS9	etc.				

Example:

MCHSTAT	0	1	3		1		0		
		9							
	FILE	change_state_example01							

Describer	Meaning
ID	ID of a matching Case Control MCHSTAT command. If ID=0 this entry is in the Marc Model definition, otherwise it is in Marc's History Definition for the applicable subcase. (Integer; no Default)
IDV	State variable identifier (1=temperature). (Integer; Default = 1) (2,1) If more than one state variable is required, enter -1.
IOPT	Option of how to enter the data. (Integer; Default = 3) (2,2) 1      Use the "ELEM" continuation line for as many elements as necessary 2      Enter the data using user subroutine NEWSV 3      Read the data from a t16 or t19 file (see IFORM)
INCR	Increment number on t16 or t19 file defining the new state values if IOPT=3. (Integer; no Default) (2,5)
NSET	Number of sets to be read to define the temperature history if Marc's iteration method is controlled using MOTHERM or MTCREEP. (Integer; no Default) (2,6)
IFORM	Designates whether a binary (t16) or formatted (t19) post file is used if IOPT=3. (Integer; Default = 0) (2,7) 0      Use binary (t16) file

Describer	Meaning
	1 Use formatted (t19) file
IPRT	Enter a value of 1 to suppress printing of state variable values defined in user subroutine NEWSV (only applicable if IOPT=2). (Integer; Default = 0) (2,8)
NPST	Post Code ID to be read into this state variable. (Integer; Default = 9 [temperature]) (2,9) See MARCOUT for a list of the post codes.
FILE	Enter the character string FILE if IOPT=3. (Character, no Default; Required if IOPT=3)
NAME	Enter the file root name of the previous heat transfer job without any extension. For example if the previous heat transfer job was heat32.dat or heat32.bdf, enter heat32 The file name must be entirely in lower case for case-sensitive computer systems and is limited to 56 characters. This file must be in the same directory as the Nastran input file. (Character, no Default.
ELEM	Enter the character string ELEM to start a list of elements and associated values if IOPT=1 (Character)
ELE1	First element with value VAL. (Integer; no Default; Required) (3,1)
ELE2	Last element with value VAL. (Integer; Default = ELE1) (3,2)
INT1	First integration point with value VAL. (Integer; no Default; Required) (3,3)
INT2	Last integration point with value VAL. (Integer; Default = INT1) (3,4)
LAY1	First cross-section layer with value VAL. (Integer; no Default; Required) (3,5)
LAY2	Last cross-section layer with value VAL. (Integer; Default = LAY1) (3,6)
VAL	New state value for these elements. (Real; no Default; Required) (4,1)
STATE	Enter the character string STATE to start a list of state variables. (Character)
NS	Number of state variables to be defined. (Integer; no Default; limited to 16 maximum)
ISi	State variable post codes. (Integer; no Default) (9,i) See MARCOUT entry for applicable post codes.

Remarks:

1. All MCHSTAT ID's must be unique.
2. This entry maps to Marc's CHANGE STATE entry.
3. This entry must be entered if the MTCREEP (Marc's AUTO THERM CREEP) entry is used.
4. (i,j) refer to Marc's CHANGE STATE (data block, field).
5. MCHSTAT (and/or MINSTAT) cannot be the only applied "loads". At least one standard load such as FORCE, PLOAD4 or a standard TEMP entry must be entered with a Case Control LOAD command that references the standard load(s). If there are no standard loads, please enter a dummy load with a very small magnitude and a Case Control LOAD command to reference it.

## MCOHE

## Interface Cohesive Zone Modeling Element Material Properties

Specifies material cohesive properties for a fully nonlinear element used to simulate the onset and progress of delamination in SOL 400 only.

Format:

1	2	3	4	5	6	7	8	9	10
MCOHE	MID	MODEL		TID					
	COHE	CRTOD	MAXOD	SNSR	EXP	VED	RRRD	SFC	
	SNER								

Example:

MCOHE	701	2		357					
	136.5	0.0	0.0	1.0	0.02	0.0		1.0	

Descriptor	Meaning
MID	Identification number of a MCOHE entry. (Integer > 0) (See Remark 1.)
MODEL	(Integer > 0; Default = 1) (See Remark 3.)
	1          Bilinear model
	2          Exponential model
	3          Linear-exponential model
	-1         User Defined Subroutine (See Remark 2.)
TID	Table identifier for a combination of TABLES1/TABLEST for cohesive energy vs temperature. (Integer ≥ 0; Default = 0)
COHE	Cohesive energy. (Real ≥ 0.0)
CRTOD	Critical opening distance. (Real ≥ 0.0)
MAXOD	Maximum opening displacement (bilinear model only). (Real ≥ 0.0)
SNSR	Shear Normal Stress Ratio. (Real > 0.0; Default = 1.0)
EXP	Exponential decay factor (linear-exponential model only). (Real > 0.0; Default = 1.0)
VED	Factor for viscous energy dissipation. (Real ≥ 0.0; Default = 0.0)
RRRD	Reference rate of relative displacement. Used only if VED ≠ 0.0 . A value of 0.0 implies that the reference rate will be automatically calculated. (Real ≥ 0.0; Default = 0.0)
SFC	Stiffening factor in compression. (Real ≥ 0.0; Default = 1.0)
SNER	Shear Normal Energy Ratio. (Real > 0.0; Default = 1.0)

**Remarks:**

1. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.
2. User subroutine UCOHES is used. User must also use the MATUDS bulk data entry.
3. For details on model see Nonlinear User's Guide (SOL 400).

**MDBCATP****Defines Parameters of Across Modules for Automatic Contact Generation**

Defines parameters for detecting contact pairs across modules for automatic contact generation (ACG). It is similar to BCAUTOP but is used for contact pair detection across modules, all the parameters for contact bodies in BCAUTOP are excluded.

Format:

1	2	3	4	5	6	7	8	9	10
MDBCATP			Param1	Value1	Param2	Value2	Param3	Value3	
			Param <i>i</i>	Value <i>i</i>					

Example:

MDBCATP			DISTANCE	0.3	DELSLD	YES			
---------	--	--	----------	-----	--------	-----	--	--	--

Describer	Meaning
Param( <i>i</i> )	Name of a parameter. Allowable names are given below (Character).
Value( <i>i</i> )	Value of the parameter. See below (Real, Integer or character). See Remark 3.

Remarks:

1. Only one entry of MDBCATP is allowed.
2. This entry does not have effect if BCONTACT=AUTO is not present in case control section.
3. The parameters in this entry may be divided into two types - primary parameters and secondary parameters. The primary parameters are the most important parameters for contact pair detection. The secondary parameters are helpful for user to provide the more detail and further requirement for contact model establishment and contact analysis with automatic contact generation. The primary and secondary parameters are listed in the tables as follows.

Table 9-28 Primary Parameters in MDBCATP

Describer	Meaning
CTYPE	Characters, one of TOUCH(default), PGLUE, SGLUE and GGLUE. If CTYPE is specified in both BCAUTOP entry and Case Control Command BCONTACT=AUTO, the specification in this entry will be used.

Describer	Meaning
DISTANCE	<p>Distance tolerance of contact pair. If the distance between any two points which are belonging to two different contact bodies is less than this value, these two contact bodies are recognized to be a contact pair. Default value of DISTANCE is 100 times of contact ERROR tolerance. ERROR may be defined in either MDBCATP or left blank. With default of ERROR, the code calculates ERROR as the smallest one of the following values:</p> <ol style="list-style-type: none"> <li>1           1/20 of the smallest nonzero element dimension (plates or solids) in the contact body.</li> <li>2           1/4 of the thinnest shell thickness in the contact body</li> </ol> <p>See BCPARA for ERROR definition in detail.</p>

Table 9-29          Secondary Parameters in MDBCATP

Describer	Meaning
BEAMCNT	<p>Characters, YES or NO (default). Determining if beam is included in contact definition.</p> <p>YES      BEAMs are included in the contact description.</p> <p>NO      No BEAM is included in the contact description.</p>
EDGECNT	<p>Characters, YES or NO (default). Determining if shell edge is included in contact description.</p> <p>YES      The free and hard shell edges are included in the contact definition.</p> <p>NO      No shell edges are included in the contact definition.</p>
FTYPE	<p>Characters, BLCOUL/BLSHEAR; or Integer, 6 / 7. BLCOUL or 6 is Bilinear Coulomb friction. BLSHEAR or 7 is Bilinear Shear friction. Default is No Friction.</p>
FRIC	<p>Friction coefficient. If the value is an integer, it represents the ID of a TABLEM1, TABLEM2 or TABL3D, i.e., a temperature-dependent or multi-dimensional table. (Real <math>\geq 0.0</math> or Integer <math>&gt; 0</math>; Default = 0.0)</p>
IGNTHK	<p>Character, YES or NO (default), Ignore thickness of shell for contact.</p> <p>YES      Ignore the thickness of the shell</p> <p>NO      Include the thickness of the shell</p>
INISTF	<p>Character, YES or NO (default). Set the option of initial stress free.</p>

Describer	Meaning
	YES Initial stress free contact.
	NO General contact without implementation of initial stress free.
SelfCont	Characters, YES or NO (default). Option of self-contact.

**Note:** The parameters defined in MDBCATP are applied only for BCONATCT=AUTO. Their default values are defined only when BCONTACT=AUTO is applied. All the parameters in BCPARA, BCONPRP and BCONPRG entries may be used in MDBCATP directly. For the detailed list of these parameters, please refer to BCPARA, BCONPRP and BCONPRG

**MDBCNCCT****Defines the Touching and Touched Contact Bodies in Different Modules**

Defines the touching and touched contact and used in SOLs 101, 103, 105, 107, 108, 109, 110, 111, 112 and 400 for general contact, glued, step glue or permanent glue between contact bodies residing in different Modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDBCNCCT	ID	BCGPID	BCPPID	MODS	IDSCND	MODP	IDPRIM		
	“SECNDRY”	MODS1	IDSEC1	MODS2	IDSEC2	MODS3	IDSEC3		
		MODS4	IDSEC4	-etc.-					
	“PRIMARY”	MODP1	IDPRIM1	MODP2	IDPRIM2	MODP3	IDPRIM3		
		MODP4	IDPRIM4	-etc.-					

Example:

MDBCNCCT	57	306		101	2	201	1002		
----------	----	-----	--	-----	---	-----	------	--	--

MDBCNCCT	9		108						
	SECNDRY	101	30	201	26				
	PRIMARY	101	294	201	135	301	528		

Descriptor	Meaning
ID	Unique identification number referenced by a MDBCTB1 entry (Integer $\geq 0$ ). See Remark 5.
BCGPID	Parameter identification number of a BCONPRG entry (Integer $\geq 0$ or blank). See Remark 6.
BCPPID	Parameter identification number of a BCONPRP entry (Integer $\geq 0$ or blank). See Remark 6.
MODS	Identification number of a Module that defines IDSCND (Integer $\geq 0$ or blank)
IDSCND	Identification number of BCBODY1 entry defining the touching body (Integer $\geq 0$ or blank). See Remarks 7. and 8.
MODP	Identification number of a Module that defines IDPRIM (Integer $\geq 0$ or blank)
IDPRIM	Identification number of BCBODY1 entry defining the touched body (Integer $\geq 0$ or blank). See Remarks 9. and 10.
“SECNDRY”	Indicates the start of the list of the touching bodies. See Remark 8.
MODSi	Identification number of a Module that defines IDSECI (Integer $\geq 0$ or blank)
IDSECI	Identification number of BCBODY1 entry defining touching bodies (Integer $\geq 0$ or blank,). See Remarks 7. and 8.

Describer	Meaning
“PRIMARY”	Indicates the start of the list of bodies touched by touching bodies. See Remark 10.
MODPi	Identification number of a Module that defines IDPRIMi (Integer $\geq 0$ or blank)
IDPRIMi	Identification number of BCBODY1 entry defining touched bodies (Integer $\geq 0$ or blank).

#### Remarks:

- Both BCTABL1 and MDBCTB1 may only be specified in the main Bulk Data section.
- BCTABL1 BCID must be unique with respect to all other BCTABL1 and MDBCTB1.
- BCONTACT Case Control command may only select BCTABL1 or MDBCTB1 but not both. If BCTABL1 is selected, then all bodies matching IDi in any and all Modules will be activated.
- Only MDBCTB1 can select MDBCNCCT.
- MDBCNCCT can be selected by the Case Control command BCONTACT=ID to define surface contact if MDBCTB1 entry does not exist. See Remarks 2 and 3 of MDBCTB1 entry.
- If BCGPID or BCPPID field is blank, then default values are set for the parameters of touching bodies.
- A short input to define a single touching body exists if the user provides IDSCND. On the other hand, if the user leaves IDSCND blank, then “SECNDRY” descriptor is required and IDSECI must be specified.
- “SECNDRY” and IDSECI fields will be ignored if IDSCND exists. If IDSCND field is blank, then “SECNDRY” and IDSECI must be specified. In this case, each IDSECI will be processed separately.
- A short input to define a single touched body exists if the user provides IDPRIM. On the other hand, if the user leaves IDPRIM blank, then “PRIMARY” descriptor is required and IDPRIM1 must be specified.
- “PRIMARY” and IDPRIMi fields will be ignored if IDPRIM exists. If IDPRIM field is blank, then “PRIMARY” and IDPRIMi must be specified.
- The concept of Secondary and Primary relation is important to the node-to-segment contact but not relevant for segment-to-segment contact. In segment-to-segment contact, they are mainly used to define the contact pair(s).
- If all the BCONPRG that are referenced by a MDBCNCCT (which is referenced by MDBCTB1) have a value of IGLUE  $> 0$ , and this MDBCNCCT is referenced in the 1st Loadcase (SOL 100\*) then the connections are considered to be permanent and do not change (unless a BCPARA is used to deactivate the permanent glue).

**MDBC PAR****Defines Candidates Modules for Automatic Contact Detection Across Modules**

Defines modules as candidates for automatic contact detection across modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDBC PAR		SET3ID							
	MODID11	MODID21			MODID12	MODID22			
	MODID13	MODID23			MODID1i	MODID2i			

Example:

MDBC PAR		2							
	2	3			4	7			

Descriptor	Meaning
SET3ID	Integer $\geq -1$ , default=-1. SET3 ID refers to a SET3 with DES="MODULE".
MODID1i	The first module ID of the candidate of contact detection between two modules
MODID2i	The second module ID of the candidate of contact detection between two modules.

Remarks:

1. Only one entry of MDBC PAR is allowed in module 0, and it must be in module 0.
2. MDBC PAR is used when BCONTACT= AUTO is set in case control command, and modules are present.
3. When SET3ID is -1, all the modules will be used to detect contact pairs across them, when it is 0, and when there is no continuation, no contact pair will be detected across modules. When SET3ID > 0, the modules defined in the SET3 entry with SID=SET3ID and DES="MODULE" will be used to detect contact pairs across them. The distance tolerance of the pair detection is defined by DISTANCE parameter in MDBC ATP.
4. Continuations are optional.
5. The pairs of MODID1i and MODID2i are the pairs of two modules to be used to detect contact pairs between them. The distance tolerance of the pair detection is defined by DISTANCE parameter in MDBC ATP

## MDBCTB1 Defines a Contact Table for Bodies in Different Modules

MDBCTB1 specifies a list of contact pairs (for bodies residing in different Modules) through the MDBCNT option for SOL 101 and SOL 400. This contact table is activated in the BCONTACT Case Control command.

Format:

1	2	3	4	5	6	7	8	9	10
MDBCTB1	BCID	MOD1	ID1	MOD2	ID2	MOD3	ID3	MOD4	
	ID4	MOD5	ID5	-etc.-					

Examples:

MDBCTB1	2	101	198	201	62	301	75	401	
	501	8	601	159	701	31	801	44	

MDBCTB1	0	1001	23	1002	56				
---------	---	------	----	------	----	--	--	--	--

Describer	Meaning
BCID	Unique identification number referenced by a BCONTACT Case Control command. See Remark 3. (Integer $\geq 0$ ; Required)
MODi	Identification number of module that defines BCONECT IDi (Integer $\geq 0$ or blank,)
IDI	Identification number of BCONECT entry (Integer $> 0$ ). See Remark 4. and 5.

Remarks:

1. MDBCTB1 defines surface contact. If MDBCTB1 does not exist, the Case Control command BCONTACT=BCID may refer to the MDBCNT Bulk Data entry directly.
2. If neither MDBCTB1 nor MDBCNT is given, the default for contact analysis is assumed, every body detects the possibility of contact relative to all other bodies and itself if it is a deformable body. If MDBCTB1 or MDBCNT is given, the default for everybody is overwritten. The touching body does not contact itself unless requested. When the touched body is deformable, double-sided contact is applied by default. MDBCTB1 or MDBCNT is useful for deactivating or activating bodies to reduce computational effort and to change contact conditions between subcases.
3. For SOLs 101 and 400, the MDBCTB1 or MDBCNT with ID=0 will be used in loadcase 0 automatically that does not need a corresponding Case Control command BCONTACT=0. The loadcase 0 is purely elastic and it can also be used to (1) move rigid contact bodies so that they just touch flexible contact bodies, and/or (2) remove any prestressed condition by adjusting the coordinates of the active nodes, which are the Grid Points on the surface of all deformable

BCBODY1's. To place an entry in any physical loadcase (SUBCASE or STEP), the BCID must be selected by the Case Control command BCONTACT=BCID or MDBCNCT=BCID. When BCONTACT=ALLBODY, there is no BCID of MDBCTB1 or MDBCNCT specified; therefore, the default values of all entries of BCONPRG and BCONPRP are assumed. Case Control command BCONTACT=ALLBODY cannot be used for permanently glued contact.

4. The "THRU" option is not supported.
5. Intervening blank fields are not allowed.
6. If Modules are present then this entry may only be specified in the main Bulk Data section.

## MDBKSYS Defines Brake System for Modules

Defines data for brake system for brake squeal calculations involving one wheel or multiple wheels with one axis or multi-axes in different modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDBKSYS	ID	OMETH	IVEC	BSONLY	ISLIDER3				
	Disk1	MODID11	BODY1ID1	MODID21	BODYID21	MOTN1ID1	MOTN2ID1	BRKPID1	
	Disk2	MODID12	BODY1ID2	MODID22	BODYID22	MOTN1ID2	MOTN2ID2	BRKPID2	
	DiskI	MODID1i	BODY1IDi	MODID2i	BODYID2i	MOTN1IDi	MOTN2IDi	BRKPIDi	

Example:

MDBKSYS	900	0.5	0	YES					
	INNER1	1	2	2	3	1	2	4	
	OUTPER	2	1	3	4	2	4	2	

Describer	Meaning
ID	Identification ID of number of a corresponding BSQUEAL Case Control command
OMETH	Specifies the corresponding load factor (or time step) where the brake squeal analysis is to be performed. (Real; Default = 0.0)
BSONLY	Brake-Squeal-Only flag to control if or not to continue nonlinear iterations after brake squeal analysis is performed. YES Means to perform brake squeal analysis only and exit nonlinear iteration immediately. NO Means to continue nonlinear analysis. (Character; Default = YES).
IVEC	Flag specifying whether friction vector at center of primary contact body is in the same direction as that of the secondary nodes; see <a href="#">Figure 9-3</a> . (Integer; Default = 0). 0: In same direction 1: In tangential direction
ISLIDEB3	Flag indicating whether contact status is treated as sliding or general static contact for brake disk/pad pairs.

Describer	Meaning
	0: (default) sliding contact for brake disk/pad pairs.
	1: general static contact as usual.
DISKi	Name of the i <sup>th</sup> brake system.
MODID1i	Module id of the BCBODY1 of the first body which is defined in this brake system.
BODY1D1i	ID of BCBODY1 of the first body which is defined in this brake system.
MODID2i	Module id of the BCBODY1 of the second body which is defined in this brake system.
BODY1D2i	ID of BCBODY1 of the second body which is defined in this brake system.
MOTN1IDi	ID of MOTION which is defined for the first body.
MOTN2IDi	ID of MOTION which is defined for the second body.
BRKPID1i	ID of BRKSYS which is defined for the first body
BRKPID2i	ID of BRKSYS which is defined for the second body

Remarks:

1. This entry must be in module 0 and modules must be present.
2. The ID must be unique.
3. BRKSYS entries with the same ID in different modules can be selected also by corresponding BSQUEAL case control command.
4. When multiple BRKSYS entries and/or MDBKSYS are selected, the first lines of those entries can be not identical, it is treated as: Use the line defined in the MDBKSYS when it exists and selected, otherwise use default value of the line. When the first lines of all the entries are identical, use the line as is.

## MDBNDRY      Module to Module Boundary Point Definitions

Defines a list of grid points in a module for the automatic boundary search between a specified Module or between all other Modules. In other words, the automatic boundary search will only search for connections in this list.

Format:

1	2	3	4	5	6	7	8	9	10
MDBNDRY	MIDA	MIDB	GIDA1	GIDA2	GIDA3	GIDA4	GIDA5	GIDA6	
	GIDA7	GIDA8	etc.						

Examples 1:

MDBNDRY	400	4	10	20	30	40			
---------	-----	---	----	----	----	----	--	--	--

Examples 2:

MDBNDRY	400	ALL	10	20	30	THRU	35		
---------	-----	-----	----	----	----	------	----	--	--

Describer	Meaning
MIDA	Module identification number. (Integer $\geq 0$ , Default=0)
MIDB	Reference Module identification number. (Integer $\geq 0$ or Character "ALL"; Default=ALL)
GIDAi	Identification number of a boundary grid point in the Module MIDA. (Integer $> 0$ or "THRU"; for "THRU" option, $GID1 < GID2$ .)

Remarks:

1. MDBNDRY may only be specified in the Main Bulk Data Section and cannot be specified in other BEGIN MODULE sections.
2. This entry is valid only if Modules exist.

**MDBOLT** Defines the Multi-Point Constraints for a Bolt Between Two Modules

Defines a rigid bolt between two Modules by a set of MPC constraints.

Format:

1	2	3	4	5	6	7	8	9	10
MDBOLT	ID	GRIDC	MODC	MODT	MODB				
	TOP	GT1	GT2	GT3	GT4	GT5	GT6		
		GT8	GT9	etc.					
	BOTTOM	GB1	GB2	GB3	GB4	GB5	GB6		
		GB8	GB9	etc.					

Example:

MDBOLT	100	1025	11	11	30				
	TOP	101	102	103	104	105			
	BOTTOM	1	2	3	4	5			

Descriptor	Meaning
ID	Element ID of the bolt. (Integer; Required; no Default)
GRIDC	Control GRID ID where forces or displacements are applied. (Integer; no Default; Required)
TOP	Enter the character string TOP to define the start of the entry that defines all of the grids at the “top” of the bolt intersection with the structure. (Integer; no Default)
MODC	Module containing the GRID entry for GRIDC. (Integer; Default=0, If MODC>0 then must be same as MODT or MODB)
MODT	Module containing the GRID entries for GTi. (Integer; Default=0)
MODB	Module containing the GRID entries for GBi. (Integer; Default=0)
GT1, GT2, etc.	Grid IDs of the grid points at the top of the bolt intersection. (Integer; no Default)
BOTTOM	Enter the character string BOTTOM to define the start of the entry that defines all of the grids at the “bottom” of the bolt intersection with the structure (do not enter the ID for GRIDC). (Integer; no Default)
GB1, GB2, etc.	Grid IDs of the grid points at the bottom of the bolt intersection. (Integer; no Default)

Remarks:

1. The MDBOLT entry must be defined in the main Bulk Data section only (Module 0).

2. See all remarks and figures under the BOLT entry description. All remarks and figures under BOLT apply to MDBOLT.

## MDBULK Module Type Definitions

Defines module search options and typing such as repeated or mirrored.

Format:

1	2	3	4	5	6	7	8	9	10
MDBULK	MODID	TYPE	RMODID	METHOD	TOL				

Example:

MDBULK	14			AUTO	1.0e-3				
--------	----	--	--	------	--------	--	--	--	--

Describer	Meaning
MODID	Module identification number. (Integer > 0 or Character = "ALL")
TYPE	Module type (Character; default = "PRIMARY")
PRIMARY	Module with at least one GRID entry in its BEGIN MODULE section.
REPEAT	Copied Module via reposition or mirroring of a primary Module. See Remarks 9 and 10.
MIRROR	Copied Module via mirroring of a primary Module. See Remarks 9 and 10.
MOVE	Copied or primary Module repositioning via MDMOVE entry. See Remarks 8 and 10.
RMODID	Identification number of the reference Module, used only if making a copy; i.e., RMODID>0 and RMODID?MODID and TYPE= "REPEAT", "MIRROR" or "MOVE". (Integer>0; Default=0). See Remarks 9 and 10.
METHOD	Method to be used when searching for boundary grid points. (Character = "AUTO" or "MANUAL"; Default= "MANUAL")
TOL	Location tolerance to be used when search for boundary grid points.  (Real; Default = 1.0e-5)

Remarks:

1. METHOD="MANUAL" requires MDCONNECT entries. MDBNDRY and MDEXCLD, that reference MODID, will produce fatal messages.
2. MDCONNECT, MDBNDRY and MDEXCLD entries can be used to augment the search procedure and/or override the global tolerance.
3. For combined automatic and manual boundary search, the METHOD="AUTO" should be specified and connections should be specified on a MDCONNECT entry.
4. TOL is the default value that can be modified between two Modules by providing the required tolerance on the MDCONNECT entry.

5. MDBULK may only be specified in the Main Bulk Data Section and cannot be placed in other BEGIN MODULE sections
6. This entry is only valid if Modules exist.
7. With MDBULK,ALL the TYPE and RMODID fields must be blank and MDBULK,ALL means that the MDBULK options METHOD and TOL will be applied to all Modules which are not already defined on an MDBULK entry.
8. TYPE="MOVE" refers to the enhanced interface. If TYPE="MOVE" then an MDMOVE Bulk Data entry must be defined. The MDMOVE entry references MDTRAN, MDROT*i*, and MDMIR*i* entries.
  - a. If TYPE="MOVE" is specified for a given Module, then MDLOC and MDMPLN cannot be specified and vice-versa.
  - b. If MDMIR*i* is referenced by MDMOVE then it must be the first MVID and cannot be specified as the second or subsequent MVIDs.
  - c. If MODID defines a secondary Module (RMODID>0) then it will automatically inherit all of the Primary Module's Bulk Data. The inheritance of a particular entry may be overridden by specifying new Bulk Data entries or ignored via the EXCLUDE Bulk Data entry in the secondary Module's Bulk Data section.
  - d. A primary Module (RMODID=0) may be re-positioned as indicated in Remark 10.
9. TYPE="REPEAT" and "MIRROR" refer to the classic interface. These types have many common features, but they also have some important differences. These are described below:
  - a. The following comments apply to both TYPE="REPEAT" and "MIRROR":
    - A Module (MODID) whose TYPE is "REPEAT" or "MIRROR" and RMODID is greater than 0 is referred to as a secondary Module. The RMODID specified in this case is regarded as the primary Module.
    - The primary Module may be re-positioned as indicated in Remark 10.
    - If MODID defines a secondary Module then it will automatically inherit all of the Primary Module's Bulk Data. The inheritance of a particular entry may be overridden by specifying new Bulk Data entries or ignored via the EXCLUDE Bulk Data entry in the secondary Module's Bulk Data section.
    - If both an MDLOC and MDMPLN entry are specified for a secondary Module, then a mirror image copy of the primary Module will be created by first using the plane defined by the MDMPLN entry and then repositioned at the location implied by the MDLOC entry.
  - b. The following comments apply only to TYPE="REPEAT":
    - The secondary Module in this case may reference an MDLOC entry, an MDMPLN entry or both or none.
    - If it references an MDLOC entry, then an identical copy of its primary Module will be positioned at the location implied by the MDLOC entry.
    - If it references an MDMPLN entry, then a mirror image copy of the primary Module will be positioned using the plane defined by the MDMPLN entry.

- If it references neither an MDLOC entry nor an MDMPLN entry, then the secondary Module will merely be a duplicate of the primary Module positioned at the same location as the primary Module. This usage is extremely uncommon. Hence the program cautions the user about this usage by issuing a user warning message
  - c. The following comments apply only to TYPE= "MIRROR":
    - The secondary Module in this case must reference an MDMPLN. (Otherwise, the program will terminate the execution with an appropriate user fatal message.)
    - If the secondary Module references only an MDMPLN entry, then a mirror image copy of the primary Module will be positioned using the plane defined by the MDMPLN entry.
10. A Module whose TYPE is "PRIMARY" (or TYPE="MOVE" and RMODID=0) may itself be repositioned by the use of MDLOC or MDMPLN entry or both (or MDTRAN, MDROTi or MDIRi or any combination).
- a. If it references an MDLOC (or MDTRAN, MDROTi) entry, then the primary Module will be positioned at the location implied by the MDLOC (or MDTRAN, MDROTi) entry.
  - b. If it references an MDMPLN (or MDMIRi) entry, then a mirror image of the primary Module will be repositioned using the plane defined by the MDMPLN (or MDMIRi) entry.
  - c. If it references both an MDLOC (or MDTRAN, MDROTi) entry and an MDMPLN (or MDMIRi) entry, then a mirror image of the primary Module will first be created using the plane defined by the MDMPLN (or MDMIRi) entry and then repositioned at the location specified by the MDLOC (or MDTRAN, MDROTi) entry.

## MDCONCT      Module Boundary Point Connections

Explicitly defines grid and scalar connection procedures for a module to module operation.

Format:

1	2	3	4	5	6	7	8	9	10
MDCONCT	BID	TYPE	TOL	X	Y	Z		CID	
	MID1	GID1	MID2	GID2	MID3	GID3	MID4	GID4	
	MID5	GID5	etc.						

Alternate Format:

1	2	3	4	5	6	7	8	9	10
MDCONCT	BID	TYPE	TOL	GRID			MODID		
	MID1	GID1	MID2	GID2	MID3	GID3	MID4	GID4	
	MID5	GID5	etc.						

Example 1:

MDCONCT	123		0.4	0.5	74.12	100.3			
	10	423	20	123					

Example 2:

MDCONCT	123	RRBE2	0.4	777					
	10		20						

Describer	Meaning
BID	Unique Boundary identification number. (Integer > 0)
TYPE	Connection Option. (Character: "MERGE", "RIGID", "RRBE2", "MRBE2" or Blank, Default="MRBE2").
TOL	Location tolerance to be used when searching or checking for boundary grid points. (Real; Default=1.0e-5)
X,Y,Z	Connection (Search) location. (Real, Default=0.0)
GRID	Grid Identification for Connection (Search). (Integer > 0) See Remark 13.
MODID	Identification number of Module containing GRID. (Integer ≥ 0, Default=0)
CID	Coordinate System in Module 0 to be applied to XYZ location. (Integer ≥ 0, Default=0)

Describer	Meaning
MIDi	Module Identification number for grid/scalar reference. (Integer $\geq 0$ )
GIDi	Identification number of a grid or scalar point in the reference module MIDi, which will be verified to be in TOL of the Location. (Integer $\geq 0$ )

#### Remarks:

1. MDCONCT may only be specified in the Main Bulk Data Section and cannot be placed in other BEGIN MODULE sections.
2. TOL can be used to override the default value specified on the MDBULK entries.
3. The continuation entry is optional when used in automatic searching.
4. The GIDi selections must be all of the same class, grids or scalar points.
5. All six degrees-of-freedom of grids will be defined as boundary degrees-of-freedom.
6. This entry is only valid if Modules exist.
7. When GIDi is blank or zero, then all grids of the module will be tested against the location and tolerance.
8. MIDi values can be specified more than once.
9. For TYPE="MERGE", the boundary grids will be moved to the location specified by MODID and connected by an RBE2 element.
10. For TYPE="MRBE2", the boundary grids will be moved to the location specified by MODID and only those grids that are specified as the independent grids on RBE2 elements will be used to connect the Modules. If any of the GIDi grids are not specified as independent grids on RBE2 elements or there are no RBE2 elements then the run will terminate with User Fatal Message 6717.
11. For TYPE="RIGID", the boundary grids will not be moved and will be connected via RBE2 elements.
12. For TYPE="RRBE2", the boundary grids will not be moved and only those grids that are specified as the independent grids on RBE2 elements will be used to connect the Modules. If any of the GIDi grids are not specified as independent grids on RBE2 elements or there are no RBE2 elements then the run will terminate with User Fatal Message 6717.
13. When GRID is used, then this identification/location will be used for the independent point of the RBE2 element.
14. When scalar points are specified for GIDi, then GRID, X, Y, Z, MODID and CID should not be specified.
15. If any GIDi are not connected due to exceeding TOL then User Fatal Message 6783 will be issued.

**MDDMIG****Direct Matrix Input at Points Defined in Two or More Modules**

Defines direct input matrices related to grid, extra, and/or scalar points defined in two or more Modules. The matrix is defined by a single header entry and one or more column entries. A column entry is required for each column with nonzero elements.

**Header Entry Format:**

1	2	3	4	5	6	7	8	9	10
MDDMIG	NAME	"0"	IFO	TIN	TOUT	POLAR		NCOL	

**Column Entry Format:**

MDDMIG	NAME	MODJ	GJ	CJ					
		MOD1	G1	C1	A1	B1			
		MOD2	G2	C2	A2	B2	-etc.-		

**Example:**

MDDMIG	STIF	0	1	3	4				
MDDMIG	STIF	11	27	1					
		20	2	3	3+5	3+3			
		20	2	4	2.5+10	0.			
		45	50		1.0	0.			

Describer	Meaning
NAME	Name of the matrix. See Remark 1 under DMIG. (One to eight alphanumeric characters, the first of which is alphabetic.)
IFO	Form of matrix input. IFO = 6 must be specified for matrices selected by the K2GG, M2GG, and B2GG Case Control commands. (Integer) <ul style="list-style-type: none"> <li>1 Square</li> <li>2 or 9 Rectangular</li> <li>6 Symmetric</li> </ul>
TIN	Type of matrix being input: (Integer) <ul style="list-style-type: none"> <li>1 Real, single precision (One field is used per element.)</li> <li>2 Real, double precision (One field is used per element.)</li> <li>3 Complex, single precision (Two fields are used per element.)</li> <li>4 Complex, double precision (Two fields are used per element.)</li> </ul>
TOUT	Type of matrix that will be created: (Integer)

Describer	Meaning
	0 Set by precision system cell (Default)
	1 Real, single precision
	2 Real, double precision
	3 Complex, single precision
	4 Complex, double precision
POLAR	Input format of Ai, Bi. (Integer=blank or 0 indicates real, imaginary format; Integer > 0 indicates amplitude, phase format.)
NCOL	Number of columns in a rectangular matrix. Used only for IFO = 9. See Remarks 5 and 6 under DMIG. (Integer > 0)
MODJ	Module IDs that contain the GRID entry for GJ. (Integer ≥ 0).
GJ	Grid, scalar or extra point identification number in Module MODJ for column index. (Integer > 0)
CJ	Component number for grid point GJ. (0 < Integer < 6; blank or zero if GJ is a scalar or extra point.)
MODi	Module IDs that contain the GRID entry for Gi. (Integer ≥ 0).
Gi	Grid, scalar, or extra point identification number in Module MODi for row index. (Integer > 0)
Ci	Component number for Gi for a grid point. (0 < CJ < 6; blank or zero if Gi is a scalar or extra point.)
Ai, Bi	Real and imaginary (or amplitude and phase) parts of a matrix element. If the matrix is real (TIN = 1 or 2), then Bi must be blank. (Real)

Remarks:

1. The MDDMIG entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the DMIG entry description. All remarks and figures under DMIG apply to MDDMIG.
3. When IFO=2 or 9, MODJ indicates the column number and not a module ID. GJ and CJ are ignored.

**MDELAM****Delamination materials in SOL 600**

Defines materials for which delamination may occur in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MDELAM		MID1	MID2	ITYPE	STRN	EXPN	STRT	EXPT	
	ITSTRN	ITEXPN	ITSTRT	ITEXPT					

Example:

MDELAM		4	5	2	35000.	1.	20000.	1.	
--------	--	---	---	---	--------	----	--------	----	--

Describer	Meaning
MID1	First material ID. (Integer; no Default; required field)
MID2	Second material ID. If MID2=MID1 delamination occurs within the material. If MID2 is not the same as MID1, delamination may occur at the interfaces between the materials. (Integer; Default = MID1)
ITYPE	Delamination type (Integer; Default = 1) 1 Determine if delamination occurs but do not actually allow delamination 2 Split the mesh when delamination occurs
STRN	Allowable normal stress (Real; no Default; required value)
EXPN	Exponent for normal stress (Real; Default = 1.0)
STRT	Allowable tangential stress (Real; no Default; required value)
EXPT	Exponent for tangential stress (Real; Default = 1.0)
ITSTRN	ID of a TABL3D entry providing the variation of STRN vs up to 4 variables. A value of zero means no table is required. (Integer; Default = 0)
ITEXPN	ID of a TABL3D entry providing the variation of EXPN vs up to 4 variables. A value of zero means no table is required. (Integer; Default = 0)
ITSTRT	ID of a TABL3D entry providing the variation of STRT vs up to 4 variables. A value of zero means no table is required. (Integer; Default = 0)
ITEXPT	ID of a TABL3D entry providing the variation of EXPT vs up to 4 variables. A value of zero means no table is required. (Integer; Default = 0)

Remarks:

- The delamination criteria is based upon  $(S_n/STRN)**EXPN+(S_t/STRT)**EXPT > 1.0$   
Where  $S_n$  and  $S_t$  are the normal and tangential stresses
- If no tables are required, the continuation entry may be omitted.

## MDEXCLD Module to Module Excluded Boundary Point Definitions

Defines a list of grid points in a Module that will be excluded during the attachment to another Module.

Format:

1	2	3	4	5	6	7	8	9	10
MDEXCLD	MIDA	MIDB	GIDA1	GIDA2	GIDA3	GIDA4	GIDA5	GIDA6	
	GIDA7	GIDA8	etc.						

Example 1:

MDEXCLD	400	4	10	20	30	40			
---------	-----	---	----	----	----	----	--	--	--

Example 2:

MDEXCLD	400	ALL	10	20	30	THRU	35		
---------	-----	-----	----	----	----	------	----	--	--

Describer	Meaning
MIDA	Module identification number. (Integer $\geq 0$ , Default=0)
MIDB	Reference Module identification number. (Integer $\geq 0$ or Character "ALL"; Default=ALL)
GIDAi	Identification number of a boundary grid point in the module MIDA to be excluded from connection to module MIDB. (Integer $> 0$ or "THRU"; for "THRU" option, $GID1 < GID2$ .)

Remarks:

1. This entry is only valid if Modules exist.
2. MDEXCLD may only be specified in the Main Bulk Data Section and cannot be placed in other BEGIN MODULE sections.

## MDFAST

## A Shell Patch Fastener Connection Between Two Modules

Defines a fastener with material orientation connecting two surface patches defined in two Modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDFAST	EID	PID	TYPE	IDA	IDB	GS	GA	GB	
	XS	YS	ZS			MODA	MODB		

Example using PROP:

MDFAST	3	20	PROP	21	24	206			
							10	20	

Example using ELEM:

MDFAST	7	70	ELEM	27	74	707			
							11	12	

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PFAST entry. (Integer > 0; Default = EID)
TYPE	Specifies the surface patch definition: (Character)  If TYPE = 'PROP', the surface patch connectivity between patch A and patch B is defined with two PSHELL (or PCOMP) properties with property ids given by IDA and IDB. Under CFAST see Remark 1. and Figure 8-28.  If TYPE = 'ELEM', the surface patch connectivity between patch A and patch B is defined with two shell element ids given by IDA and IDB. Under CFAST see Remark 1. and Figure 8-28.
IDA,IDB	Property id (for PROP option) or Element id (for ELEM option) defining patches A and B in Modules MODA and MODB, respectively. IDA≠IDB (Integer > 0)
GS	Grid point defining the location of the fastener. Its GRID entry must be defined in the main Bulk Data section (Module 0). See also Remark 2. under CFAST. (Integer > 0 or blank)
GA,GB	Grid ids of piercing points on patches A and B. Their GRID entries must be defined in the main Bulk Data section (Module 0). See also Remark 2. under CFAST. (Integer > 0 or blank)

Describer	Meaning
XS,YS,ZS	Location of the fastener in basic. Required if neither GS nor GA is defined. See also Remark <a href="#">2</a> .under CFAST. (Real or blank)
MODA,M ODB	Module IDs that contain the surface patches defined by property or element entries IDA and IDB (Integer $\geq 0$ ).

**Remarks:**

1. The MDFAST entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the CFAST entry description. All remarks and figures under CFAST apply to MDFAST.

**MDFSET****Set Definition for Fluid Elements or Grid Points in Modules**

Defines a set of fluid grid points or element identification numbers in a Module to be referenced by the ACMODL Bulk Data entry.

Format:

1	2	3	4	5	6	7	8	9
MDFSET	MODID	ID1	ID2	ID3	ID4	ID5	ID6	ID7
	ID8	-etc.-						

Example 1:

MDFSET	22	31	62	93	124	16	17	18
	19							

Example 2:

MDFSET	22	29	32	THRU	50	61	THRU	70
	17	57						

Describer	Meaning
MODID	Module identification number (Integer $\geq 0$ )
IDI	List of fluid grid point or element identification numbers. (Integer $> 0$ or "THRU"; for the "THRU" option: ID1 $<$ ID2).

Remarks:

1. The MDFSET entry can only be used in the presence of Modules and can only be specified in the main Bulk Data section or Module 0.
2. The MDFSET entry is used when FSET is set to -1 on the ACMODL entry.
3. Multiple MDFSET entries may reference more than one Module.

## MDLABEL

## Module Output Label

Defines a label or name to be printed in the Module's results output page headings.

Format:

1	2	3	4	5	6	7	8	9	10	
MDLABEL	MID	LABEL								

Example:

MDLABEL	400	LEFT REAR FENDER, MODEL XYZ2000								
---------	-----	---------------------------------	--	--	--	--	--	--	--	--

Describer	Meaning
MID	Module identification number. (Integer ≥ 0, Default=0)
LABEL	Label associated with Module MID for results output page headings. (Character)

Remarks:

1. MDLABEL can only be specified in the main Bulk Data Section and is ignored in-between the BEGIN MODULE=n and ENDMODULE commands.
2. Only one MDLABEL per Module may be specified.
3. The label will appear in all Module's results output page headings. However, in some headings the label may be truncated.
4. This entry is valid only if Modules exist.

**MDLOC****Module Reposition by Translation and/or Rotation**

Defines reposition of a Module by listing three non-collinear points in the Module and three corresponding points in Module 0.

Format:

1	2	3	4	5	6	7	8	9	10
MDLOC	MODID	PA1	PA2	PA3	PB1	PB2	PB3		

Example:

MDLOC	110	10	100	111	1010	112	30		
-------	-----	----	-----	-----	------	-----	----	--	--

Describer	Meaning
MODID	Module identification number of primary, repeated, or mirrored module (Integer>0).
PAi	GRID or POINT identification numbers of three non-collinear points in (Integer>0): <ul style="list-style-type: none"> <li>■ "RMODID's Bulk Data section. RMODID is referenced on MDBULK if this MODID is a secondary (copied) Module</li> <li>■ "Module MODID's Bulk Data section if this is a primary Module.</li> </ul>
PBi	GRID or POINT identification numbers of three non-collinear points in Module 0 (main Bulk Data section). Must have the same relative locations as PAi. (Integer>0).

Remarks:

1. MDLOC can only be specified in the main Bulk Data Section and will cause a fatal error message if it appears after the BEGIN MODULE=n command.
2. The Module will be rotated and translated for alignment of the PAi and PBi locations.
3. The PAi and PBi can be either GRIDs or POINTs.
4. PA1, PA2, and PA3 must be contained in the BEGIN Module=MODID Bulk Data section.
5. PB1, PB2, and PB3 must be specified in the main Bulk Data Section or Module 0. If they belong to a Module that is also relocated, then the original (unmoved) positions of PB1, PB2, and PB3 are used.
6. PB1, PB2, and PB3 must have the same relative locations as PA1, PA2, and PA3.
7. Three GRIDs or POINTs are required even if the Module connects to only one or two boundary grids.
8. Coordinate systems, global displacement directions, and element coordinate systems for the Module will rotated and translated.

9. The global coordinate directions of the grid points in the Module will be transformed internally to the global coordinate directions of the grid points in the Module 0. For displacement data recovery, the output will be in the original global coordinate system.
10. The translation and rotation of the Module to the new position is accomplished by defining local rectangular coordinate systems based on the specified grid locations:
  - The local systems have their origin at PX1 and the x-axis points from PX1 to PX2.
  - The y-axis lies in the plane containing PX1, PX2, and PX3, is perpendicular to the x-axis, and points toward PX3.
  - The z-axis is defined by the cross product of the x-axis into the y-axis.
  - The rotation and translation transformation aligns the local system defined by the Module grids with the local system defined by the main Bulk Data Section grids
11. This entry will only work if Modules (BEGIN MODULE) exist.

## MDLPRM

## Model Parameters

Specifies parameters which affect the solution of the structural model.

Format:

1	2	3	4	5	6	7	8	9	10
MDLPRM	PARAM1	VAL1	PARAM2	VAL2	PARAM3	VAL3	-etc.-		

Example:

MDLPRM	QR6ROT	2	QRSHEAR	1					
--------	--------	---	---------	---	--	--	--	--	--

Describer	Meaning
PARAMi	Name of the parameter. Allowable names are given in <a href="#">Table 20</a> . (Character)
VALi	Value of the parameter. (Real or Integer; see <a href="#">Table 20</a> )

Remark:

- Multiple entries of MDLPRM are allowed in the Bulk Data Section. However, multiple entries of a particular parameter PARAMi are illegal.
- This entry is not supported in SOL 600.
- If Modules are present then this entry may only be specified in the main Bulk Data section.

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values
BOLTCNEL	Flag to control automatic mapping of BOLT1 elements to Advanced Nonlinear Elements using internally generated nonlinear property extensions.
	0                      Map BOLT1 elements as well as other elements that share same element properties with BOLT1 elements (Default).
	1                      Map all elements connected to BOLT1 elements as well as other elements that share same element properties.
BRTOBM	Flag to determine whether to convert a CBAR element to a CBEAM element for the nonlinear analysis.
	0                      Do not convert CBAR to CBEAM. (Default)
	1                      Convert CBAR to CBEAM.
	-1                     Same as 1, but print the converted Bulk Data entries on f06 file.

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values
BUSHRT	Flag to control large rotation effects for CBUSH or CFAST elements in nonlinear analysis (SOL400). For CBUSH, this flag is overridden by the LRGR field on the element PBUSHT entry.
	0 Large rotation effects are included. Element coordinate system is rotated with the rotation of grid A. (Default)
	1 No large rotation effects. Small rotation is used.
	2 Large rotation effects are included. A mid-increment method is used to rotate the element system. This is recommended for large rotation analysis. For the CBUSH element, CID must equal zero.
COMPN1	Control if stresses and strains of advanced composite elements use MSC Nastran conventional layer format
	NO (default) Don't use
	YES Use conventional layer format
DBCTOLE	Tolerance for DBC date conversion, real(default=1.e-4) >= 0.0
DCFLTEXP	Determines the exponent of the tolerance value used to filter out small entries from the coefficient matrix before a matrix decomposition. In each column, matrix entries which are DCFLTEXP orders of magnitude smaller than the diagonal entry of the column are filtered out. If DCFLTEXP=0, then the coefficient matrix is not altered. (Integer; Default = 0)
DELELAS	Randomly delete c*100% of CELASi elements in a job. ( $0.0 \leq c \leq 1.0$ ; Default: c = 0.02). If entry is not present, all CELASi elements are retained. Default of .02 is used only if entry is written as: MDLPRM, DELELAS.
DELFAST	Randomly delete c*100% of CFAST elements in a job. ( $0.0 \leq c \leq 1.0$ ; Default: c = 0.02). If entry is not present, all CFAST elements are retained. Default of .02 is used only if entry is written as: MDLPRM, DELFAST  The value on this entry will override the PARAM, CFRANDEL, value entry. PARAM, CFDIAGP, YES will give the ID of the CFAST elements deleted.
DELMASS	Randomly delete c*100% of CMASSi, CONM1, and CONM2 elements in a job. ( $0.0 \leq c \leq 1.0$ ; Default: c = 0.02). If entry is not present, all CMASSi elements are retained. Default of .02 is used only if entry is written as: MDLPRM, DELMASS.
DELSEAM	Randomly delete c*100% of CSEAM elements in a job. ( $0.0 \leq c \leq 1.0$ ; Default: c = 0.02). If entry is not present, all CSEAM elements are retained. Default of .02 is used only if entry is written as: MDLPRM, DELSEAM.

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values				
DELWELD	<p>Randomly delete <math>c \cdot 100\%</math> of CWELD elements in a job. (<math>0.0 \leq c \leq 1.0</math>; Default: <math>c = 0.02</math>). If entry is not present, all CWELD elements are retained. Default of .02 is used only if entry is written as: MDLPRM, DELWELD.</p> <p>The value on this entry will override the PARAM, CWRANDEL, value entry. PARAM, CWDIAGP, YES will give the ID of the CWELD elements deleted.</p>

For elements not overwritten case, set $GMOVR3 = 1$ . The elements to be overwritten are defined on a $GMOVR3$ Bulk Data entry.	4	GMOVR3 Perturbation is overwritten for the REFGRID grid of specific RBE3 elements in SOL400, RIGID=LAGRANGE, for any RBE3 element with REFGRID grid coincident with all its connected $G_{i,j}$ nodes. For elements not overwritten case, set $GMOVR3 = 2$ . The elements to be overwritten are defined on a $GMOVR3$ Bulk Data entry.
-1	Do not check coincidence												
0	Check coincidence but do not perturb. The program issues a fatal message and aborts run while coincidence happens.												
1	Perturbate all coincident coordinates of the connected $G_{i,j}$ nodes.												
2	Perturbate the coincident REFGRID grid.												
3	GMOVR3 Perturbation is overwritten for the $G_{i,j}$ nodes of specific RBE3 elements in SOL400, RIGID=LAGRANGE, for any RBE3 element with REFGRID grid coincident with all its connected $G_{i,j}$ nodes. For elements not overwritten case, set $GMOVR3 = 1$ . The elements to be overwritten are defined on a $GMOVR3$ Bulk Data entry.												
4	GMOVR3 Perturbation is overwritten for the REFGRID grid of specific RBE3 elements in SOL400, RIGID=LAGRANGE, for any RBE3 element with REFGRID grid coincident with all its connected $G_{i,j}$ nodes. For elements not overwritten case, set $GMOVR3 = 2$ . The elements to be overwritten are defined on a $GMOVR3$ Bulk Data entry.												

Table 20 PARAMi Names and Descriptions

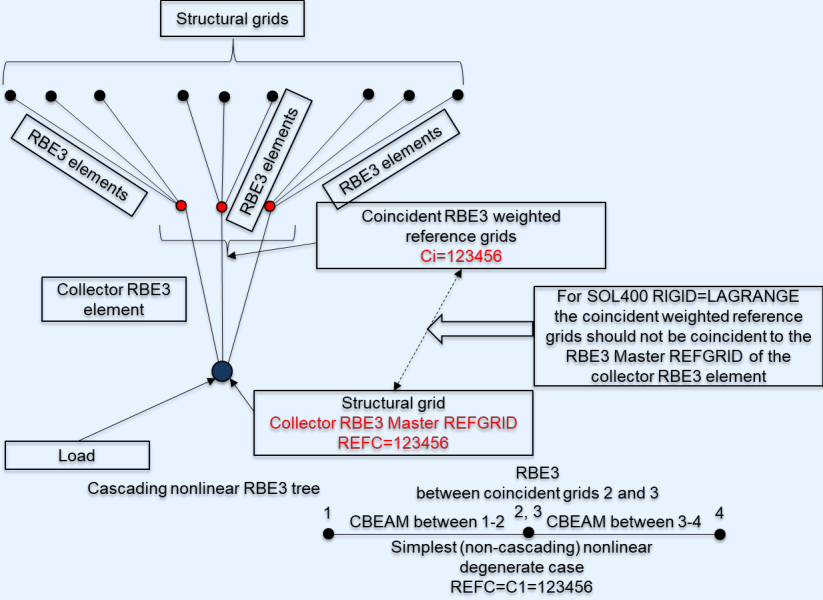

Name	Description, Type, and Default Values			
GMOVRD	<p>The Grids defined by above GMOVR3 entry will be given a <math>\Delta v = \text{GMOVRD}</math> value. The user should avoid very small perturbation values as the point is to provide a finite rotation length. For large structural models, <math>0.01 \leq \text{GMOVRD} \leq 0.1</math> seem to have relatively small effect on displacement values and reasonable convergence times. (Real; Default=0.01)</p> 			
GMOVR3T	Coincident grid zero tolerance. (Real $\geq 0.0$ ; Default=0.001)			
GNLSTN	Strain formulation flag for QUADR/TRIAR elements used in geometric nonlinear analysis. (Parameter LGDISP=1)			
	<table border="1"> <tr> <td data-bbox="432 1185 589 1220">0</td> <td data-bbox="589 1185 1318 1220">Small strain. (Default)</td> </tr> <tr> <td data-bbox="432 1220 589 1255">1</td> <td data-bbox="589 1220 1318 1255">Green strain.</td> </tr> </table>	0	Small strain. (Default)	1
0	Small strain. (Default)			
1	Green strain.			
HDF5	Parameter to create NH5RDB database			
	-1 Do not create NH5RDB(default)			
	0 Create NH5RDB without compression			
	1 Create NH5RDB with compression			
	2 Create uncompressed NH5RDB database without input data.			
3 Create compressed NH5RDB database without input data.				

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values	
H5GM34	Write GEOM3 and GEOM4 data in NH5RDB	
	1	Write GEOM3 and GEOM4 data in NH5RDB.
	0	Do not write GEOM3 and GEOM4 data in NH5RDB.
	-1	Use OP2GM34 setting for GEOM3 and GEOM4 output (Default).
H5INFO	Write job run information in NH5RDB or not.	
	1	Yes (Default)
	0	No
H5MDL	Write model input data in separate file	
	2	Write model input data only
	1	Write model input data into a separate file
	0	Do not write model input data into a separate file (Default)
	-1	Use OP2GM34 setting for GEOM3 and GEOM4 output
H5MTX	Write matrix data in separate file	
	1	Write matrix data into a separate file
	0	Do not write matrix data into a separate file (Default)
H5NORDOF	Parameter to suppress output rotational components to NH5RDB database	
	0	Output both translational and rotational components to NH5RDB database (Default).
	1	Do not output rotational components to NH5DB database.
		Only used when HDF5 is 0 or 1.
H5SGENL	Set compression factor for NLOUT output datasets	
	0 to 10	Scale factor with scaleoffset lossy compression (Default=3)
	-1	Use lossless compression
H5SSTRN	Set compression factor for NLOUT strain type output datasets	
	0 to 10	Scale factor with scaleoffset lossy compression (Default=6)
	-1	Use lossless compression
H5XHH	Write BHH, MHH and KHH matrices in NH5RDB	
	0	Do not write BHH, MHH and KHH in NH5RDB (Default)
	1	Write BHH, MHH and KHH in NH5RDB

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values	
IGNSHBDN	Check adjacent shell elements have opposite direction of normal vector, if found	
	0(default)	Issue a user fatal message
	1	Issue a user warning message
INTOUT	Flag to control FORCE/STRESS/STRAIN OUTPUT location for QUADR/TRIAR elements	
	0	Corner output. (Default)
	1	Integration point output.
LMT2MPC	Parameter to enable the use of elimination method to process Lagrange Multipliers.	
	0	Do not force the use of elimination method. (Default)
	1	Use elimination method to process Lagrange Multipliers using unsymmetric method.
	2	Use elimination method to process Lagrange Multipliers using symmetric method (may be faster).
LRGDHFLT	The threshold ratio to set small terms in displacement gradient matrix for Lagrange rigid elements to zero to overcome numerical difficulties.	
	Suppose HMAX is the maximum absolute element of the matrix, H is another element, if $ABS(H) \leq LRGDHFLT * HMAX$ , set H to zero. (Real, LRGDHFLT $\geq$ 0.0, Default: LRGDHFLT = 1.E-10)	
MLTSPLIN	Parameter to specify whether an aerodynamic grid can be splined more than once.	
	0	References on separate splines to the same aero grid are not allowed. (Default)
	1	Aero grids can be referenced on multiple spline entries.
MPCF129	Request the calculation of MPC forces in SOL129. The forces include only the contributions from linear elements.	
	0	Don not compute MPC Forces (default)
	1	Compute MPC Forces
MXMNMEM	Working area memory size of MAXMIN command in machine words. (Integer, MXMNMEM > 0, Default: MXMNMEM = 9710).	

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values
NLDIFF	Flag to determine whether the differential stiffness matrix and follower force stiffness are to be computed for nonlinear elements with geometric nonlinear analysis (parameter LGDISP=1) in SOL 400. Options 3, 4, and 5 are available only for elements with PSHNL1, PSHNL2, PSLN1, or PSHEARN Bulk Data entry.
	0 Compute. (Default except for CTRLDEF=SEVERELY of NLSTEP and not 3D contact analysis)
	1 Do not compute
	2 The differential stiffness matrix and follower force stiffness will not be computed if the tangential stiffness matrix is negative definite (Default for CTRLDEF=SEVERELY of NLSTEP and not 3D contact analysis).
	3 Include only the deviatoric part of the differential (or initial stress or geometric) stiffness
	4 Include only the tensile part of the differential (or initial stress or geometric) stiffness
	5 Include the stress at the beginning of the increment for the differential (or initial stress or geometric) stiffness
NLRSTRM	Flag to allocate extra necessary memory in a cold start run with Advanced Nonlinear Elements to allow subsequent NLRESTART to be used in a linear perturbation analysis when the cold start run itself is not a linear perturbation analysis.
	0 Do not allocate extra memory in cold start run (Default)
	1 Allocate extra memory in cold start run to allow NLRESTART to be used with Advanced Nonlinear Elements in a linear perturbation analysis.
NONUIV	Parameter to select the numeric compute kernel and pivoting methods in MSCLDL and MSCLU sparse direct solvers.
	0 Use the native Bunch-Kauffman threshold pivoting in MSCLDL, and the native threshold partial pivoting in MSCLU (Default).
	1 Use no numeric pivoting in MSCLDL and MSCLU. BLAS3 TRSMs are called to compute the pivot column update to improve performance. Ill-conditioned models may die of “singular matrix” during sparse factorization.
	2 Not documented.
	3 LAPACK SYTRFs with Bunch-Kaufman pivoting and GETRFs with partial pivoting are called to perform factorizations, and BLAS3 TRSMs are called to compute pivot column update to improve performance.

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values
NSGRDS4	Number of structural grids to be used in dividing a SPLINE4 using the RIS spline method. The spline will be divided into NGRIDS/NSGRDS4 regions, where NGRIDS is the number of grids listed on the associated SET1 entry. (Integer > 0, default=0. If NGRIDS < NSGRDS4, or NSGRDS4 is not specified, no divisions will occur.)
OFFDEF	Element offset definition. A flag to determine how shell elements and bar and beam elements behave when the user supplies ZOFF values on the shell connection entries (CQUAD4, CQUADR, CTRIA3, CTRIAR, CQUAD8, and CTRIA6) and WiA and WiB on CBAR, CBEAM, and CBEAM3 connection entries. (Character)
ELMOFF	Standard Nastran offset method. The ZOFF rotate with the shell element. The WiA and WiB offsets for beams are fixed. MD Nastran R3 and earlier. (Character, Default)
LROFF	<b>Large rotation offsets.</b> The shell normal directions are used to define the offset direction at each shell grid for CQUAD4, CTRIA3, CQUADR, CTRIA4, CQUAD8 and CQUAD8 elements. For beams, WiA and Wib defines the offset direction. This method allows for thermal load effects on ZOFF for shells and WiA and WiB for beams. Thermal load effect for offset is computed based on the grid point or element temperature, and thermal coefficient of the element (see NOTHRM). The mass moment of inertia is computed for the offset due to the grid point location change introduced by offset. Differential stiffness is computed for the offset using the same method as that of the Lagrange formulation of the RBAR. Not supported in SOL106, SOL129 and SOL 200. (Character)
NODIF	LROFF is used but the differential stiffness effect is turned off. (Character)
NOTHRM	LROFF is used but the thermal load effects are turned off. The thermal load has two effects: 1) the location of thermal load changes due to offset and 2) the length of offset changes due to thermal load. Effect (1) is computed for all solution sequences and Effect (2) is computed for SOL 400 only. Both effects are turned off by NOTHRM. (Character)
NODT	LROFF is used but the differential stiffness and thermal load effect are turned off. (Character)
ELMZ	LROFF is used but the element z-direction is used for the offset direction. IF PARAM, SNORM, 0.0 or the computed value for SNORM is greater then the PARAM,SNORM,value, then the LROFF option will revert to this method for CQUAD4, CTRIA3, CQUADR, CTRIAR, CQUAD8 and CTRIA6. This option is not applicable for beams. (Character)
NOMASS	LROFF is used but the no mass effects are included. (Character)

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values									
	NDMTZ	LROFF is used but the element z-direction is used for the offset direction and the differential stiffness, the thermal load effects, and the mass effects are turned off. For CQUAD4 and CTRIA3 elements this method should get similar results to the standard ELMOFF method. (Character)								
	<p>Note: This entry only effects ZOFF calculations for ZOFF specified on the shell connection entries. For Z0 specified on the PCOMP or PCOMPG entries, the standard ELMOFF method will be used.</p>									
	If the computed value for SNORM is greater then the PARAM,SNORM,value and the user wishes not to change the parameter value, the Bulk Data entry SNORM can be used to override the shell normal.									
	Solution sequences affected: For linear - all solution sequences. For nonlinear - SOL 400 only. <i>The LROFF method is not implemented into SOLs 106 and 129.</i>									
PEXTS4	Used in conjunction with NSGRDS4. After partitioning the spline, each of the smaller splines will be extended by PEXTS4 in each direction (top,bottom, left and right). The value is expressed in percent so that PEXTS4=10.0 would extend the four boundaries by 10%. Real (0.0<PEXTS4<100.0, default=10.0)									
PIVTHRS4	<p>Parameter to set the threshold 'uu' for numeric pivot selection in the MSCLU and Intel MKL Pardiso solvers.</p> <table border="1" data-bbox="421 921 1322 1239"> <tr> <td data-bbox="421 921 582 1164">0 (Default)</td> <td data-bbox="582 921 1322 1164">           uu is set to           <ul style="list-style-type: none"> <li>■ MSCLU: <math>10^{-9}</math></li> <li>■ MKL Pardiso: <math>10^{-13}</math> for non-symmetric matrices and <math>10^{-8}</math> for symmetric indefinite matrices. -i	uu is set to $10^{-i}$ for both MSCLU and MKL Pardiso (where i is between 1 and 20)									
PRDIDPVT	<p>Control of pivoting in Intel MKL Pardiso, when solving symmetric indefinite matrices. For more information, see <a href="#">Intel MKL Pardiso iparm Parameter Table</a>, iparm(21).</p> <table border="1" data-bbox="421 1308 1322 1510"> <tr> <td data-bbox="421 1308 582 1355">0</td> <td data-bbox="582 1308 1322 1355">1x1 diagonal pivoting</td> </tr> <tr> <td data-bbox="421 1355 582 1402">1</td> <td data-bbox="582 1355 1322 1402">1x1 and 2x2 Bunch-Kaufman pivoting (Default)</td> </tr> <tr> <td data-bbox="421 1402 582 1449">2</td> <td data-bbox="582 1402 1322 1449">1x1 diagonal pivoting without automatic iterative refinement</td> </tr> <tr> <td data-bbox="421 1449 582 1510">3</td> <td data-bbox="582 1449 1322 1510">1x1 and 2x2 Bunch-Kaufman pivoting without automatic iterative refinement</td> </tr> </table>		0	1x1 diagonal pivoting	1	1x1 and 2x2 Bunch-Kaufman pivoting (Default)	2	1x1 diagonal pivoting without automatic iterative refinement	3	1x1 and 2x2 Bunch-Kaufman pivoting without automatic iterative refinement
0	1x1 diagonal pivoting									
1	1x1 and 2x2 Bunch-Kaufman pivoting (Default)									
2	1x1 diagonal pivoting without automatic iterative refinement									
3	1x1 and 2x2 Bunch-Kaufman pivoting without automatic iterative refinement									

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values	
PRDITRFN	Control of iterative refinement step for Intel MKL Pardiso. For more information, see <a href="#">Intel MKL Pardiso iparm Parameter Table</a> , iparm(8).	
	0	Solver automatically performs two steps of iterative refinement (Default)
	>0	Maximum number of iterative refinement steps, up to a maximum of nine.
	<0	Same as above, but residual is computed using extended precision. Maximum of nine steps.
PRDMTYPE	Control of matrix type for Intel MKL Pardiso. For more information, see <a href="#">Intel MKL Pardiso documentation</a> , Input Parameters.	
	1	real structurally symmetric
	2	real symmetric positive definite (SOL 101 default)
	-2	real symmetric indefinite (SOL 400 default)
	3	complex structurally symmetric
	4	complex Hermitian positive definite
	-4	complex Hermitian indefinite
	6	complex symmetric (SOL 108 & 111 default)
	11	real unsymmetric
13	complex unsymmetric (SOL 107 default)	
PRDOOC	Control of out-of-core (OOC) solution algorithm in Intel MKL Pardiso. For more information, see <a href="#">Intel MKL Pardiso iparm Parameter Table</a> , iparm(60).	
	0	In-core mode
	1	Choose between in-core and OOC mode based on memory (opencore) size
	2	Out-of-core mode
PRDWMTCH	Control of weighted matching algorithm in Intel MKL Pardiso. For more information, see <a href="#">Intel MKL Pardiso iparm Parameter Table</a> , iparm(13).	
	0	Disable matching (SOL 101 default)
	1	Enable matching (SOL 107, 108, 111, and SOL 400 default)
PRTELAS	Print list of ID's of CELASi elements that are deleted.	
	NO (or blank)	Turn off the print. (Default)
	YES	Turn on the print.

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values	
PRTFAST	Print list of ID's of CFAST elements that are deleted.	
	NO (or blank)	Turn off the print. (Default)
	YES	Turn on the print.
PRTMASS	Print list of ID's of CMASSi, CONM1 and CONM2 elements that are deleted.	
	NO (or blank)	Turn off the print. (Default)
	YES	Turn on the print.
PRTSEAM	Print list of ID's of CSEAM elements that are deleted.	
	NO (or blank)	Turn off the print. (Default)
	YES	Turn on the print.
PRTWELD	Print list of ID's of CWELD elements that are deleted.	
	NO (or blank)	Turn off the print. (Default)
	YES	Turn on the print.
QR6ROT	Parameter to determine whether the drilling degrees-of-freedom are to be deactivated for QUADR/TRIAR elements. If the drilling degrees-of-freedom are deactivated, the QUADR/TRIAR become elements similar to QUAD4/TRIA3. QR6ROT has the following values:	
	0	The drilling degrees-of-freedom are active. (Default)
	1	The drilling degrees-of-freedom are deactivated for all QUADR/TRIAR element in the model.
	2	The drilling degrees-of-freedom are deactivated for those QUADR/TRIAR which have membrane stiffness only (MID2 and MID3 are blank on the PSHELL entry)
QRSHEAR	Parameter to select the off-plane shear formulation for the QUADR element. There are two types of off-plane shear formulations: the stiffness method and the flexibility method. The stiffness method is a new method implemented in QUADR. The flexibility method was the method implemented in the QUAD4 element. Therefore, if the flexibility method is selected, the solution results of QUADR are closer to those of QUAD4. QRSHEAR has the following values:	
	0	Use stiffness method if MID3 $\neq$ 0 on the PSHELL Bulk Data entry. Use the flexibility method if MID3 = 0. (Default)
	1	Use flexibility method.
	2	Use the stiffness method.

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values												
RDBOTH	<p>Parameter to select Rayleigh damping approach for rotordynamics (compatibility with MSC Nastran 2005) implementation, Integer. A cumulative sum can be provided in case multiple features are desired in the analysis. The parameter is allowed to take values of 1, 2, 4, 8, 16, or any combination of them except both 4 and 8 are included, such as 12, 13, 14 etc. Default value for this parameter is 0.</p> <table border="1" data-bbox="429 421 1326 999"> <tr> <td data-bbox="429 421 589 496">0</td> <td data-bbox="589 421 1326 496">Uses implementation for Rayleigh Damping as described in RSPINR/RSPINT entry description (Default)</td> </tr> <tr> <td data-bbox="429 496 589 666">1</td> <td data-bbox="589 496 1326 666">Switch to V2005 implementation of Rayleigh damping where damping coefficients specified in the model through "PARAM, ALPHA1" and "PARAM, ALPHA2" are applied to the complete model and Rayleigh damping specified through "ALPHAR1" and "ALPHAR2" in RSPINR/RSPINT is set to 0.0.</td> </tr> <tr> <td data-bbox="429 666 589 708">2</td> <td data-bbox="589 666 1326 708">Ignore circulation effects in rotordynamic analysis.</td> </tr> <tr> <td data-bbox="429 708 589 817">4</td> <td data-bbox="589 708 1326 817">Include effect of stress stiffening using method = 1 (see RFORCE entry). Using RFORCE load step to include differential stiffness in SOL 400 since RDBOTH=4 is not supported in SOL 400.</td> </tr> <tr> <td data-bbox="429 817 589 927">8</td> <td data-bbox="589 817 1326 927">Include effect of stress stiffening using method = 2 (see RFORCE entry). If ALPHA is not zero for ANY r-element in ANY superelement (SEID&gt;0) then transfer ALL r-elements in ALL superelements to the residual structure.</li> </ol>	1	Transfer all r-elements in the superelements to the residual structure.								
0	(Default) Automatic selection: <ol style="list-style-type: none"> <li>a. If ALPHA is zero for ALL r-elements in ALL superelements (SEID&gt;0) then keep of these r-elements in the superelements with RIGID=LINEAR formulation.</li> <li>b. If ALPHA is not zero for ANY r-element in ANY superelement (SEID&gt;0) then transfer ALL r-elements in ALL superelements to the residual structure.</li> </ol>												
1	Transfer all r-elements in the superelements to the residual structure.												

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values	
RMRBE3RT	Parameter to control if remove rotational dof from REFC of any RBE3 which reference grid point(REFG) is used by solid elements only and REFC has rotational dof..	
	0(default)	Don't remove.
	1	Remove rotational dof.
RSTIGNDP	A flag to determine if ignoring duplicate PARAM entries between a restart run and its initial run.	
	0(default)	Don't ignore duplicating.
	>0	Ignore duplicating.
SHEARP	Parameter to select the new HARDER shear panel over the classic GARVEY panel. The HARDER panel through testing appears to be superior to the GARVEY panel especially in cases of thermal loading. (Character-all required)	
	GARVEY	GARVEY SHEAR PANEL (Default)
	HARDER	HARDER SHEAR PANEL - NEW
SHRTOQ4	Flag to determine whether to convert a CSHEAR element to a CQUAD4 element for nonlinear analysis. Cannot be used with the PSHEARN entry.	
	0	Do not convert CSHEAR to CQUAD4. (Default)
	1	Convert CSHEAR to CQUAD4.
	2	Do converting and print out converted Bulk Data entries on f06 file.
SOLCTLBC	Backward compatibility in SOL 400 with older Nastran versions. (Integer; Default = 0). Each BIT of this flag can be turned on individually.	
	0	Updating the calculation of residual force with damping effect; releasing residual immediately in the beginning of subsequent load steps.
	-1	Activate all of following flags (back to 2020 SP1).
	1	Old logic which misses NDAMP effect in residual force calculation.
	2	Ramping down residual gradually in subsequent load steps.
SPBLNDX	Factor to be applied to D1 and D2 blend depths on the SPBLND1 and SPBLND2 bulk data entries for determining the structural grids in the blended region. (Real, $\geq 1.0$ , default = 1.0)	
STREQCNT	Flag to control calculation method for equivalent von Mises stress/strain at element center for advanced nonlinear solid elements in SOL 400.	
	0	Average integration point equivalent stress/strain (Default).
	1	Average integration point stress/strain components then compute equivalent value at element center.

Table 20 PARAMi Names and Descriptions

Name	Description, Type, and Default Values	
TWBRBML	Parameter to select method for computing properties of PBARL/PBEAML.	
	0	Select Finite Element Method. (Default)
	1	Select Beam Library Equations.
BCSOL129	Controls the convergence parameter computation method, iteration information printing format, and divergence solution sequence checking for SOL 400.	
	0	The current format. (Default) Two formats are available: static and dynamic.
		Static format will be used for static analysis.
		Dynamic format will be used for dynamic analysis.
-1	Using the format and algorithm similar to SOL 129.	

## MDMIAUX

## Matrices from Marc - SOL 600

Specifies the DOMAINSOLVER command to be used in conjunction with secondary spawned jobs when MDMIOUT is used. SOL 600 only. (See the MDMIOUT Bulk Data entry.)

Format:

1	2	3	4	5	6	7	8	9	10
MDMIAUX	ID								
	"FMS"	STRF1							
		STRF2							
	"EXEC"	STRE1							
		STRE2							

Example:

MDMIAUX	2									
	FMS	ASSIGN OUTPUT2=MODEL1.OP2,UNIT=50,DELETE								
	EXEC	DOMAINSOLVER ACMS (PRINT=YES,UPFACT=3.5)								

Describer	Meaning
ID	ID of a matching IAUX field on the corresponding MDMIOUT entry. (Integer; no Default)
"FMS"	Enter the string FMS to start a series of FMS strings that should appear before the SOL entry for the secondary spawned job. (Character; no Default)
STRFi	Series of FMS strings, entry as many as desired. (Character; no Default)
"EXEC"	Enter the string EXEC to start a series of strings that should appear after the SOL entry for the secondary spawned job. (Character; no Default)
STREi	Series of Executive Control strings, enter as many as desired. (Character; no Default)

Remarks:

1. This entry is not active unless a matching MDMIOUT entry is found in the input.
2. STRFi and STREi may occupy fields 3-9. (columns 9 to 72).
3. Standard FMS and Executive Control continuation rules apply to the strings.

## MDMIOUT

## Matrices from Marc - SOL 600

Defines full or reduced stiffness and mass matrices to be output from the Marc portion of SOL 600. This entry may be used to generate External Superelements using DMIG Matrices or an MSC Adams MNF File from the Marc portion of a SOL 600 analysis. SOL 600 only. (See the MNF600 and DMIGOUT Bulk Data entries.)

Format:

1	2	3	4	5	6	7	8	9	10
MDMIOUT	ID	IDOF	G1	THRU	G2	ITYPE	NAME	IAUX	
	IDOF2	G3	THRU	G4	IDOF3	G5	THRU	G6	
	etc.								

Example:

MDMIOUT	100	123456	1	THRU	5456	1	m343	1	
---------	-----	--------	---	------	------	---	------	---	--

Describer	Meaning
ID	Subcase for which the reduced matrices will be output. ID must correlate to a SUBCASE Case Control ID, for example, if the case control contains SUBCASE 20, ID would be 20. (Integer; Default = 1)
IDOF, IDOF2	List of DOF's to be output (any or all of the integers 1-6 are acceptable). (Integer; Default = 123456)
G1, G3	Starting grid ID for reduced matrices. (Integer; Required; no Default)
G2, G4	Ending grid ID for reduced matrices. (Integer; Required; no Default)
ITYPE	Type of file to generate. (Integer; Default = 1) 1           DMIG Matrices 2           Adams MNF
NAME	Name of file containing the output (Character; no Default; limited to 8 characters, should be in lower case, <b>the extension .dmi is added automatically</b> )
IAUX	ID of a MDMIAUX entry if the secondary run requires the use of file management entries or additional Executive Control statements such as the DOMAINSOLVER option for parallel processing. (Integer; Default = 0) A value of zero means that no auxiliary entries are required.
ISOL	Solution sequence to run using the DMIG matrices. To speed up the solution, use DOMAINSOLVER ACMS (PARTOP=DOF) for eigenvalues and set ISOL to the negative value of the solution sequence desired (-103, -111 or -112). (Integer absolute value > 100; Default = 0 which means do not run any solution sequence using the DMIG's created by Marc in this execution)

## Remarks:

1. The continuation line(s) are not required.
2. This entry corresponds to Marc's entry, SUPERELEM with a value of 1 in the second line 4th field and produces DMIG's or an MDF file for the initial geometry prior to any nonlinear iterations.
3. DMIG output will be in `jid.marc_dmigst_0001`.
4. The reduced matrices may be used in the Nastran analysis for eigenvalue extraction or any other purpose by invoking the `CONTINUE=5` option on the SOL 600 entry.
5. If the SOL 600 CONTINUE options is invoked, case control commands and a bulk data entry include statements to receive the matrices will be automatically added to the original input data file. A second Nastran execution will be spawned from the original Nastran execution after completion of the Marc execution.
6. ID must be 106 or 129 in the Executive Control statement, SOL 600, ID.
7. Only one MDMIOUT entry should be entered per run. If more are entered, only the first will be used.
8. MNF controls for other solution sequences are ignored for SOL 600.
9. For the case where DMIG's are generated and a continuation option is used, the following Bulk Data parameters are usually required in addition to the MDMIOUT entry:  

```
$2345678x234567890123456x34567890123456  
param   marcfile           nastb.rc  
param   marcfil1          m3356
```
10. For a more general form of the DMIG output, see Bulk Data entry, DMIGOUT.

## MDMIR1

## Module Reposition by Mirroring - Option 1

Defines reposition of a Module with a mirror plane defined by three non-collinear points in Module 0.

Format:

1	2	3	4	5	6	7	8	9	10
MDMIR1	MVID	P1	P2	P3					

Example:

MDMIR1	110	12	45	1125					
--------	-----	----	----	------	--	--	--	--	--

Describer	Meaning
MVID	Move identification number to be referenced on an MDMOVE entry. (Integer>0).
Pi	GRID or POINT identification numbers of three non-collinear points in Module 0. (Integer>0).

Remarks:

1. MDMIR1 can only be specified in the main Bulk Data Section (Module 0) and will cause a fatal error message if it appears after the BEGIN MODULE=n command.
2. MDMIR1 must be referenced by an MDMOVE entry in order to reposition a Module.
3. GRIDs or POINTs referenced on this entry must be defined in the main Bulk Data Section (Module 0).

## MDMIR2

## Module Reposition by Mirroring - Option 2

Defines a Module mirror by specifying a pair of coordinate system axes on the mirror plane in Module 0.

Format:

1	2	3	4	5	6	7	8	9	10
MDMIR2	MVID	CID	RID	AXES					

Example:

MDMIR2	110		45	XZ					
--------	-----	--	----	----	--	--	--	--	--

Describer	Meaning
MVID	Move identification number to be referenced on an MDMOVE entry. (Integer>0).
CID	Coordinate system identification number of a CORDij entry. Blank or zero means basic coordinate system. Module will be mirrored about CID's origin if RID is blank. (Integer ≥ 0, default=0)
RID	GRID or POINT identification number or coordinates of reference point through which mirror plane will be applied. If RID is blank, then the origin of CID will be used (Integer ≥ 0, default=0)
AXES	Coordinate system axes pair: "XY", "XZ", "YZ", "YX", "ZX", or "ZY" (Character).

Remarks:

1. MDMIR2 can only be specified in the main Bulk Data Section (Module 0) and will cause a fatal error message if it appears after the BEGIN MODULE=n command.
2. MDMIR2 must be referenced by an MDMOVE entry in order to reposition a Module.
3. CORDij, GRID or POINT entries referenced on this entry must be defined in the main Bulk Data Section (Module 0).

**MDMOVE**

Defines a Module repositioning sequence

Defines a Module repositioning sequence by referencing MDMIRi, MDROTi, and MDTRAN entries.

Format:

1	2	3	4	5	6	7	8	9	10
MDMOVE	MODID	MVID1	MVID2	MVID3	-etc.-				

Example:

MDMOVE	40	10	11	12					
--------	----	----	----	----	--	--	--	--	--

Describer	Meaning
MODID	Module identification number of a primary or copied module (Integer>0)
MVIDi	Move identification number of an MDTRAN, MDROTi or MDMIRi Bulk Data entry (Integer>0).

Remarks:

1. MDMOVE can only be specified in the main Bulk Data Section (Module 0) and will cause a fatal error message if it appears after the BEGIN MODULE=n command.
2. In order to use MDMOVE, an MDBULK entry with the same MODID must be specified with TYPE="MOVE".
3. If MDMIRi is referenced on an MDMOVE then its MVID must be specified in the MVID1 field and not in the second or subsequent MVIDi fields.

## MDMPC

## Multipoint Constraint Between Two or More Modules

Defines a multipoint constraint equation of the form

$$\sum_j A_j u_j = 0$$

where  $u_j$  represents degree-of-freedom  $C_j$  at grid or scalar point  $G_j$ .  $G_j$  may be contained in different Modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDMPC	SID	MOD1	G1	C1	A1				
	MOD2	G2	C2	A2	MOD3	G3	C3	A3	
	MOD4	G4	C4	A4	-etc-				

Example:

MDMPC	3	10	28	3	6.2				
	11	2		4.29	21	1	4	-2.91	

Descriptor	Meaning
SID	Set identification number. (Integer > 0)
MODj	Module IDs that contain the GRID entries for $G_j$ . (Integer ≥ 0).
$G_j$	Identification number of grid or scalar point. (Integer > 0)
$C_j$	Component number. (Any one of the Integers 1 through 6 for grid points; blank, zero or 1 for scalar points.)
$A_j$	Coefficient. (Real; Default = 0.0 except A1 must be nonzero.)

Remarks:

1. The MDMPC entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the MPC entry description. All remarks and figures under MPC apply to MDMPC.

**MDMPLN****Module Reposition by Mirroring**

Defines reposition of a Module with a mirror plane defined by three non-collinear points in Module 0.

Format:

1	2	3	4	5	6	7	8	9	10
MDMPLN	MODID	P1	P2	P3					

Example:

MDMPLN	110	12	45	1125					
--------	-----	----	----	------	--	--	--	--	--

Describer	Meaning
MODID	Module identification number of a primary or secondary (copied) module (Integer>0).
Pi	GRID or POINT identification numbers of three non-collinear points in Module 0 (Integer>0).

Remarks:

1. MDMPLN can only be specified in the main Bulk Data Section (Module 0) and will cause a fatal error message if it appears after the BEGIN MDMPLN=n command.
2. GRID or POINT entries referenced on this entry must be defined in the main Bulk Data Section (Module 0).

## MDRBE2

## Rigid Body Element Between Two or More Modules, Form 2

Defines a rigid body with independent degrees-of-freedom that are specified at a single grid point and with dependent degrees-of-freedom that are specified at an arbitrary number of grid points. All grid points may be defined in different Modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDRBE2	EID	MODN	GN	CM	MOD1	GM1	MOD2	GM2	
	MOD3	GM3	MOD4	GM4	MOD5	GM5	MOD6	GM6	
	MOD7	GM7	MOD8	GM8	-etc.-	ALPHA	TREF		

Example:

MDRBE2	9	101	8	12	201	10	202	12	
	202	14	203	15	203	16	6.5-6		

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000).
MODN	Module ID that contains the GRID entry for GN. (Integer ≥ 0).
GN	Identification number of grid point to which all six independent degrees-of-freedom for the element are assigned. (Integer > 0)
CM	Component numbers of the dependent degrees-of-freedom in the global coordinate system at grid points GMi. See Remark 12. under RBE2. (Integers 1 through 6 with no embedded blanks.)
MODi	Module IDs that contain the GRID entries for GMj. (Integer ≥ 0).
GMi	Grid point identification numbers at which dependent degrees-of-freedom are assigned. (Integer > 0)
ALPHA	Thermal expansion coefficient. See Remark 11. under RBE2. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

Remarks:

1. The MDRBE2 entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the RBE2 entry description. All remarks and figures under RBE2 apply to MDRBE2.

**MDRBE3****Interpolation Constraint Element Between Two or More Modules**

Defines the motion at a reference grid point as the weighted average of the motions at a set of other grid points.

Format:

1	2	3	4	5	6	7	8	9	10
MDRBE3	EID	REFMOD	REFGRID	REFC	WT1	C1	MOD1,1	G1,1	
	MOD1,2	G1,2	MOD1,3	G1,3	WT2	C2	MOD2,1	G2,1	
	MOD2,2	G2,2	-etc.-	WT3	C3	MOD3,1	G3,1	MOD3,2	
	G3,2	-etc.-	WT4	C4	MOD4,1	G4,1	MOD4,2	G4,2	
	-etc.-								
	“UM”	MOD1	GM1	CM1	MOD2	GM2	CM2		
		MOD3	GM3	CM3	-etc.-				
	“ALPHA”	ALPHA	TREF						

Example:

MDRBE3	14	1000	100	1234	1.0	123	101	1	
	102	3	103	5	4.7	1	101	2	
	102	4	103	6	5.2	2	101	7	
	102	8	103	9	5.1	1	104	15	
	105	16							
	UM	101	100	14	102	5	3		
		103	7	2					
	ALPHA	6.5-6							

Describer	Meaning
EID	Element identification number. Unique with respect to all elements. (0 < Integer < 100,000,000)
REFMOD	Module IDs that contain the GRID entry for REFGRID. (Integer ≥ 0).
REFGRID	Reference grid point identification number. (Integer > 0)
REFC	Component numbers at the reference grid point. (Any of the integers 1 through 6 with no embedded blanks.)
WT <sub>i</sub>	Weighting factor for components of motion on the following entry at grid points G <sub>i,j</sub> . (Real)
C <sub>i</sub>	Component numbers with weighting factor WT <sub>i</sub> at grid points G <sub>i,j</sub> . (Any of the integers 1 through 6 with no embedded blanks.)
MOD <sub>i,j</sub>	Module IDs that contain the GRID entries for G <sub>i,j</sub> . (Integer ≥ 0).

Gi,j	Grid points with components Ci that have weighting factor WTi in the averaging equations. (Integer > 0)
“UM”	Indicates the start of the degrees-of-freedom belonging to the dependent degrees-of-freedom. The default action is to assign only the components in REFC to the dependent degrees-of-freedom. (Character)
MODk	Module IDs that contain the GRID entries for GMk. (Integer ≥ 0).
GMi	Identification numbers of grid points with degrees-of-freedom in the m-set. (Integer > 0)
CMi	Component numbers of GMi to be assigned to the m-set. (Any of the Integers 1 through 6 with no embedded blanks.)
“ALPHA”	Indicates that the next number is the coefficient of thermal expansion. (Character)
ALPHA	Thermal expansion coefficient. See Remark 14. under RBE3. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

Remarks:

1. The MDRBE3 entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the RBE3 entry description. All remarks and figures under RBE3 apply to MDRBE3.

## MDRJNT

## Rigid Joint Between Two Modules

Defines a rigid joint element connecting two coinciding grid points in two different Modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDRJNT	EID	MODA	GA	MOdB	GB	CB			

Example:

MDRJNT	5	11	1	21	2	12345		1	
--------	---	----	---	----	---	-------	--	---	--

Describer	Meaning
EID	Element identification number. (Integer > 0)
MODA,MOdB	Module IDs that contain the GRID entries for GA and GB in Modules MODA and MOdB, respectively. (Integer ≥ 0).
GA, GB	Grid point identification numbers. (Integer > 0)
CB	Component numbers in the global coordinate system at GB. These degrees-of-freedom are constrained to move with the same degrees-of-freedom at GA. See Remarks 4. and 5. under RJOINT. (Integers 1 through 6 with no embedded or blank.)

Remarks:

1. The MDRJNT entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the RJOINT entry description. All remarks and figures under RJOINT apply to MDRJNT.

## MDROT1

## Module Reposition by Rotation - Option 1

Defines a Module rotation by specifying a rotation vector and reference point in Module 0.

Format:

1	2	3	4	5	6	7	8	9	10
MDROT1	MVID	RID	IDS	IDE	MAG				

Example:

MDROT1	110		45	72	90.				
--------	-----	--	----	----	-----	--	--	--	--

Describer	Meaning
MVID	Move identification number to be referenced on an MDMOVE entry. (Integer>0).
RID	GRID or POINT identification number of a reference point at which rotation will occur. If blank or 0 then Module will be rotated about rotation vector defined from IDS to IDE. (Integer ≥ 0, Default=0).
IDS	GRID or POINT identification number of rotation vector's starting point. (Integer>0)
IDE	GRID or POINT identification number of rotation vector's end point. (Integer>0)
MAG	Magnitude of rotation in degrees. (Real ≠ 0.0).

Remarks:

1. MDROT1 can only be specified in the main Bulk Data Section (Module 0) and will cause a fatal error message if it appears after the BEGIN MODULE=n command.
2. MDROT1 must be referenced by an MDMOVE entry in order to reposition a Module.
3. GRID or POINT entries referenced on this entry must be defined in the main Bulk Data Section (Module 0).

**MDROT2****Module Reposition by Rotation - Option 2**

Defines a Module rotation by specifying a coordinate system axis for the rotation vector.

Format:

1	2	3	4	5	6	7	8	9	10
MDROT2	MVID	CID	RIDS	AXIS	MAG				

Example:

MDROT2	40		45	Y	90.				
--------	----	--	----	---	-----	--	--	--	--

Describer	Meaning
MVID	Move identification number to be referenced on an MDMOVE entry. (Integer>0).
CID	Coordinate system identification number of a CORDij entry. Blank or zero means basic coordinate system. Module will be rotated about CID's origin if RID is blank. (Integer ≥ 0, default=0).
RID	GRID or POINT identification number of a reference point at which rotation will occur. If RID is blank or 0 then the origin of CID will be used. (Integer ≥ 0, Default=0)
AXIS	Coordinate system axis: "X", "Y", "Z", "MX", "MY", or "MZ". The latter three values indicate the negative side of the axis. (Character)
MAG	Magnitude of rotation in degrees. (Real ≠ 0.0).

Remarks:

1. MDROT2 can only be specified in the main Bulk Data Section (Module 0) and will cause a fatal error message if it appears after the BEGIN MODULE = n command.
2. MDROT2 must be referenced by an MDMOVE entry in order to reposition a Module.
3. CORDij, GRID or POINT entries referenced on this entry must be defined in the main Bulk Data Section (Module 0).

## MDRROD

## Rigid Pin-Ended Element Connection Between Two Modules

Defines a pin-ended element that is rigid in translation between two Modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDRROD	EID	MODA	GA	MODB	GB	CMA	CMB	ALPHA	
	TREF								

Example:

MDRROD	14	11	1	21	2	2		6.5-6	
--------	----	----	---	----	---	---	--	-------	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
MODA,MODB	Module IDs that contain the GRID entries for GA and GB (Integer ≥ 0).
GA, GB	Grid point identification numbers of connection points in Modules MODA and MODB, respectively. (Integer > 0)
CMA,CMB	Component number of one and only one dependent translational degree-of-freedom in the global coordinate system assigned by the user to either GA or GB. See Remark 3. under RROD. (Integer 1, 2, or 3. Either CMA or CMB must contain the integer, and the other must be blank for the linear MDRROD. For Lagrange MDRROD, both CMA and CMB can be blank.)
ALPHA	Thermal expansion coefficient. See Remark 11. under RROD. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

Remarks:

1. The MDRROD entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the RROD entry description. All remarks and figures under RROD apply to MDRROD.

**MDSEAM****A Shell Patch SEAM Connection Between Two Modules**

Defines a SEAM connecting two surface patches in two Modules.

Format:

1	2	3	4	5	6	7	8	9	10
MDSEAM	EID	PID	SMLN	CTYPE	IDAS	IDBS	IDAE	IDBE	
	GS	GE					MODA	MODB	

Alternate Format:

1	2	3	4	5	6	7	8	9	10
MDSEAM	EID	PID		CTYPE	IDAS	IDBS	IDAE	IDBE	
	XS	YS	ZS	XE	YE	ZE	MODA	MODB	

Example:

MDSEAM	552	297			43	48			
	30422	77987					15	32	

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
PID	Property identification number of a PSEAM entry. (Integer > 0)
SMLN	SEAM line identification. See Remark 2. under CSEAM. (CHAR or blank)
CTYPE	Connectivity search type. (Character)
	If CTYPE = "PSHELL", IDAS and IDBS are property identification numbers of PSHELL's. (Default)
	If CTYPE = "ELEM", IDAS and IDBS are element identification numbers.
IDAS, IDBS	Used to define patch A and B in Modules MODA and MODB or the start of patch A or B for a tailored blank in Modules MODA and MODB. See Remark 2. under CSEAM (Integer > 0)
	If CTYPE = "PSHELL", required property id defining patches A and B in Modules MODA and MODB. If CTYPE = "PSHELL" and IDAS = IDBS or IDBS = blank the patch will be considered as two-sided and the property identification numbers of PSHELL's will be the same for both the top and bottom. See Remark 6. under CSEAM.
	If CTYPE = "ELEM", required element id defining patches A and B in Modules MODA and MODB. IDAS ≠ IDBS.

Describer	Meaning
IDAE, IDBE	<p>Used to define the end of patch A and the end of patch B for a tailored blank in Modules MODA and MODB. See Remark 4. under CSEAM. (Integer &gt; 0 or blank)</p> <p>If CTYPE = "PSHELL", property id defining patches A and B. If CTYPE = 'PSHELL' and IDAE = IDBE or IDBE=blank the patch will be considered as two-sided and the property identification numbers of PSHELL's will be the same for both the top and bottom.</p> <p>If CTYPE = "ELEM", element id defining patches A and B in Modules MODA and MODB. IDAE ≠ IDBE.</p>
GS, GE	Grid ids of piercing points on patches A and B of the Start and End of the SEAM. Their GRID entries must be defined in the main Bulk Data section (Module 0). (Integer > 0)
XS, YS, ZS	Location of the SEAM Start. (Real or blank)
XE, YE, ZE	Location of the SEAM End. (Real or blank)
MODA, MODB	Module IDs that contain the surface patches defined by property or element entries IDAS/IDAE and IDBS/IDBE, respectively (Integer ≥ 0).

Remarks:

1. The MDSEAM entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the CSEAM entry description. All remarks and figures under CSEAM apply to MDSEAM.

## MDSSET

### Set Definition for Structural Elements or Grid Points in Modules

Defines a set of structural grid points or element identification numbers in a Module to be referenced by the ACMODL Bulk Data entry.

Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>
MDSSET	MODID	ID1	ID2	ID3	ID4	ID5	ID6	ID7
	ID8	-etc.-						

Example 1:

MDSSET	22	31	62	93	124	16	17	18
	19							

Example 2:

MDSSET	22	29	32	THRU	50	61	THRU	70
	17	57						

Describer	Meaning
MODID	Module identification number (Integer ≥ 0)
IDI	List of structural grid point or element identification numbers. (Integer > 0 or “THRU”; for the “THRU” option: ID1 < ID2).

Remarks:

1. The MDSSET entry can only be used in the presence of Modules and can only be specified in the main Bulk Data section or Module 0.
2. The MDSSET entry is used when SSET is set to -1 on the ACMODL entry.
3. Multiple MDSSET entries may reference more than one Module.

## MDTRAN

## Module Reposition by Translation

Defines a Module translation by specifying a vector in Module 0.

Format:

1	2	3	4	5	6	7	8	9	10
MDTRAN	MVID	IDS	IDE	MAG					

Example:

MDTRAN	110	72	45						
--------	-----	----	----	--	--	--	--	--	--

Describer	Meaning
MVID	Move identification number to be referenced on an MDMOVE entry. (Integer>0).
IDS	GRID or POINT identification number of translation vector's starting point. (Integer>0).
IDE	GRID or POINT identification number of translation vector's end point. (Integer>0).
MAG	Magnitude of translation. If blank or zero, then the length of the vector will be used. (Real, Default=0.0)

Remarks:

1. MDTRAN can only be specified in the main Bulk Data Section (Module 0) and will cause a fatal error message if it appears after the BEGIN MODULE = n command.
2. MDTRAN must be referenced by an MDMOVE entry in order to reposition a Module.
3. GRID or POINT entries referenced on this entry must be defined in the main Bulk Data Section (Module 0).

**MDWELD****Weld or Fastener Element Connection Between Two Modules**

Defines a weld or fastener connecting two surface patches or points between two Modules.

Format PARTPAT:

1	2	3	4	5	6	7	8	9	10
MDWELD	EWID	PWID	GS	"PARTPAT"	GA	GB		MCID	
	PIDA	PIDB			MODA	MODB			
	XS	YS	ZS						

Example:

MDWELD	101	8	203	PARTPAT					
	21	33			11	21			

Alternate formats and examples:

Format ELPAT:

1	2	3	4	5	6	7	8	9	10
MDWELD	EWID	PWID	GS	"ELPAT"	GA	GB		MCID	
	SHIDA	SHIDB			MODA	MODB			
	XS	YS	ZS						

Example:

MDWELD	103	5	403	ELPAT					
	309	511			11	21			

Format ELEMID:

MDWELD	EWID	PWID	GS	"ELEMID"	GA	GB		MCID	
	SHIDA	SHIDB	MODS		MODA	MODB			

Example:

MDWELD	103	5	403	ELEMID					
	309	511			11	12			

Format GRIDID:

MDWELD	EWID	PWID	GS	"GRIDID"	GA	GB	SPTYP	MCID	
					MODA	MODB			
	GA1	GA2	GA3	GA4	GA5	GA6	GA7	GA8	
	GB1	GB2	GB3	GB4	GB5	GB6	GB7	GB8	

Example:

MDWELD	7	29	233	GRIDID			QT		
					11	21			
	15	28	31	35	46	51	55	60	
	3	5	8						

Format ALIGN:

MDWELD	EWID	PWID		"ALIGN"	GA	GB		MCID	
					MODA	MODB			

Example:

MDWELD	7	29		ALIGN	103	259			
					11	21			

Describer	Meaning	Type	Default
EWID	MDWELD element identification number. See Remark 1 under CWELD.	0 < Integer < 100,000,000	Required
PWID	Property identification number of a PWELD entry.	Integer > 0	Required
GS	Identification number of a grid point which defines the location of the connector. GRID entry for GS must be defined in main Bulk Data section only (Module 0) except for a point-to-patch connection with OPTION="ELEMID" in which case GS must be defined in Module MODS. See Remarks 2. and 3. under CWELD.	Integer > 0 or blank	

Describer	Meaning	Type	Default
	Character string indicating the type of connection. The format of the subsequent entries depends on the type. "PARTPAT", for example, indicates that the connectivity of surface patch A to surface patch B is defined with two property identification numbers of PSHELL entries, PIDA in Module MODA and PIDB in Module MODB, respectively. The "PARTPAT" format connects up to 3x3 elements per patch. See Remark 4. under CWELD.	Character	Required
GA, GB	Grid point identification numbers of piercing points on surface A and surface B, respectively. GRID entries for GA and GB must be defined in the main Bulk Data section only (Module 0) except for OPTION="ALIGN". See Remark 5. under CWELD.	Integer > 0 or blank	Blank
MCID	Specifies the element stiffness coordinate system. See Remark 16. under CWELD	Integer > -1 or blank	Default = -1
MODS	Module ID that contains GRID entry for GS. Only used for point-to-patch connection with OPTION="ELEMID".	Integer ≥ 0	Default = 0
MODA, MODB	Module IDs that contain the surface patches defined by (1) property entries PIDA and PIDB, (2) element entries SHIDA and SHIDB or (3) GRID entries GAI and GBi, respectively.	Integer ≥ 0	Default = 0
PIDA, PIDB	Property identification numbers of PSHELL entries defining surface A in Module MODA and B in Module MODB, respectively.	Integer > 0	Required for "PARTPAT"
XS, YS, ZS	Coordinates of spot weld location in basic. See Remark 2. under CWELD.	Real	Required if GS and GA are not defined.

For the alternate formats, the describer meaning are described below:

Describer	Meaning	Type	Default
“ELPAT”	Character string indicating that the connectivity of surface patch A to surface patch B is defined with two shell element identification numbers, SHIDA in Module MODA and SHIDB in Module MODB, respectively. The “ELPAT” format connects up to 3x3 elements per patch. See Remark 6. under CWELD.	Character	Required
SHIDA, SHIDB	Shell element identification numbers of elements on patch A in Module MODA and B in Module MODB, respectively.	Integer > 0	Required for “ELPAT”
“ELEMID”	Character string indicating that the connectivity of surface patch A to surface patch B is defined with two shell element identification numbers, SHIDA in Module MODA and SHIDB in Module MODB, respectively. The “ELEMID” format connects one shell element per patch. See Remark 7. under CWELD.	Character	Required
SHIDA, SHIDB	Shell element identification numbers of elements on patch A in Module MODA and B in Module MODB, respectively.	Integer > 0	Required for “ELEMID”
“GRIDID”	Character string indicating that the connectivity of surface patch A in Module MODA to surface patch B in Module MODB is defined with two sequences of grid point identification numbers, GAi in Module MODA and GBi in Module B, respectively. The “GRIDID” format connects the surface of any element. See Remark 8. under CWELD.	Character	Required
SPTYP	Character string indicating types of surface patches A and B. SPTYP = “QQ”, “TT”, “QT”, “TQ”, “Q” or “T”. See Remark 9. under CWELD.	Character	Required for “GRIDID”

Describer	Meaning	Type	Default
GAi	Grid identification numbers of surface patch A. GA1 to GA3 are required. Their GRID entries must be defined in Module MODA only. See Remark 10. under CWELD.	Integer > 0	Required for "GRIDID"
GBi	Grid identification numbers of surface patch B. Their GRID entries must be defined Module MODB only. See Remark 10. under CWELD.	Integer > 0	
"ALIGN"	Character string indicating that the connectivity of surface A to surface B is defined with two shell vertex grid points GA in Module MODA and GB in Module MODB, respectively. See Remark 11. under CWELD.	Character	Required
GA, GB	Vertex grid identification number of shell A and B, respectively. GA and GB GRID entries must be defined in Module MODA and Module MODB, respectively.	Integer > 0	Required for "ALIGN"

#### Remarks:

1. The MDWELD entry must be defined in the main Bulk Data section only (Module 0).
2. See all remarks and figures under the CWELD entry description. All remarks and figures under CWELD apply to MDWELD.

## MESH

## Mesh Generator

Defines a mesh. Used in SOL 700 only.

Format:

1	2	3	4	5	6	7	8	9	10
MESH	MID	TYPE	DXEL	DYEL	DZEL	XREF	YREF	ZREF	
	X0	Y0	Z0	DX	DY	DZ			
	NX	NY	NZ	SUBMESH	NSTGP	NSTEL	PROP	PID	
	RESIZE	TID-X	TID-Y	TID-Z	METHOD				
	BIAS	GROWX	GROWY	GROWZ	IBIDX	IBIDY	IBIDZ		
	XOBY	YOBY	ZOBY	DXBY	DYBY	DZBY			
	CID								
	NELCUBE	NBX	NBY	NBZ	PROCDIR	NPX	NPY	NPZ	

Example:

MESH	1	ADAPT	0.1	0.2	0.3				
	SCALE	101			ALL				
	CENTER	1.2	1.2	1.2					

Descriptor	Meaning
MID	Unique MESH number. See Remark 1. (Integer > 0; no Default)
TYPE	Type of mesh generation: See Remark 1. (Character; Required)
ADAPT	An Euler mesh will be created around a coupling surface. This option is only valid for PROP=EULER, and requires that the MID of the MESH is referenced from the MESHID of a COUPLE card. During the simulation, when the coupling surface moves or deforms, the Euler mesh will adapt itself by adding and removing elements. The adapt algorithm ensures that the coupling surface is contained inside the Euler mesh at all times with the minimum amount of elements. The Euler elements are aligned with the basic coordinate.
BOX	A rectangular mesh will be created, that is aligned with the basic coordinate system. The mesh will use CHEXA elements.
DXEL,DYEL, DZEL	Euler element sizes. See Remark 1. (Real)

Describer	Meaning
XREF,YREF,ZREF	Coordinates of reference point. For TYPE=ADAPT, these coordinates provide control over the location of the Euler mesh, to avoid that faces of the Euler mesh are initially at the same location as faces of the coupling surface. For TYPE=BOX, these coordinates will be used as the origin of the mesh. They are the default setting for (X0, Y0, Z0). (Real; Default = -1e-6)
X0,Y0,Z0	Coordinates of point of origin. (Real, XREF, YREF, ZREF) Not used for TYPE=ADAPT
DX,DY,DZ	Width of mesh in different directions. For TYPE=ADAPT, these values will only be used if (DXEL, DYEL, DZEL) are left blank. See Remark 1. for more detail. (Real)
NX,NY,NZ	Number of elements in the different directions. For TYPE=ADAPT, these values will only be used if (DXEL, DYEL, DZEL) are left blank. See Remark 1. for more detail. (Integer > 0)
SUBMESH	Allows using smaller mesh sizes for a part of the mesh. SUBMESH is the MESH ID of a finer mesh that is to replace part of the mesh. See Remark 8. (Integer ≥ 0, default=0)
NSTGP	Starting grid-point number. Not used for TYPE=ADAPT. If there are multiple couple surfaces then the starting grid-point number can only be specified if param,flow-method,facet has been activated. See Remark 2. (Integer > 0)
NSTEL	Starting element number. Not used for TYPE=ADAPT. If there are multiple couple surfaces then the starting element number can only be specified if param,flow-method,facet has been activated. See Remark 2. (Integer > 0)
PROP	Property type: (Character; default=EULER) EULER            An Eulerian mesh will be created.
PID	ID of a PEULER or PEULER1 entry. (Integer > 0, Required.)
RESIZE	Only valid for TYPE=ADAPT. See Remark 6. (Character, NONE) Option to change the element size during the simulation: NONE            No resizing of DX,DY,DZ during simulation. SCALE           The elements are resized by a scale-factor as a function of time. LENGTH        The elements are resized by specifying the length as a function of time.
TID-X	ID of a TABLED1. See RESIZE for contents of table. It must define a step function. See Remarks 4. and 5. (Integer > 0; Blank)
TID-Y	ID of a TABLED1. See RESIZE for contents of table. It must define a step function. See Remarks 4. and 5. (Integer > 0; TID-X)
YID-Z	ID of a TABLED1. See RESIZE for contents of table. It must define a step function. See Remarks 4. and 5. (Integer > 0; TID-X)
METHOD	Method for determining when to create Euler elements: (Character; ALL)

Describer	Meaning
	<p>ALL Always re-mesh any existing Euler element. Maintains existing void regions. Only used for resizing.</p> <p>MATERIAL Only re-mesh those Euler elements that contain material. Removes void regions. See Remark 7.</p>
BIAS	Adds bias to the mesh. (Character; Blank)
	<p>CENTER Starting at the center of the BOX the mesh size gradually changes such that the mesh size at the boundaries of the BOX is GROWX times the mesh size at the center.</p> <p>REF Starting at the reference point the mesh size gradually changes such that the mesh size at the boundaries of the BOX is GROWX times the mesh size at the center</p>
GROWX, GROWY, GROWZ	Total grow factor. Is the ratio between finest and coarsest element size. (Real > 0; Only required if BIAS is not blank)
IBIDX, IBIDY, IBIDZ	BIAS ID reference. See Remarks 9. and 10. (Integer; Default = 0)
X0BX,Y0BX,Z 0BX,DXBX,D YBX,DZBX	Definition of an auxiliary box for output purposes. By defining an auxiliary box all adaptive elements that are within the box for one of the cycles requested are stored in the archive. This allows multiple cycles in one Euler archive. This box should be sufficiently large such that it contains all elements. The fields X0BX, Y0BX and Z0BX specify the start point and DXBX, DYBX and DZBX specify the width of box. If there are adaptive elements outside the box the run is terminated and a larger box needs to be specified. Only used for TYPE=ADAPT. (Real; Blank) See Remark 14.
CID	ID - number of a local coordinate system. (Integer ≥ 0; Default=0)
NELCUBE	The number of elements per cube. This number is used as a guideline. The actual number used per cube can differ and can be found in the OUT file. See Remark 12. (Integer ≥ 1; Default=1)
NBX	Overrules NELCUBE. The number of cubes in the x-direction. (Integer ≥ 0; Default=1)
NBY	The number of cubes in the y-direction.(Integer ≥ 0; Default=NBX)
NBZ	The number of cubes in the z-direction. (Integer ≥ 0; Default=NBX)
PROCDIR	This directive controls the way cubes are distributed across processors. The effect can be checked by checking the Eulerian output variable PARTITION. (Char, Default=X)
	<p>X Partition in global X direction first.</p> <p>Y Partition in global Y direction first.</p> <p>Z Partition in global Z direction first.</p> <p>USER Define user defined partitioning.</p>

Describer	Meaning
	SIMPLE Partition Euler cubes in a simple pattern.
NPX	The number of cubes in the x-direction. Required for PROCDIR=USER. (Integer, Default=1)
NPY	The number of cubes in the y-direction. (Integer, Default=NPX)
NPZ	The number of cubes in the z-direction. (Integer, Default=NPX)

#### Remarks:

1. The grid-points of the mesh are generated at following locations:

Type=ADAPT:  $(x,y,z)=(XREF+i*DXEL, YREF+j*DYEL, ZREF+k*DZEL)$

Grid-points and elements located a certain distance outside the coupling surface will not be created. This saves memory and CPU time.

When (XREF, YREF, ZREF) are outside the coupling surface, no grid-point will be created at this location, but the mesh will be shifted appropriately.

Type=BOX:  $(x,y,z) = (X0+i*DXEL, Y0+j*DYEL, Z0+k*DZEL)$

Nodes and Elements will always be created, even if the MESH is referenced from the MESHID of a COUPLE entry.

One of the following input combinations is required:

TYPE=ADAPT

- a. (DXEL, DYEL, DZEL)

or

- b. 1

- c. (DX, DY, DZ) and (NX, NY, NZ)

➔  $DXEL = DX/NX$  ;  $DYEL=DY/NY$  ;  $DZEL=DZ/NZ$

TYPE=BOX

- a. (DXEL, DYEL, DZEL) and (NX, NY, NZ)

or

- b. (DX, DY, DZ) and (NX, NY, NZ)

➔  $DXEL = DX/NX$  ;  $DYEL=DY/NY$  ;  $DZEL=DZ/NZ$

2. When the starting grid point and/or element number is left blank, then the default start number for the elements and grid-points is equal to the maximum number used +1. For simulations with multiple coupling surfaces two methods of treating transport between the Euler meshes are available. One method supports meshes of TYPE = ADAPT, but does not allow the specification of starting element or starting grid-point number.
3. The PID should refer to an existing property id, which can handle the property type given by PROP.

4. To avoid that the Euler mesh will be resized every time-step, the functions defined by TID-X, TID-Y, TID-Z must describe a 'step-function', like in this example:
- i. TABLED1,1,,,,,,,,,+
  - ii. +,0.0,1.0,,,,,,,,,+
  - iii. +,1.E-3,1.0,,,,,,,,,+
  - iv. +,1.E-3,1.1,,,,,,,,,+
  - v. +,2.E-3,1.1,,,,,,,,,+
  - vi. +,2.E-3,1.2

Which specifies following function:

5. Care must be taken when refining the Euler mesh. To avoid instabilities, it is advised to stay within the following guidelines:
  - a. Each refining step, use a scale factor larger than 0.5
  - b. Allow the solution to become smooth again after each refining step. For airbag simulations, use an interval larger than  $5 * \text{diameter\_airbag} / \text{soundspeed}$
6. Resizing is not available for the Multi-material solver.
7. In most cases METHOD = ALL is the preferred method. Using METHOD=MATERIAL may be helpful in case of instabilities due to presence of void regions.
8. SUBMESH glues a fine mesh into a coarse mesh and uses the same gluing functionality as PARAM, GRADED MESH. If the fine mesh is completely contained inside the coarse mesh no restrictions apply. Then to avoid any restrictions the grid points of the fine mesh are slightly displaced. But if parts of the fine mesh are outside the coarse mesh a restriction applies. In that case an Euler element of the coarse mesh has to be fully active or fully inactive. This means that the coarse element should not intersect elements of the fine mesh or it should be fully covered by the fine elements. Fine elements are not allowed to cover any part of the coarse elements. In practice, this means that the fine mesh has to fit nicely in the coarse mesh. For details refer to the section "Graded meshes" in the MSC Nastran Explicit Nonlinear User's Manual.

When running on one cpu the elements of the Euler mesh and the submesh will be put into one euler archive. But when running with multiple cpus, the mesh and sub mesh will be put in different euler archives. To distinguish the archives, the name `_FVX` is added to the Euler archive names. Here X is the MESH-ID MID. The Euler archive of the mesh and the submesh can be read simultaneously into Patran.

9. A biased mesh has nonconstant element sizes in selected directories. Neighbor element size can have a constant ratio or have identical size. In literature, this type of mesh is also referred to as a nonuniform mesh or a locally refined mesh.
10. A block mesh consists of a number of planes in all three directions. For a nonbiased mesh, these planes are at fixed distance from each other. In a biased mesh, the distance between subsequent planes can differ. The varying element size is determined by:
  - a. IBIDX
  - b. GROWX
  - c. The constant step size specified by X0, NX, DX.

Here, IBIDX overrules GROWX and GROWX overrules the X0, NX DX specification. Likewise, for the other directions. The locations of the planes are written out in the OUT file. Intersecting an x-plane with a y-plane and z-plane will give a grid point. By carrying out all intersections, the grid points are constructed.

11. Defining the CID allows for positioning the mesh box arbitrarily in space. When active, the following restrictions apply:
  - MESH,ADAPT cannot be used
  - The use of single material Euler with strength elements is not supported
12. Setting NELCUBE, NBX, NBY, NBZ allow to divide the Euler mesh into a number of cubes. By setting NELCUBE equal to 2000, optimal use is made of memory caching during Euler computation. This can give a speedup of 1.5. If NBX is defined, also NBY and NBZ need to be defined. Defining NBX overrules the definition of NELCUBE.

When using multiple Euler cubes the BARRIER and FLOW definitions only support geometric conditions like boundary face direction and square definition.

13. There are several ways to distribute cubes across processors. Some ways may lead to bad load balancing. To avoid this it is possible to control the way Euler cubes are distributed across processors by defining PROCDIR.

When option PROCDIR=USER, the values for NBX, NBY, and NBZ must be such that NBX is equal or a multiple of NPX, NBY is equal or a multiple of NPY and NBZ is equal or a multiple of NPZ. Also for this option,  $NPX \cdot NPY \cdot NPZ$  must be equal to the number of processors used in the cluster.

For option PROCDIR=SIMPLE, the values NBX, NBY, and NBZ on DYPARAM,EULERCB must be such that  $NBX \cdot NBY \cdot NBZ$  is equal or a multiple of the number of processors used. For instance, if the number of processors in the cluster is 4,  $NBX \cdot NBY \cdot NBZ$  must be equal to either 4 or 8 or 12, etc. Otherwise, the calculation will terminate prematurely with an error message.

When using these options the Barrier and FLOW definitions only support geometric conditions like boundary face direction and a square definition

14. To determine a suitable size for the static output box, the simulation can be run first without the fields X0BX, Y0BX, Z0BX, DXBX, DYBX, and DZBX set. In the ,OUT file each summary of adaptive meshing gives the smallest box surrounding all adaptive elements so far. The last summary then yields the dimension of the static output box. To accommodate for elements that are not completely inside the box, the actual static output box is automatically extended a little. The actual dimensions are written in the out file after the first adaptive meshing summary. It is not needed to set the XREF, YREF, and ZREF option. If they are set the static output box will be compatible with the defined reference point.

**MESUPER****Defines External Superelement DMIG Input for SOL 600 Residual Analyses**

Superelement DMIG matrices are created by Nastran and used when Marc is spawned from Nastran, SOL 600 only.

**Format:**

1	2	3	4	5	6	7	8	9	10	
MESUPER	ID	Fname								

**Example:**

MESUPER	1	super1.pch								
MESUPER	2	super2.pch								

Describer	Meaning
ID	Superelement ID. (Integer; no Default)
Fname	Filename containing external superelement data from the creation run (using Case Control EXTSEOUT (ASMBULK, DMIGPCH,EXTID=ID) (Character; no Default). Left justify in field, see Remark 8.

**Remarks:**

1. Enter as many MESUPER lines as necessary to define all external superelements.
2. This entry can presently only be used with SOL 600,106, SOL 600,101, SOL 600,nlstatic, or SOL 600,sestatic. External Superelements are not presently available for other types of SOL 600 analyses such as nonlinear (or linear) transient dynamics, eigenvalue analysis or buckling.
3. Fname is limited to 56 characters.
4. Include entries with the same Fname must be specified as include files in the Nastran input file. The include specifications must appear at the end of the Bulk Data portion of the file.
5. External superelement creation runs should use the Case Control command:  
EXTSEOUT(ASMBULK,DMIGPCH,EXTID=N)  
where N is the external superelement ID number. All creation runs must have the same number of subcases and use the same subcase IDs.
6. The SOL 600 residual input file must have the same number of subcases and subcase numbers as the creation runs.
7. This entry acts like an element, in other words it is not controlled by a case control command. It is always active if entered.

8. The MESUPER entries should normally be coded in small fixed field format. If coded in small format free field, Fname is limited to 8 characters. If coded in large format free field, Fname is limited to 16 characters. The filename may be extended to a continuation line. All filenames should be entered in lower case. Nastran will convert to upper case, and the SOL 600 translator will reconvert to lower case. The creation runs should also use lower case for all external superelement punch filenames for case-sensitive computer systems.
9. If there are no elements in the residual (that is, all elements are in the external superelements, PARAM,MARCND99,-1 is required to output the displacements in the Marc .out file regardless of the specified Case Control request.
10. The ASMBULK option in the creation runs is required for SOL 600 when outr options are specified. It is recommended whether or not outr options are specified. All .asm files (created by the ASMBULK option) for all external superelements should be included in the Bulk Data before any punch files (produced using the DMIGPCH option). See the following input file examples.
11. At present, an OP2 with results datablocks only can be produced by a SOL 600 External Superelement residual execution. OP2 files which combine geometry and results datablocks cannot be produced. Other outr options such as xdb, f06 and punch are also not available for SOL 600 External Superelement residual runs.
12. For the External Superelement Initial run(s) to generate punch and asm files, no Case Control output requests should be made and the following DMAP should be inserted in the Executive Control in order to prevent extra information (which will cause an error) for being inserted into the punch file:

```
compile extout
alter 'sdr2' $
delete /iug1,,,, $
alter 'sdr2' (2) $
delete /igulo,,,, $
```

13. If data exists after ENDDATA, including any characters on the ENDDATA line, after the word ENDDATA in the creation run input, this data must be removed.

Typical File Setup for External Superelement Creation Run for SOL 600 (same as for other solution sequences)

```
SOL 101
compile extout
alter 'sdr2' $
delete /iug1,,,, $
alter 'sdr2' (2) $
delete /iug1o,,,, $
CEND

## METADATA

## Metadata for the input section

Defines the entry metadata.

Format:

1	2	3	4	5	6	7	8	9	10
METADATA	META								
	METAINFOR								

Example:

METADATA	Rear_Fender							
	This is line 1 of metadata							
	This is line 2 of metadata							
	This is line 3 of metadata...							

Describer	Meaning
META	Character handle of up to 24 characters identifying the metadata.
METAINFO	A open-ended list of strings of 64 characters that represents the user information.

Remarks:

1. META can include any character from defined bulk character set
2. METAINFO can contain basic Nastran characters and special symbols.

## MFLUID Fluid Volume Properties

Defines the properties of an incompressible fluid volume for the purpose of generating a virtual mass matrix.

Format:

1	2	3	4	5	6	7	8	9	10
MFLUID	SID	CID	ZFS	RHO	ELIST1	ELIST2	PLANE1	PLANE2	
	RMAX	FMEXACT							

Example:

MFLUID	3	2	15.73	1006.	3	4	S	N	
		100.							

Describer	Meaning
SID	Set identification number. (Integer > 0)
CID	Identification number of rectangular coordinate system used to specify the orientation of the free surface (normal to $X_3$ ) and of planes of symmetry, if any. (Integer $\geq 0$ or blank)
ZFS	Intercept of the free surface on the $X_3$ axis of the coordinate system referenced by CID. If $X_3$ of a grid > ZFS then there is no fluid. See Remark 3. (Real; Default means that the free surface is located at an infinitely large positive value of XFS.)
RHO	Density of the fluid (Real).
ELIST1	Identification number of an ELIST entry that lists the IDs of two-dimensional elements that can be wetted on one side by the fluid. Only those elements connected to at least one grid point below ZFS are wetted by the fluid. See Remarks 3. and 5. (Integer $\geq 0$ )
ELIST2	Identification number of an ELIST entry that lists the IDs of two-dimensional elements that can be wetted on both sides by the fluid. Only those elements connected to at least one grid point below ZFS are wetted by the fluid. (Integer $\geq 0$ ; ELIST1 + ELIST2 > 0)
PLANE1, PLANE2	Planes of symmetry, antisymmetry, or no symmetry. "S" means that plane 1, which is the plane containing the $X_1$ and $X_3$ axes of CID, is a plane of symmetry. "A" means that plane 1 is a plane of antisymmetry. "N" means that it is neither. See Remark 5. Plane 2 uses "S", "A", or "N" for the $X_2$ and $X_3$ plane. (Character: "S", "A", or "N")
RMAX	Characteristic length. Interactions between elements with separation that is greater than RMAX will be neglected. (Real > 0.0; Default = 1.0E 10)
FMEXACT	Exact integration is used if the distance between two elements is less than FMEXACT times the square root of the area of the larger element. Otherwise, center point integration is used by default. (Real; Default = 1.0E 15)

## Remarks:

1. The MFLUID entry must be selected with the Case Control command MFLUID = SID.
2. Several MFLUID entries corresponding to different fluid volumes can be used simultaneously.
3. The wetted side of an element in ELIST1 is determined by the presence or absence of a minus sign preceding the element's ID on the ELIST entry. A minus sign indicates that the fluid is on the side opposite to the element's positive normal, as determined by applying the right-hand rule to the sequence of its corner points. The same element can appear on two ELIST entries, indicating that it forms a barrier between the unconnected fluids.
4. The fluid volume may be finite (interior) or infinite (exterior). The volume may be bounded by a free surface and one or two planes of structural symmetry. If structural symmetry is used, the structure must have the symmetric or antisymmetric boundary corresponding to the selection in fields 8 and 9. Interior fluids must have ELIST1 data and a free surface or plane of antisymmetry.
5. The planes of symmetry and/or antisymmetry defined in fields 8 and 9 must be planes of symmetry for the entire analysis. The user may apply appropriate structural boundary conditions at all grid points lying in these planes.
6. The current list of elements that may be placed in ELIST1 and ELIST2 include CTRIA3, CQUAD4, CTRIAR, and CQUADR.
7. The continuation entry is optional.
8. If there is ELIST1 data and no free surface nor plane of antisymmetry, the program assumes a special form of external fluid. These special external fluids must have a CID (field 3) such that the origin of the fluid coordinate system is near the center of the enclosed volume, since the singularity for volume change will be placed at the origin. Special external fluids are supported only in SOLs 103 and 107 through 112. If used in conventional solution sequences, System Fatal Message 3001 results for file 205.
9. See PARAM,VMOPT in [Parameters](#). VMOPT controls when the virtual mass is included in the mass matrix.
10. If any MFLUID entry is changed or added on restart then a complete re-analysis may be performed. Therefore, MFLUID entry changes or additions are not recommended on restart.
11. A tolerance is computed for each wetted element, with the value of  $0.01 \sqrt{2A}$ , where A is the area of the element. If any grid point connected to the element lies within TOL below the free surface it is moved to the free surface.
12. Any element that has all grids on or above the free surface, after the grid points are moved by the procedures given in Remark 11, is removed from the ELIST. It is not included in the VM effects, and will produce no pressure output.

## MGRSPR Defines Grids to Add Soft Spring to Ground - SOL 600

This entry is used to add soft springs to ground at selected grids to stabilize the structure in a nonlinear analysis. It is most often used with contact to stabilize free-free bodies before they come into contact. The spring rates selected should be stiff enough to allow matrix decomposition but weak enough so they are not significant once full contact is achieved. Values on the order of 1.0E-6 to 1.0E-4 times the average main diagonal terms in the stiffness matrix for the grids selected are recommended.

Format:

1	2	3	4	5	6	7	8	9	10
MGRSPR	ID1	THRU	ID2	IDIR	K				

Example:

MGRSPR	100	THRU	200	123	10.0				
	500	THRU	520	123456	1.0				

Describer	Meaning
ID1	Starting grid ID. (Integer; Required; no Default)
THRU	Enter the character string THRU if more than one grid is desired.
ID2	Ending grid ID of the range. (Integer; or blank. If blank; ID2=ID1)
IDIR	Directions that the spring(s) will be added in, any unique combination of the integers 1 through 6 with no embedded blanks. (Integer; Required)
K	Spring rate. (Real; Required)

Remarks:

1. If springs are to be added to all grids, PARAM,MRSRING may be used instead of this entry.
2. Do not use PARAM,MRSRING and this entry in the same model.
3. Grids that do not exist in the range ID1 to ID2 will automatically not have springs in the Marc input.

**MINSTAT**                      Option to Define Initial State Variables for SOL 600

This option is used to enter initial (stress free) temperatures calculated from a previous heat transfer analysis and saved on a t16 or t19 file. (MCHSTAT is used to define the temperatures that cause thermal strains). This entry may also be used to initialize other state variables if required.

Format:

1	2	3	4	5	6	7	8	9	10
MINSTAT	IDV	IOPT		INCR		IFORM	IPRT	NPST	
	"FILE"	Name							
	"ELEM"	ELE1	ELE2	INT1	INT2	LAY1	LAY2	VAL	
	"STATE"	NS	IS1	IS2	IS3	IS4	IS5	IS6	
		IS7	IS8	IS9	etc.				

Example:

MINSTAT	1	3		1		0		9	
	FILE	initial_state_example							

Descriptor	Meaning
IDV	State variable identifier (1=temperature). (Integer; Default = 1) (2,1) If more than one state variable is required, enter -1.
IOPT	Option of how to enter the data. (Integer; Default = 3) (2,2) 1        Use the "ELEM" continuation line for as many elements as necessary 2        Enter the data using user subroutine INITSV 3        Read the data from a t16 or t19 file (see IFORM)
INCR	Increment number on t16 or t19 file defining the new state values if IOPT=3. (Integer; no Default) (2,5)
IFORM	Designates whether a binary (t16) or formatted (t19) post file is used if IOPT=3. (Integer; Default = 0) (2,7) 0        Use binary (t16) file 1        Use formatted (t19) file
IPRT	Enter a value of 1 to suppress printing of state variable values defined in user subroutine INITSV (only applicable if IOPT=2). (Integer; Default = 0) (2,8)
NPST	Post Code ID to be read into this state variable. (Integer; Default = 9 [temperature]) (2,9) See MARCOUT for a list of the post codes.
FILE	Enter the character string FILE if IOPT=3. (Character; no Default; Required if IOPT=3)

Descriptor	Meaning
NAME	Enter the file name without the extension (.marc.t16 or .marc.t19). (Character; no Default) The file name must be entirely in lower case for case-sensitive computer systems and is limited to 56 characters. This file must be in the same directory as the Nastran input file.
ELEM	Enter the character string ELEM to start a list of elements and associated values if IOPT=1. (Character)
ELE1	First element with value VAL. (Integer; no Default; Required) (3,1)
ELE2	Last element with value VAL. (Integer; Default = ELE1) (3,2)
INT1	First integration point with value VAL. (Integer; no Default; Required) (3,3)
INT2	Last integration point with value VAL. (Integer; Default = INT1) (3,4)
LAY1	First cross-section layer with value VAL. (Integer; no Default; Required) (3,5)
LAY2	Last cross-section layer with value VAL. (Integer; Default = LAY1) (3,6)
VAL	New state value for these elements. (Real; no Default; Required) (4,1)
STATE	Enter the character string STATE to start a list of state variables. (Character)
NS	Number of state variables to be defined. (Integer; no Default; limited to 16 maximum)
ISi	State variable post codes. (Integer; no Default) (9,i) See MARCOUT entry for applicable post codes.

#### Remarks:

1. Only one MINSTAT entry may be entered in the input. If additional entries are found, the first will be used.
2. This entry maps to Marc's INITIAL STATE entry
3. (i,j) refer to Marc's INITIAL STATE (data block, field)
4. MINSTAT (and/or MCHSTAT) cannot be the only applied "loads". At least one standard load such as FORCE, PLOAD4 or a standard TEMP entry must be entered with a LOAD Case Control command that references the standard load(s). If there are no standard loads, please enter a dummy load with a very small magnitude and a LOAD Case Control command to reference it.

## MISLAND

## SOL 600

Defines an island of connected elements that will be completely removed if the number of elements within the island becomes smaller than a specified value in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MISLAND	NELEM								

Example:

MISLAND	20								
---------	----	--	--	--	--	--	--	--	--

Describer	Meaning
NELEM	Number of elements to use as a limit for element deactivation. If the number of elements in an island is less than or equal to this number, all elements in this island are deactivated. (Integer; no Default; Required field)

Remarks:

1. If this entry is made in the model, it subdivides the entire mesh into islands of connected regions. If the number of elements in a particular island is less than or equal to the specified value, all elements of this island are deactivated. This check is performed after element deactivation has taken place where the deactivation can be due to model input options, deactivation user subroutines, or through material damage or failure. Two elements are considered connected if they share a node for line elements, an edge for 2-D elements, or a face for 3-D solid elements. This option is useful for cases where unconnected elements or regions of elements might exist after the neighboring elements have been deactivated. There is no check performed to see if the island to be deactivated has enough boundary conditions. Only the number of elements in the island is used for determining if the elements should be deactivated.
2. Only one MISLAND entry should be placed in the input. If more than one is entered, the first will be used.

**MIXTURE****Constituents of "Composite" Material on Original and Potentially Damaged State - SOL 600**

Defines constituents of "composite" material on original and potentially damaged state. Used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MIXTURE	MID	ITYPE	IALPH	ISET	M1	FRACT1	M2	FRACT2	
	M3	FRACT3	M4	FRACT4	M5	FRACT5	etc.		

Example:

MIXTURE	120	3	1	200	10	.2	20	.2	
	30	.2	40	.2	50	.2			

Describer	Meaning
MID	Material ID (Integer; no Default, required field)
ITYPE	Mixture rule (Integer; Default = 1) 1 Weighted average of material properties based upon volume fraction. 2 Weighted average of Hooke's law based upon volume fraction 3 Weighted average of nonlinear stress strain curve based on volume fraction
IALPH	Flag controlling averaging procedure for thermal expansion (Integer; Default = 1) 1 Weighted average based upon volume fraction 2 Not currently available
ISET	ID of a SET3 containing the all the elements making up this material (Integer; no Default; Required)
Mi	Identification of a previously defined material, defined on a MATxxx entry (for example the MID on a MAT1 entry) (Integer; no Default)
FRACTi	Fraction for the ith component (see ITYPE). The sum of all FRACTi must add to 1.0 (Real; no Default)

Remarks:

1. Enter as many Mi, FRACTi components as desired. Each may have different properties, and failure criteria.
2. Fields 2-4 of each continuation entry are required, fields 5-9 may be left blank.

3. This option allows one to create a new material comprised of a number of other materials. The material behavior is based upon a "mixture" of the individual components using a mixture rule. Several of these mixture rules are only appropriate for linear elastic materials but also allow for temperature dependent material properties. The most sophisticated model (ITYPE=3) allows for the mixture of materials which undergo elastic-plastic behavior.
4. If void ratio or porosity is defined, it applied to all components in a uniform manner.
5. ITYPE 1 and 2 only support linear elastic material.
6. ITYPE 3 is not available using updated Lagrange - use PARAM,MARCPLAS,1 or PARAM,MARCPLAS,2 if any of the component materials have plasticity. The mixture will be limited to small strains, but large displacement, large rotation and follower forces and follower pressures can be included.
7. ITYPE 3 may not include the following material laws in any of the components.
  - Thermo-pore
  - Gurson damage
  - Simplified damage models 9 and 10
  - Gasket material
  - Shape memory material
  - Soils
  - User defined generalized stress strain
  - ORNL
  - Rigid-Plastic
  - Grain size effects
  - Rubber material (mooney, ogden, foam, gent, arruda-boyce)
  - Cohesive
8. Rebar elements and shell elements with offsets or non-composites with different properties for bending vs membrane (which use the Marc PSHELL option) may not be used for mixtures.
9. Within a layer, if the components are orthotropic or anisotropic, the preferred directions must be aligned.
10. The material identification number must be unique for all COHESIV, MAT1, MAT2, MAT3, MAT8, MATDIGI, MATG, MATHE, MATHP, MATNLE, MATORT, MATPE1, MATSMA, MATUSR, MCOHE, MIXTURE, and MATD\* entries.

## MKAERO1

## Mach Number - Frequency Table

Provides a table of Mach numbers (m) and reduced frequencies (k) for aerodynamic matrix calculation.

Format:

1	2	3	4	5	6	7	8	9	10
MKAERO1	m1	m2	m3	m4	m5	m6	m7	m8	
	k1	k2	k3	k4	k5	k6	k7	k8	

Example:

MKAERO1	.1	.7							
	.3	.6	1.0						

Describer	Meaning
mi	List of from 1 to 8 Mach numbers. (Real $\geq$ 0.0). See remark 8.
kj	List of from 1 to 8 reduced frequencies. (Real > 0.0)

Remarks:

- Blank fields end the list, and thus cannot be used for 0.0.
- All combinations of (mi, kj) will be used.
- The continuation entry is required.
- Multiple MKAERO1 entries are permitted.
- For the lifting surface theories (Doublet-Lattice and Mach Box), the maximum value of kj should be less than one quarter of the number of boxes on a representative chord (i.e.,  $\text{MAX}(kj) < \bar{C}/4\Delta x$  where  $\bar{C}$  is the reference chord and  $\Delta x$  is a typical box chord length).
- In SOL 146, the program selects only one value of mi to use in computing the dynamic response solution and, by default, the lowest value is selected. The PARAM,MACH,m entry may be specified to select a different value. If PARAM,MACH,m is specified, then the value of mi closest to m will be selected.
- The very low nonzero value of kj required for aeroelastic divergence analysis of restrained vehicles with the K- and KE-methods of flutter analysis must be included on this entry.
- mi = 1.0 is not supported except when used in conjunction with CAERO4 entry (Strip Theory).

## MKAERO2

### Mach Number - Frequency Table

Provides a list of Mach numbers (m) and reduced frequencies (k) for aerodynamic matrix calculation.

Format:

1	2	3	4	5	6	7	8	9	10
MKAERO2	m1	k1	m2	k2	m3	k3	m4	k4	

Example:

MKAERO2	.10	.30	.10	.60	.70	.30	.70	1.0	
---------	-----	-----	-----	-----	-----	-----	-----	-----	--

Describer	Meaning
mi	Mach numbers. (Real $\geq$ 0.0). See remark 5.
ki	Reduced frequencies. (Real > 0.0)

Remarks:

1. MKAERO2 will cause the aerodynamic matrices to be computed for the given sets of parameter pairs. Embedded blank pairs are skipped.
2. No continuation entries are allowed, but multiple MKAERO2 entries are permitted.
3. In SOL 146, the program selects only one value of mi to use in computing the dynamic response solution and, by default, the lowest value is selected. The PARAM,MACH,m entry may be specified to select a different value. If PARAM,MACH,m is specified, then the value of mi closest to m will be selected.
4. The very low nonzero value of ki required for aeroelastic divergence analysis of restrained vehicles with the K- and KE-methods of flutter analysis must be included on this entry.
5. mi = 1.0 is not supported except when used in conjunction with CAERO4 entry (Strip Theory).

## MLAYOUT

## SOL 600

Selects layered composite shell output to be placed in Marc's t16 and/or t19 files and (if requested) to be transferred from Marc to the Nastran Database. The MARCOUT entry with LAYCODE of 3 or 103 must be used in conjunction with this entry. Used in SOL 600 only.

### Format:

1	2	3	4	5	6	7	8	9	10
MLAYOUT	L1	THRU	L2	BY	L3				
	L4	THRU	L5	BY	L6				

### Example:

MLAYOUT	2	THRU	5						
	11	THRU	51	BY	10				
	52	THRU	54						
	21	THRU	20	BY	10				

Descriptor	Meaning
L1, L4	Starting layer of a sequence. (Integer; Required; no Default)
L2, L5	Ending layer of a sequence. (Integer; Default = L1 or L4)
L3, L6	Increment value for the sequence. (Integer; Default = 1)

### Remarks:

1. This entry must be used in conjunction with MARCOUT with LAYCODE=3 or 103.
2. L2 must be larger than L1.
3. L1, L4, etc. must be positive integers of 1 or larger.
4. L2, L5 should not exceed the largest number of layers in the model.
5. Selection of all layers can lead to extremely large output files.
6. In the example, L1 could also be 1 instead of 2 and the largest layer could be 55 instead of 54 with causing an error.
7. If the layers designated on this entry are to apply to selected elements, enter the elements on the T16SEL entry. It is not currently possible to process different layered output for multiple groups of elements (i.e., it is not currently possible to request output of layers 1-20 for some elements and 1-10 for others.)

## MNF600

## Defines Auxiliary Data for MSC Adams MNF Files - SOL 600

Generated by the Marc portion of a SOL 600 execution. Used in SOL 600 only. (See also the MDMIOU Bulk Data entry.)

Format:

1	2	3	4	5	6	7	8	9	10
MNF600	ID	ISTRESS	ISTRAIN	ISHELL	MASSU	LENGU	TIMEU	FORCU	

Example:

MNF600	100	1	1	3	2	7	3	2	
--------	-----	---	---	---	---	---	---	---	--

Describer	Meaning
ID	Subcase for which the reduced matrices will be output. ID must correlate to a SUBCASE Case Control ID, for example, if the case control contains SUBCASE 20, ID would be 20. Must match the MDMIOU entry. At present, ID is ignored and the first entry will apply to all subcases. (Integer; Default = 1)
ISTESS (2)	Flag to compute stress and place in the MNF file (0=no stress, 1=stress) (Integer; Default = 0)
ISTRAIN (3)	Flag to compute strain and place in the MNF file (0=no strain, 1=strain) (Integer; Default = 0)
ISHELL (4)	For shell elements, this entry describes which location the stresses or strains will be output to the MNF file. 1=top, 2=center, 3=bottom (Integer; Default = 1)
MASSU [2,1]	Mass units for MNF file. (Integer; Default = 1: kilogram) The following possible values may be entered: 1:kilogram (Default) 2:pound mass 3:slug 4:gram 5:ounce mass 6:kpound mass 7:megagram 8:dozen slug

Describer	Meaning
LENGU	Length units for MNF file (Integer; Default = 2: meter) The following possible values may be entered: 1:kilometer 2:meter (Default) 3:centimeter 4:millimeter 5:mile 6:foot 7:inch
TIMEU [2,3]	Time units for MNF file (Integer; Default = 3: second). The following possible values may be entered: 1:hour 2:minute 3:second (Default) 4:millisecond
FORCEU [2,4]	Force units for MNF file (Integer; Default = 1: newton). The following possible values may be entered: 1:Newton (Default) 2:pound force 3:kilogram force 4:ounce force 5:dyne 6:kNewton 7:kpound force

#### Remarks:

1. The MDMIOUT entry is the primary entry which generates an MNF file. This entry, MNF600 is only necessary if one or more of the fields is required to define non-default values, for example to generate stresses or strains or to specify the units.
2. The ID must be the same as the MDMIOUT ID.
3. Only one MNFDAT entry is allowed in an input file. If more than one is entered, the first will be used.
4. All remarks concerning MNF files for the MDMIOUT entry are also applicable to this entry.
5. (i) Indicates the corresponding field of Marc's MNF Parameter.
6. [i,j] Indicates the corresponding datablock and field of Marc's MNF units entry.

## MODTRAK

## Mode Tracking Parameters

Specifies parameters for mode tracking in design optimization (SOL 200).

Format:

1	2	3	4	5	6	7	8	9	10
MODTRAK	SID	LOWRNG	HIGHRNG	MTFILTER					

Example:

MODTRAK	100	1	26	0.80					
---------	-----	---	----	------	--	--	--	--	--

Describer	Meaning
SID	Sets identification number that is selected in the Case Control Section with the MODTRAK command. See Remark 1. (Integer; no Default)
LOWRNG	Lowest mode number in range to search. See Remark 2. (Integer $\geq 0$ ; Default = 0. If nonzero, LOWRNG < HIGHRNG.)
HIGHRNG	Highest mode number in range to search. See Remark 2. (Integer > 0; Default = number of eigenvalues extracted. If nonzero, LOWRNG < HIGHRNG.)
MTFILTER	Filtering parameter used in mode cross-orthogonality check. See Remark 3. (Real; Default = 0.9)

Remarks:

1. Only the designed modes for the subcase will be tracked. A designed mode is one that is used in the design model (in connection with either objective or constraints) and, therefore, identified on a DRESP1 entry.
2. The range of modes LOWRNG through HIGHRNG, inclusive, will be used to track the designed modes. If LOWRNG and HIGHRNG are both blank, then all computed modes will be used to search for the designed modes. Since large numbers of computed modes will result in higher computational costs, limiting the search range with LOWRNG and HIGHRNG is recommended.
3. Modes are considered to correlate if their mass normalized cross orthogonalities are greater than MTFILTER.

## MOMAX Conical Shell Static Moment

Defines a static concentrated moment load on a ring of a conical shell.

Format:

1	2	3	4	5	6	7	8	9	10
MOMAX	SID	RID	HID	S	MR	MP	MZ		

Example:

MOMAX	1	2	3	1.0	0.1	0.2	0.3		
-------	---	---	---	-----	-----	-----	-----	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
RID	Ring identification number. See the RINGAX entry. (Integer > 0)
HID	Harmonic identification number or a sequence of harmonics. See Remark 5. (Integer $\geq 0$ or Character)
S	Scale factor. (Real)
MR, MP, MZ	Moment components in the r, $\phi$ , z directions. (Real)

Remarks:

1. MOMAX is allowed only if an AXIC entry is also present.
2. Load sets must be selected with the Case Control command LOAD=SID.
3. A separate entry is needed for the definition of the moment associated with each harmonic.
4. For a discussion of the conical shell problem, see [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide*.
5. If a sequence of harmonics is to be placed in HID, the form is as follows: "Sn1Tn2", where n1 is the start of the sequence and n2 is the end of the sequence; i.e., for harmonics 0 through 10, the field would contain "S0T10".

**MOMENT**

## Static Moment

Defines a static concentrated moment at a grid point by specifying a scale factor and a vector that determines the direction.

Format:

1	2	3	4	5	6	7	8	9	10
MOMENT	SID	G	CID	M	N1	N2	N3		

Example:

MOMENT	2	5	6	2.9	0.0	1.0	0.0		
--------	---	---	---	-----	-----	-----	-----	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
G	Grid point identification number at which the moment is applied. (Integer > 0)
CID	Coordinate system identification number. (Integer ≥ 0 or blank)
M	Scale factor. (Real)
Ni	Components of the vector measured in the coordinate system defined by CID. (Real; at least one Ni ≠ 0.0 unless M is zero)

Remarks:

1. The static moment applied to grid point G is given by

$$\vec{m} = M\vec{N}$$

where  $\vec{N}$  is the vector defined by (N1, N2, N3). The magnitude of  $\vec{m}$  is equal to M times the magnitude of  $\vec{N}$ .

2. In the static solution sequences, SID must be selected by the LOAD Case Control command. In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
3. A CID of zero or blank references the basic coordinate system.
4. For scalar points see SLOAD.
5. For TYPE=12 or TYPE=13 on the TLOAD1, G is the ID of a rigid body; the MID of a rigid material (MATRIG) or the EID of a RBE2D. The MID of a rigid material and the EID of RBE2 must be different when both of a RBE2D and a rigid material are used with these TYPEs. SOL 700 only.

## MOMENT1

## Follower Moment, Alternate Form 1

Defines a concentrated moment at a grid point by specifying a magnitude and two grid points that determine the direction.

Format:

1	2	3	4	5	6	7	8	9	10
MOMENT1	SID	G	M	G1	G2				

Example:

MOMENT1	6	13	-2.93	16	13				
---------	---	----	-------	----	----	--	--	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
G	Grid point identification number at which the moment is applied. (Integer > 0)
M	Magnitude of moment. (Real)
G1, G2	Grid point identification numbers used to define the unit vector $\vec{n}$ . (Integer > 0; G1 and G2 cannot be coincident.)

Remarks:

- The concentrated moment applied to grid point G is given by

$$\vec{m} = M\vec{n}$$

where  $\vec{n}$  is a unit vector parallel to a vector from G1 to G2.

- In the static solution sequences, SID must be selected by the LOAD Case Control command. In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- The follower force effects due to loads from this entry are included in the stiffness in all linear solution sequences that calculate a differential stiffness. The solution sequences are SOLs 103, 105, 107 to 112, 115 and 116 (see also the parameter [FOLLOWK, 835](#)). In addition, follower force effects are included in the force balance in the nonlinear static and nonlinear transient dynamic solution sequences, SOLs 106, 129, 153, 159, and 400, if geometric nonlinear effects are turned on with PARAM,LGDISP,1. The follower force stiffness is included in the nonlinear static solution sequences (SOLs 106, 153 and 400) but not in the nonlinear transient dynamic solution sequences (SOLs 129 and 159).

## MOMENT2

### Follower Moment, Alternate Form 2

Defines a concentrated moment at a grid point by specification of a magnitude and four grid points that determine the direction.

Format:

1	2	3	4	5	6	7	8	9	10
MOMENT2	SID	G	M	G1	G2	G3	G4		

Example:

MOMENT2	6	13	-2.93	16	13	17	13		
---------	---	----	-------	----	----	----	----	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
G	Grid point identification number at which the moment is applied. (Integer > 0)
M	Magnitude of moment. (Real)
Gi	Grid point identification numbers used to determine the unit vector $\vec{n}$ . (Integer > 0; G1 and G2 cannot be coincident; G3 and G4 cannot be coincident.)

Remarks:

1. The concentrated moment applied to grid point G is given by

$$\vec{m} = M\vec{n}$$

where  $\vec{n}$  is the unit vector parallel to the cross product of the vectors from G1 to G2, and G3 to G4.

2. In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
3. The follower force effects due to loads from this entry are included in the stiffness in all linear solution sequences that calculate a differential stiffness. The solution sequences are SOLs 103, 105, 107 to 112, 115 and 116 (see also the parameter [FOLLOWK, 835](#)). In addition, follower force effects are included in the force balance in the nonlinear static and nonlinear transient dynamic solution sequences, SOLs 106, 129, 153, 159, and 400 if geometric nonlinear effects are turned on with PARAM,LGDISP,1. The follower force stiffness is included in the nonlinear static solution sequences (SOLs 106, 153 and 400) but not in the nonlinear transient dynamic solution sequences (SOLs 129 and 159).

## MONCARL

### Parameters for Monte-Carlo simulation

Parameters for conducting Monte-Carlo simulation using the non-parametric variability method (NPVM).

Format:

1	2	3	4	5	6	7	8	9	10
MONCARL	SID	VARTYP							
	STRVAR	MSVAR	KSVAR	BSVAR					
	FLUVAR	MFVAR	KFVAR	BFVAR					

Example:

MONCARL	100	DELTAVAR							
	STRVAR	0.001	0.05	0.002					
	FLUVAR	0.0	0.001	0.0					

Describer	Meaning
SID	Set identification number referenced by MONCARL case control. (Integer > 0; Required)
VARTYP	Select the type of variabilities that follow (Character; Default = ALPHAVAR)  ALPHAVAR Variabilities in this entry are Alpha variabilities.  DELTAVAR Variabilities in this entry are Delta variabilities.
“STRVAR”	Indicates Structural variability parameters follow. (String)
MSVAR	Structural mass variability. (Real >= 0.0; Default = 0.0)
KSVAR	Structural stiffness variability. (Real >= 0.0; Default = 0.0)
BSVAR	Structural damping variability. (Real >= 0.0; Default = 0.0)
“FLUVAR”	Indicates Fluid variability parameters follow (String)
MFVAR	Fluid mass variability. (Real >= 0.0; Default = 0.0)
KFVAR	Fluid stiffness variability. (Real >= 0.0; Default = 0.0)
BFVAR	Fluid damping variability. (Real >= 0.0; Default = 0.0)

#### Remarks

1. Please use below as the guideline for selecting above mentioned structural and fluid alpha variabilities (which should be > 0.0):
  - a. Low variability level = 0.001
  - b. Medium variability level = 0.01

- c. High variability level = 0.05
2. Alpha variabilities are related to delta variabilities through the order of the matrix to be randomized,  $n$  (or equivalently the number of modes),

$$a = \delta \sqrt{\frac{2}{n+1}}$$

3. There is a limitation in the admissible values for the variability level. The maximum value for delta variability equals,

$$\delta_{max} = \sqrt{\frac{n+1}{n+5}}$$

On a model with a large amount of modes ( $n \gg 1$ ), the maximum value of delta tends to 1 ( $\delta_{max} \approx 1$ ).

The maximum value of alpha variability using the above equations equals,  $a_{max} = \sqrt{\frac{2}{n+5}}$

4. An unphysical (larger than permissible or negative value) selection of a variability would result in a FATAL.

## MONCNCM

## Nondimensional Normal Force and Pitching Moment

Provides a stripwise aerodynamic normal force and pitching moment coefficients for CAERO1 based aerodynamics.

Format:

1	2	3	4	5	6	7	8	9	10	
MONCNCM	NAME	LABEL								
	MREF	CAERID1	CAERID2	...	CAERIDn					

Example:

MONCNCM	LEFT	Normal force and pitching moment values for strips on the left wing.							
		2001	3001						

Describer	Meaning
NAME	Unique character string of up to 8 characters identifying the family of chord-wise strips. (Character)
LABEL	A string comprising no more than 56 characters (fields 3 through 9) that identifies and labels the component. (Optional)
MREF	Fractional chord location of the aerodynamic strip about which the pitching moment is to be calculated. (Real; $0.0 \leq MREF \leq 1.0$ ; Default = 0.25)
CAERID1	ID of a CAERO1 entry that contains aero boxes for which strip results are to be produced. (Integer > 0 or "ALL"). See Remarks 2. and 3.

Remarks:

1. The LABEL is optional.
2. Output is produced for all chordwise strips on the referenced CAERO1 entries. If a strip spans CAERO1 panels, results are output for the total strip.
3. If CAERID1 is the character string "ALL", then output will be produced for all strips.
4. Strips are identified based on the y and z coordinates in the aerodynamic coordinate system.
5. If strips from separate CAERO1's have the same y and z coordinate and the same strip width and share an xlocation (i.e., the leading edge of one strip equals the trailing edge from another) then they are processed as a single strip.
6. The normal force component is normalized by the dynamic pressure times the surface area of the strip. The moment component is normalized by the dynamic pressure times the surface area of the strip times the chord length at the center of the strip. The moment is calculated about the MREF location of the strip with the quarter-chord of the strip as the default.
7. Only CAERO1 id's are supported.

## MONDSP1

## Displacement Monitor Point

Defines a virtual point displacement response at a user-defined reference location (coordinates and coordinates system) as a weighted average of the motions at a set of grid points.

Format:

1	2	3	4	5	6	7	8	9	10	
MONDSP1	NAME	LABEL								
	AXES	COMP	CP	X	Y	Z	CD	INDDOF		

Example:

MONDSP1	WING195	Wing twist at station 150.							
	5	WING150	1001	120	150.0	17.0	1002		

Describer	Meaning
NAME	Character string of up to 8 characters identifying the monitor point (Character)
LABEL	A string comprising no more than 56 characters (fields 3 through 9) that identifies and labels the monitor point.
AXES	Component axes to monitor. (Any unique combination of the integers 1 through 6 with no embedded blanks.)
COMP	The name of an AECOMP or AECOMPL entry that defines the set of grid points over which the monitor point is defined.
CP	The identification number of a coordinate system in which the input (x,y,z) coordinates are defined. (Integer $\geq 0$ ; Default = 0)
X,Y,Z	The coordinates in the CP coordinate system at which the displacement is to be monitored.
CD	The identification number of a coordinate system in which the resulting displacement components are output. (Integer $\geq 0$ ; Default = the coordinate system specified by the CP field)
INDDOF	Component numbers of all the independent grids from which the derived, dependent, monitor DOF's are to be computed. (Any unique combination of the integers 1 through 6 with no embedded blanks.) See Remark 3. (Default = 123)

Remarks:

1. The MONDSP1 is available for SOLs 101, 103, 105, 108, 109, 111, 112, 144, 146 and 200.
2. The entry can create either an aerodynamic or a structural MONDSP1, depending on the data provided in the COMP field. A structural MONDSP1 can have the same name as an aerodynamic MONDSP1, but two structural or two aerodynamic MONDSP1s cannot have the same name.

3. The INDDOF field defines the Ci field on the virtual RBE3; that is, it defines the components of the grids on the AECOMP that will be sampled to define the dependent (monitor point) displacement. Typically, the default is the correct choice. However, if there is only a single grid point, all six DOF's can be used.

## MONGRP

## Specification of a Monitor Group

Defines a collection of monitor points into a group available for postprocessing.

Format:

1	2	3	4	5	6	7	8	9	10
MONGRP	GNAME	LABEL							
	NAME1	CLASS1	REAL1	INT1	STRING1				
	NAME2	CLASS2	REAL2	INT2	STRING2				
	NAME(m)	CLASS(m)	REAL(m)	INT(m)	STRING(m)				

Example:

MONGRP	WING	A COLLECTION OF MONITOR POINTS ON THE WING							
	WING195	SMONPT1		1	WL195				
	WING205	SMONPT1		2	WL205				
	WINGDSP	SMONDP1	20.0		GRID20				

Descriptor	Meaning
GNAME	A character string of up to 8 characters identifying the monitor group. (Character)
LABEL	A String comprising no more than 56 characters (fields 3 through 9) that identifies and labels the monitor point.
NAME(i)	Name of an existing monitor point. (Character)
CLASS(i)	Type of monitor point (either AMONPT1, AMONDP1, SMONPT1, SMONDP1, MONPT2, MONPT3)
REAL(i)	Optional real value to designate a real property of the monitor point.
INT(i)	Optional integer value to designate a integer property of the monitor point.
STRING	A label of the current monitor type. (Character string of no more than 32 character)

Remarks:

1. The MONGRP entry provides the user a means of specifying groups of monitor point data but does not produce any output on its own.
2. Aerodynamic (AMONPT1 and AMONDP1) and structural (SMONPT1, SMONDP1, MONPT2, MONPT3) cannot be mixed in a given group.
3. The REAL(i), INT(i) and STRING(i) data are provided to facilitate user display of the monitor data and can be used, for example, to label xy plots.
4. The LABEL should be unique across MONGRP entries.

## MONPNT1 Integrated Load Monitor Point

Defines an integrated load monitor point at a point (x,y,z) in a user defined coordinate system. The integrated loads about this point over the associated nodes will be computed and printed for statics, dynamics and static aeroelastic trim analyses and from integrated loads on the nonlinear static aeroelastic database.

Format:

1	2	3	4	5	6	7	8	9	10	
MONPNT1	NAME	LABEL								
	AXES	COMP	CP	X	Y	Z	CD			

Example:

MONPNT1	WING155	Wing Integrated Load to Butline 155							
	34	WING		0.0	155.0	15.0			

Describer	Meaning
NAME	Character string of up to 8 characters identifying the monitor point (Character; no Default)
LABEL	A string comprising no more than 56 characters (fields 3 through 9) that identifies and labels the monitor point. (Character; optional)
AXES	Component axes to monitor. (Any unique combination of the integers 1 through 6 with no embedded blanks.)
COMP	The name of an AECOMP or AECOMPL entry that defines the set of grid points over which the monitor point is defined. (Character; no Default)
CP	The identification number of a coordinate system in which the input (x,y,z) coordinates are defined. (Integer ≥ 0; Default = 0)
X,Y,Z	The coordinates in the CP coordinate system about which the loads are to be monitored. (Real; Default = 0.0).
CD	The identification number of a coordinate system in which the resulting load components are output. (Integer ≥ 0; Default = the coordinate system specified by the CP field)

Remarks:

1. The MONPNT1 is available for SOLs 101, 108, 109, 111, 112, 144, 146, 200 and 400 (ANALYSIS = NLSTAT or NLTRAN).
2. The entry can create either an aerodynamic or a structural MONPNT1, depending on the data provided in the COMP field. A structural MONPNT1 can have the same name as an aerodynamic MONPNT1, but two structural or two aerodynamic MONPNT1s cannot have the same name.

3. In SOL 144, static aeroelasticity, the structural MONPNT1 integration is modified to account for the redistribution of loads and inertia caused by MPCs and rigid elements. In all other supported solution sequences, the integration is done using the g-set loads on all grid points specified on the referenced SET1 entry.

## MONPNT2

## Internal Load Monitor Point

Element Monitor Output Results Item.

Format:

1	2	3	4	5	6	7	8	9	10	
MONPNT2	NAME	LABEL								
	TABLE	TYPE	NDDLitem	EID						

Example:

MONPNT2	SB100	Leading edge stringer at root							
	STRESS	CBAR	SX2A	100					

Describer	Meaning
NAME	Unique character string of up to 8 characters identifying the monitor point (Character; no Default)
LABEL	An optional string comprising of no more than 56 characters (fields 3 through 9) that identifies the monitor point. (Character; Default = Blank)
TABLE	Type of output to be monitored. Options are STRESS, FORCE or STRAIN. (Character; no Default)
TYPE	Element type (Character; no Default)
NDDLitem	Component for this type to be monitored. This is the NDDL label for the particular Table and element type. (Character; no Default)
EID	Element ID. (Integer > 0)

Remarks:

1. The MONPNT2 is available for SOLs 101, 103, 108, 109, 111, 112, 144, 146 and 200.
2. Most element types have some items that can be monitored.
3. An assumption is made that the desired component is linear with respect to the displacement vector. If this assumption is not valid, the results will be incorrect.
4. Fictitious Table/Type/NDDLitems/EID generate a warning message and are ignored.
5. NDDL descriptions for Table=FORCE can be found in the [MSC Nastran DMAP Programmer's Guide](#) within the OEF datablock description. Table=STRESS and STRAIN are contained in the OES datablock description.

Once within the datablock description you can search for the element name (or better yet, element number, see the following table) you are interested in. There can be several different descriptions for an element type. For example, real vs. complex, thermal, stress vs. strain (within the OES description), linear vs nonlinear. In addition, the shell class of elements (quad4, quad8, quadr, tria3, tria6, triar) will have a composite form (quad4lc, quud8lc, quadrlc, tria3lc, .., i.e., basename + “LC”), corner or bilin stresses (basename + “C”).

By looking at the comments contained in the text make sure you are reading from the appropriate section. The NDDLitem is labeled as the ‘NAME’ field within the [MSC Nastran DMAP Programmer’s Guide](#).

You can also print the NDDL description for the entire database by running the following 4 statement bulk data file.

```
sol loadnddl  
compile nddl=nddl,list  
cend  
enddata
```

## MONPNT3

## Integrated Load Monitor Point

Sums select Grid Point Forces to a user chosen monitor point.

Format:

1	2	3	4	5	6	7	8	9	10	
MONPNT3	NAME	LABEL								
	AXES	GRIDSET	ELEMSET	CP	X	Y	Z	XFLAG		
	CD									

Example:

MONPNT3	t0	Fuselage station 1105							
	123456	1	2	0	30.0			ASM	

Describer	Meaning
NAME	Unique character string of up to 8 characters identifying the monitor point (Character, Required)
LABEL	A optional string comprising of no more than 56 characters (fields 3 through 9) that identifies the monitor point.
AXES	Component axes about which to sum. Any unique combination of the integers 1 through 6 with no embedded blanks. (Integer; Required)
GRIDSET	Refers to a SET1 entry that has a list of grids to be included in the monitored point. (Integer; Required)
ELEMSET	Refers to a SET1 entry that has a list of elements to include at the monitored point. (Integer; optional)
CP	The identification number of a coordinate system in which the (x,y,z) coordinates are defined. (Integer ≥ 0; Default=0)
X,Y,Z	The coordinates in the CP coordinate system about which the forces are to be summed. (Real; Default = 0.0).
XFLAG	Exclusion flag. Exclude the indicated Grid Point Force types from summation at the monitor point. Default = blank (no type excluded). See Remark 4.
	S            SPCforces
	M            MPC forces
	A, L, or P    applied loads
	D            dmig's (and any other type not described above) at the monitored point.
	C            contact forces (SOL 400 only).
CD	The identification number of a coordinate system in which the results are output. (Integer>=0, Default = the coordinate system specified by the CP field.

**Remarks:**

1. The MONPNT3 is available for SOLs 101, 103, 108, 109, 111, 112, 144, 146, 200 and 400 (ANALYSIS = NLSTAT or NLTRAN). Note that MONPNT3 output to csv file is available only to SOL 144.
2. If ELEMSET is blank, no contributions are made from the set of elements attached to the grid.
3. Fictitious grids or elements do not produce error or warning messages.
4. For linear solution sequences, if the exclusion flags omit some grid point force types but not all of them (i.e; if the field is not blank and is not SMAD) then the following limitations exist:
  - The results for that MONPNT3 will not be exported to a CSV file, for SOL 144 only.
  - That MONPNT3 may not be used on a MONSUM, MONSUM1 or MONSUMT entry.
  - It is only available in SOLs 101, 103, 144 and SOL 200 (ANALYSIS = STATICS, MODES, or SAERO).
5. MONPNT3 can be useful in calculating shear, moment and torque from the internal loads in a structure. For example, if a split is made in a fuselage component and all the grids that reside on this split are placed in the GRIDSET, differing internal loads resultants can be obtained based on the ELEMSET and XFLAG values. If a cut is made in a structure, there are three types of loads:
  - A - loads that come from the elements upstream of the cut.
  - B - loads that are applied to the grids on the cut from any other source.
  - C - loads that come from the elements downstream of the cut.Where  $A + B + C = 0$   
Useful options for these two values are:
  - a. If the ELEMSET includes all the elements that connect to the GRIDSET that are on the upstream/outboard part of the split and the XFLAG value is blank then the internal load is calculated using the elements that connect to the GRIDSET that are NOT included in ELEMSET. The direction of this load is reversed. So actually -C will be calculated which matches A+B. This in effect gives the resultants on the downstream/inboard side of the split pointing into upstream/ outboard direction which will include any loads applied to the GRIDSET from any source.
  - b. If the ELEMSET includes all the elements that connect to the GRIDSET that are on the upstream/outboard part of the split and the XFLAG value is SMAD then the internal load is calculated using the elements listed in ELEMSET. In that case, A will be calculated. This in effect gives the resultants on the upstream/outboard side of the split and does not include loads applied to the GRIDSET from any other source.
6. For SOL 400 (ANALYSIS = NLSTAT or NLTRAN), the following limitations exist:
  - The results for that MONPNT3 will not be exported to a CSV file, for SOL 144 only.
  - That MONPNT3 may not be used on a MONSUM, MONSUM1 or MONSUMT entry.
  - Thermal loads are not supported.

7. For linear solution sequences with XFLAG= blank or SMAD, the program applies a mini-EMA (element matrix assembly) algorithm that bypasses GPFDR (grid point force data recovery) and another modules to improve performance. This algorithm forms a stiffness matrix that just includes those elements specified in MONPNT3 entries. The monitor point results are computed directly from multiplying this matrix by an integration matrix that transfers forces to the monitor points. These results may be slightly different from the GPFDR results, such as clean zero forces versus small residual forces.

## MONSUM

## Linear Combinations of Monitor Point Components

Defines a new monitor result that is the weighted sum of existing monitor results. The existing monitor points do not need to be of the same type but they must be of similar type (see Remark 5.)

Format:

1	2	3	4	5	6	7	8	9	10
MONSUM	NAME	LABEL							
	NEWAXISA	MTYPE1A	NAME1A	AXES1A	COEF1A	NAME2A	AXES2A	COEF2A	
			NAME3A	AXES3A	COEF3A	etc.			
		MTYPE2A	NAME2A	etc.					
	NEWAXISB	MTYPE1 B	NAME1B	AXES1B	COEF1B	NAME2B	etc.		
		MTYPE1C	etc.						

Example: Create a new monitor point result by adding an aerodynamic monpnt1 and a monpnt3

MONSUM	AM1PSM3	Adding the wing lift to a free body load							
	3	AMONPNT1	WING	3	1.0				
		MONPNT3	FREEW	3	1400.	FREEW	5	-1000	

Alternate Format:

1	2	3	4	5	6	7	8	9	10
MONSUM	NAME	LABEL							
	MTYPE	NEWAXISA	NAME1A	AXES1A	COEF1A	NAME2A	AXES2A	COEF2A	
			NAME3A	AXES3A	COEF3A	etc.			
		NEWAXISB	NAME2A	AXES1B	COEF1B	NAME2B	AXIS2B	COEF2B	
			NAME3B	AXES3B	COEF3B	etc.			
		NEWAXISC	etc.						

Alternate Example: Scale an existing monitor point

MONSUM	ROOT	Scale from in-lbs to newton-cm and from lbs to newtons							
	AMONPNT1	123456	ROOT	123	4.482	ROOT	456	11.385	

Describer	Meaning
NAME	Character string of up to 8 characters identifying the monitor result. (Character)
LABEL	A string comprising of no more than 56 characters (fields 3 through 9) that identifies and labels the merged monitor result.
NEWAXISj	The component axis of the newly-created monitor point into which the summed quantity will be stored (integer, any unique combination of the integers 1 to 6 with no embedded blanks, see Remarks 7. and 8.)
MTYPij	Monitor type to be merged. (Character, one of “AMONPNT1”, “AMONDSP1”, “SMONPNT1”, “SMONDSP1”, or “MONPNT3”; no Default). See Remarks 5. and 6.

Descriptor	Meaning
MTYPE	Monitor type to be merged in the alternate format. (Character; one of “AMONPNT1”, “AMONDSP1”, “SMONPNT1”, “SMONDSP1”, or “MONPNT3”; no Default). See Remarks 5. and 6.
NAMEij	Name of the monitored quantity that is to be merged
AXESij	Component axes that are to be summed. (any unique combination of the integers 1 to 6 with no embedded blanks)
COEFij	Coefficient to be applied to the component(s) called out on AXESij field. (Real; Default = 1.0)

#### Remarks:

1. The MONSUM is available in SOLs 101, 103, 108, 109, 111, 112, 144, 146, 200 and 400 (ANALYSIS = NLSTAT or NLTRAN).
2. The LABEL is a 56 character string that should be unique.
3. The MONSUM can be used to update an existing monitor result by setting all the NAMEij terms equal to NAME. In this case, the alternate format is available and the NEWAXISj component is a scalar multiple of the original component:

$$MONSUM_j = MR_j COEF_j$$

4. When the NAME differs from the NAMEij values, it must be unique with respect to all monitor quantities. The result of the MONSUM entry is to create new monitor point(s) that are equal to:

$$MONSUM_j = \sum_i^n COEF_{ij} MR_{ij}$$

where  $MR_{ij}$  is the result from the individual component.

5. The merged monitor points must be of a similar type. “Similar” types are defined as:  
Force and moment summation monitor points: AMONPNT1, SMONPNT1, MONPNT3  
Average displacement monitor points: AMONDSP1 and SMONDSP1
6. For MONPNT1’s and MONDSP1’s, the MTYPij can be aerodynamic or structural. MTYPij=AMxxx1 designates aerodynamic while SMxxx1 designates a structural monitor point.
7. If multiple components are to be summed, the NEWAXISj field must be the union of subsequent AXISij fields. If the subsequent AXISij field is blank, the components are determined from NEWAXISj.
8. If the NEWAXISj field indicates a single output, the AXISij fields must reference a single input, but it can be any value from 1 to 6.
9. The same component cannot be referenced multiple times on the NEWAXISj fields for a single MONSUM entry.
10. Structural monitor points may span superelements.

11. If multiple types are specified on a MONSUM, the resulting entry is of a type that appears on the MONSUM with the following order of precedence: smonpnt1, smondsp1, monpnt3, amonpnt1, amondsp1. E.g., a amonpnt1 and a monpnt3 appearing on the same entry will result in a monpnt3 regardless of which appears first.
12. If all the MTYPij values are of the same type, the alternate format provides a simplified interface.
13. A MONSUM can reference another MONSUM (including itself) as long as there is not a circular reference. A MONSUM cannot reference another MONSUM1.
14. MONPNT3's that have one, two or three excluded items (e.g., XFLAG=SMA) cannot be referenced on a MONSUM.
15. Since CP,X,Y,Z and CD are not known with certainty for a MONSUM, they are not printed as part of the monitor point output. Further, in SOL's 101 and 144, COMP=**\*\*SUM\*\***, is used to indicate that the associated monitor point has been derived from a MONSUM.

**MONSUM1**

Linear combination of two or more monitor points.

Defines a new monitor result that is the weighted sum of existing monitor results. The location of the computed MONSUM1 is specified. The existing monitor points do not need to be of the same type but they must be of similar type (See Remark 3.)

Format:

1	2	3	4	5	6	7	8	9	10
MONSUM1	NAME	LABEL							
	CP	X	Y	Z	CD				
	NEWAXES	MTYP1	NAME1a	AXES1A	COEF1A	NAME2A	AXES2A	COEF2A	
			NAME3A	AXES3A	COEF3A	Etc			
		MTYP2	NAME2A	AXES1B	COEF1B	NAME2B	AXIS2B	COEF2B	
			NAME3B	AXES3B	COEF3B	Etc.	.		
		MTYP3	Etc						

Example: Create a new monitor point result by adding an aerodynamic monpnt1 and a monpnt3

MONSUM1	ROOT	SCALE FROM IN-LBS TO NEWTON-CM AND FROM LBS TO NEWTONS							
		500.	0.0	25.0	20	200			
	123456	MONPNT3	FS_1000	123	-4.482	FS_1000	356	-11.385	
		AMONPNT1	ROOT	123	4.482	R00T	456	11.385	

Alternate Format:

1	2	3	4	5	6	7	8	9	10
MONSUM1	NAME	LABEL							
	CP	X	Y	Z	CD				
	MTYPE	NEWAXISA	NAME1a	AXES1A	COEF1A	NAME2A	AXES2A	COEF2A	
			NAME3A	AXES3A	COEF3A	Etc			
		NEWASIXB	NAME2A	AXES1B	COEF1B	NAME2B	AXIS2B	COEF2B	
			NAME3B	AXES3B	COEF3B	Etc.	.		
		NEWAXISC	Etc						

Alternate Example: Create a new monitor point result by adding an aerodynamic monpnt1 and a monpnt3

MONSUM1	ROOT	SCALE FROM IN-LBS TO NEWTON-CM AND FROM LBS TO NEWTONS							
		500.	0.0	25.0	20				
	MONPNT3	123456	FS_1000	123	-4.482	FS_1000	456	-11.385	
	AMONPNT1	123456	ROOT	123	4.482	R00T	456	11.385	

Describer	Meaning
NAME	Character string of up to 8 characters identifying the monitor result (Character)
LABEL	A string comprising no more than 56 characters (fields 3 through 9) that identifies and labels the merged monitor result.
CP	The identification number of a coordinate system in which the input (x,y,z) coordinates are defined. (Integer > 0; Default = 0)
X,Y,Z	The coordinates in the CP coordinate system about which the loads are to be monitored. (Real; Default = 0.0).
CD	The identification number of a coordinate system in which the resulting load components are output. (Integer > 0; Default = the coordinate system specified by the CP field)
NEWAXESj	The component axis of the newly-created monitor point into which the summed quantity will be stored (integer, any unique combination of the integers 1 to 6 with no embedded blanks, see Remarks 5. and 6.)
MTYPi	Monitor type to be merged. (Character, one of “AMONPNT1”, “SMONPNT1”, or “MONPNT3”, no default). See Remarks 3. and 4.
NAMEij	Name of the monitored quantity that is to be summed.
AXESij	Component axes that are to be scaled. (any unique combination of the integers 1 to 6 with no embedded blanks. Must be a subset of NEWAXESj).Default =same as NEWAXESj
COEFij	Scaling coefficient to be applied to the component(s) called out on AXESij field. (Real, Default=1.0)

#### Remarks:

1. The LABEL is a 56 character string that should be unique.
2. The result of the MONSUM1 entry is to create new monitor point(s) as follows:

$$MONSUM1_j = \sum_i^n COEF_{ji} MR_i$$

Where  $MR_i$  is the result from the individual component.

3. The merged monitor points must be of a similar type. “Similar” types are defined as:
  - Force and moment summation monitor points: AMONPNT1, SMONPNT1, MONPNT3
4. For MONPNT1’s the MTYPij can be aerodynamic or structural. MTYPij=AMONPNT1 designates aerodynamic while SMONPNT1 designates a structural monitor point.
5. If multiple components are to be summed, the NEWAXISj field must be the union of subsequent AXISij fields. If the subsequent AXISij field is blank, the components are the same as NEWAXISj.

6. If the NEWAXISj field indicates a single output, the AXISij fields must reference a single input, but it can be any value from 1 to 6. There may be as many as 6 AXISij and COEFij for each referenced NAMEij.
7. The same component cannot be referenced multiple times on the NEWAXISj fields for a single MONSUM1 entry.
8. If multiple types are specified on a MONSUM1, the resulting entry is of a type that appears on the MONSUM1 with the following order of precedence: SMONPNT1 (structural MONPNT1), MONPNT3, AMONPNT1 (aerodynamic MONPNT1). E.g., a AMONPNT1 (aerodynamic MONPNT1) and a MONPNT3 appearing on the same entry will result in a MONPNT3 regardless of which appears first.
9. A MONSUM1 can reference the results of another MONSUM1 or a MONSUMT as long as there is not a circular reference.
10. The MONSUM1 entry is available in SOLs 101,103,108,109,111,112,144,146, 200 and 400 (ANALYSIS = NLSTAT or NLTRAN).
11. The CP, CD, and XYZ location coordinates are for reference only and do not affect the calculations.

**MONSUMT** Linear combination of two or more monitor points with moment transfer

Defines a new monitor result that is the sum of existing monitor results. The existing monitor points do not need to be of the same type but they must be of similar type (See Remark 3) 3.)

Format:

1	2	3	4	5	6	7	8	9	10
MONSUMT	NAME	LABEL							
	AXES	CP	X	Y	Z	CD			
	MTYP1	NAME1a	NAME1b	NAME1c	NAME1d	NAME1e	NAME1f	NAME1g	
	MTYP2	NAME2a	NAME2b	NAME2c	NAME2d	NAME2e	NAME2f	NAME2g	

Example: Create a new monitor point result by adding an aerodynamic and a monpnt3

MONSUMT	FS_900	FUSELAGE STATION 900							
	123456		500.	0.0	25.0	20			
	MONPNT3	FS_1000	FS_1100	FS_1200	MONPNT3				
	AMONPNT1	HTP_ROOT	AMONPNT1						

Descriptor	Meaning
NAME	Character string of up to 8 characters identifying the monitor result (Character)
LABEL	A string comprising no more than 56 characters (fields 3 through 9) that identifies and labels the merged monitor result.
CP	The identification number of a coordinate system in which the input (x,y,z) coordinates are defined. (Integer > 0; Default = 0)
X,Y,Z	The coordinates in the CP coordinate system about which the loads are to be monitored. (Real; Default = 0.0).
CD	The identification number of a coordinate system in which the resulting load components are output. (Integer > 0; Default = the coordinate system specified by the CP field)
AXES	The component axis of the newly-created monitor point into which the summed quantity will be stored (integer, any unique combination of the integers 1 to 6 with no embedded blanks.
MTYPi	Monitor type to be merged. (Character, one of “AMONPNT1”, “SMONPNT1”, or “MONPNT3”, no default). See Remarks 3. and 4.
NAMEij	Name of the monitored quantity that is to be summed.

Remarks:

1. The LABEL is a 56 character string that should be unique.
2. The NAME must be unique with respect to all monitor quantities. The result of the MONSUMT entry is to create new monitor point(s) as follows:

$$MONSUMT_j = \sum_i^n T_{ji} MR_i$$

Where  $MR_i$  is the result from the monitor points being summed and  $T_{ji}$  is set of partial rigid body vectors for the locations of the monitor points being summed, with the origin at the X, Y, Z location.

3. The summed monitor points must be of a similar type. “Similar” types are defined as:
  - Force and moment summation monitor points: AMONPNT1, SMONPNT1, MONPNT3
4. For MONPNT1’s the MTYPij can be aerodynamic or structural. MTYPij=AMONPT1 designates aerodynamic while SMONPNT1 designates a structural monitor point.
5. If multiple types are specified on a MONSUMT, the resulting entry is of a type that appears on the MONSUMT with the following order of precedence: SMONPNT1 (structural MONPNT1), MONPNT3, AMONPNT1 (aerodynamic MONPNT1). E.g., a AMONPNT1 (aerodynamic MONPNT1) and a MONPNT3 appearing on the same entry will result in a MONPNT3 regardless of which appears first.
6. A MONSUMT can reference the results of another MONSUMT or a MONSUM1 as long as there is not a circular reference.
7. The MONSUMT entry is available in SOLs 101,103,108,109,111,112,144,146, 200 and 400 (ANALYSIS = NLSTAT or NLTRAN).

## MOTION

Specifies Motion Direction in Brake System for Brake Squeal Analysis Using SOL 400

Defines motion direction of brake system for brake squeal calculations.

Format:

1	2	3	4	5	6	7	8	9	10
MOTION	ID		Velocity						
	FORM	COSX	COSY	COSZ	X	Y	Z		

Example:

1	2	3	4	5	6	7	8	9	10
MOTION	18		50.0						
	ROTAT	0.5	0.2	0.9	12.0	7.5	-2.0		

or

1	2	3	4	5	6	7	8	9	10
MOTION	18		100.0						
	TRANS	0.7	0.3	0.9					

Describer	Meaning
ID	Identification ID of the Motion referred by other entry card like <a href="#">BRKSYS</a>
VELOCITY	Angular velocity of rotation or moving velocity of translation motion (not used now, designed for velocity-related brake analysis in future).
FORM	Type of motion  ROTAT - rotating motion; or TRANS - translation moving
COSX(Y,Z)	For FORM=ROTAT, X (Y, Z) direction cosine (basic coordinate system) of axis of rotation For FORM=TRANS, X (Y, Z) direction cosine (basic coordinate system) of moving direction
X (Y, Z)	X (Y, Z) coordinate in basic coordinate system of rotation center

Remarks:

1. ROTAT and TRANS cannot be defined together in same entry card.

## MPC Multipoint Constraint

Defines a multipoint constraint equation of the form

$$\sum_j A_j u_j = 0$$

where  $u_j$  represents degree-of-freedom  $C_j$  at grid or scalar point  $G_j$ .

Format:

1	2	3	4	5	6	7	8	9	10
MPC	SID	G1	C1	A1	G2	C2	A2		
		G3	C3	A3	-etc.-				

Example:

MPC	3	28	3	6.2	2		4.29		
		1	4	-2.91					

Describer	Meaning
SID	Set identification number. (Integer > 0)
$G_j$	Identification number of grid or scalar point. (Integer > 0)
$C_j$	Component number. (Any one of the Integers 1 through 6 for grid points; blank, zero or 1 for scalar points.)
$A_j$	Coefficient. (Real; Default = 0.0 except A1 must be nonzero.)

Remarks:

- Multipoint constraint sets must be selected with the Case Control command MPC = SID.
- The first degree-of-freedom ( $G_1$ ,  $C_1$ ) in the sequence is defined to be the dependent degree-of-freedom. A dependent degree-of-freedom assigned by one MPC entry cannot be assigned dependent by another MPC entry or by a rigid element.
- Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.
- The m-set degrees-of-freedom specified on this entry may not be specified on other entries that define mutually exclusive sets. See the [Degree-of-Freedom Sets](#) for a list of these entries.
- By default, the grid point connectivity created by the MPC, MPCADD, and MPCAX entries is not considered during resequencing, (see the PARAM,OLDSEQ description in [Parameters](#). In order to consider the connectivity during resequencing, SID must be specified on the PARAM,MPCX entry. Using the example above, specify PARAM,MPCX,3.

## MPCADD

## Multipoint Constraint Set Combination

Defines a multipoint constraint set as a union of multipoint constraint sets defined via MPC entries.

Format:

1	2	3	4	5	6	7	8	9	10
MPCADD	SID	S1	S2	S3	S4	S5	S6	S7	
	S8	S9	-etc.-						

Example:

MPCADD	101	2	3	1	6	4			
--------	-----	---	---	---	---	---	--	--	--

Describer	Meaning
SID	Set identification number. (Integer > 0)
Sj	Set identification numbers of multipoint constraint sets defined via MPC entries. (Integer > 0)

Remarks:

1. Multipoint constraint sets must be selected with the Case Control command MPC = SID.
2. The Sj must be unique and may not be the identification number of a multipoint constraint set defined by another MPCADD entry.
3. MPCADD entries take precedence over MPC entries. If both have the same SID, only the MPCADD entry will be used.
4. By default, the grid point connectivity created by the MPC, MPCADD, and MPCAX entries is not considered during resequencing, (see the PARAM,OLDSEQ description in [Parameters](#). In order to consider the connectivity during resequencing, SID must be specified on the PARAM,MPCX entry. Using the example above, specify PARAM,MPCX,101.
5. If Modules are present then this entry may only be specified in the main Bulk Data section.

## MPCAX Conical Shell Multipoint Constraint

Defines a multipoint constraint equation of the form

$$\sum_j A_j u_j = 0$$

for conical shell coordinates, where  $u_j$  represents the degree-of-freedom  $C_j$  at ring  $RID_j$  and harmonic  $HID_j$ .

Format:

1	2	3	4	5	6	7	8	9	10
MPCAX	SID				RID1	HID1	C1	A1	
	RID2	HID2	C2	A2	-etc.-				

Example:

MPCAX	32				17	6	1	1.0	
	23	4	2	-6.8					

Describer	Meaning
SID	Set identification number. (Integer > 0)
RID <sub>j</sub>	Ring identification number. (Integer > 0)
HID <sub>j</sub>	Harmonic identification number. (Integer > 0)
C <sub>j</sub>	Component number. (1 ≤ Integer ≤ 6)
A <sub>j</sub>	Coefficient. (Real; Default = 0.0 except A1 must be nonzero.)

Remarks:

- MPCAX is allowed only if an AXIC entry is also present.
- The first degree-of-freedom in the sequence is assumed to be the dependent degree-of-freedom. A dependent degree-of-freedom assigned by one MPCAX entry cannot be assigned dependent by another MPCAX entry.
- Multipoint constraint sets must be selected with the Case Control command MPC = SID.
- Dependent degrees-of-freedom appearing on MPCAX entries may not appear on OMITAX, SPCAX, or SUPAX entries.
- See [Conical Shell Element \(RINGAX\)](#) (Ch. 3) in the *MSC Nastran Reference Guide* for further discussion of the problem.
- By default, the grid point connectivity created by the MPC, MPCADD, and MPCAX entries is not considered during resequencing, (see the PARAM,OLDSEQ description in [Parameters](#)). In order to consider the connectivity during resequencing, SID must be specified on the PARAM,MPCX entry. Using the example above, specify PARAM,MPCX,32.

**MPCD** Load Selectable Value for  $Y_m$  of Non Homogenous Multipoint Constraint

Defines a load selectable value for  $Y_m$  of a MPCY entry.

Format:

1	2	3	4	5	6	7	8	9	10
MPCD	SID	GM1	CM1	YM1	GM2	CM2	YM2		

Example:

MPCD	700	101	2	.06					
------	-----	-----	---	-----	--	--	--	--	--

Describer	Meaning
SID	Set identification number of the MPCD entry. (Integer > 0)
GMi	Grid or scalar point identification number. Along with Ci it identifies the Equation of a MPCY. (Integer > 0)
Ci	Component number. (Any one of the Integers 1 through 6 for grid points, blank, zero or 1 for scalar points.)
YMi	Right hand side value of MPC equation. (Real)

Remarks:

1. In static solution sequences, the SID is selected by the LOAD Case Control command.
2. The Gi,Ci referenced on this entry must also be referenced on a MPCY Bulk Data entry and selected by an MPC Case Control command.
3. Values YMi will override the value specified on an MPCY Bulk Data entry.
4. The LOAD Bulk Data entry will not combine an MPCD load entry.
5. Two separate MPC equations may be pointed to per entry.

**MPCREEP****SOL 600 Advanced Creep Options**

Specifies input values for Marc's creep parameter when creep analysis is performed using SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MPCREEP	ITYPE	IMPLK	IIMPLM	IHOW					

Example:

MPCREEP	1	0	0	0					
---------	---	---	---	---	--	--	--	--	--

Describer	Meaning
ITYPE	Type of explicit creep analysis enter one of the following: (Integer; Default = 0) 0 Normal creep (Maxwell Model) 1 Viscoplastic creep 2 Viscoplastic creep with nonassociative flow rule.
IMPLK	Flag determining if the explicit Kelvin model is to be used. (Integer; Default = 0) 0 Explicit Kelvin model is not used 1 Explicit Kelvin model is used.
IMPLM	Flag determining if the implicit Maxwell creep or implicit viscoplastic model is to be used. (Integer; Default = 0) 0 These models are not used. 1 The implicit Maxwell creep or implicit viscoplastic model is used.
IHOW	Flag specifying how the Maxwell creep model or implicit viscoplastic model is used. (Integer; Default = 0) 0 Use elastic tangent 1 Use secant tangent 2 Use radial return

Remarks:

1. Set IHOW=0 or leave field blank if IMPLM=0.
2. When using the implicit Maxwell creep model, the stress dependence must be in exponential form and the CRPLAW user subroutine cannot be used.
3. Only one MPCREEP entry may be entered in the input. If additional MPCREEP entries are found, the first will be used.
4. If ITYPE > 0, Bulk Data entry, MACREEP or MTCREEP is required in addition to this entry.

5. This entry maps to Marc's CREEP parameter.
6. This entry is not necessary if fields 2-5 are all zero or blank.
7. Kelvin creep requires user subroutines.

## MPCY Non Homogenous Multipoint Constraint

Defines a multipoint constraint equation of the form

$$A_m u_m + \sum_i A_i u_i = Y_m$$

where  $u_m$  represents degree-of-freedom  $C_m$  at grid or scalar point  $G_m$  defined to be the dependent degree-of-freedom.  $u_i$  represents degree-of-freedom  $C_i$  at grid or scalar point  $G_i$  defined to be the independent degree-of-freedom.  $Y_m$  is a value for the equation.

Format:

1	2	3	4	5	6	7	8	9	10
MPCY	SID	GM	CM	AM	YM				
		G1	C1	A1	G2	C2	A2		
		G3	C3	A3	...				

Example:

MPCY	70	205	1	1.0	.02-3				
		1608	1	1.2					

Describer	Meaning
SID	Set identification number of a multi-point constraint set. (Integer > 0)
GM	Identification number of grid or scalar point. (Integer > 0)
Cj	Component number. (Any one of the Integers 1 through 6 for grid points; blank, zero or 1 for scalar points.)
AM	Coefficient. (Real nonzero value)
YM	Right hand side value. (Real; Default = 0.0)
Gi	Identification number of grid or scalar point. (Integer > 0)
Ci	Component number. (Any one of the Integers 1 through 6 for grid point; blank or zero for scalar points.)
Ai	Coefficient. (Real; Default = 0.0)

Remarks:

1. Multipoint constraint sets must be selected with Case Control command, MPC=SID.

2. The  $m$ -set degree-of-freedom specified on this entry may not be specified on other entries that define mutually exclusive sets. The GM term is an equation marker. If PARAM,AUTOMSET,YES is on Nastran may choose internally another  $G_i$  as the actual dependent degree-of-freedom.

**MPHEAT****Maps to Marc's HEAT parameter for SOL 600 heat transfer analysis**

Maps to Marc's HEAT parameter for SOL 600 heat transfer analysis.

Format:

1	2	3	4	5	6	7	8	9	10
MPHEAT	IDIST	LHMAX	INTPT	ICONVT	ILAYC	LINR	NONH		

Example:

MPHEAT	1	1	1	0	3	1	0		
--------	---	---	---	---	---	---	---	--	--

Describer	Meaning
IDIST	Temperature distribution in thickness direction of heat transfer shell elements. (Integer; Default = 0) 0 Linear Variation (membrane) 1 Quadratic variation
LHMAX	Maximum number of latent heats associated with any material. (Integer; Default = 0)
INTPT	Controls integration point output. (Integer; Default = 0) 0 No integration point output 1 Gradients and fluxes at integration points 2 Save as 1 plus flux values at grid points
ICONVT	Flag to include convective terms. (Integer; Default = 0) 0 Do not include convective terms 2 Include convective terms
LAYC	Number of through thickness layers for heat transfer shells. (Integer; Default = 1)
LINR	Flag controlling linearization of surface energy and receding surface calculations. (Integer; Default = 1) 1 Linearize the calculations 2 Do not linearize the calculations
NONH	Flag to store nonhomogeneous density for postprocessing. (Integer; Default = 0) 0 Do not store the values 1 Store the values

**MPROCS**

Defines a Processor Entry to be Used in the SOL 600 Marc Parameter Section

Defines a processor entry to be used in the SOL 600 Marc Parameter Section. It controls the use of vectorization and parallelization in the element assembly phase in Marc. Used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MPROCS	I2	I3	I4	I5	I6	I7			
	IRF	IFGF	IAXIS	WGHT					
	Dx	Dy	Dz	X	Y	Z			

Example:

MPROCS	1	1	1	1	11				
--------	---	---	---	---	----	--	--	--	--

Describer	Meaning
I2	Value of Marc's 2nd processor field. Number of CPUs to use. (Integer; Default = 0)
I3	Value of Marc's 3rd processor field. Optimal vector length (Defaults to 32 or 64 depending on the computer system). (Integer; Default = 0)
I4	Value of Marc's 4th processor field (enter 1 if beta matrices are to be formed in parallel). (Integer; Default = 0)
I5	Value of Marc's 6th processor field (enter 1 to use DDM single file input). (Integer; Default = 0)
I6	Value of Marc's 7th processor field -- Domain Decomposition Method. (Integer; Default = 0) Enter 11 to use Metis Best (best method of 12, 13 or 14) decomposition; Default. Enter 12 to use Metis Element-Based decomposition. Enter 13 to use Metis Node-Based decomposition. Enter 14 to use Vector decomposition. Enter 15 to use Radial decomposition. Enter 16 to use Angular decomposition.
I7	Value of Marc's 8th processor field. Enter 0 to use in-core storage for DDM single file creation. Enter 1 to use out-of-core storage. (Integer; Default = 0)
IRF	Island removal flag for domain decomposition. (Default = 0) 0 Do not remove islands 1 Attempt to remove islands
IFGF	Fine graph flag for domain decomposition. (Default = 0) 0 Coarse graph 1 Fine graph

Describer	Meaning
IAXIS	Control of point on axis of rotation for radial/angular domain decomposition 0        Use centroid of the boundary box of the model 1        User supplied point (supply X, Y, Z below)
WGHT	Element coefficient weight. Controls balance between computational costs of domains, range is 0.0 to 1.0. (Default = 1.0; Use full element weight) 0.0 - Do not use element weight
Dx	First direction cosine of vector used for decomposition method 14, 15, or 16
Dy	Second direction cosine of vector used for decomposition method 14, 15, or 16
Dz	Third direction cosine of vector used for decomposition method 14, 15, or 16
X	X coordinate of point on axis
Y	Y coordinate of point on axis
Z	Z coordinate of point on axis

#### Remarks:

1. This entry should only be made for special cases when using DDM with Marc's single file parallel capability. Do not enter except for SOL 600 parallel executions.
2. Consult the Marc documentation volumes A, B, C for more detailed descriptions of this entry.
3. Enter only one of MPROCS entry in any given file. If more than one is entered, the first encountered will be used.
4. The continuation lines may be omitted if not required.
5. I2, I3, and I4 are no longer used and should be zero or blank.

**MREVERS** Defines Which Elements Require Node Numbering to be Reversed - SOL 600

This entry is only used if the checks built into SOL 600 somehow fail to predict some elements which need node numbering reversed. Nastran allows clockwise as well as counter clockwise node numbering. Marc only allows counter clockwise numbering for most elements. SOL 600 has builtin logic to check for node reversal, however there may be some instances where Marc gives an “inside out” message during increment (before any nonlinear loads have been applied). This rarely happens unless field 7 of the GRID entry is set, in which case it sometimes happens. When this happens, the user can apply this entry to instruct SOL 600 how to renumber elements which have “inside out” messages during increment zero. (If “inside out” messages occur after increment zero, this is normally due to large loads and the element has either failed or the model needs to be re-meshed).

**Format:**

1	2	3	4	5	6	7	8	9	10
MREVERS	N1	M1	N2	M2	N3	M3	N4	M4	
	ID1	ID2	ID3	ID4	ID5	ID6	ID7	ID8	
	ID9	ID10	etc.						

**Example:**

MREVERS		2	3						
	500	510	520	888	889				
	950								

Describer	Meaning
Ni	Node number location to be reversed. (Integer; no Default; see Remark 1.)
Mi	Paired node number location to be reversed. (Integer; no Default; see Remark 1.)
IDI	Element identification number. (Integer; no Default)

**Remarks:**

- Example of node number locations are as follows:  
 For 4-node quads the node number locations are 1, 2, 3, 4  
 For 8-node hexas the node number locations are 1, 2, 3, 4, 5, 6, 7, 8
- The 2<sup>nd</sup> and succeeding lines may be used to make it easy to enter elements with “inside out” messages in a preliminary marc.out file. The user can grep for “inside out”, save the message in a file, easily edit the file to retain only the element numbers and then add these to lines 2 and subsequent of the alternate format.
- Up to four pairs of node locations may be reversed per entry. If additional paris are necessary, repeat the entry and its continuation lines.
- The example will reverse nodes locations 2 and 3 for elements 500, 510, 520, 888, 889 and 950.

5. This entry may only be used in MD Nastran R2.1 and later versions.
6. See PARAM,MAXIREVV for a similar option.

## MRSSCON

### Auxiliary data for RSSCON for use in SOL 600

Defines auxiliary data for RSSCON for use in SOL 600. Used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MRSSCON	ICONV	IDB	IDP	IDM	A	J	I	E	

Example:

MRSSCON	0	5000	5000	900	20.0	200.	100.	30.0E	
---------	---	------	------	-----	------	------	------	-------	--

Describer	Meaning
ICONV	Flag indicating how RSSCON rigid elements will be converted in SOL 600. (Integer; Default = 0) 0 Convert all RSSCON to CBEAM using values in fields 2-8 1 Convert all RSSCON to RBE2 using 3 degrees of freedom 2 Convert all RSSCON to RBE2 using 6 degrees of freedom
IDB	Starting CBEAM ID for all RSSCON's that are mapped to CBEAM's or RBE2 ID if RSSCON's are mapped to RBE2's (Integer; Default = 99000; see Remark 1.)
IDP	PBEAM ID for use by all RSSCON's in the model mapped to CBEAM's. See Remark 5. (Integer; Default = 99000)
IDM	MAT1 ID for use by all RSSCON's in the model mapped to CBEAM's. See Remark 6. (Integer; Default = 99000)
A	Area to be placed in the PBEAM (Real; Default = 10.0)
J	Torsional moment of inertia to be placed in the PBEAM (Real; Default = 20.0)
I	Moment of inertia (in both directions) to be placed in the PBEAM (Real; Default = 10.0)
E	Elastic modulus to be placed in the IDM MAT1 entry (Real; Default = 1.0E6)

Remarks:

1. ICONV=1 or 2 may cause MPC conflicts and/or may fail if AUTOMSET,YES is used.
2. RSSCON type=elem is not presently supported by SOL 600.
3. This entry applies to RSSCON type=grid where ES1, EA1, EB1 all have different coordinates, and if used ES2, EA2 and EB2 do not have the same coordinates as each other (see RSSCON entry for meaning of these values).
4. Only one MRSSCON entry should be include in the input data. If more than one is included, the first as determined by XSORT, will be used.

5. If IDP is entered, a PBEAM with and id of IDP and properties A, J, and I will automatically be created.
6. If IDM is entered, a MAT1 with a Young's modulus of E and Poisson ratio of 0.3 will automatically be created.

**MSTACK**

Defines the Direction in Which 3D Solid Composites are Stacked -SOL 600

Defines the direction in which 3D Solid Composites are stacked. Used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MSTACK	ID1	THRU	ID2	IDIR					

Example:

MSTACK	100	THRU	200	1					
--------	-----	------	-----	---	--	--	--	--	--

Describer	Meaning
ID1	Starting solid element ID (Integer; Required; no Default)
THRU	Enter the character string THRU if more than one element is desired
ID2	Ending solid element in a range of ID1 to ID2 (Integer; optional; no Default)
IDIR	Stacking direction for this range of solid elements (Integer; Required; Default = 1)
	1 Thickness direction is 1-2-3-4 face to 5-6-7-8 face (for CHEXA)
	2 Thickness direction is 1-5-8-4 face to 2-6-7-3 face (for CHEXA)
	3 Thickness direction is 2-6-5-1 face to 3-7-8-4 face (for CHEXA)

Remarks:

1. Enter as many MSTACK lines as necessary to define any solid composites where the defaults do not apply. If IDIR is 1 for all elements in the range, this entry is not required.
2. This entry equates to Marc's EGEOM3 value for solid composite elements (for example element 149).

**MT16SEL**

Limits results to selected elements or grids for t16 and t19 for SOL 600

Limits elements and/or grid results to selected elements or grids for t16 and t19 file results. Used in SOL 600.

**Format**

1	2	3	4	5	6	7	8	9	10
MT16SEL	TYPE	ID1	THRU	ID2	BY	ID3			
	TYPE	ID1	THRU	ID2	BY	ID3			

**Example:**

MT16SEL	GRID	1	THRU	100					
	GRID	2525	THRU	3000	BY	10			
	ELEM	100	THRU	500	BY	2			
	ELEM	1000	THRU	2000					

Descriptor	Meaning
TYPE	Type of output - Enter one of the values “GRID”, or “ELEM”, for “GRID”, nodal results such as displacement, spc force, etc are selected. For “ELEM”, element results such as stress, strain, etc. are selected. This entry should normally be used in combination with MARCOUT unless the MARCOUT defaults are satisfactory for the model.
ID1	Starting ID of above selection. (Integer; no Default required value)
ID2	Ending ID of above selection. (Integer; Default = ID1)
ID3	Increment by value. (Integer; Default = 1)

**Remarks:**

1. It is highly recommended that all grid and element output be placed on the t16 file since it is not usually known where the maximum values will occur and the max/min values could easily be missed. Also, if all grid/element values are not selected, contour plots could be misleading. To output all grid/element results in the t16 file, do not make any MT16SEL entries.
2. This entry may not be used when OUTF options (which requires a t16 to op2 conversion) on the SOL 600 entry are requested. If this entry is made together with any OUTF options, this entry will be ignored and a warning message issued.
3. ID2 must be blank, zero or greater than ID1 (if ID2 is blank or zero, only ID1 will be used)
4. ID3 must not be negative. It can be blank or zero in which case it is reset to one.
5. This entry (with the exception of Remark 3) activates Marc's POST version 13 and overrides any other POST version specifications such as PARAM,MARCPST.
6. This entry can be used to also obtain a t19 file with selected element and/or grid results by placing PARAM,MARCT19,1 in the bulk data.

7. It is not presently possible to only create a t19 file with selected element/grid results using SOL 600. If a t19 file is desired, a t16 file must also be created.

**MT16SPL****Split a Marc t16 file into one or more smaller t16 files in SOL 600**

Determines how to split a Marc t16 file into one or more smaller t16 files in SOL 600. Splitting of a large t16 file is sometimes necessary if the postprocessor aborts due to the large amount of data or if the results need to be transferred to another computer for postprocessing.

Format: This entry is available in small field format only:

1	2	3	4	5	6	7	8	9	10
MT16SPL	IOPT	NVECT	FNAME						
	ID1	START	LAST	INCR	(remark 4)				
	ID2	START	LAST	INCR	LastFew				

Examples:

MT16SPL	0								
	1	5	100	5	3				

MT16SPL	0		old1.mar	c.t16					
	1	10	80	10	3				
	2	90	100	5	4				

MT16SPL	1	1							
	1	100							

MT16SPL	3	2	old2.t16						
	1	10	100	10	3				

Create several new t16 files with 2 increments each using original increments 10, 20, ... 98, 99, 100. This is a restart job and uses old2.t16 (from a standalone Marc run). New files will be created as follows:

jid.0001.t16 with old increments 10, 20  
 jid.0002.t16 with old increments 30, 40  
 jid.0003.t16 with old increments 50, 60  
 jid.0004.t16 with old increments 70, 80  
 jid.0005.t16 with old increments 90, 98  
 jid.0006.t16 with old increments 99, 100

Describer	Meaning
IOPT	Option of how to split up the "old" t16 file. (Integer; Default = 0)
0	Split into as many new t16 files as there are continuation lines of this entry, use the current jid.marc.t16 file, FNAME should not be entered.
1	Split into as many new t16 files with NVECT original increments each, use the current jid.marc.t16 file, FNAME should not be entered.

Describer	Meaning
	2 Split into as many new t16 files as there are continuation lines of this entry, use a previously generated t16 file whose name is specified by FNAME.
	3 Split into as many new t16 files with NVECT original increments each, use a previously generated t16 file whose name is specified by FNAME.
NVECT	Number of increments to be placed on each new t16 file (only used if IOPT is 1 or 3) (Integer; no Default)
FNAME	Original t16 filename - Only used if IOPT is 2 or 3. (Character; no Default) The filename may extend from fields 4-9. If it is more than 8 characters long, this entry must be made in fixed format. the entire t16 filename including the t16 extension should be entered. No upper case letters may be used. (Integer > 0)
IDI	New t16 plot ID (must start with 1 and increase by 1 on each continuation line.) (Integer; no Default)
START	Starting Marc increment to be placed on new t16 file. (Integer; Default = 1)
LAST	Last Marc increment in range of start-last-incr to be n new t16 file. (Integer; Default is last increment on original t16 file if FNAME is blank. If FNAME is not blank, LAST must be an accurate value which can be obtained from the .sts file of the original run that produced FNAME.)
INCR	Increments to be used for start-last-incr to be on new t16 file. (Integer; Default = 1)
Last Few	In addition to START, LAST, INCR the last several increments may be placed on the t16 file. In the first example increments 5, 10, 15, ..., 100, 99, 98 are placed on the new t16 file. LastFew may only be entered on the last line. (Integer; Default = 2)

#### Remarks:

1. Sometimes large SOL 600 models do not converge on a user wishes to examine output at unknown time intervals. To determine what is happening, it is frequently necessary to plot the results at several output intervals. In fact, sometimes the last increment may have bogus results due to divergence. At present, MSC GUI programs sometimes are not capable of postprocessing the large amount of data one would like to include in a single t16 file. This option allows you to break up the t16 file into one or more smaller files.
2. GUI's might only be able to handle one increment per t16 file for extremely large models. To specify this, only enter ID and START as in the 3rd example.
3. All t16 files will have the geometry as well as the specified output increments.
4. LastFew may only be entered on the last line.
5. Nastran may be restarted to perform this step. To do so, enter  

```
SOL 600, ID t16split=fname
```

Where fname is the jid of the original job.
6. The new files will be named jid.ID.t16. Examples are as follows:

Case 1 - Split up t16 as part of current run starting with jid1.dat as the Nastran input SOL 600 will create jid1.marc.t16 with a full set of output increments (unless reduced by you).

jid1.0001.t16

jid1.0002.t16

etc.

Case 2 - Split up a t16 file formed by a previous SOL 600 run named jid1.dat (the t16 file is named jid1.marc.t16). The current Nastran input file to split up the original t16 is named jid2.dat. The new t16 files will be designated:

jid2.00001.t16

jid2.00002.t16

etc.

7. Nastran will spawn Marc's pldump2000 program to split up the original t16 file.
8. If FNAME is entered (IOPT=2 or 3), OUTF options (on SOL600,ID) will be ignored. If FNAME is blank and IOPT=0 or 1 and OUTF options are requested, the t16op2 translator process the full (unsplit) jid.marc.t16 file. Future implementations may allow processing of the split t16 files.
9. Only one MT16SPL (plus many continuation lines as necessary) is allowed per job.

**MTABRV** Defines a List of Tables to Modify and/or Positions of Values - SOL 600

In some cases, a model is built with tables defined backwards. For example, for a stress-strain curve the compression position of the curve might really need to be the tension portion and visa versa. This entry allows them to be reversed. In addition, this entry allows a user to add a point to the lower and/or upper end of the tables in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MTABRV	ID1	THRU	ID2	IREV	XLOW	YLOW	XHIGH	YHIGH	

Example:

MTABRV	1	THRU	10	1	-100.	-1.0E7	0.01	1.0E7	
	21	THRU	25	1					
	45	THRU	48				25.5	66523.	

Describer	Meaning
ID1	Starting table ID to be reversed. (Integer; Required; no Default)
THRU	Enter the character string THRU if more than one grid is desired.
ID2	Ending table ID of the range. (Integer; or blank. If blank; ID2=ID1)
IREV	Option to reverse (flip) positive and negative values and change the sign for tables in the range ID1 to ID2. (Integer; Default = 0)
	0 Do not reverse
	1 Reverse
XLOW	Option to add a point to the lower end of these tables. If so, XNEG is the lower end X value to be added (after reversal, if IREV=1). (Real; Default = 0.0)
YLOW	Option to add a point to the lower end of these tables. If so, YNEG is the lower end Y value to be added (after reversal, if IREV=1). (Real; Default = 0.0)
XHIGH	Option to add a point to the upper end of these tables. If so, XPOS is the upper end X value to be added (after reversal, if IREV=1). (Real; Default = 0.0)
YHIGH	Option to add a point to the upper end of these tables. If so, YPOS is the upper end Y value to be added (after reversal, if IREV=1). (Real; Default = 0.0)

Remarks:

1. Missing tables in the range ID1 to ID2 will be ignored and no error will be produced.
2. This capability is limited to tables defined using TABLES1, TABLED1 and/or TABLEM1 and the behavior in the x and y directions must be linear.

3. Values XLOW, YLOS, XHIGH, YHIGH are not reversed and the signs are not changed even if IREV=1.
4. The first example reverses tables 1-10 and also adds a point at the lower and upper end. The second example reverses tables 21-25, no additional points are added. The third example adds a point to the upper end of tables 45-48, does not reverse the tables or add a point to the lower end.
5. This entry will reverse both X and Y of the specified tables and is not capable of reversing only X or Y.

## MTCREEP

## AUTO THERM CREEP Iteration Control - SOL 600

Controls a transient thermal creep analysis. This entry or the MACREEP entry is required if ITYPE is not zero on the MPCREEP entry in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
MTCREEP	ID	Tchg	Nmax	Iasmb	Ttot	Tincr	Tcrep	Nsub	
	Maxit	Nupd	VV1	VV2	VV3	IABS			

Example:

MTCREEP	11	1.0	99999	1	2000.	10.	1000.	50	
	5	1	.5	.1	.05				

Describer	Meaning
ID	Identification number of a matching NLPARM Case Control command (for statics) or entry (for dynamics). (Integer; no Default; Required field)
Tchg	Maximum temperature change to be used per step of the stress analysis. (Real; no Default; Required value) (2,1)
Nmax	Maximum number of increments allowed. (Integer; Default = 999999) (2,2)
Iasmb	Reassembly interval for element matrices. (Integer; Default = 1) (2,3)
Ttot	Total transient time from corresponding heat transfer analysis. (Real; no Default) (2,4)
Tincr	Suggested time increment for creep analysis (Real; no Default) (3,1)
Tcrep	Total creep time to be covered in this creep analysis (Real; no Default) (3,2)
Nsub	Maximum number of subincrements to be allowed during this creep analysis (Integer; Default = 50). (3,3)
Maxit	Maximum number of iterations allowed to modify the time step during any increment. (Integer; Default = 5) (3,4)
Nupd	Number of increments between stiffness matrix updates. (Integer; Default = 1) (3,5)
VV1	Tolerance value #1. (Real; see below for defaults) (4,1)
	IABS=0     Enter the tolerance on the creep strain increment relative to the elastic strain. (Default = 0.5)
	IABS=1     Enter the maximum creep strain increment. (Default = 0.01)
VV2	Tolerance value #2 (Real; see below for defaults) (4,2)
	IABS=0     Enter the tolerance on the stress change per increment divided by the total stress. (Default = 0.1)
	IABS=1     Enter the maximum stress increment. (Default = 100.0)

Describer	Meaning
VV3	Tolerance on low stress point cutoff. Points with a stress lower than this ratio relative to the maximum stress in the structure are not used in the creep tolerance checking. (Real; Default = 0.05) (4,3)
IABS	Flag controlling relative or absolute convergence testing. (Integer; Default = 0) (4,5)
	0           Relative checking is used
	1           Absolute checking is used

Remarks:

1. This entry maps to Marc's AUTO THERM CREEP entry.
2. This entry will be used to instead of AUTO STEP or AUTO INCREMENT entries in the Marc file. It is suggested that if this entry is used, NLAUTO and NLSTRAT should not be specified (and will be ignored if entered).
3. Bulk Data entries, MPCREEP and MCHSTAT, must also be entered in addition to this entry.
4. (i,j) refer to Marc's AUTO THERM CREEP (data block, field).
5. Bulk Data entries MACREEP and MTCREEP should not be entered in the same input file.

**M THERM** Iteration Control for Automatic Thermal Loading for Structural Analysis Following a SOL 600 Heat Transfer Analysis

Iteration control for automatic thermal loading for structural analysis following a SOL 600 heat transfer analysis.

Format:

1	2	3	4	5	6	7	8	9	10
M THERM	ID	Tchg	Nmax	Iasmb	Ttot	Tincr			

Example:

M THERM	21	1.0	99999	1	2000.	10.			
---------	----	-----	-------	---	-------	-----	--	--	--

Describer	Meaning
ID	Identification number of a matching Case Control NLPARM command (for statics) or entry (for dynamics). (Integer; no Default; Required field)
Tchg	Maximum temperature change to be used per step of the stress analysis. (Real; no Default; Required value) (2,1)
Nmax	Maximum number of increments allowed. (Integer; Default = 999999) (2,2)
Iasmb	Reassembly interval for element matrices. (Integer; Default = 1) (2,3)
Ttot	Total transient time from corresponding heat transfer analysis. (Real; no Default) (2,4)
Tincr	Suggested time increment for creep analysis. (Real; Default = 0.0; leave blank if analysis is not a creep analysis) (2,5)

Remarks:

1. This entry maps to Marc's AUTO THERM entry.
2. This entry will be used to instead of AUTO STEP or AUTO INCREMENT entries in the Marc file. It is suggested that if this entry is used, NLAUTO and NLSTRAT should not be specified (and will be ignored if entered).
3. (i,j) refer to Marc's AUTO THERM (data block, field).
4. This entry may be omitted in which case an AUTO THERM entry as follows will be used  
 AUTO THERM  
 1., 9999, 0, 1.0

## NHRMPRM

## Parameters for Nonlinear frequency response analysis (SOL 128)

Format:

1	2	3	4	5	6	7	8	9	10
NHRMPRM	PARAM1	VAL1	PARAM2	VAL2					

Example:

NHRMPRM	MNCSF	3	NLHDIAG	1					
---------	-------	---	---------	---	--	--	--	--	--

Var Name	Type/ Default	Description
NLHRED	I = -1	Use reduction for nonlinear analysis.
NHPLUS	I = 20	Number of extra points to avoid aliasing.
NLHTOL	R = 1.0E-5	Tolerance for convergence.
NLHTWK	R = 1.1	Push-off factor for line search in case convergence fails.
MXICODE0	I = 5	If solution fails to converge for mxicode0 steps, new trial displacement is used.
TICPNCH	I = 0	If TICPNCH = -1 then write a TIC Bulk Data entry for each degree-of-freedom in the d-set to be included in a subsequent transient analysis run.
MNCSF	I = 1000	Max number of non-converged sequential frequencies for RESET.
MFRINT	R = 10.	Maximum frequency interval for RESET.
NLHDIAG	I = 0	Output additional diagnostic messages.
CONTP	I = 0	Continuation procedure.

Remarks:

1. Following parameters can also be specified using PARAM option: NLHRED, NHPLUS, NLHTOL, NLHTWK, TICPNCH and MXICODE0.  
See description under PARAM for more details about these variables.  
In case a parameter is specified in NHRMPRM and also using PARAM, the value specified using PARAM entry is used.
2. Parameters MNCSF or MFRINT can be used to reset initial condition in case of non-convergence. If both these parameters are specified, the condition which is satisfied first is used.
3. CONTP = 1 is used to initiate continuation procedure method. In this case, following parameters are not used in the analysis: NLHRED, MNCSF, MFRINT. Currently, the CONTP option is available for frequency-independent analysis only.  
Here, NLHRED is set to 0 to not use the reduction method. And initial condition for the continuation procedure is determined using the results from two previously converged solutions.

## NLADAPT

## Additional Parameters for Automatic Load or Time Stepping

Defines additional parameters for automatic load or time stepping used with enhanced nonlinear in SOL 400. *NLADAPT is an obsolete option from MD Nastran 2010 onwards. It is recommended that NLADAPT be replaced by NLSTEP.*

Format:

1	2	3	4	5	6	7	8	9	10
NLADAPT	ID								
	“STEP”	RSMALL	RBIG	TSMIN	TSMAX	NSMAX	NRECYC	SFACT	
		IDAMP	DAMP						
	“CREEP”	RAC	TCSTRN	TCSTRC	TCOFF				

Example:

NLADAPT	700								
	STEP								
		4							
	CREEP	1							

NLADAPT	800								
	CREEP	1							
	STEP								
		4							

Describer	Meaning
ID	Identification number of a NLPARM or entry. (Integer > 0)
“STEP”	Keyword indicating the following entries are for enhanced general load step or time step convergence. (Character)
RSMALL	Smallest scale factor for time step changes. See Remark 5. (Real; Default= 0.1)
RBIG	Largest scale factor for time step changes. See Remark 5. (Real; Default = 1.5)
TSMIN	Smallest ratio of a time step to the total time. (Real; Default = total time divided by number of time steps)
TSMAX	Largest ratio of a time step to the total time. (Real; Default = 0.5)
NSMAX	Maximum number of steps allowed. (Integer; Default = 99999)
NRECYC	Number of recycles per increment. (Integer; Default = 10)
SFACT	Scale factor for time step changes. See Remark 6. (Real; Default = 1.2)
IDAMP	Enter 4 to activate artificial damping. (Integer 0 or 4; Default = 0)
DAMP	Damping factor for activated artificial damping. (Real; Default = 2.E-4)

“CREEP”	Keyword indicating the following entries are for enhanced creep analysis. (Character)
RAC	Flag controlling relative or absolute convergence. (Integer 0 or 1; Default = 0)
	0           Relative checking used.
	1           Absolute checking used.
TCSTRN	Creep strain tolerance. (Real)
	RAC = 0     Enter the tolerance on the creep strain increment divided by the elastic strain. (Real; Default = 0.5)
	RAC = 1     The maximum creep strain increment allowed. (Real; Default = 0.1)
TCSTRS	Creep stress tolerance (Real)
	RAC = 0     Enter the tolerance on the stress increment divided by the total stress. (Real; Default = 0.1)
	RAC = 1     enter the maximum stress increment. (Real; Default = 100.0)
TCOFF	Tolerance on low stress point cutoff. Points with a stress lower than this ratio relative to the maximum stress in the structure are not used in the creep tolerance checking. (Real; Default = 0.05)

**Remarks:**

1. This entry must point to an existing NLPARM or entry and is only used in SOL 400.
2. The keywords and their associated entries may occur in any order.
3. This entry computes an initial time step  $TINIT=1.0/NINC$  if pointing to a NLPARM entry and  $TINT=1.0/DT$  if pointing to a entry.
4. If this entry is used, it is preferred KMETHOD on the NLPARM or METHOD on the be set to PFNT, FNT, ITER, or AUTO.
5. The scale factor is defined as the new step size divided by the time step size.
6. SFACT is only used when artificial damping is activated.

## NLAUTO Parameters for Automatic or Fixed Load/Time Stepping - SOL 600

Defines parameters for automatic or fixed load/time stepping used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
NLAUTO	ID	TINIT	TFINAL	RSMALL	RBIG	TSMIN	TSMAX	NSMAX	
	NRECYC	IENHAN	IDAMP	NSTATE	NCUT	LIMTAR	IFINISH	FTEMP	
	SFACT	IFLAG	IDTAB	DAMP	IDMPFLG		IPHYS	I313	
	CRITERIA	SETID	Y1	X1	Y2	X2	Y3	X3	
		Y4	X4						

Example:

NLAUTO	1	.01	1	1	10	-1.5	.5		
	5		1			-1			
	1.2								

Describer	Meaning
ID	Identification number referenced by the NLPARM, , or TSTEP Case Control command for the applicable subcase. See Remarks 1. and 2. Include a NLPARM or entry for the subcase in addition to the NLAUTO entry. See Remarks 1. and 2. (Integer > 0; no Default)
TINIT (2,1)	Initial time step. (Real; Default is determined by NLPARM NINC or DT, see Remark 8.)
TFINAL (2,2)	Total time period. If OUTR options are used, for a static analysis, TFINAL must be 1.0. (Real; Default is 1.0 or Remark 8.)
RSMALL (2,3)	Smallest ratio between steps. (Real; Default = 0.1 or Remark 7.)
RBIG (2,4)	Largest ratio between steps. (Real; Default = 10.0 or Remark 7.)
TSMIN (2,5)	Minimum time step. (Real; Default is total time divided by number of time steps or Remark 7.)
TSMAX (2,6)	Maximum time step. (Real; Default is total time or Remark 7.)
NSMAX (2,7)	Maximum number of steps allowed. If IENHAN=2, NSMAX is the number of fixed time steps. (Integer; Default = 999999 or Remark 7.)

Describer	Meaning
NRECYC (2,8)	Desired number of recycles per increment. For beam or shell bending NRECYC should be set to 10. If large deformation is anticipated, NRECYC = NO is necessary for plate and shell buckling. PARAM,MARCDEF,0 can be used to set NRECYC=10 without entering NLAUTO. (Integer; Default = 5 or Remark 7.)
IENHAN (2,9)	Enter 1 to activate the enhanced scheme, 0 otherwise. Enter 2 to use fixed time stepping (enter the number of time steps using NSMAX) (Integer)
IDAMP (2,10)	Artificial damping control. (Integer; Default = 1, or Remark 7.) Enter 0 to not use artificial damping Enter 1 to use artificial damping if time step is less than minima time step. Reduce the minimum time step by 1000. IDAMP=1 is usually necessary (in combination with NRECYC=10) for plate and shell buckling models. Enter 2 to always use artificial damping. The value to use is given by DAMP which scales the damping matrix. Enter 4 to always use artificial damping which is determined by the strain energy in the first increment of the present load case. DAMP is used to scale the strain energy. Enter 5 to set the time step as if artificial damping was being used, but do not actually add artificial damping. Enter 6 to add artificial damping when the minimum time step has been reached.
NSTATE (3,1)	Number of states for post file. (Integer; enter only if ienhan = 1)
NCUT (3,2)	Maximum number of times to cut down time step in an increment. (Integer) (Default = 10 or Remark 7.; enter only if ienhan = 1)
LIMTAR (3,3)	Enter 0 to create criteria as limits, 1 to treat criteria as targets. (Integer, Default = 0 or Remark 7.; enter only if ienhan = 1)
IFINISH (3,4)	Enter 1 to finish time period when all nodal temperatures fall below FTEMP. Enter -1 if all nodal temperatures should exceed FTEMP. Enter 0 to omit temperature check. (Integer; enter only if ienhan = 1, Default = 0 or Remark 7.)
FTEMP (3,5)	Finish temperature, use with IFINISH. (Real; enter only if ienhan = 1, Default = 0.0 or Remark 7.)
SFACT (3,6)	Scale factor for time step changes other than changes due to user criteria. (Real) (Default = 1.2 or Remark 7.; enter only if ienhan = 1)
IFLAG (3,7)	Enter flag to override CREEP and DYNAMIC parameters as specified in the Marc input parameter section for this load case. (Integer) 0 Do not override parameters. 1 Turn off CREEP and DYNAMICS. 2 Turn off CREEP. 3 Turn off DYNAMICS.
IDTAB (3,8)	Table ID scaling damping factor (see next item) (Integer)

Descriptor	Meaning
DAMP (3,9)	Damping factor for artificial damping. The number entered here depends on the IDAMP option. If IDAMP is 1, the damping matrix is scaled by setting this factor to be the ratio of the initial damping energy to the initial strain energy (Defaults to 1e-5). If IDAMP is 2, the damping matrix is directly scaled by this factor. If IDAMP is 4, the estimated total damping energy in the subcase will be this factor times the estimated total strain energy. (Default value of 2.e-4 or Remark 7.)
IDMPFLG (3,10)	Enter 1 to put states reached by the above IDMPFLG flag on the post file. (Integer)
IPHYS (3,12)	Flag to determine if automatic physical criteria should be added and how analysis should proceed if they are not satisfied. (Integer) 2 Do not add automatic physical criteria. Stop when any user criteria are not satisfied. 1 Add automatic physical criteria. Stop when any user criteria are not satisfied. -1 Add automatic physical criteria. Continue when any user criteria are not satisfied. -2 Do not add automatic physical criteria. Stop when any user criteria are not satisfied.
I313 (3,13)	Flag to check if dynamic integration error checks should be made while determining the timestep (single step Humbolt and Newmark-Beta only) (Integer, Default = 0 or Remark 7). 0 Skip error check. 1 Include error check.
CRITERIA (4,1)	Enter an integer corresponding to the criteria desired. See Remark 1. (Integer; no Default)
SETID (4,2)	Case Control Set ID of nodes or elements for which this criteria will apply. Restriction: Must be one of first 25 sets entered in the case control. Leave blank if "ALL" is desired. (Integer; Default is all or Remark 7.)
Y1 (4,3)	Time step adjustment value. See Remark 10. (Real)
X1 (4,4)	Time step adjustment value. See Remark 10. (Real)
Y2 (4,5)	Time step adjustment value. See Remark 10. (Real)
X2 (4,6)	Time step adjustment value. See Remark 10. (Real)
Y3 (4,7)	Time step adjustment value. See Remark 10. (Real)
X3 (4,8)	Time step adjustment value. See Remark 10. (Real)

Describer	Meaning
Y4 (4,9)	Time step adjustment value. See Remark 10. (Real)
X4 (4,10)	Time step adjustment value. See Remark 10. (Real)

#### Remarks:

1. Enter the following index in the CRITERIA field (a limit of 9 criteria may be specified and the usual option is to specify none).

1	Strain Increment	2	Plastic Strain Increment
3	Creep Strain Increment	4	Normalized Creep Strain Increment
5	Stress Increment	7	Strain Energy Increment
8	Temperature Increment	9	Displacement Increment
10	Rotation Increment	12	Stress
13*100+n	State Variable n		

2. Values entered on NLAUTO override values with the same meaning if entered elsewhere (for example, on the NLPARM or entry).
3. If the NLAUTO entry is used, there should also be a corresponding NLPARM or . The matching NLPARM entry must have KMETHOD=AUTO or ITER. If is the matching entry, then field 6 must be blank or have the value ADAPT.
4. Values such as (3,7) indicated corresponding item on Marc's AUTOSTEP data block 3 field 7.
5. Items (3,7) to (3,13) were implemented starting with MSC Nastran 2004.0.4 and are not in previous versions.
6. The continuation lines may be omitted if not needed. If one of the continuation lines is needed, all proceeding continuation lines must be entered and at least one value per line is specified (no blank lines are allowed).
7. If an NLAUTO field is blank for the second and following subcases, the value will be assumed to be the same as that of the proceeding subcase for the same field. If this is not the behavior that is desired, be sure not to leave fields blank that should vary between the current and previous subcases.
8. Dynamics TINIT and TFINAL are determined from and TABLED1 entries. They are ignored if entered using NLAUTO. For statics, TINIT and TFINAL, if specified on NLAUTO override the values from NLPARAM.
9. Fixed time stepping is triggered by setting NSMAX equal to the number of steps (N) and IENHAN=2. It may also be triggered by using bulk data PARAM,MARCITER,N.
10. The time step is adjusted based upon:

if  $X < X1$              $Y(\text{calculated})/Y1$   
 if  $X1 < X < X2$          $Y(\text{calculated})/Y2$   
 if  $X2 < X < X3$          $Y(\text{calculated})/Y3$   
 if  $X3 < X < X4$          $Y(\text{calculated})/Y4$

where

Criterion	X	Y
1	Strain	Strain increment
2	Plastic strain	Plastic strain increment
3	Creep strain	Creep strain increment
4	Creep strain	Creep strain increment/Elastic strain
5	Stress	Stress increment
7	Strain energy	Strain energy increment
8	Temperature	Temperature increment
9	Displacement	Displacement increment
10	Rotation	Rotation increment
12	Stress	Stress increment/Stress
13*100+n	State variable n	Increment in state variable n

**NLBSH3D****Nonlinear 3-dimensional rotor loading**

Defines connectivity of a three-dimensional nonlinear load as a function of relative deflection and velocity of a grid pair which in turn is a function of rotor speed.

Format:

1	2	3	4	5	6	7	8	9	10
NLBSH3D	SID	GA	GB	Blank	LID-1	LID-2			

Describer	Meaning
SID	Nonlinear load set identification number. (Integer > 0; Required)
GA	Inner grid. (Integer > 0; Required)
GB	Outer grid. (Integer > 0; Required)
LID-1	Load vs deflection group ID of a LBSH3DG (Integer > 0; Required)
LID-2	Load vs velocity group ID of a LBSH3DG (Integer > 0; Required)

**Remarks:**

- NLBSH3D are selected with the Case Control command `NONLINEAR = SID`.
- In order to ensure correct results, GRID points GA and GB must satisfy the following three conditions:
  - They must both be grid points
  - They must be coincident
  - They must have parallel displacement coordinate systems

The program checks for the above conditions. If they are not satisfied, the program will terminate the run with an appropriate fatal message.
- Multiple NLBSH3D may reference the same SID but require different GA, GB grid pairs.
- Multiple NLBSH3D entries may refer to the same LID independent of SID.
- Non-linear load is calculated as a function of relative deflection and velocity, which in turn are functions of rotor speed, between GRID points GA and GB. Till version 2019FP1, non-linear load = load (deflection (rotor speed)).
- The loads are applied to the DOFs of GA and GB, based on the difference in displacement ( $u_b - u_a$ ) or velocity ( $v_b - v_a$ ) at the 2 GRID points, according to the tables referenced on the LBSH3DG entries. A positive difference in the displacement/velocity results in a positive force being applied to GA and a negative force being applied to GB
- GA and GB must have all 6 DOF in D-set. Both grids should not be dependent on any RBE or MPC and must not be constrained by an SPC. The program checks for active DOFs of both the grids. If they are not satisfied, the program will terminate the run with an appropriate fatal message.

**NLCYSYM** Defines Information to Perform Nonlinear Cyclic Symmetry Analysis using SOL 600

A limited capability is available to analyze structures with a geometry and a loading varying periodically about a symmetry axis. This capability is termed Nonlinear Cyclic Symmetry. This is done by developing a special set of tying constraints on the boundaries of the “pie-sliced” segment being analyzed. For more details on the type of structures that may be analyzed using this method and its restrictions, please see the Remarks.

Format:

1	2	3	4	5	6	7	8	9	10
NLCYSYM	ID	DC1	DC2	DC3	X	Y			
	ANG	TOL	IRB	LinFlag					

Examples:

NLCYSM		0.0	0.0	1.0	0.0	0.0	0.0		
	30.0		-1	-1					

Describer	Meaning
ID	Identification number not presently used. (Integer or blank, Default = 0)
DC1	First component of the direction cosine of the symmetry axis. (Real; Default = 0.0)
DC2	Second component of the direction cosine of the symmetry axis. (Real; Default = 0.0)
DC3	Third component of the direction cosine of the symmetry axis. (Real; Default = 0.0)
X	X coordinate of a point on the symmetry axis. (Real; Default = 0.0)
Y	Y coordinate of a point on the symmetry axis. (Real; Default = 0.0)
Z	Z coordinate of a point on the symmetry axis. (Real; Default = 0.0)
ANG	Cyclic angle in degrees. (Real; no Default)
TOL	Cyclic symmetry tolerance. (Real; Default = 0.5 times the minimum element size)
IRB	Rigid body mode suppression flag. (Integer; Default = -1)
	-1 Automatically suppress rigid body mode.
	0 Do not suppress the rigid body mode.
	N Suppress rigid body mode at grid point N. (N > 0)
LinFlag	Linearization flag to be used if a cyclic symmetric structure consists of quadratic elements. (Integer; Default = 1)

Describer	Meaning
1	The outer boundary of the structure is described based on the corner nodes only. Multipoint constraints due to cyclic symmetry are not assigned to midside nodes. Instead, they are linearly tied to the corresponding corner nodes.
-1	The outer boundary of the structure is described using a quadratic field. Due to cyclic symmetry, full quadratic multipoint constraints are set up; they are assigned both to corner and midside nodes.

Remarks:

1. A full and “pie-shaped” structure to be analyzed using nonlinear cyclic symmetry shown below:

Looking at points and on this segment, the displacement vectors should fulfill:

$$u'_B = u_A$$

which can also be written as:

$$u_B = Ru_A$$

where the transformation matrix R depends on the symmetry axis (which, in the example above, coincides with the global Z-axis) and the sector angle. The input for the nonlinear cyclic symmetry option consists of the direction vector of the symmetry axis, a point on the symmetry axis and the sector angle. The following items should be noted:

- a. The meshes do not need to line up on both sides of a sector (for example, see the following figure)

- b. Any shape of the sector sides is allowed provided that upon rotating the sector  $360/\alpha$  times about the symmetry axis over the sector angle will result in the complete model.
- c. The nonlinear cyclic symmetry option can be combined with standard contact. In this case, both sides of the cyclic symmetry sectors need to belong to the same contact body.
- d. The nonlinear cyclic symmetry option can be combined with global remeshing (not currently available).
- e. In a coupled thermo-mechanical analysis, the temperature is forced to be cyclic symmetric (TA=TB) (not currently available).
- f. A nodal point on the symmetry axis is automatically constrained in the plane perpendicular to the symmetry axis.
- g. Possible rigid body motion about the symmetry axis can be automatically suppressed.
- h. Cyclic Symmetry is valid for:
  - Primarily for continuum elements. However, the presence of beams and shells is allowed, but there is not connection of shells to shells across the symmetry plane, so the shell part can, for example, be a turbine blade and the volume part is a turbine rotor. The blade is connected to the rotor and if there are 20 blades, 1/20 of the rotor is modeled plus one complete blade.
  - Nonlinear static analysis including remeshing as well as coupled analysis
  - Valid for all analysis involving contact
  - Valid also for: eigenvalue analysis such as buckling or modal extraction, and linear transient dynamic analysis.
  - Cyclic Symmetry is invalid for pure heat transfer.
  - The contact status can be viewed. Grids tied across the symmetry plane will have a value of 2.

To prevent confusion, it must be emphasized that the cyclic symmetry feature described above is different than linear cyclic symmetry commonly used in modal analysis where physical quantities such as  $x_n$ , displacements, forces, stresses and temperature in the n-th segment are expanded in a Fourier

series with terms of the cyclic components,  $u^k$ , in the fundamental region, like:

$$x_n = \frac{1}{N}u^0 + \sqrt{\frac{2}{N}} \sum_{k=1}^K [u^{k,c} \cos(n-1)k\alpha + u^{k,s} \sin(n-1)k\alpha] + \frac{(-1)^{n-1}}{\sqrt{N}}u^{N/2}$$

where  $k$  is the harmonic order;  $N$  is the total number of sectors;  $\alpha$  is the fundamental inter-sector phase shift defined as  $2\pi/N$ ; and  $K$  is defined as:

$$K = \begin{cases} \frac{N-1}{2} & \text{if } N \text{ is odd} \\ \frac{N-2}{2} & \text{if } N \text{ is even} \end{cases}$$

There are considerable savings in both computing time and data storage associated with the use of the linear cyclic symmetry concept. Assuming a finite element model with a sector size of  $m$  degrees of freedom, a real-valued cyclic symmetry approach leads, in the worst case, to one eigenvalue problem of size  $m$  and  $(N-1)/2$  eigenvalue problems of size  $2m$ . A complex approach leads to  $N$  eigenvalue problems of size  $m$ ; while the full analysis leads to a single, but very costly, eigenvalue problem of size  $Nm$ .

Although linear cyclic symmetry can reduce the problem size greatly, it is restricted to linear analysis, and the sector must have its surface mesh on the symmetry planes to be identical on each side of the sector. The nonlinear cyclic symmetry implemented in SOL 600 can be used for nonlinear problems, such as contact, and the nodes do not need to line up on both symmetry planes of the sector.

## NLDAMP

## Damping Constants - SOL 600

Defines damping constants for nonlinear analysis when Marc is executed from SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
NLDAMP	EID1	EID2	ALPHA	BETA	GAMMA				

Examples:

NLDAMP	1	2000	.025	4.5	1.0				
--------	---	------	------	-----	-----	--	--	--	--

Describer	Meaning
EID1	First element for which the damping values will be used. (Integer $\geq 0$ ; Required)
EID2	Last element for which the damping values will be used. (Integer $\geq 0$ or blank)
ALPHA	Mass Matrix Multiplier. (Real; Default = 0.0)
BETA	Stiffness Matrix Multiplier. (Real; Default = 0.0)
GAMMA	Numerical Damping Multiplier. (Real; Default = 0.0)

Remarks:

1. This entry matches Marc's Damping definition.
2. NLDAMP is recognized only when Marc is executed from SOL 600.

## NLFREQ Frequency List for Nonlinear Harmonic Response

Defines explicit forcing frequencies for nonlinear harmonic response.

Format:

1	2	3	4	5	6	7	8	9	10
NLFREQ	ID	F1	F2	F3	F4	F5	F6	F7	
	F8	F9	-etc.-						

Examples:

NLFREQ	17	3.	7.	21.	14.				
--------	----	----	----	-----	-----	--	--	--	--

Describer	Meaning
ID	Identification number referenced by the NLFREQ field (field 5) of an NLHARM Bulk Data entry. (Integer > 0)
F1...Fn	Forcing frequency values in cycles per unit time. (Real $\geq$ 0.0)

Remarks:

1. The frequencies may be specified in any order; they do not have to be in ascending or descending order.
2. Only one NLFREQ or NLFREQ1 entry with the same ID is allowed.

## NLFREQ1 Frequency List for Nonlinear Harmonic Response, Alternate Form 1

Defines a set of forcing frequencies for nonlinear harmonic response by specification of a starting frequency, frequency increment, and the number of increments/decrements desired.

Format:

1	2	3	4	5	6	7	8	9	10
NLFREQ1	ID	F1	DF	NDF					

Examples:

NLFREQ1	17	3.	2.	6					
---------	----	----	----	---	--	--	--	--	--

Descriptor	Meaning
ID	Identification number referenced by the NLFREQ field (field 5) of an NLHARM Bulk Data entry. (Integer > 0).
F1	First forcing frequency in the set. (Real $\geq$ 0.0)
DF	Frequency increment. See Remark 1. (Real $\neq$ 0.0; Required)
NDF	Number of frequency increments/decrements. (Integer > 0; Default = 1)

Remarks:

1. If DF is positive, it defines a frequency increment. In this case, the first excitation frequency will be F1 with all subsequent excitation frequencies being of larger value than F1. If DF is negative, it defines a frequency decrement. In this case, the first excitation frequency will still be F1, but now all subsequent excitation frequencies will be of smaller value than F1. In both cases, the initial conditions for a frequency are the response configuration at the previous excitation frequency. The initial conditions for the first frequency are zero.
2. Only one NLFREQ or NLFREQ1 entry with the same ID is allowed.

## NLHARM Parameters for Nonlinear Harmonic Response Control

Defines parameters for nonlinear harmonic response analysis.

Format:

1	2	3	4	5	6	7	8	9	10
NLHARM	ID	SUBFAC	NHARM	NLFREQ					

Examples:

NLHARM	41		3	15					
--------	----	--	---	----	--	--	--	--	--

Describer	Meaning
ID	Identification number referenced by the NLHARM Case Control command. (Integer > 0)
SUBFAC	Factor for capturing sub-harmonic response. See Remark 3. (Integer ≥ 1; Default = 1)
NHARM	The number of harmonics to include in the solution. See Remark 2. (Integer > 0)
NLFREQ	Identification number of the NLFREQ or NLFREQ1 entry specifying the forcing frequency list. (Integer > 0)

Remarks:

1. The NLHARM ID must be unique among all NLHARM entries.
2. The greater the degree of nonlinearity, the larger the number of harmonics required to find a solution (if one exists). The number of harmonics (NHARM) used may influence the ability of the algorithm to find solutions to the nonlinear problem posed. However, the larger the number of harmonics, the more computational effort is required to find a solution.
3. The response frequencies in linear harmonic analysis are the same as the forcing frequency. Permanent oscillations whose frequencies are a fraction of the forcing frequency ( $\frac{1}{2}$ ,  $\frac{1}{4}$ , ...) may occur in a nonlinear system; these oscillations are known as sub-harmonic response.

**NLHEATC** Defines Numerical Analysis Parameters for SOL 600 Heat Transfer Analysis

Format:

1	2	3	4	5	6	7	8	9	10
NLHEATC	ID	MLS	MRC	MMIN	NPOS	IASMB			
	TCHG	TEVAL	TERR						

Examples:

NLHEATC		9999	10	1	1	1			
	10.	999999.	20.						

Describer	Meaning
ID	Not presently used, leave blank.
MLS	Maximum number of load steps in the run. (Integer; Default = 4). [2,1]
MRC	Maximum number of recycles during an increment due to temperature dependent material properties. (Integer; Default = 3) [2,2]
MMIN	Minimum number of recycles during an increment. This value is forced even if convergence appears to occur in a fewer number of cycles. (Integer; Default = 1) [2,3]
NPOS	Nonpositive definite flag. (Integer; Default = 0) [2,7]
	0 Solution of nonpositive definite matrices will fail.
	1 Solution of nonpositive definite matrices is forced (computer time is greater if nonpositive matrices do not exist)
IASMB	Flag to assemble conductivity matrix. (Integer; Default = 0) [2,12]
	0 Conductivity matrix is not assembled each iteration
	1 Conductivity matrix is assembled each iteration
TCHG	Maximum nodal temperature change allowed. (Real; Default = 20.0) [3,1]
TEVAL	Maximum temperature change before properties are re-evaluated and matrices reassembled. (Real; Default = 100.0) [3,2]
TERR	Maximum error in temperature estimate used for property evaluation. It provides a recycling capability to improve accuracy for highly nonlinear heat transfer such as latent heat and radiation. (Real; Default = 0.0) [3,3]

Remarks:

1. Only one NLHEATC entry should be entered.
2. This entry maps to Marc's CONTROL history definition entry for heat transfer. [i,j] indicates the datablack and field of this Marc entry.

## NLMOPTS

## Nonlinear Multiple Options

Specifies nonlinear material options and composite options. The nonlinear material options are for advanced materials used in SOL400. The composite options (TSHEAR and INLAM, CPROJ) are applicable to all solution sequences in which Layered Solid Elements (PCOMPLS) are available, namely, SOL600, SOL400, SOL200 (analysis only), and all linear solution sequences between SOL101 and SOL112.

Format:

1	2	3	4	5	6	7	8	9	10
NLMOPTS	"CREEP"	valc1	valc2	valc3	valc4				
	"ASSM"	vala							
	"TSHEAR"	vals							
	"LRGSTRN"	valle							
	"HEMICUBE"	VALUE	NPIXEL		CUTOFF	FRACTION	FACCNT	FACTOL	
	"TEMPP"	valtd							
	"TEMGO"	vmaptg							
	"SPROPMAP"	PROPMAP	PROPBEH	DIRECT	THICKOP	IPRINT			
	"SPCRMPT"	vramp							
	"DEACTEL"	vald1	vald2						
	"ENTHALP"	valclu	valen1						
	"MAPTOL"	vmptol							
	"INLAM"	vcoord	cproj						

Examples:

NLMOPTS	CREEP	0							
	HEMICUBE	1	500		0	0.01			

Describer	Meaning
"CREEP"	<p>Keyword that indicates that creep is possible during one or more steps in the job. It also indicates the formulation for creep analysis. It should be noted that this keyword is only valid for elements with extended property extensions (PSLDN1, PSHLN1, etc.). (Character Default CREEP). Creep data should be entered using MATVP, not the CREEP bulk data entry.</p>
	<p>There are 2 kinds of creep models</p>
	<p>(a) Explicit Creep - ValC1 and ValC2 are used for this.</p>
valc1	<p>0 : Maxwell Model Creep (default) 1 : Explicit Viscoplastic Creep (only supported via user subroutine CRPLAW)</p>
valc2	<p>(Blank or 0) : (Default) 1: (Reserved)</p>
	<p>(b) Implicit Creep - ValC3 and ValC4 are used for this.</p>
valc3	<p>0 : Implicit Creep off 1 : Implicit Creep on</p>
valc4	<p>(Blank or 0) : elastic tangent (Default) 1: secant tangent 2: radial return</p>
	<p>Note that:</p>
	<p>(1) ValC3 = 0 means Explicit Creep (see ValC1). ValC3 = 1 means Implicit Creep.</p>
	<p>(2) ValC4 is only used in conjunction with Valc3=1. The recommended value for ValC4 is 1 (secant tangent).</p>
	<p>The CREEP option on NLMOPTS is generally used in conjunction with the following bulk data entries - the user can refer to each of the bulk data entries identified below for more information.</p>
NLSTEP	<p>The "CREEP" field on this entry indicates that creep is active for the particular step using the NLSTEP card. Note that the permanent creep flag through the NLMOPTS,CREEP keyword should be turned on along with the NLSTEP,CREEP keyword.</p>
MATVP	<p>The material data for creep are entered through this card. It should be noted that the data through MATVP is only for elements with extended property extensions. For elements without extended property extensions, material data for creep should be specified through the CREEP entry.</p>
MATEP	<p>Optional data for plasticity in combination with implicit or explicit creep is specified through this entry.</p>

Describer	Meaning
“ASSM”	Keyword indicating that the item following applies to assumed strain. See Remark 3. (Character; Default = See Remark 3.)
vala	ASSUME for assumed strain formulation D OFF for no assumed strain formulation.
“TSHEAR”	Keyword indicating that the item following applies to a parabolic shear distribution through the shell thickness (or ply thickness). See Remark 4.
vals	TSHEAR for parabolic distribution. (Character; Default = blank)
“LRGSTRN”	Keyword indicating that the item following applies to a formulation for large strain. (Default; Integer = 0)
valle	-1 No large strain formulation. 0 Mean normal return. 1 Hypoelasticity and additive plasticity with mean normal return. 2 Hyperelasticity and multiplicative plasticity with radial return.
“HEMICUBE”	Keyword to select the view factor calculation method. See Remarks 2. and 7.
	Field 3 VALUE=0 - Use Nastran finite difference, contour integration, or Gaussian integration method (Default). =1 - (HEMI) Use pixel based modified hemicube method. This method is not available for axisymmetric view factor calculations.
	Field 4 NPIXEL - Enter the number of pixels (Default = 500).
	Field 6 CUTOFF - Enter the fraction of the maximum view factor that is to be used as a cutoff. View factors calculated below this cutoff are ignored (Default = 0).
	Field 7 FRACTION - Enter the fraction of the maximum view factors that is to be treated implicitly. View factors values smaller than this cutoff are treated explicitly (Default = 1.0E-2).
	Field 8 FACCNT - Set 1 to activate explicit treatment of reflection matrix. Default = 0)
	Field 9 FACTOL - Tolerance to be used on the above iteration on the Poljak equations.
“TEMPP”	Keyword indicating temperature distribution across the thickness of advanced heat shell elements. Internal invisible scalar points will be created to store these extra variables. LINE and QUAD options require shell elements to have full 3-D thermal material data. When the temperature results of these internal points are applied to calculating thermal loading effect in a separate mechanical analysis, this keyword must also be specified in the structural model (See Remarks 12. ,13. and 14.).
valtd	CONS Constant distribution. (Default)

Describer	Meaning
	LINE      Linear distribution. (Character)
	QUAD      Quadratic distribution.
“TEMGO”	Keyword indicating user request identified in .f06 file, the mapping of user supplied and internally generated grids for the linear and quadratic thermal shell elements. See Remark 8.
vmaptg	NO          Do not show grid mapping. (Character; Default)
	YES          Show mapping.
“SPROPMAP”	Keyword controlling automated inclusion of nonlinear property options for SOL 400. See Remark 9.
PROPMAP	(Integer $\geq -1$ and $\leq 3$ ; Default 0)
	-1          No mapping considered
	0          Map to full integration elements associated with nonlinear property extension entries when necessary
	1          Map to reduced integration elements associated with nonlinear property extension entries when necessary
	2          Map to full integration elements associated with nonlinear property extension entries when possible
	3          Map to reduced integration elements associated with nonlinear property extension entries when possible
	<b>Note:</b> The nonlinear property extension entries refer to: PBARN1, PBEMN1, PRODN1, PSHEARN, PSHLN1, PSHLN2 and PSLDN1 entries. To ensure that the automatic mapping is unique for an element ID, whenever advanced elements are detected / specified by the user, ELTPRT will be automatically called.
PROPBEH	Property behavior flag. Valid values are 1D, 3D, PLST, PSTR, AXI. (Default = None for 1D, 3D. PLST for 2D; Character)
DIRECT	Layer direction flag. Valid values; 1, 2, 3. (Integer > 0; Default 1)
THICKOP	For 2D solids: out of plane thickness. (Real $\geq 0.0$ ; Default 1.0)
IPRINT	Print flag for generated property flags.
	0          Blank (Default)
	1          Print
	2          Punch
	3          Print and Punch
“SPCRMPT”	Keyword indicating heat transfer SPC is to be applied instantaneously or by linear step. (Character Default SPCRMPT)
vramp	0          SPC applied instantaneously. (Integer or blank; Default = blank)
	1          SPC applied by linear step.

Describer	Meaning
“DEACTEL”	Keyword controlling default behavior and output diagnostics for element deactivation
vald1	Select default deactivation rules for each physics pass in the analysis. See Remark 10. -1 Default deactivation rules are always ignored. (Default in single physics analysis) 0 Default deactivation rules are always applied. (Default in coupled analysis) 1 Default deactivation rules are applied in a mechanical pass only. 2 Default deactivation rules are applied in a thermal pass only.
vald2	Select diagnostic output behavior for active and deactivated elements. 0 A summary of all deactivated elements is printed. If no elements get deactivated output is skipped. (Default) 1 A detailed list of all deactivated elements is printed. If no elements get deactivated output is skipped. 2 A summary of all deactivated and all remaining active elements is printed. 3 A detailed list of all deactivated and all remaining active elements is printed.
“ENTHALP”	Keyword controlling the scheme used to form the capacitance matrix and the enthalpy vector for elements with nonlinear property extensions in transient heat transfer. See Remark 10.
valclu	Select option to form copacitance matrix for elements with nonlinear property extensions. 0 Use same scheme as that for linear elements without property extensions 1 Use consistent capacitance matrix 2 Use coupled capacitance matrix 3 Use lumped capacitance matrix
valen1	Select option to form enthalpy vector for elements with nonlinear property extensions 0 Form enthalpy using automatic scheme. (Default) 1 Form enthalpy explicitly through time integration for material behavior 2 Form enthalpy via multiplication of temperature with capacitance
“MAPTOL”	Keyword controlling the tolerance used to check if a structural node lies inside a thermal element.
vmptol	Value of MAPTOL. (Real > 0.0; Default = 0.2)
INLAM	(Character; Default Blank)
vcoord	Selects coordinate system for interlaminar stress output. Blank Using the original coordinate system for interlaminar stress output

Describer	Meaning
cproj	BOTT      Using the ply coordinate system of bottom layer of the interlaminare
	TOP        Using the ply coordinate system of above layer of the interlaminare
	Activates projection system for projecting X-axis of CORDM onto layer plane. See remark 5.
	OFF        Does not project (Default).
	ON         Projection scheme is activated.

Remarks:

1. The keyword entries may occur in any order or not at all. If a keyword entry is missing, its defaults are assumed.
2. The material and property related keywords associated with the entry (CREEP, ASSM, TSHEAR, LRGSTRN, TEMPP and ENTHALP) are only applicable to elements associated with PAXISYM, PBARN1, PBEMN1, PRODN1, PSHLN1, PSHLN2, PSLDN1, PLCOMP, PCOMPLS, and PCOHE entries. Other keywords (SPCRMPT, HEMICUBE, DEACTEL, MAPTOL) are more generally applicable. Keyword SPCRMPT applies to all SPC temperature boundary conditions, HEMICUBE applies to radiation boundary conditions and DEACTEL applies to all elements on the job.
3. The setting of ASSUMED STRAIN in SOL 400 is automatic for the following three elements with some conditions.
  - a. 4 nodes full integration Plane Stress (PLPLANE + PSHLN2 with PSTRS -- BEH4=PSTRS, INT4=L);
  - b. 4 nodes full integration Plane Strain (PLPLANE + PSHLN2 with PSTRN -- BEH4=PLSTRN, INT4=L); and
  - c. 8 nodes full integration HEXA (PSOLID + PSLDN1 -- BEH8=SOLID, INT8=L,)

The application conditions are summarized here.

OFF                      Assumed strain always turned off.

- ASSUMED      Assumed strain will be turned on manually for 3 element types (PSTRS, PSTRN, PSLDN1) under the following cases:
- a. Elastic / Elasto-Plastic materials using small strain formulation (i.e., PARAM,LGDISP,-1 / NLMOPTS,LRGSTRN,-1). This includes isotropic and non-isotropic materials.
  - b. Elastic / Elasto-Plastic materials using large strain additive formulation (i.e., PARAM,LGDISP,1 / NLMOPTS,LRGSTRN,0 or 1). This includes isotropic and non-isotropic materials.

Assumed strain flag will be turned off for all materials using the Multiplicative Formulation (NLMOPTS,LRGSTRN,2).

- Default      Assumed Strain will be turned on automatically for 3 element types (PSTRS, PSTRN, PSLDN1) under the following cases:
- a. Isotropic Elastic materials using small strain formulation (i.e., PARAM,LGDISP,-1 / NLMOPTS,LRGSTRN,-1)
  - b. Isotropic Elastic materials using large strain additive formulation (i.e., PARAM,LGDISP,1 / NLMOPTS,LRGSTRN,0 or 1)

Note that this turns on Total Lagrange Formulation currently by default for the isotropic elastic materials.

Assumed Strain will be turned off automatically for the following cases:

- a. Any material that uses Updated Lagrange in either Additive or Multiplicative Formulation
  - b. Any non-isotropic material
4. TSHEAR allows a parabolic shear distribution for the BEH4=DCT, INT4=L or LRIH (shell) elements, and BEH8 or BEH20=SLCOMP, INTi=L, Q (Layered Solid) or ASTN (Layered Solid Shell) elements.

5. In Figure 9-102, plane ABCD is the layer plane of interest.  $Z_m$  is normal to the layer plane (or is the thickness direction).  $X_m$  is the projection of the X axis of the MCID coordinate system on the layer plane.  $Z_m \times X_m$  gives the  $Y_m$ . Angle  $\theta$  is measured counter-clockwise from  $X_m$  axis about the  $Z_m$  axis.

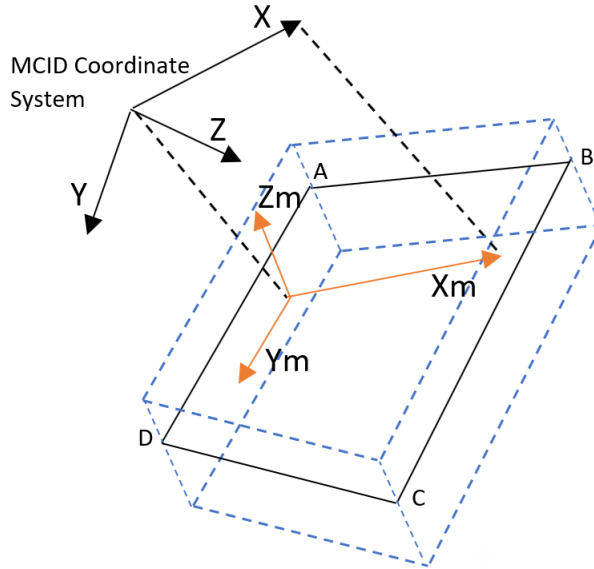

Figure 9-102 Projection Scheme

6. NLMOPTS,LRGS,valle can be used separately or in conjunction with the PARAM,LGDISP option. Two separate cases can be identified:
- Only NLMOPTS,LRGS specified. In this case, valle = -1 and valle = 0 mean the same, i.e., no large strain flags are turned on for the applicable elements identified in remark 2. Valle = 1 flags the additive framework and valle = 2 flags the multiplicative framework.
  - Both NLMOPTS,LRGS and PARAM,LGDISP,N ( $N > -1$ ) specified. In this case, valle = -1 supercedes the PARAM,LGDISP option and turns off all large displacement / large strain flags for the applicable elements identified in remark 2. Also, valle = 0 behaves the same way as valle = 1 (i.e., for the applicable elements, both options flag the additive framework).
7. Definition of the radiation exchange matrix as in the *MSC Nastran Thermal User's Guide*, Eq. 0-15.

$$R = \sigma[A\varepsilon - A\alpha(A - F(I - \alpha))^{-1}F\varepsilon]$$

in which the reflection matrix is:

$$[A - F(I - \alpha)]^{-1}$$

Note that the reflection term is costly, since it involves the factorization of a dense matrix.

For the SOL 400 Newton’s method, the previous exchange matrix multiplied by a function of the temperature is added to the stiffness. If the exchange matrix is dense, which is generally the case, the sparse stiffness matrix consequently also becomes dense, and the factorization of the stiffness matrix becomes much more expensive.

The input options are as follows. All options with the exception of the “faccnt” option, are available in SOLs 153, 159, and 400. The “faccnt” option is only available in SOL 400:

hemi, value, npixel, cutoff, fraction, faccnt, factol

where

- value            1 to flag hemicube method. Default is 0. The following options are available only if value = 1.
- npixel           Number of pixels per quarter section, where total number of pixels =  $(2 \cdot \text{npixel})^2$ . Default is 500.
- cutoff            Factor below which viewfactors will be set to zero. This one is applied during the last viewfactor calculation. It results in a less dense exchange matrix and therefore a faster calculation of the reflection term and of the stiffness matrix factorization. Default is 0.0.
- fraction        Factor below which radiation exchange matrix terms are not added to the stiffness matrix. For each equation in the radiation exchange matrix, the fraction is multiplied by the diagonal term, and all terms in the equation less than this value is not added to the stiffness matrix. This procedure does not affect the density of the radiation exchange matrix or the cost of calculating it, including the reflection term, but reduces the density of the stiffness matrix and the cost of factorizing the stiffness matrix. Note that the full radiation exchange matrix still is used to calculate fluxes. Default is 0.01.
- faccnt           Set to 1 to activate explicit treatment of reflection matrix. Default is 0. In this procedure, the radiation exchange matrix is constructed to be:  

$$R = \sigma[A\varepsilon - A\alpha F\varepsilon]$$

Note that the expensive reflection term is absent. This reduced form of the radiation exchange matrix is added to the stiffness matrix. Since the reflection matrix never is calculated and factorized, the calculation of the radiation exchange matrix is significantly cheaper. Since this reduced radiation exchange matrix is less dense, the factorization of the stiffness matrix also is significantly faster.

For the flux calculation, an iterative procedure is used based on iterating towards a solution simultaneously satisfying both Poljak equations in the *MSC Nastran Thermal User’s Guide*, Eqs. 6-11 and 6-12, respectively.

$$A\{q\}_e^{\text{IN}} = [F]\{q\}_e^{\text{OUT}}$$

$$\{q\}_e^{\text{OUT}} = \sigma[\varepsilon]\{u_e\}^4 + [I - \varepsilon]\{q\}_e^{\text{IN}}$$

The value of “facnt” also can be set to the maximum allowable number of iterations to be used in this procedure. If the value is set to 1, the maximum allowable number is internally set to 100. This procedure currently is available only in SOL 400 and is not available for wavelength-dependent emissivities.

The “cutoff” and “fraction” parameters can be specified concurrently with this option.

factol tolerance to be used on the previous iterative procedure on the Poljak equations.

8. TEMGO,YES results in the following type of print.

USER GRID POINT(TOP) MAPPING TO BOT/MID INTERNAL GRID										
TOP	1	2	3	4	5	6	7	8	9	10
BOT	101000001	101000002	101000003	101000004	101000005	101000006	101000007	101000008	101000009	101000010
MID	0	0	0	0	0	0	0	0	0	0
...										

9. The “SPROPMAP” keyword provides a convenient option to automatically flag secondary properties like PBARN1, PBEMN1, PRODN1, PSHEARN, PSHLN1, PSHLN2, and PSLDN1. Note that these secondary property entries expose the user to a set of sophisticated 2-D continuum and 3-D beam, shell and continuum elements in SOL 400. The rules governing the generation of the additional properties are many and are a function of the problem dimension, material type, and procedure. All these rules have been incorporated into the automatic generation option. These are briefly summarized in the table below for the default SPROPMAP = 0 case:

Secondary Property	Primary Property	Dimension	Material	Notes	Unsupported Features of Primary Entry
PBARN1	PBARL	1-D	MAT4	Note 4	Tapered Sections
			MATS1	Note 1	
			MATEP		
			MATF		
			MATSMA	Note 2	
			MATVE		
			MATVP	Note 3	
PBEMN1	PBEAML	1-D	MAT4	Note 4	
			MATS1	Note 1	
			MATEP		
			MATF		
			MATSMA	Note 2	
			MATVE		
			MATVP	Note 3	

Secondary Property	Primary Property	Dimension	Material	Notes	Unsupported Features of Primary Entry
PRODN1	PROD	1-D	MAT4	Note 4	J,C

			MATEP		
			MATF		
			MATORT		
			MATSMA		
			MATVE		
MATVP					

Note:	1.	Only when NLMOPTS, LRGSTRN, 1 is flagged or HGENPLAS is provided NLSTEP entry for coupled analysis.
	2.	For shape memory materials, define through MATSMA only the thermo-mechanical model is available.
	3.	For creep, define through MATVP, VALC=0 must be set on NLMOPTS for explicit formulation.
	4.	Only when phase changes are flagged.
	5.	Gasket materials for BEH4=COMPS or AXCOMP,INT4=L.
	6.	For shape memory materials, define through MATSMA and BEH=PLSTRS only the thermo-mechanical model is available.
	7.	For creep, define through MATVP and BEH=PLSTRS VALC=0 must be set on NLMOPTS for explicit formulation.
	8.	The "SPROPMAP" does not support MATDIGI.

In the previous table, the Secondary Property (Column 1) is automatically flagged depending on the Primary Property (Column 2) and the Primary/Secondary Materials (Column 4). The Comments column (Column 5) indicates any special conditions that are followed by the program while doing this mapping. The Unsupported Features column (Column 6) indicates the list of options on the Primary Property entry that are not supported by the Secondary Property.

It should be noted that the Secondary Property additions offer a wide range of element formulations that primarily cater to nonlinear extension but can also serve for linear applications. By default, the PROPMAP field is set to 0 and maps to the full integration elements of the secondary property only if necessary. For a less memory intensive element, the PROPMAP field can be manually set to 1 and this then maps to the equivalent reduced integration element of the secondary property only if available and necessary. PROPMAP field can be manually set to 2 or 3 when secondary properties need to be tagged to all elements in the model. In this case, the special conditions given in the 5th column above are ignored and the mapping is carried out for both linear and nonlinear materials (if allowed). PROPMAP = 2 maps to full integration elements whenever possible and PROPMAP = 3 maps to reduced integration elements whenever possible.

- a. Property mapping is considered for all possible elements (i.e., PROPMAP = 0/1 is automatically converted to PROPMAP = 2/3) for the following conditions:
  - When IDAMP (damping scheme specified through the NLSTEP entry) > 0 is used for static analysis. Note that the damping scheme is only available for elements with nonlinear property extensions.
  - When CRITID (user criteria specified through the NLSTEP entry) and the associated TABSCTL entry refer to displacement / stress / strain criteria for all elements in the model. Note that the user criteria are only supported for elements with nonlinear property extensions.

- When a small displacement analysis is flagged for thermo-mechanical coupled analysis specified through SUBSTEP or for real-time thermo-mechanical chained analysis specified through TEMP(Load,HSub,HStep,HTime). Note that for real-time temperatures to be transferred from the heat pass to the structural pass, all elements need to be processed in the nonlinear program flow and this is accomplished by flagging all possible elements with nonlinear property extensions.
- b. Property mapping is provided for elements that are associated with special procedures / flags:
- Elements whose grids are specified on the VCCT Bulk Data entry. VCCT is only supported for grids of elements with nonlinear property extensions.
  - Elements that are specified on the IPSTRN / ISTRESS commands. These are only supported for elements with nonlinear property extensions.
  - Elements that are specified on the BOLT1 entry. BOLT1 is only supported for elements with nonlinear property extensions.

It should be noted also that while the NLMOPTS,SPROPMAP option is powerful and allows a user-friendly way to map to advanced elements, it does not provide a substitute for all cases. Defaults are provided for the most common cases on the NLMOPTS,SPROPMAP entry itself. This includes PROPBEH - especially useful to distinguish between plane strain and plane stress, DIRECT - the layer thickness direction for gaskets, THICKOP - the out-of-plane thickness for the planar case. It should be noted that these defaults are global defaults and apply to all the elements for which the secondary properties are added. If such defaults are not applicable (for e.g., different out-of-plane thicknesses), it is the user's responsibility to add individual secondary property entries. No mapping to advanced nonlinear elements takes place for PSHELL entries with MID greater than 100,000,000 to avoid conflicts with internally generated material IDs.

IPRINT can be used to get additional information on the secondary properties that have been added. Default is 0 in which case, there is no print-out. IPRINT = 1 allows the print-out in the .f06 file, IPRINT = 2 allows the print-out in the .pch file, IPRINT = 3 allows print-out in both the .f06 and .pch files.

Example 1: 8 noded CHEXA, PSOLID, MAT1	
SPROPMAP	Added Secondary Property
-1	No mapping considered
0	No mapping done - not necessary
1	No mapping done - not necessary
2	PSLDN1: C8, BEH8 = SOLID, INT8 = L, BEH8H = SOLID, INT8H = L
3	PSLDN1: C8, BEH8 = SOLID, INT8 = LRIH, BEH8H = SOLID, INT8H = LRIH

Example 2: 4 noded CQUAD4, PSHELL, MATF	
SPROP MAP	Added Secondary Property
-1	No mapping (note that MATF will not work in this case)
0	PSHLN1: C4, BEH4 = DCT, INT4 = L, BEH4H = DCT, INT4H = L
1	PSHLN1: C4, BEH4 = DCT, INT4 = LRIH, BEH4H = DCT, INT4H = L
2	PSHLN1: C8, BEH8 = DCT, INT4 = L, BEH4H = DCT, INT4H = L
3	PSHLN1: C4, BEH4 = DCT, INT4 = LRIH, BEH4H = DCT, INT4H = L

- The **vald1** value in “DEACTEL” determines in which physics pass the default deactivation rules are applied. If **vald1** is positive the deactivation rules are applied in the specified pass only and in all other passes the defaults are switched off, meaning that in those passes all elements remain active unless a DEACTEL Bulk Data input deactivates some of them.

The default deactivation rules are summarized in the following table:

Element Types	By Default Deactivated in Pass
Connector elements CWELD, CFAST, CSEAM	Thermal
Rigid body elements Rxxx	Thermal
CONMi and CMASSi elements	Thermal
Interface elements CIFxxx	Thermal
Surface elements CHBDYx	Mechanical
Heat convection elements CONVx	Mechanical
Radiation boundary elements RADBC	Mechanical
CDAMP4 elements originating from CMB or CMS fields in BCBODY input	Mechanical

The default for elements of all other types is that they are active in every pass.

- The “ENTHALP” keyword is applicable to elements associated with the nonlinear property extensions PRODN1, PSHEARN, PSHLN1, PSLDN1 and for axisymmetric heat transfer shells specified through PAXISYM. It provides different options to form the capacitance matrix and enthalpy vector for these elements through **valclu** and **valenl** respectively.

The **valclu** value allows the choice of 3 different capacitance formulations: consistent, coupled (average of consistent and lumped) and lumped. The default value of **valclu = 0** allows the nonlinear elements to follow the same scheme as that for linear elements; lumped for rods and 3D shells, coupled for axisymmetric shells and linear hexes, pentas, tetras and consistent for quadratic hexes, pentas and tetras. Values of **valclu > 0** allow the user to pick specific capacitance formulations for all elements.

The **valenl** value allows the user the choice of 2 different enthalpy vector formulations: time integration of the enthalpy at each integration point or product of the nodal temperature with the capacitance. The default value of **valenl = 0** allows the program to pick automatically: use the time integration option for nonlinear specific heat / latent heat, use the nodal product option for linear specific heat. Values of **valenl > 0** allow the user to pick the approach. Note that for nonlinear problems, the time integration approach is more accurate.

12. To compute the thermal loads of 3D thermal shells in a separate mechanical run, a consistent temperature distribution type must be specified in mechanical models, i.e. LINE must be defined if the thermal model has a linear temperature distribution using LINE, or QUAD must be specified for the thermal model with a quadratic temperature distribution defined by QUAD. If LINE or QUAD is specified, the program will switch the structural shell elements to advanced elements automatically by generating PSHLN1 entries internally if no PSHLN1 or PSHLN2 entries are specified in the original model.
13. MSC NASTRAN thermal analysis does not differentiate between top and bottom faces while applying loads or boundary conditions on shell, even though the top and bottom temperatures may be different through specifying TEMPP = LINE or QUAD.
14. TEMPP keyword is supported in coupled analysis or in separate runs of thermal and mechanical analyses. This keyword is not supported in chained thermal and mechanical analyses.

**NLOUT****Selects Additional Nonlinear Output Quantities as Referenced By NLSTRESS Case Control Command**

Selects additional nonlinear output quantities as referenced by NLSTRESS Case Control Command in SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
NLOUT	ID	AIO1	AIO2	AIO3	AIO4	AIO5	AIO6	AIO7	
	AIO8	AIO9	etc.						
	ESV	SV2	SV3	etc.					

Example:

NLOUT	1	TOTTEMP							
-------	---	---------	--	--	--	--	--	--	--

NLOUT	1	TOTTEMP							
	ESV	SV2	SV3						

Describer	Meaning
ID	Identification number of a NLOUT entry. Selected by the NLOUT keyword on the NLSTRESS Case Control command. (Integer > 0)
AIO <sub>i</sub>	Additional Output request. See Remark 3. (Character)
ESV	Keyword indicating the following are user state variables, it is optional.
SV <sub>i</sub>	State variable names selected for output.

Remarks:

1. The keywords can appear in any order.
2. Any item selected that is inappropriate for the element will be ignored.
3. The request codes, meaningful only to elements who refer to PRODN1, PBARN1, PBEMN1, PSHLN1, PSHLN2, PSLDN1, PLCOMP, PCOMLS, or PCOHE entries, are as follows:

Additional Output Code Keywords	
Keyword	Description
CCASTRSS	Components of Cauchy Stress
CTOTSTRN	Components of Total Strain
CELASTRN	Components of Elastic Strain
CPLASTRN	Components of Plastic Strain

Additional Output Code Keywords	
Keyword	Description
CCRPSTRN	Components of Creep Strain
CTHMSTRN	Components of Thermal Strain
TSTRNPS	Thickness Strain for Plane Stress
MAJESTRN	Major Engineering Strain
MINESTRN	Minor Engineering Strain
CURVOL	Current Volume
ORGVOL	Original Volume
TOTTEMP	Total Temperature
INCTEMP	Incremental Temperature
EQVMSTRS	Equivalent von Mises Stress
EQSTRSA	Equivalent Stress/Yield Stress Ratio
EQELSTRN	Equivalent Elastic Strain
EQPLSTRN	Equivalent Plastic Strain
EQCRSTRN	Equivalent Creep Strain
TTSTRNED	Total Strain Energy Density
ELSTRNED	Elastic Strain Energy Density
PLSTRNED	Plastic Strain Energy Density
PLSTRNRT	Plastic Strain Rate
ILNMSTRS	Interlaminar Normal Stress. See Remark 5.
ILSHSTRS	Interlaminar Shear Stress. See Remark 5.
ILSHTKCX	X-component of the interlaminar shear stress for thick composite shells.
ILSHTKCY	Y-component of the interlaminar shear stress for thick composite shells
CSTRSCRD	Components of Stress Preferred System
GSKTCLST	Gasket Pressure
GSKTCLSR	Gasket Closure
PGSKTCLS	Plastic Gasket Closure
FAILINDX	Failure Index (%)
TOTVSV1	Total Value of First State Variable
TOTVSV2	Total Value of Second State Variable
TOTVSV3	Total Value of Third State Variable

Additional Output Code Keywords	
Keyword	Description
EQPHSTRN	Equivalent phase transformation strain
EQTWSTRN	Equivalent TWIN strain
EQTPSTRN	Equivalent TRIP strain 75
CPHSTRN	Phase transformation strain tensor
VOLFMART	Volume fraction of Martensite

- User state variable name following the ESV keyword can be the default nominal name or user defined name in UDSESV.
- ILNMSTRS and ILSHSTRS are stress tensors formed in the basic coordinate system, their principal directions are the directions of stress vector of interlaminar normal and shear stresses respectively.

More precisely, the tensor components  $\sigma_{ij}$  satisfy below equation:

$$(\sigma_{ij} - \delta_{ij}\sigma)n_j = 0$$

where;

$n_j$  is the stress vector direction,

$\sigma$  is the normal of stress vector, and

$\delta_{ij} = 0$  when  $i \neq j$  and  $\delta_{ij} = 1$  when  $i = j$ .

## NLOUTUD

### User Defined Output Requests For Nonlinear Explicit Analysis.

User defined output requests for elements or Lagrangian grid points. Use in SOL700 only.

Format:

1	2	3	4	5	6	7	8	9	10
NLOUTUD	NID	GROUP	UNAME	DTOUT	STEPS	OUTNAME			
+	EL1/G1	EL2/G2	Eli/Gli						

Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE myuds 'SCA.MDSolver.Obj.Uds.Dytran.InitOut '
```

*In Bulk Data:*

NLOUTUD	4	MYUDS	EEXOUT	0.01		OUTPUTR1			
+	1	2	3	4					

Field	Contents
NID	Unique output number. (Integer > 0; Required)
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default)
UNAME	Name User subroutine name associated with the entry. (Character; default=EEXOUT)  EEXOUT: Output for elements  GEXOUT: Output for Lagrangian grid points
DTOUT	Output time interval. (Real > 0.0; default=blank)
STEPS	Output step interval. (Integer > 0; default=blank)
OUTNAME	Name for output request. (Character; required.)
Eli	Element id for user output. (Integer > 0; required)
Gi	Grid point id for user output. (Integer > 0; required)

Remarks:

1. Only can be used for SOL 700.
2. UNAME can be EEXOUT or GEXOUT.
3. Only one of DTOUT and STEPS is available.

4. When UNAME is set to EEXOUT, element id's are required for user output and when UNAME is set to GEXOUT, grid point id's are required for user output.
5. The file names that will be generated are:  
`{jobname}_{OUTNAME}_{cycle number}.[THS,ARC]`

## NLPARM

## Parameters for Nonlinear Static Analysis Control

Defines a set of parameters for nonlinear static analysis iteration strategy. NLSTEP is the preferred option for SOL 400.

Format:

1	2	3	4	5	6	7	8	9	10
NLPARM	ID	NINC	DT	KMETHOD	KSTEP	MAXITER	CONV	INTOUT	
	EPSU	EPSP	EPSW	MAXDIV	MAXQN	MAXLS	FSTRESS	LSTOL	
	MAXBIS				MAXR		RTOLB	MINITER	

Example:

NLPARM	15	5		ITER					
--------	----	---	--	------	--	--	--	--	--

Describer	Meaning
ID	Identification number. (Integer > 0)
NINC	Number of increments. See Remark 16. (Integer > 0)
DT	Incremental time interval for creep analysis. See Remark 3. (Real $\geq$ 0.0; Default = 0.0 for no creep.)
KMETHOD	Method for controlling stiffness updates. See Remark 4. (Character = "AUTO", "ITER", "SEMI", "FNT", or "PFNT"; Default = "AUTO" for SOL 106, "AUTO" for SOL 400 with non-contact analysis, and "FNT" for SOL 400 with contact analysis.)
KSTEP	Number of iterations before the stiffness update for ITER method. See Remarks 5. For the FNT and PFNT usage of KSTEP, please see Remark 19. (Integer $\geq$ -1; Default = 5 for SOL 106 and 10 for SOL 400)
MAXITER	Limit on number of iterations for each load increment. See Remark 6. (Integer $\neq$ 0; Default = 25)
CONV	Flags to select convergence criteria. See Remarks 7., 21., and 22. (Character = "U", "P", "W", "V", "N", "A" or any combination; Default = "PW". (See Remark 4 for additional default comment.)
INTOUT	Intermediate output flag. See Remark 8. (Character = "YES", "NO", "ALL" or Integer > 0 for SOL 400 only; Default = NO)
EPSU	Error tolerance for displacement (U) criterion. See Remarks 4., 16., 17. and 20. (Real > 0.0; Default = 1.0E-2)
EPSP	Error tolerance for load (P) criterion. See Remarks 4., 16. and 17. (Real > 0.0; Default = 1.0E-2)
EPSW	Error tolerance for work (W) criterion. See Remarks 4., 16., 17. and 20. (Real > 0.0; Default = 1.0E-2)

Describer	Meaning
MAXDIV	Limit on probable divergence conditions per iteration before the solution is assumed to diverge. See Remark 9. (Integer $\neq$ 0; Default = 3)
MAXQN	Maximum number of quasi-Newton correction vectors to be saved on the database. See Remark 10. (Integer $\geq$ 0; Default = MAXITER for all methods except PFNT. For PFNT, Default = 0)
MAXLS	Maximum number of line searches allowed for each iteration. See Remark 11. (Integer $\geq$ 0; Default = 4 for all methods except PFNT. For PFNT, Default = 0)
FSTRESS	Fraction of effective stress ( $\bar{\sigma}$ ) used to limit the subincrement size in the material routines. See Remark 12. (0.0 < Real < 1.0; Default = 0.2)
LSTOL	Line search tolerance. See Remark 12. (0.01 < Real < 0.9; Default = 0.5)
MAXBIS	Maximum number of bisections allowed for each load increment. See Remark 13. (-10 $\leq$ MAXBIS $\leq$ 10; Default = 5 except for MAXITER < 0; Default = 0 if MAXITER < 0)
MAXR	Maximum ratio for the adjusted arc-length increment relative to the initial value. See Remark 14. (1.0 $\leq$ MAXR $\leq$ 40.0; Default = 20.0)
RTOLB	Maximum value of incremental rotation (in degrees) allowed per iteration to activate bisection. See Remark 15. (Real > 2.0; Default = 20.0)
MINITER	Minimum number of iterations for each increment, SOL 101 with contact and SOL 400 only. (Integer > 0; Default = 1; In contact analysis, Default = 2) When high accuracy is required, it is also recommended to set MINITER = 2.

Remarks:

1. The NLPARM entry is selected by the Case Control command NLPARM = ID. Each solution subcase requires an NLPARM command.
2. In cases of static analysis (DT = 0.0) using Newton methods, NINC is the number of equal subdivisions of the load change defined for the subcase. Applied loads, gravity loads, temperature sets, enforced displacements, etc., define the new loading conditions. The differences from the previous case are divided by NINC to define the incremental values. In cases of static analysis (DT = 0.0) using arc-length methods, NINC is used to determine the initial arc-length for the subcase, and the number of load subdivisions will not be equal to NINC. In cases of creep analysis (DT > 0.0), NINC is the number of time step increments.
3. For creep analysis, the unit of DT must be consistent with the unit used on the CREEP entry that defines the creep characteristics. Total creep time for the subcase or step is DT multiplied by the value in the field NINC; i.e., DT\*NINC. For SOL 400 with advanced nonlinear elements (elements with PSLDN1, PSHLN1, etc.) for creep analysis, if the total time does not equal 1.0, then the NLSTEP Bulk Data entry must be used. For SOL 600 DT is ignored except for creep analyses.

4. The stiffness update strategy is selected in the KMETHOD field.
  - If the AUTO option is selected, the program automatically selects the most efficient strategy based on convergence rates. At each step the number of iterations required to converge is estimated. Stiffness is updated, if (i) estimated number of iterations to converge exceeds MAXITER, (ii) estimated time required for convergence with current stiffness exceeds the estimated time required for convergence with updated stiffness, and (iii) solution diverges. See Remarks 9. and 13. for diverging solutions.
  - If the SEMI option is selected, the program for each load increment (i) performs a single iteration based upon the new load, (ii) updates the stiffness matrix, and (iii) resumes the normal AUTO option.
  - If the ITER option is selected, the program updates the stiffness matrix at every KSTEP iterations and on convergence if  $KSTEP \leq MAXITER$ . However, if  $KSTEP > MAXITER$ , stiffness matrix is never updated. Note that the modified Newton-Raphson iteration method is obtained by selecting the ITER option and  $KSTEP = MAXITER$ . The "U" convergence test is not used if ITER-1 is selected.
  - If the FNT option is selected, the program will use the full Newton iteration method for which the stiffness matrix will be updated at every iteration. FNT option is available for SOL 400 only. For SOL 106, please use "KMETHOD=ITER and KSTEP=1" instead. In comparison with the PFNT method, the defaults for FNT are EPSU=0.01, EPSW=0.01 and MAXLS=4. See Remark 19.
  - If the PFNT option is selected, the program will use the Pure Full Newton iteration method. The PFNT method is the same as the FNT method except that the defaults for PFNT method are internally set as EPSU=-0.01, EPSW=-0.01, and MAXLS=0. The PFNT method is available for SOL 400 only. See Remark 19.
5. For AUTO and SEMI options, the stiffness matrix is updated on convergence if KSTEP is less than the number of iterations that were required for convergence with the current stiffness.
6. The number of iterations for a load increment is limited to MAXITER. If the solution does not converge in MAXITER iterations, the load increment is bisected and the analysis is repeated. If the load increment cannot be bisected (i.e., MAXBIS is attained or MAXBIS = 0) and MAXDIV is positive, the best attainable solution is computed and the analysis is continued to the next load increment. One best solution is computed for SOL 106 and 4 best solutions are computed for SOL 400. The analysis is terminated if the solution still diverges. If MAXDIV is negative, the analysis is terminated immediately.

For SOL 400 only, MAXITER can be negative. If MAXITER is negative, the solution is continued to the end of the current step, even if the solution is divergent. In this case, the best attainable solution is computed for each load increment. The default for MAXBIS = 0, if MAXITER < 0. Also, for SOL 400, the value of MAXITER for the AUTO method is an approximation. The program will try to obtain a converged solution if it senses the solution can converge.

7. The test flags (U = displacement error, P = load equilibrium error, W = work error, V = vector component method, N = length method, and A = auto switch) and the tolerances (EPSU, EPSP, and EPSW) define the convergence criteria. All the requested criteria (combination of U, P, W, V and/or N) are satisfied upon convergence. For SOL 400, if the U criterion is selected together with P or W,

then for the first iteration of a load increment, the U criterion will not be checked. For SOL 400 if CONV = 'blank' the code will use a default of "UPW" if no contact analysis and "PV" if a contact analysis is performed. See the *MSC Nastran Handbook for Nonlinear Analysis* for more details on convergence criteria. For V and N, see Remark 21. For A, see Remark 22.

8. INTOUT controls the output requests for displacements, element forces and stresses, etc. YES or ALL must be specified in order to be able to perform a subsequent restart from the middle of a subcase.

INTOUT	Output Processed
YES	For every computed load increment.
NO	For the last load of the subcase or step.
ALL	For every computed and user-specified load increment.

- For the Newton family of iteration methods (i.e., when no NLPCI command is specified), the option ALL is equivalent to option YES since the computed load increment is always equal to the user-specified load increment.
  - For SOL 400 only, if the adaptive time stepping scheme is used (i.e., when a NLAUTO Bulk Data entry with the same ID is specified), INTOUT is allowed to be Integer > 0. In this case, the load step is divided into INTOUT increments for output. For example, if INTOUT=5, the output will be at load increments 0.2, 0.4, 0.6, 0.8, and 1.0. Please note that INTOUT defines only the output load increments, which are different from the analysis increments. The analysis load increment size is smaller than or equal to the output load increment size.
  - For arc-length methods (i.e., when the NLPCI command is specified) the computed load increment in general is not going to be equal to the user-specified load increment, and is not known in advance. The option ALL allows the user to obtain solutions at the desired intermediate load increments.
  - For SOL 600 only, the default is YES (see Remark 18.)
9. The ratio of energy errors before and after the iteration is defined as divergence rate ( $E^i$ ), i.e.,

$$E^i = \frac{\{\Delta u^i\}^T \{R^i\}}{\{\Delta u^i\}^T \{R^{i-1}\}}$$

Depending on the divergence rate, the number of diverging iteration (NDIV) is incremented as follows:

If  $E^i \geq 1$  or  $E^i < -10^{12}$ , then  $NDIV = NDIV + 2$

If  $-10^{12} < E^i < -1$ , then  $NDIV = NDIV + 1$

The solution is assumed to diverge when  $NDIV \geq |MAXDIV|$ . If the solution diverges and the load increment cannot be further bisected (i.e.,  $MAXBIS$  is attained or  $MAXBIS$  is zero), the stiffness is updated based on the previous iteration and the analysis is continued. If the solution diverges again in the same load increment while  $MAXDIV$  is positive, the best solution is computed and the analysis is continued to the next load increment. If  $MAXDIV$  is negative, the analysis is terminated on the second divergence.

10. The BFGS update is performed if  $MAXQN > 0$ . As many as  $MAXQN$  quasi-Newton vectors can be accumulated. The BFGS update with these QN vectors provides a secant modulus in the search direction. If  $MAXQN$  is reached, no additional QN vectors will be accumulated. Accumulated QN vectors are purged when the stiffness is updated and the accumulation is resumed.
11. The line search is performed as required, if  $MAXLS > 0$ . In the line search, the displacement increment is scaled to minimize the energy error. The line search is not performed if the absolute value of the relative energy error is less than the value specified in  $LSTOL$ .
12. The number of subincrements in the material routines (elastoplastic and creep) is determined so that the subincrement size is approximately  $FSTRESS \cdot \bar{\sigma}$  (equivalent stress).  $FSTRESS$  is also used to establish a tolerance for error correction in the elastoplastic material; i.e.,

$$\text{error in yield function} < FSTRESS \cdot \bar{\sigma}$$

If the limit is exceeded at the converging state, the program will exit with a fatal message. Otherwise, the stress state is adjusted to the current yield surface.

13. The number of bisections for a load increment/arc-length is limited to the absolute value of  $MAXBIS$ . Different actions are taken when the solution diverges depending on the sign of  $MAXBIS$ . If  $MAXBIS$  is positive, the stiffness is updated on the first divergence, and the load is bisected on the second divergence. If  $MAXBIS$  is negative, the load is bisected every time the solution diverges until the limit on bisection is reached. If the solution does not converge after  $|MAXBIS|$  bisections, the analysis is continued or terminated depending on the sign of  $MAXDIV$ . See Remark 9.
14.  $MAXR$  is used in the adaptive load increment/arc-length method to define the overall upper and lower bounds on the load increment/arc-length in the subcase; i.e.,

$$\frac{1}{MAXR} \leq \frac{\Delta l_n}{\Delta l_o} \leq MAXR$$

where  $\Delta l_n$  is the arc-length at step  $n$  and  $\Delta l_o$  is the original arc-length. The arc-length method for load increments is selected by an NLPCI Bulk Data entry. This entry must have the same ID as the NLPARM Bulk Data entry.

15. The bisection is activated if the incremental rotation for any degree-of-freedom ( $\Delta\theta_x$ ,  $\Delta\theta_y$ , or  $\Delta\theta_z$ ) exceeds the value specified by  $RTOLB$ . This bisection strategy is based on the incremental rotation and controlled by  $MAXBIS$ .

16. The default for NINC is 10, except if there is a GAP, Line Contact, Heat Transfer or PARAM,NLTOL,0, in which case the default is 1. Default tolerance sets are determined based on model type and desired accuracy. Accuracy is under user control and can be specified on the PARAM, NLTOL entry. For SOL 106, NLTOL's value is used only if the CONV, EPSU, EPSP and EPSW fields are blank, and if NINC is set to a value of 10 or larger. Otherwise, the NLTOL selection will be overridden. The overridden values are CONV=PW, EPSP=1.0E-3, and EPSW=1.0E-7. For SOL 400, NLTOL's value is used if the value of CONV, EPSU, EPSP, or EPSW fields are blank. The tables below list tolerances according to NLTOL selections:

**Table 21** Default Tolerances for Static Nonlinear SOL 106 Models Without Gaps, Contact or Heat Transfer

NLTOL	Designation	CONV	EPSU	EPSP	EPSW
0	Very high	PW	_____	1.0E-3	1.0E-7
1	High	PW	_____	1.0E-2	1.0E-3
2	Engineering	PW	_____	1.0E-2	1.0E-2
3	Prelim Design	PW	_____	1.0E-1	1.0E-1
None	Engineering	PW	_____	1.0E-2	1.0E-2

**Table 22** Default Tolerances for Static Nonlinear SOL 106 Models With Gaps or Contact (Enter NLTOL Values of 0 or 2 Only or Omit the Parameter)

NLTOL	Designation	CONV	EPSU	EPSP	EPSW
0	Very high	PW	_____	1.0E-3	1.0E-7
2	Engineering	PW	_____	1.0E-3	1.0E-5
None	Engineering	PW	_____	1.0E-3	1.0E-5

**Table 23** Default Tolerances for Static Nonlinear SOL 106 or 153 Models With Heat Transfer (Enter NLTOL Value of 0 Only or Omit the Parameter)

NLTOL	Designation	CONV	EPSU	EPSP	EPSW
0	Very high	PW	_____	1.0E-3	1.0E-7
None	Very high	PW	_____	1.0E-3	1.0E-7
