3	Prelim Design	PW	-	1.0E-1	1.0E-1
None	Engineering	PW	-	1.0E-2	1.0E-2

**Table 25** Default Tolerances for Static Nonlinear SOL 400 Models With Gaps or Contact (Enter NLTOL Values of 0 or 2 Only or Omit the Parameter)

NLTOL	Designation	CONV	EPSU	EPSP	EPSW
0	Very high	PW	-	1.0E-3	1.0E-3
2	Engineering	PW	-	1.0E-3	1.0E-3
None	Engineering	PW	-	1.0E-3	1.0E-3

17. The method to compute the energy (work) error is different for SOL 106 and SOL 400. For SOL 106, the energy error is computed based on the residue forces. While, for SOL 400, the energy error computed is the total energy error, which is based on the nonlinear forces acting on the structure. At the start of the iteration, these two methods give approximately the same value. However, near convergence, the SOL 106 method will field a much smaller value than that provided by the SOL 400 method. The difference in these two methods is reflected in the default values shown in Remark 16. The reason for a new method used in SOL 400 is that it gives the true error of the physical energy. On the other hand, the error computed in SOL 106 has no counter part in the physical world.
18. For SOL 600, the only fields used are ID, NINC, DT (creep only), KMETHOD and INTOUT, however, PARAM,MARCOTIM is recommended instead of INTOUT. For other fields, advanced convergence controls are available using NLAUTO, NLSTRAT and PARAM,MARCDEF Bulk Data entries. For SOL 600, if INTOUT is specified all NLPARM's in the file must use the same values. The first INTOUT encountered is what is actually used. The default for INTOUT is YES. For SOL 600, the initial time step for each subcase is 1/NINC of the NLPARM applicable to that subcase. If TINIT or the NLAUTO entry is entered it overrides 1/NINC as the initial time step. For arc length methods NLPCI with the same ID as NLPARM must be entered and if AIFRACT or the NLSTRAT entry is entered it will override 1/NINC as the initial increment size. Beware that NLSTRAT entries, if used, must be entered for each subcase as well as for "subcase zero". The ID of NLSTRAT do not correspond to the NLPARM Id or to the subcase ID but are numbered sequentially starting with zero for Marc increment zero, one for the first subcase (regardless of its ID) etc. For KMETHOD only, strings AUTO and ITER are supported. If any other string is entered it will be assumed to be the same as AUTO in SOL 600.

19. For FNT and PFNT methods, whether the stiffness matrix will be updated between the convergence of a load increment and the start of the next load increment depends on the value of KSTEP. In this case, KSTEP = -1, 'BLANK', or 1. A user fatal error will be issued if other value is input. If KSTEP = 1, the stiffness matrix will not be updated. If KSTEP = 'BLANK', the program will decide whether to update depending element type. If KSTEP = -1, the stiffness matrix will be forced to be updated.
20. If EPSU > 0.0, the displacement error is computed with respect to the total displacements. If EPSU < 0.0, the displacement error is computed with respect to the delta displacements of a load increment. If EPSW > 0.0, the energy error is computed with respect to the total energy. If EPSW < 0.0, the energy error is computed with respect to the delta energy of a load increment. The options EPSU < 0.0 and EPSW < 0.0 are available for SOL 400 only.
21. V and N are additional methods for convergence checking using the displacement (U) and/or load (P) criteria. V stands for vector component checking. In this method, convergence checking is performed on the maximum vector component of all components in the model. N stands for length checking. In this method, the length of a vector at a grid point is first computed by the SRSS (square root of the sum of the squares) method. Then convergence checking is performed on the maximum length of all grid points in the model. For example, if CONV=UV, then V checking method will be performed with the U criteria, i.e., the maximum displacement component of all displacement components in the model is used for convergence checking. For V and N, the EPSU is always negative, i.e., the error is computed with respect to the delta displacements of a load increment, even if positive value is requested by users. CONV=V is the same as CONV=UPV. If both V and N are specified; V will take precedence over N. For example, CONV=VN is the same as CONV=V.  
 By default, for UPV or UPN, separate checks are made over force and moment vectors, and translation and rotation vectors. While the force/translation check is valid always, the moment or rotation check is only valid for 6 DOF elements (beams, shells, etc.). In certain cases (i.e., simply supported or hinged structures where moments are numerically small, small rotation problems), it may be beneficial to turn off the additional convergence testing done for moments and/or rotations.
22. For SOL 400, the convergence checking flag "A" is implemented. "A" means automatically switching to an appropriate convergence checking flag if an unappropriated one is selected for a particular problem. For example, for the problem of stress-free contact analysis, the convergence checking flag PV is inappropriate because this may result of zero divided by zero in convergence checking computation. In this case, PV is switched to UV automatically if A is selected and the residual force is small, i.e., PVA → UVA. The legal combinations for A and PA, UA, WA, PVA, UVA, PNA, and UNA. The rules for auto-switching are that P is switched to U, U is switched to P, and W is switched to UP. For example, PVA → UVA, PVA → UNA, etc. For all other combinations, the A selection is ignored, for example, UPA is the same as UP.
23. For SOL 101 contact, NLPARM can be used to control nonlinear solution process, such as the number of load increments. Since the only source of nonlinearity comes from contact, some fields, however, are neither relevant to the iterative solution nor considered as user-controllable. These fields include DT(=0.0), KMETHOD(=AUTO), KSTEP(=500), INTOUT(=NO) and MAXLS(=0).

NLPARM is not required for running SOL 101 contact jobs. If it is not provided by the user, Nastran will create one. All the values of its fields are printed in F06 file under `NON - LINEAR I T E R A T I O N S O L U T I O N C O N T R O L P A R A M E T E R S`. Listed below are the remaining defaults for SOL 101 contact analysis.

NINC	MAXITER	CONV	MAXDIV	MAXQN	FSTRESS	LSTOL	MAXBIS	MAXR	RTOLB	MINITER
10	25	"PV"	3	0	0.2	0.5	5	20.0	20.0	2

Note that the defaults for EPSU, EPSP and EPSW are different for  $NINC < 10$  and  $NINC \geq 10$ .

	EPSU	EPSP	EPSW
$NINC < 10$	1.e-3	1.e-3	1.e-7
$NINC \geq 10$	1.e-2	1.e-2	1.e-2

24. If Modules are present then this entry may only be specified in the main Bulk Data section.

## NLPCI

## Parameters for Arc-Length Methods in Nonlinear Static Analysis

Defines a set of parameters for the arc-length incremental solution strategies in nonlinear static analysis (SOL 106 and SOL 400). This entry will be used if a subcase contains an NLPARM command (NLPARM = ID).

Format:

1	2	3	4	5	6	7	8	9	10
NLPCI	ID	TYPE	MINALR	MAXALR	SCALE		DESITER	MXINC	

Example:

NLPCI	10	CRIS	1.0	1.0			12	10	
-------	----	------	-----	-----	--	--	----	----	--

Describer	Meaning
ID	Identification number of an associated NLPARM entry. (Integer > 0)
TYPE	Constraint type. See Remark 2. (Character: “CRIS”, “RIKS”, or “MRIKS”; Default = “CRIS”)
MINALR	Minimum allowable arc-length adjustment ratio between increments for the adaptive arc-length method. See Remarks 3. and 4. (0.0 < Real ≤ 1.0; Default = 0.25)
MAXALR	Maximum allowable arc-length adjustment ratio between increments for the adaptive arc-length method. See Remarks 3. and 4. (Real ≥ 1.0; Default = 4.0)
SCALE	Scale factor (w) for controlling the loading contribution in the arc-length constraint. SOL 106 only. (Real ≥ 0.0; Default = 0.0)
DESITER	Desired number of iterations for convergence to be used for the adaptive arc-length adjustment. See Remarks 3. and 4. (Integer > 0; Default = 12)
MXINC	Maximum number of controlled increment steps allowed within a subcase. See Remark 5. (Integer > 0; Default = 20)

Remarks:

- The NLPCI entry is selected by the Case Control command NLPARM = ID. There must also be an NLPARM entry with the same ID. However, for creep analysis (DT ≠ 0.0 in NLPARM entry), the arc-length methods cannot be activated, and the NLPCI entry is ignored if specified. The NLPCI entry is not recommended for heat transfer analysis in SOL 153. Arc-length method is not supported in contact analysis.
- The available constraint types are as follows:  
TYPE = “CRIS”:

$$\left\{ u_n^i - u_n^0 \right\}^T \left\{ u_n^i - u_n^0 \right\} + w^2 (\mu^i - \mu^0)^2 = \Delta l_n^2$$

TYPE = “RIKS”:

$$\left\{ u_n^i - u_n^{i-1} \right\}^T \left\{ u_n^1 - u_n^0 \right\} + w^2 \Delta \mu^i = 0$$

TYPE = “MRIKS”:

$$\left\{ u_n^i - u_n^{i-1} \right\}^T \left\{ u_n^{i-1} - u_n^0 \right\} + w^2 \Delta \mu^i (\mu^{i-1} - \mu^0) = 0$$

where:

$w$  = the user-specified scaling factor (SCALE)

$\mu$  = the load factor

$\Delta l$  = the arc-length

The constraint equation has a disparity in the dimension by mixing the displacements with the load factor. The scaling factor ( $w$ ) is introduced as user input so that the user can make constraint equation unit-dependent by a proper scaling of the load factor  $\mu$ . As the value of  $w$  is increased, the constraint equation is gradually dominated by the load term. In the limiting case of infinite  $w$ , the arc-length method is degenerated to the conventional Newton’s method.

3. The MINALR and MAXALR fields are used to limit the adjustment of the arc-length from one load increment to the next by:

$$\text{MINALR} \leq \frac{\Delta l_{\text{new}}}{\Delta l_{\text{old}}} \leq \text{MAXALR}$$

The arc-length adjustment is based on the convergence rate (i.e., number of iterations required for convergence) and the change in stiffness. For constant arc-length during analysis, use MINALR = MAXALR = 1.

4. The arc-length  $\Delta l$  for the variable arc-length strategy is adjusted based on the number of iterations that were required for convergence in the previous load increment ( $I_{\text{max}}$ ) and the number of iterations desired for convergence in the current load increment (DESITER) as follows:

$$\Delta l_{\text{new}} = \Delta l_{\text{old}} \sqrt{\frac{\text{DESITER}}{I_{\text{max}}}}$$

5. The MXINC field is used to limit the number of controlled increment steps in case the solution never reaches the specified load. This field is useful in limiting the number of increments computed for a collapse analysis.
6. NLPCI does not support general contact in SOL 400.

## NLRGAP

## Nonlinear Load Proportional to Gap

Defines a nonlinear radial (circular) gap for transient response or nonlinear harmonic response.

Format:

1	2	3	4	5	6	7	8	9	10
NLRGAP	SID	GA	GB	PLANE	TABK	TABG	TABU	RADIUS	

Example:

NLRGAP	21	3	4	XY	3	10	6	1.6	
--------	----	---	---	----	---	----	---	-----	--

Describer	Meaning
SID	Nonlinear load set identification number. (Integer > 0)
GA	Inner (e.g., shaft) grid for radial gap. (Integer > 0)
GB	Outer (e.g., housing) grid for radial gap. (Integer > 0)
PLANE	Radial gap orientation plane: XY, YZ, or ZX. (Character; Default = XY.)
TABK	TABLED1 ID defining gap stiffness vs. time or frequency (Integer > 0) or the TABLED1 ID defining gap force vs. penetration (Integer < 0), or TABLED5 ID defining frequency and (gap force vs. penetration) for nonlinear harmonic response only. See Remark 11.
TABG	Table ID for radial gap clearance as function of time for transient response or frequency for nonlinear harmonic response. (Integer > 0)
TABU	Table ID for radial coefficient of friction as function of time for transient response or frequency for nonlinear harmonic response. (Integer > 0)
RADIUS	Shaft radius. (Real $\geq$ 0.0; Default = 0.0)

Remarks:

1. NLRGAP must be selected with the Case Control command NONLINEAR = SID.
2. Multiple NLRGAP entries with the same SID are allowed.
3. The NLRGAP is not an element, but a nonlinear load similar to the NOLINi Bulk Data entries. It computes the relative displacements of GA and GB in the selected plane and applies appropriate nonlinear loads to simulate the radial contact.
4. The degrees-of-freedom in the XY, YZ, or ZX planes (depending on the PLANE) of GA and GB must be members of the solution set. This means the e-set for modal formulation and the d-set for direct formulation. If RADIUS is > 0.0, then the in-plane rotation degree-of-freedom must also be in the solution set.

5. The NLRGAP is limited to use in direct transient or nonlinear harmonic response solution sequences. When enforced motion is used, the NLRGAP requires that PARAM,ENFMETH,ABS be specified because the generated loads are a function of total displacement and not relative displacement.
6. The XY, YZ and ZX planes are relative to the displacement coordinates systems of GA and GB. In order to ensure correct results, points GA and GB must satisfy the following three conditions:
  - a. They must both be grid points
  - b. They must be coincident
  - c. They must have parallel displacement coordinate systemsThe program checks for the above conditions. If they are not satisfied, the program terminates the execution with an appropriate fatal message. The coincident check can be skipped by specifying `system(648)=1`. The default is 0.
7. The shaft radius is used only for the computation of friction induced torque.
8. In the underlying equations, a positive coefficient of friction is consistent with counter-clockwise shaft rotation from axis 1 towards axis 2 (anti-clockwise). A negative coefficient of friction is consistent with clockwise shaft rotation from axis 2 towards axis 1 (clockwise). See [Figure 9-103](#).
9. Nonlinear forces for the grids referenced on the NLRGAP can be output with the NLLOAD Case Control command. See [Figure 9-103](#) for the sign conventions.

Figure 9-103 Radial Gap Orientation and Nonlinear Load Sign Conventions

10. The time step algorithm in transient solution sequences may lose unconditional stability when this load entry is used. In most practical cases, the time step size chosen to reach a certain accuracy is below the stability limit. It is recommended to decrease the time step if results diverge. Additional recommendations are outlined in the user guides.
11. TABK may reference either a TABLED1 ID or a TABLED5 ID.

For transient response, only a TABLED1 entry may be referenced. There are two possible scenarios:

- a. The number entered in the TABK field is a positive integer. In this case the integer references a TABLED1 entry defining pairs of time vs. gap stiffness.
- b. The number entered in the TABK field is a negative integer. In this case the absolute value of the integer references a TABLED1 entry defining pairs of gap penetration vs. gap force.

For nonlinear harmonic response either a TABLED1 entry or a TABLED5 entry may be referenced leading to three possible scenarios:

- a. The number entered in the TABK field is a positive integer referencing a TABLED1 entry. In this case, the pairs of values defined on the TABLED1 entry are frequency vs. gap stiffness.
- b. The number entered in the TABK field is a negative integer, the absolute value of which references a TABLED1 entry. In this case, the pairs of values defined on the TABLED entry are gap penetration vs. gap force.

- c. The number entered in the TABK field is a positive integer referencing a TABLED5 entry. In this case, the pairs of values defined on the TABLED5 entry are frequency vs. a TABLED1 ID that defines pairs of gap penetration vs. gap force.
12. Forces due to TABK and TABU at GA and GB are only present when the gap is closed. A moment is applied only when the gap is closed and  $RADIUS > 0.0$ .

## NLRSD

## Nonlinear Transient Load Proportional to a Squeeze Film Damper

Defines a nonlinear transient radial squeeze film damper.

Format:

1	2	3	4	5	6	7	8	9	10
NLRSD	SID	GA	GB	PLANE	BDIA	BLEN	BCLR	SOLN	
	VISCO	PVAPCO	NPORT	PRES1	THETA1	PRES2	THETA2	NPNT	
	OFFSET1	OFFSET2	GROUP NAME	NAME2					
	RDATA1	RDATA2	RDATA3	RDATA4	RDATA5	RDATA6	RDATA7	RDATA8	

Example:

NLRSD	100	1001	1002	XY	1.0	2.0	0.05	LONG	
	2.1	300.0	1	100.0	30.0	120.0	90.0	51	
	0.01	0.0	GRPNAME						
	0.0				0.0	0.	0.0	0.0	

Alternate Example with UDS:

NLRSD	100	1001	1002	XY	1.0	1.0	1.0		
	1.0	1	1	1.0	1.0	1.0	1.0	1	
	1.0	1.0	MYSUB	EXT					
	1.0E-4								

Describer	Meaning
SID	Nonlinear load set identification number. (Integer > 0; Required)
GA	Inner (e.g., damper journal) grid for squeeze film damper. (Integer > 0; Required)
GB	Outer (e.g., housing) grid for squeeze film damper. (Integer > 0; Required)
PLANE	Radial gap orientation plane: XY, XZ, or ZX. See Remark 1. (Character; Default = XY)
BDIA	Inner journal diameter. (Real > 0.0; Required)
BLEN	Damper length. (Real > 0.0; Required)
BCLR	Damper radial clearance. (Real > 0.0; Required)
SOLN	Solution option: LONG or SHORT bearing. (Character; Default = LONG)
VISCO	Lubricant dynamic viscosity. (Real > 0.0; Required)
PVAPCO	Lubricant vapor pressure. (Real; Required)
NPORT	Number of lubrication ports: 1 or 2 (Integer; no Default)
PRES1	Boundary pressure for port 1. (Real ≥ 0.0; Required if NPORT = 1 or 2)

Descriptor	Meaning
THETA1	Angular position for port 1. ( $0.0 \leq \text{Real} < 360.0$ ; Required if NPORT = 1 or 2). See Remark 2.
PRES2	Boundary pressure for port 2. ( $\text{Real} \geq 0.0$ ; Required if NPORT = 2).
THETA2	Angular position for port 2. See Remark 2. ( $0.0 \leq \text{Real} < 360.0$ ; Required if NPORT = 2)
NPNT	Number of finite difference points for damper arc. (Odd Integer $\leq 201$ ; Default = 101)
OFFSET1	Offset in the SFD direction 1. (Real; Default = 0.0)
OFFSET2	Offset in the SFD direction 2. (Real; Default = 0.0)
GRPNAME	The GRPNAME is the name used for the group on the FMS CONNECT SERVICE statement; this is used with an external User Defined Service (UDS). See Remark 6. (Character or Blank)
EVALNAME	Value passed to the external User Defined Service as argument "evalname". (Character or Blank)
RDATAi	Parameters passed to the external User Defined Service as arguments "parmi". (Real; Default = 0.0). See Remark 7.

Remarks:

1. The XY, YZ, and ZX planes are relative to the displacement coordinates of GA and GB. The plane coordinates correspond to the NLRSD directions 1 and 2.

In order to ensure correct results, points GA and GB must satisfy the following three conditions:

- a. They must both be grid points
- b. They must be coincident
- c. They must have parallel displacement coordinate systems

The program checks for the above conditions. If they are not satisfied, the program terminates the execution with an appropriate fatal message.

2. The angular measurement is counterclockwise from the displacement x-axis for the XY plane, the y-axis for the YZ plane, and the z-axis for the ZX plane.
3. OFFSET1 = Damper housing ID center offset displacement relative to OD center in the horizontal direction. Entered as a positive value for horizontally to the left (negative x-direction) displacement (inches).
4. OFFSET2 = Damper housing ID center offset displacement relative to OD center in the vertical direction. Entered as a positive value for downward (negative y-direction) displacement (inches). Positive entry typically used for -1 g compensation.
5. The time step algorithm in transient solution sequences may lose unconditional stability when this load entry is used. In most practical cases, the time step size chosen to reach a certain accuracy is below the stability limit. It is recommended to decrease the time step if results diverge. Additional recommendations are outlined in the user guides.

6. If GRPNAME is blank, the NLRSD entry used the values defined in the fields prior to GRPNAME. If GRPNAME contains a valid group (as defined on the FMS CONNECT SERVICE entry), the values in fields BDIA, BLEN, BCLR, SOLN, VISCO, PVAPCO, NPORT, PRES1, THETA1, PRES2, THETA2, NPNT, OFFSET1 and OFFSET2 are ignored and the NLRSD will obtain its characteristics from an external source via the CONNECT SERVICE architecture.
7. Parameters may be changed by the external service; the changed values will be stored and returned on a subsequent call.
8. The squeeze films damper defined via the CONNECT SERVICE architecture in NLRSD does not support rotors defined using ROTORSE.

**NLSTEP**

Describes the Control Parameters for Mechanical, Thermal and Coupled Analysis in SOL 400 and for Contact Analysis in SOL 101.

Specifies the convergence criteria, step size control and numerical procedure for time/load stepping in SOL 400. For multi-physics, it controls both structural and thermal analysis. Defines analysis preference and control parameters for contact analysis in SOL 101.

There are three groups of data that can be entered through this option:

1. General data which defined parameters that may be used for a variety of simulations. This data is provided by the GENERAL keyword.
2. Selecting the type of procedure used to control the time/load stepping procedure. These procedures are activated by the keywords: LCNT, FIXED, ADAPT, or ARCLN (arc length or continuation method). Only one of the keywords may be chosen in a loadcase.
3. Data associated with the physics type that are activated by the keywords: MECH, HEAT, COUP, and RCHEAT. One can enter as many as necessary.

The NLSTEP is selected by the Case Control Command NLSTEP=ID.

Format: (For SOL 400)

1	2	3	4	5	6	7	8	9	10
NLSTEP	ID	TOTTIME	CTRLDEF						
	"GENERAL"	MAXITER	MINITER	MAXBIS	CREEP				
	"FIXED"	NINC	NO						
	"ADAPT"	DTINITF	DTMINF	DTMAXF	NDESIR	SFACT	INTOUT	NSMAX	
		IDAMP	DAMP	CRITID	IPHYS	LIMTAR	RSMALL	RBIG	
		ADJUST	MSTEP	RB	UTOL

	"RCHEAT"	SOLVER	DRLXCA	ARLXCA	BALENG	DAMPC	GRVCON	CSGFAC	
		NRLOOP	OUTINV	DTIME1					

Format: (For SOL 101)

1	2	3	4	5	6	7	8	9	10
NLSTEP	ID		CTRLDEF						
	"LCNT"	NINCC	CONVC	EPSUC	EPSPC	EPSWC	MAXDIVC	MAXBIS	
		MAXITERC	MINITERC						

Example: (Fixed stepping, 30 increments, total time 4.3, max 5 bisections)

NLSTEP	10	4.3							
	GENERAL			5					
	FIXED	30							
	MECH	PV		0.01					

Example: (Automatic stepping, total time 4.3. Start out with 2%)

NLSTEP	20	4.3							
	GENERAL			5					
	ADAPT	0.02	1.-5		5		20		

Example: (Using SEVERELY default setting with automatic time stepping)

NLSTEP	10	4.3	SEVERELY						
	ADAPT								

Example: (Select the default control parameters for accuracy preference in SOL 101)

NLSTEP	10		LCACCU						
--------	----	--	--------	--	--	--	--	--	--

Example: (Four increments, P convergence criterion with error tolerance 1.e-4. The other parameters are defaults for performance preference in SOL 101)

NLSTEP	10		LCPERF						
	LCNT	4	P		1.e-4				

Describer	Meaning
ID	Identification number. (Integer > 0)
TOTTIM	Total time for the load case. (Real; Default = 1.0)

Describer	Meaning
CTRLDEF	<p>This Keyword is applicable in SOL101 static contact analysis or in SOL400 nonlinear static and transient analysis.</p> <p>For SOL400, the values "QLINEAR", "MILDLY", and "SEVERELY" are available along with the option of leaving blank. See Remark 14. for detail description of these three keyword options and the blank option.</p> <p>For SOL101, the values "LCPERF" or "LCACCU" are available along with the option of leaving blank. See Remark 15. for detail description of these two keyword options. If left blank the values as described under the "LCNT" keyword entry will be used.</p> <p>If SOL400 keyword values are present in a SOL101 static contact analysis run or SOL101 keyword values are present in a SOL400 nonlinear static run, the keywords are ignored.</p> <p>In SOL400 nonlinear transient analysis, the use of keywords "QLINEAR", "MILDLY", and "SEVERELY" or blank <i>cannot</i> properly set a "FIXED" NINC value or an "ADAPT" DTINITF value so the user <i>still must</i> set whichever one of these keyword entries value is relevant for a transient run.</p> <p>The keywords "QLINEAR", "MILDLY", and "SEVERELY" are ignored for a RC Network heat transfer simulation.</p>
"GENERAL"	Keyword for parameters used for overall analysis.
MAXITER	Maximum number of iterations allowed for each increment. See Remark 6. (Integer; Default = 10)
MINITER	Minimum number of iterations needed for each increment. (Integer >0; Default = 1) In contact analysis or CTRLDEF = SEVERELY, Default = 2). When high accuracy is required, it is also recommended to set MINITER = 2.
MAXBIS	Maximum number of bisections allowed in the current step. (Default = 10). See remark 17. for more information.
CREEP	<p>This flag allows the activation of creep for a particular step. Note: the permanent creep flag specified through the NLMOPTS, CREEP option should also be flagged for the activation. If set to 1, creep will be used; if set to 0, creep will not be used (even if creep data has been defined for a material using MATVP). (Integer 0 or 1; Default = 0).</p> <p>Adaptive load stepping based upon creep can be flagged using CRITTID below. For enhanced nonlinear elements only.</p>
"FIXED"	Keyword to indicate that fixed time stepping is to be used. See Remark 1.
NINC	Number of increments for fixed time stepping. (Integer > 0; Default = 50). The time step of each increment will be TOTTIME/NINC.
NO	Interval for output. Every NO-th increment will be saved for output. (Integer $\geq$ 0; Default = 1).

Descriptor	Meaning
"ADAPT"	Keyword to indicate that the adaptive load stepping procedure should be used. See Remark 1.
DTINITF	Initial time step defined as fraction of total load step time (TOTTIM). (Real; Default 0.01). If DTINITF >= DTMAXF then, DTINITF is reset to DTMAXF. If CTRLDEF is set to QLNEAR, the user should set DTINITF equal to TOTTIM.
DTMINF	Minimum time step defined as fraction of total load step time (TOTTIM). (Real; Default 1e-5).
DTMAXF	Maximum time step defined as fraction of total load step time (TOTTIM). (Real; Default 0.5). For most nonlinear problems, this should be between 0.05 and 0.2 for dynamic simulations.
NDESIR	Desired number of iterations per increment. See Remark 2. (Integer; Default = 4)
SFACT	Factor for increasing time steps due to number of iterations. See Remark 4. (Real; Default = 1.2).
INTOUT	Output flag. Integer $\geq -1$ . (Default = 0) -1 Only the last increment of the step will be output. 0 Every computed load increment will be output. > 0 The output will be obtained at INTOUT equally spaced intervals. The time step will be temporarily adjusted if necessary in order to reach these points in time.
NSMAX	Maximum number of increments in the current load case. (Integer; Default = 99999). The job will stop if this limit is reached.
IDAMP	Flag for activating artificial damping for static analysis. (Integer, Default = 0). See Remarks 27. 0 No damping considered 4 Artificial damping is always turned on 5 Artificial damping is not turned on. But time step is adjusted based on damping energy as 4 6 When the time step reaches the minimum value and artificial damping is turned on
DAMP	Damping ratio. (Real; Default = 2.e-4).
CRITTID	ID of Bulk Data TABSCTL entry which defines the user criteria to use. See Remark 5. (Integer; Default 0)
IPHYS	Flag to determine if automatic physical criteria should be added and how analysis should proceed if a user criterion is not satisfied. (Integer; Default = 2) It is recommended to use 1.

Describer	Meaning
	2 Do not add automatic physical criteria; stop when any user criterion is not satisfied
	-2 Do not add automatic physical criteria; continue when user criteria are not satisfied
	1 Add automatic physical criteria; stop when any user criterion is not satisfied
	-1 Add automatic physical criteria; continue when any user criterion is not satisfied
LIMTAR	Enter 0 to treat user criteria as limits, 1 to treat user criteria as targets. (Integer; Default = 0). Only used if a user criterion is given through CRITTID. See Remark 5.
RSMALL	Smallest ratio between time step changes due to user criteria. (Real; Default = 0.1)
RBIG	Largest ratio between time step changes due to user criteria. (Real; Default = 10.0)
ADJUST	Time step skip factor for automatic time step adjustment. Only for dynamics. See Remark 16. (Integer; Default = 0).
MSTEP	Number of steps to obtain the dominant period response. See Remark 16. ( $10 \leq \text{Integer} \leq 200$ or $= -1$ ; Default = 10).
RB	Define bounds for maintaining the same time step for the stepping function during the adaptive process. See Remark 16. ( $0.1 \leq \text{Real} \leq 1.0$ ; Default = 0.6).
UTOL	Defines tolerance on displacement. ( $.0001 \leq \text{Real} \leq 1.0$ ; Default = 1.0)
"LCNT"	Keyword to indicate that the contact analysis in SOL101 should be used. See Remark 15.
NINCC	Number of increments. (Integer > 0; Default = 10 for CTRLDEF=""; Default=1 for CTRLDEF="LCPERF" or "LCACCU")
CONVC	Flags to select convergence criteria. (Character="U", "P", "W", "V", or any combination; Default = "PV" for CTRLDEF = "" or "LCPERF"; Default = "UPV" for CTRLDEF="LCACCU"). See Remark 19.
EPSUC	Error tolerance for displacement (U) criterion. (Real > 0.0; Default = 1.0E-3 for CTRLDEF = "LCPERF"; Default = 1.0E-2 for CTRLDEF=" " or "LCACCU")
EPSPC	Error tolerance for load (P) criterion. (Real > 0.0; Default = 1.0E-3 for CTRLDEF = "LCPERF"; Default = 1.0E-2 for CTRLDEF=" " or "LCACCU")
EPSWC	Error tolerance for work (W) criterion. (Real > 0.0; Default = 1.0E-7 for CTRLDEF = "LCPERF"; Default = 1.0E-2 for CTRLDEF=" " or "LCACCU")
MAXDIVC	Limit on probable divergence conditions per iteration before the solution is assumed to diverge. (Integer $\neq 0$ ; Default = 3 for CTRLDEF = "" or "LCPERF"; Default = 5 for CTRLDEF="LCACCU").
MAXBISC	Maximum number of bisections allowed for each load increment. ( $-10 \leq \text{Integer} \leq 10$ ; Default = 5)
MAXITERC	Limit on number of iterations for each load increment. (Integer $\geq 0$ , Default = 25)

Descriptor	Meaning
MINITERC	Minimum number of iterations of a load increment. (Integer > 0; Default = 1. In contact analysis, Default = 2).
“ARCLN”	Keyword to indicate that an arc length load stepping procedure is to be used. It does not support general contact in SOL 400. See Remark 1.
TYPE	Constraint type. (Character: “CRIS”, “RIKS”, or “MRIKS”; Default = “CRIS”) See Remark 7.
DTINITFA	Initial time step defined as a fraction of the load step time (TOTTIME) for the arc-length procedure. (Real; Default .01)
MINALR	Minimum allowable arc-length adjustment ratio between increments for the adaptive arc-length method. See Remarks 8. and 9. (0.0 < Real < 1.0; Default = 0.25)
MAXALR	Maximum allowable arc-length adjustment ratio between increments for the adaptive arc-length method. See Remarks 8. and 9. (Real > 1.0; Default = 4.0)
NDESIRA	Desired number of iterations for convergence to be used for the adaptive arc-length adjustment. (Integer > 0; Default = 4) See Remarks 8. and 9.
NSMAXA	Maximum number of increments in the current load case. (Integer; Default = 1000). The job will stop if this limit is reached
“HEAT”	Keyword for parameters for heat transfer analysis.
CONVH	Flags to select convergence criteria. (Character = “U”, “P”, “W”, “V”, “N”, “A” or any combination. (Default UPW)
EPSUH	Error tolerance for temperature (U) criterion. (Real; Default =1.0E-2)
EPSPH	Error tolerance for heat flux (P) criterion. (Real; Default =1.0E-2)
EPSWH	Error tolerance for work (W) criterion. (Real; Default =1.0E-2)
KMETHODH	Method for controlling stiffness updates. (Character = “PFNT”, “AUTO” or “ITER”). Default = “AUTO”. See Remark 22.
KSTEPH	Number of iterations before the stiffness update for the ITER method. (Integer; Default = 1).
MAXQNH	Maximum number of quasi-Newton correction vectors to be saved on database. (Integer; Default = MAXITER). Not used for PFNT.
MAXLSH	Maximum number of line searches allowed for each iteration. (Integer; Default = 4). Not used for PFNT.
LSTOLH	Line Search tolerance. (0.01 < Real < 0.9; Default = 0.5)
“MECH”	Keyword for parameters for mechanical analysis
CONV	Flags to select convergence criteria. (Character = “U”, “P”, “W”, “V”, “N”, “A” or any combination; Default = PV). See Remark 19.
EPSU	Error tolerance for displacement (U) criterion. (Real; Default = -0.1)
EPSP	Error tolerance for residual load (P) criterion. (Real; Default = 0.1)

Describer	Meaning
EPSW	Error tolerance for work (W) criterion. (Real; Default = 0.1)
KMETHOD	Method for controlling stiffness updates. (Character = "PFNT" or "ITER"; Default = "PFNT"). See Remark 22.
KSTEP	Number of iterations before the stiffness update for the ITER method. (Integer; Default = 10).
MRCONV	Flag to specify if rotations and moments should be included in the convergence testing when CONV is set to UV, UN, PV, PN, UPV or UPN: (Integer; Default = 3) 0 check on forces, moments, displacements and rotations 1 check on forces, moments and displacements 2 check on forces, displacements and rotations 3 check on forces and displacements If there is no V and N in the CONV, MRCONV is ignored and all translational and rotational quantities are used to compute the convergence criteria.
MAXQN	Maximum number of quasi-Newton correction vectors to be saved on the database. (Integer; Default = MAXITER). Not used for PFNT.
MAXLS	Maximum number of line searches allowed for each iteration. (Integer; Default = 4). Not used for PFNT.
LSTOL	Line Search tolerance. (0.01 < Real < 0.9; Default = 0.5). Not used for PFNT.
FSTRESS	Fraction of effective stress used to limit the sub increment size in material routines (0.0 < Real < 1.0; Default = 0.2) For non material enhanced elements only.
"COUP"	Keyword for parameters for coupled analysis.
HGENPLAS	Conversion factor for heat generated due to plasticity. (Real; Default = 0.0)
HGENFRIC	Conversion factor for heat generated due to friction. (Real; Default = 0.0)
"RCHEAT"	Keyword to indicate that RC Heat Transfer Analysis is to be performed. See Remark 10.
SOLVER	The Relaxation scheme to be used. See Remark 12. (Character; Default = "SNSOR")
DRLXCA	Diffusion node convergence criterion. See Remark 11. (Real $\geq$ 0; Default = 1.e-3)
ARLXCA	Arithmetic node convergence criterion. See Remark 11. (Real $\geq$ 0.0; Default = 1.0e-3 degrees)
BALENG	Allowable system energy imbalance. See Remark 11. (Real $\geq$ 0.0; Default 0.0 energy/time)
DAMPC	Damping constant. (Real $\geq$ 0.0; Default 0.0 non dimensional)
GRVCON	Gravitation constant. (Real $\geq$ 0.0; Default 9.81 length/time <sup>2</sup> )
CSGFAC	Time step control factor. See Remark 13. (Real $\geq$ 0.0; Default 1.0 nondimensional)
NRLOOP	Number of relaxation loops allowed. (Integer $\geq$ 0; Default 5 loop)
OUTINV	Output interval. See Remark 13. (Real $\geq$ 0.0; Default 60.0 time)
DTIME1	Time step. See Remark 13. (Real $\geq$ 0.0; Default 0.0 time)

**Remarks:**

1. Note that the following applies:
  - a. Only one of LCNT, FIXED, ADAPT, ARCLN, or RCHEAT time/load stepping scheme can be used on a specific NLSTEP entry.  
Note that only LCNT may be used in SOL 101. If other selection of load stepping scheme is used, it will be ignored, and the default value of LCNT will be applied
  - b. FIXED or ADAPT may be used for a single physics STEP or for a coupled physics STEP/SUBSTEP.
  - c. If no LCNT, FIXED, ADAPT, or ARCLN appear on a NLSTEP entry, then the default is FIXED with 50 increments.
  - d. The ARCLN method is not supported in contact analysis.
  - e. The ARCLN method should not be used in transient dynamic analysis.
  - f. The ARCLN method should not be used in conjunction with HEAT or COUP.
  - g. The ARCLN method cannot be used with the Intel MKL PARDISO solver.
  - h. In one simulation, one cannot use both HEAT and RCHEAT.
  - i. One cannot use both COUP and RCHEAT.
  - j. The LCNT keyword can only be used in a SOL 101 static analysis.
2. The desired number of recycles (NDESIR) can be used in static mechanical, dynamic mechanical (see Remark 16) and heat transfer.
3. In coupled analysis, the time step change is calculated separately for heat and mechanical and the smallest of the two is used.
4. When the time step is increased due to desired number of recycles, the previous time step is multiplied with SFACT. When the time step is decreased the factor is calculated internally based upon the minimum time step.
5. User criteria can be given in the TABSCTL entry via CRITTID. These criteria include rotation, displacements, stresses, strains, creep strains. The time step is decreased if the current value of the value is larger than the user specified limit. If LIMTAR is equal to 1 (“target”) it also increases the time step for the next increment if the current value is smaller than the target value given.  
User criteria are generally useful for explicit creep analysis with adaptive time stepping. The two recommended criteria in this case would be:
  - (i) Normalized creep strain increment  $< 0.5$
  - (ii) Normalized stress change increment  $< 0.1$
6. If MAXITER is given a negative value and the MAXITER number of iterations are obtained, convergence is assumed and the analysis will continue with the next increment.
7. The “ARCLN” entry is applicable to “MECH” analysis only and is ignored for creep analysis. The available constraint types are as follows.

TYPE = “CRIS”:

$$\left\{ U_n^i - U_n^O \right\}^T \left\{ U_n^i - U_n^O \right\} + w^2 (\mu^i - \mu^O)^2 = \Delta I_n^2$$

TYPE = "RIKS":

$$\left\{ U_n^i - U_n^{i-1} \right\}^T \left\{ U_n^i - U_n^O \right\} + w^2 \Delta \mu^i = 0$$

TYPE = "MRIKS":

$$\left\{ U_n^i - U_n^{i-1} \right\}^T \left\{ U_n^{i-1} - U_n^O \right\} + w^2 \Delta \mu^i (\mu^{i-1} - \mu^O) = 0$$

where:

$w$  = user specified scaling factor (SCALEA)

$\mu$  = load factor

$l$  = the arc-length

The constraint equation has a disparity in the dimension by mixing the displacements with the load factor. The scaling factor ( $w$ ) is introduced as user input so that the user can make constraint equation unit-dependent by a proper scaling of the load factor ( $\mu$ ). As the value of  $\mu$  is increased, the constraint equation is gradually dominated by the load term. In the limiting case of infinite, the arc-length method is degenerated to the conventional Newton's method

8. The MINALR and MAXALR fields are used to limit the adjustment of the arc-length from one increment to the next by:

$$\text{MINALR} \leq \Delta l_{new} / \Delta l_{old} \leq \text{MAXALR}$$

The arc-length adjustment is based on the convergence rate (i.e., number of iterations required for convergence) and the change in stiffness. For constant arc-length during analysis, use:

$$\text{MINALR} = \text{MAXALR} = 1$$

9. The arc-length  $l$  for the variable arc-length strategy is adjusted based on the number of iterations that were required for convergence in the previous increment ( $I_{max}$ ) and the number of iterations desired for convergence in the current increment (NDESIRA) as follows:

$$\Delta l_{new} = \Delta l_{old} (\text{NDESIRA} / I_{max})^{1/2}$$

10. This entry is required for a non finite element, Resistance-Capacitor network method of analysis for heat transfer.

11. Convergence is determined by the combination of DRLXCA, ARLXCA, and BALENG. DRLXCA and ARLXCA determine if relaxation is met on a node by node basis, rather than a residual vector length.
12. If in Case Control the ANALYSIS=RCNS, then valid values of SOLVER are:

SNSOR (Default)	Successive over-relaxation method
STDSTL	An iterative solver aimed at the fourth root of a quartic for the network equations (good for strong radiation dependence).

If in Case Control the ANALYSIS=RCNT, then valid values are

SNDUFR (Recommended)	An unconditionally stable, explicit method based on a modified Dufort-Frankel scheme
SNFRDL	Fast, accurate explicit forward differencing transient method
FWDBKL	Implicit forward/backward differencing Crank Nicolson method
SNADE	Alternating direction explicit method
ATSDUF	SNFUFR with automatic time step based on ERRMIN/ERRMAX
ATSF BK	FWDBKL with automatic time step based on ERRMIN/ERRMAX
SNTSM	Weighted implicit forward/backward differencing method
SNTSM3	Weighted implicit forward/backward differencing method
SNTSM1	Weighted implicit forward/backward differencing method
SNTSM4	Weighted implicit forward/backward differencing method

If SOLVER is left blank or set to SNSOR and ANALYSIS=RCNT then internally the RC code will select SNDUFR.

13. About the time step:
  - a. The default computed time step (DTIMEU) = CSGMIN\*CSGFAC. CSGMIN is based on the conductance in the model and can be checked in the .sot file. If CSGFAC is not specified, it is internally set to 1.0.
  - b. In a normal sized model, CSGMIN is usually small enough for the time step which will assure a convergent transient run.
  - c. CSGFAC is used to adjust the time step. It is recommended to determine the best CSGFAC to the model while maintaining acceptable temperature errors.
  - d. If OUTPUT < CSGFAC\*CSGMIN or OUTPUT < DTIMEI, then OUTPUT becomes the time step. All the OUTPUT points are automatically required to be calculated.
  - e. DTIMEI is the forced time step which will ignore any other factors. Sometimes it may lead to inaccurate answers if it is too large. DTIMEI does not affect the automatic time step solvers.

- f. If the model size is very small, CSGMIN may be too big for the time step. A small CSGFAC or DTIMEI should be used to adjust the time step.
- g. CSGFAC\*CSGMIN or DTIMEI should be small enough to “catch” any details in time fields, temperature fields or flux arrays.
14. In SOL 400, CTRLDEF entry is only valid for "MECH", "HEAT" and "COUP". The description and default of each option is listed below.

CTRLDEF	<p>Keyword to select the default setting of the control parameters. (Character = "QLINEAR", "MILDLY", "SEVERELY". No default.</p> <p>Stress analysis (NLSTAT, NLTRAN):</p> <pre> QLINEAR : FIXED = 1 inc, ADAPT : initial time ratio = 1.0 (maximum time ratio = 1.0) MILDLY  : FIXED = 10 inc, ADAPT : initial time ratio = 0.1 SEVERELY : FIXED = 50 inc, ADAPT : initial time ratio = 0.01 Blank   : FIXED = 50 inc, ADAPT : initial time ratio = 0.01  QLINEAR   CONV      EPSU*      EPSP      EPSW      KMETHOD PV         0.001     0.001     0.001     ---      PFNT MILDLY    PV         0.01      0.01      ---      PFNT SEVERELY  PV         0.1       0.01      ---      PFNT Blank     PV         0.1       0.1       ---      PFNT </pre> <p>[Note] EPSU* is a suggestion when user wants to set CONV=UPV</p> <p>Thermal analysis (HSTAT, HTRAN) :</p> <pre> QLINEAR : FIXED = 1 MILDLY  : FIXED = 10 SEVERELY : FIXED = 50 Blank   : FIXED = 50  QLINEAR   CON VH      EPSUH      EPSPH      EPSWH      KMETHOD UPW       0.001     0.001     0.001     0.001     AUTO MILDLY    UPW       0.01      0.01      0.01      AUTO SEVERELY  UP       0.01      0.01      ---      AUTO Blank     UPW       0.01      0.01      0.01      AUTO </pre> <p>For stress analysis, both (1) CTRLDEF and (2) "FIXED" or "ADAPT" have to be set. For heat analysis, both CTRLDEF and "FIXED" have to be set. Otherwise the standard default setting for "FIXED" or "ADAPT" will be set.</p>
---------	---

15. "LCPERF" specifies the performance preference during analysis, while "LCACCU" prefers accuracy for analysis. These keywords must be defined if the smart contact in SOL 101 default is required. Specification of LCNT keyword is optional. Listed below are default control parameters of contact in SOL 101 if LCNT keyword or some of its fields are not defined. If the CTRLDEF field is blank, default control parameters will be same as those of NLPARM Bulk Data entry.

CTRLDEF	NINCC	CONVC	EPSUC	EPSPC	EPSWC	MAXDIVC	MAXBISC	MAXITERC	MINITERC
LCPERF	1	PV	1.e-3	1.e-3	1.e-7	3	5	25	2
LCACCU	1	UPV	1.e-2	1.e-2	1.e-2	5	5	25	2
	10	PV	1.e-2	1.e-2	1.e-2	3	5	25	2

The default error tolerances EPSPC and EPSWC are relaxed for the accuracy preference LCACCU. These relaxations are imperative to avoid convergence problems with an additional displacement convergence criterion. The default control parameters are selected based on the test results of typical contact in SOL 101 models. Therefore, these empirical data are only served for the purpose of general convenience. The users can customize any control parameters while performing their analysis.

For some contact models, specifying "LCPERF" or "LCACCU" preference may result in poor convergence. In these cases, the user may increase the number of increments (NINCC) to achieve optimal results.

16. If  $10 \leq \text{MSTEP} \leq 200$  : activating frequency based adaptive time step adjustment with bounds (RB) when specified increment (controlled by ADJUST) converges. It cannot be combined with iteration based adaptive time step adjustment, controlled by NDESIR, and NDESIR is always ignored in this case. If  $\text{MSTEP} = -1$ : activating frequency based adaptive time step adjustment without bounds (RB). It can be combined with iteration based adaptive time step adjustment controlled by NDESIR. If  $\text{NDESIR}=0$ , time step is only adjusted after the increment converges.
17. If MAXBIS is positive and the solution does not converge after MAXBIS bisections, the best solution is computed and the analysis is continued to the next time step. If MAXBIS is negative and the solution does not converge in  $|\text{MAXBIS}|$  bisection, the analysis is terminated. It is recommended to enter 0.
18. SOL400 only support the displacement error computation with respect to the delta displacement of a load increment for EPSU. Although a positive EPSU is assigned, internally it will be changed into a negative value. If  $\text{EPSW} > 0.0$ , the energy error is computed with respect to the total energy. If  $\text{EPSW} < 0.0$ , the energy error is computed with respect to the delta energy of a load increment.
19. The test flags (U = displacement error, P = load equilibrium error, W = work error, V = vector component method, N = length method, and A = auto switch) and the tolerances (EPSU, EPSP, and EPSW) define the convergence criteria. All the requested criteria (combination of U, P, W, V and/or N) are satisfied upon convergence. For SOL 400, if the U criterion is selected together with P or W, then for the first iteration of a load increment, the U criterion will not be checked. For SOL 400 if  $\text{CONV} = \text{'blank'}$  the code will use a default of "UPW" if heat analysis and "PV" if a structural stress analysis is performed. See the *MSC Nastran Handbook for Nonlinear Analysis* for more details on convergence criteria. For V and N, see Remark 20. For A, see Remark 21.
20. V and N are additional methods for convergence checking using the displacement (U) and/or load (P) criteria. V stands for vector component checking. In this method, convergence checking is performed on the maximum vector component of all components in the model. N stands for length checking. In this method, the length of a vector at a grid point is first computed by the SRSS (square root of the sum of the squares) method. Then convergence checking is performed on the maximum length of all grid points in the model. For example, if  $\text{CONV}=\text{UV}$ , then V checking method will be performed with the U criteria, i.e., the maximum displacement component of all displacement components in the model is used for convergence checking. For V and N, the EPSU is always negative, i.e., the error is computed with respect to the delta displacements of a load increment, even if positive value is requested by users.  $\text{CONV}=\text{V}$  is the same as  $\text{CONV}=\text{UPV}$ . If both V and N are specified; V will take precedence over N. For example,  $\text{CONV}=\text{VN}$  is the same as  $\text{CONV}=\text{V}$ .

By default, for UPV or UPN, separate checks are made over force and moment vectors, and translation and rotation vectors. While the force/translation check is valid always, the moment or rotation check is only valid for 6 DOF elements (beams, shells, etc.). In certain cases (i.e., simply supported or hinged structures where moments are numerically small, small rotation problems), it may be beneficial to turn off the additional convergence testing done for moments and/or rotations.

21. For SOL 400, the convergence checking flag “A” is implemented. “A” means automatically switching to an appropriate convergence checking flag if an unappropriated one is selected for a particular problem. For example, for the problem of stress-free contact analysis, the convergence checking flag PV is inappropriate because this may result of zero divided by zero in convergence checking computation. In this case, PV is switched to UV automatically if A is selected and the residual force is small, i.e.,  $PVA \rightarrow UVA$ . The legal combinations for A are PA, UA, WA, PVA, UVA, PNA, and UNA. The rules for auto-switching are that P is switched to U, U is switched to P, and W is switched to UP. For example,  $PVA \rightarrow UVA$ ,  $PVA \rightarrow UNA$ , etc. For all other combinations, the A selection is ignored, for example, UPA is the same as UP.
22. The stiffness update strategy is selected in the KMETHOD and KMETHODH field for mechanical and thermal analysis, respectively.
- AUTO may be used for thermal analysis only. PFNT and ITER may be used in both mechanical and thermal analysis.
  - In the thermal analysis, if the AUTO option is selected, the program automatically selects the most efficient strategy based on convergence rates. At each step the number of iterations required to converge is estimated. Stiffness is updated, if (i) estimated number of iterations to converge exceeds MAXITER, (ii) estimated time required for convergence with current stiffness exceeds the estimated time required for convergence with updated stiffness, and (iii) solution diverges. See Remarks 17. and 23. for diverging solutions. Available for the heat transfer pass only.
  - If the ITER option is selected, the program updates the stiffness matrix at every KSTEP iterations and on convergence if  $KSTEP < MAXITER$ . However, if  $KSTEP > MAXITER$ , stiffness matrix is never updated. Note that the modified Newton-Raphson iteration method is obtained by selecting the ITER option and  $KSTEP = MAXITER$ .
  - If the PFNT option is selected, the program will use the Pure Full Newton iteration method.
23. The ratio of energy errors before and after the iteration is defined as divergence rate ( $E^i$ ), i.e.,

$$E^i = \frac{\{\Delta u^i\}^T \{R^i\}}{\{\Delta u^i\}^T \{R^{i-1}\}}$$

Depending on the divergence rate, the number of diverging iteration (NDIV) is incremented as follows:

If  $E^i \geq 1$  or  $E^i < -10^{12}$ , then  $NDIV = NDIV + 2$

If  $-10^{12} < E^i < -1$ , then  $NDIV = NDIV + 1$

The solution is assumed to diverge when  $NDIV \geq |MAXDIVC|$ . If the solution diverges and the load increment cannot be further bisected (i.e., MAXBIS is attained or MAXBIS is zero), the stiffness is updated based on the previous iteration and the analysis is continued. If the solution diverges again in the same load increment while MAXDIVC is positive, the best solution is computed and the analysis is continued to the next load increment. If MAXDIVC is negative, the analysis is terminated on the second divergence.

24. Please note that in NLTRAN analysis, the output is also influenced by NLPACK. For example, one NLTRAN analysis has NLSTEP as:

```
NLSTEP, 900, 0.2
, fixed, 2000, 20
, mech, u
```

It has total 2000 increments, and asks output every 20 increments. Therefore, total output is 100 time step. In NASTRAN, default value of NLPACK for NLTRAN is 100, in this model, therefore, NASTRAN will write the results to OP2 after collecting 100 output, i.e., this model will write results to OP2 only one time. With intermediate output request, only one OP2 file will be created.

If NLPACK=1, NASTRAN will write results to OP2 for every output request. In this model, NASTRAN will write results to OP2 for every output request, i.e., writing 100 times in this model. With "intermediate output request, 100 OP2 files will be created.

If NLPACK=2, NASTRAN will write results to OP2 for every two output requests. In this model, NASTRAN will write results to OP2 for every two output request, i.e., writing 50 times in this model. With "intermediate output request, 50 OP2 files will be created.

For NO of FIXED in NLSTEP, it is similar to INTOUT of ADAPT.

25. If Modules are present then this entry may only be specified in the main Bulk Data section.
26. NLSTEP entry does not work for creep analysis when using the traditional elements. In SOL 400, NLPARM entry must be used to perform creep analysis with the traditional elements model.
27. Artificial damping takes effect in the following way with different options.

IDAMP=4: Artificial damping is always turned on. Both time stepping and added damping are controlled through the step.

- A comparison of the incremental damping energy to the predicted incremental total strain energy is used as a criterion for time step control.
- The damping factor to be used is computed based on the estimated damping energy and the estimated total energy for the step.

IDAMP=5: Artificial damping is not turned on. Similar algorithm as IDAMP = 4 except that only the time stepping is controlled based on the damping.

- A comparison of the incremental damping energy to the predicted incremental total strain energy is used as a criterion for time step control.

IDAMP=6: When the time step reaches the minimum value and the analysis is going to stop prematurely, two attempts are made to avoid a premature exit:

- The increment is repeated with a new time step = 10 tmin and quasi-static damping is added in a manner similar to the IDAMP = 4 scheme.

- If this does not work, the increment is repeated with a new time step = 100 tmin and the process is repeated. Note that once damping is turned on to avoid the premature stop, it remains on for the rest of the step.

**NLSTRAT****Strategy Parameters for SOL 600 Nonlinear Structural Analysis**

Defines strategy parameters for nonlinear structural analysis used in SOL 600 only. For SOL 600 Heat Transfer, see NLHEATC.

Format:

1	2	3	4	5	6	7	8	9	10
NLSTRAT	ID	Param1	Value1	Param2	Value2	Param3	Value3		
	Param4	Value4	Param5	Value5	etc				

Example:

NLSTRAT	501	CONVTYP	4	RESPF	.015	ALPHA	.05		
	KNONPOS	1							

Descriptor	Meaning
ID	Identification number referenced by a Case Control command with regard to time steps or load steps (such as SUBCASE). If ID = 0, the values entered will be used for Marc increment zero. For the first subcase ID = 1; for the second subcase ID = 2, etc. If there are no subcases in the model, enter ID = 1. If NLSTRAT with ID > 0 is entered and if the ISOLVER option is entered, another NLSTRAT entry with ID = 0 and the same ISOLVER option must be entered. If NLSTRAT is used, there must be an NLSTRAT entry for each subcase. Multiple NLSTRAT entries with the same ID are not allowed. (Integer ≥ 0)
PARAMi	Name of the NLSTRAT parameter. Allowable names are given in <a href="#">Table 9-30</a> . (Character).
VALi	Value of the parameter. See <a href="#">Table 9-30</a> . (Real or Integer)

Table 9-30 Parameters

Name	Description, Type and Value Convergence Criteria
CONVTYP	Convergence Criteria -- (Integer) - If not set, value will be determined by NLPARM or entry - CONTROL(2,4) The possibilities are: 0 -- Convergence based on residuals 1 -- Convergence based on displacements 2 -- Convergence based on energy 4 -- Convergence based on residuals or displacements 5 -- Convergence based on residuals and displacements
IRELABS	Flag for relative or absolute convergence criteria (Integer) CONTROL(2,5) 0 -- Testing is done on relative error 1 -- Testing is done on absolute value 2 -- Testing is done on relative error testing unless reactions or incremental displacements are below minimum value, in which case absolute tolerance testing is used.
RCK1	Used for Relative Checking - Maximum residual force ratio (maximum allowable value of maximum residual force divided by maximum reaction force) or displacement ratio (maximum allowable value of the change in displacement increment divided by displacement increment) depending on CONVTYP. (Real $\geq 0$ ; CONTROL(3,1); Default = 0.1)
RCK2	Used for Relative Checking - Maximum residual moment ratio or if autoswitch is on, the rotation ratio depending on CONVTYP (Real $\geq 0$ ; CONTROL(3,2); Default = no checking)
RCK3	Used for Relative Checking - Minimum reaction force ratio or minimum displacement ratio depending on CONVTYP. (Real $\geq 0$ ; CONTROL(3,3); no Default; if 0.0, checking is bypassed or absolute testing is performed)
RCK4	Used for Relative Checking - Minimum moment ratio or rotation ratio depending on CONVTYP. (Real $\geq 0$ ; CONTROL(3,4))
ABCK1	Used for Absolute Checking - Maximum residual force ratio or displacement ratio depending on CONVTYP. (Real $\geq 0$ ; CONTROL(3,5); Default = no checking)
ABCK2	Used for Absolute Checking - Maximum residual moment ratio or rotation ratio depending on CONVTYP. (Real $\geq 0$ ; CONTROL(3,6) - Default = no checking)
MAXDI	Maximum change in displacement increment divided by displacement increment (Real) Default is no checking (real) - CONTROL (3a-1) - Enter only if CONVTYP is 4 or 5.
MAXRI	Maximum change in rotational increment divided by rotational increment (Real) Default is no checking (Real) - CONTROL (3a-2) - Enter only if CONVTYP is 4 or 5.
MINDI	Minimum change in displacement increment divided by displacement increment (real) Default is no checking (Real) - CONTROL (3a-3) - Enter only if CONVTYP is 4 or 5.
MINRI	Minimum change in rotational increment divided by rotational increment (real) Default is no checking (Real) - CONTROL (3a-4) - Enter only if CONVTYP is 4 or 5.

Table 9-30 Parameters (continued)

Name	Description, Type and Value Convergence Criteria
MAXD	Maximum value of displacement increment (Real) Default is no checking (real) - CONTROL (3a-5) - Enter only if CONVTYPE is 4 or 5.
MAXR	Minimum value of rotational increment (real) Default is no checking (Real) - CONTROL (3a-6) - Enter only if CONVTYPE is 4 or 5.
IPRCONV	Flag controls printing of convergence. CONTROL(2,9) (Integer; Default = 0 = no print)
AUTOSW	Flag to turn on or off Marc's Auto Switch (Integer) Controls switching between convergence testing of residuals and displacements when residuals are small - CONTROL (2,11). 0 -- Off (Default unless NLAUTO entry is entered) 1 -- On (Default only if NLAUTO entry is entered)
Newton Iterations	
MAXSTEP	Maximum number of load steps. CONTROL(2,1) (Integer; Default = 9999)
MAXREC	Maximum number of recycle steps per load step (Integer; Default = 3) If set to a negative value, if convergence is not obtained after maxrec recycles, a warning is issued and the analysis proceeds to the next step (not recommended) CONTROL(2,2)
MINREC	Minimum number of recycle steps per load step. CONTROL(2,3) (Integer; Default = 0)
IKMETH	Newton method (Integer; Default = 1) 1 = Full Newton, 2 = Modified Newton, 3 = Newton-Raphson with strain correction, 8 = Secant stiffness CONTROL(2,6)
IKUPD	Reassembly interval of stiffness and mass. AUTO LOAD (2,2) DYNAMIC CHANGE (2,5) (Integer)
IKNONPOS	Solve a non positive definite stiffness (1) or not (0). CONTROL(2,7) For jobs with multiple subcases, use IKNONPOS instead of NONPOS if some subcases should handle nonpositive-definite systems and other should not. (Integer)
IKINIT	Initial stiffness control (Integer) CONTROL (2,10) 0 - Normal full contribution 1 - For Mooney material, reduced contribution of hydrostatic pressure based on initial stress 2 - No initial stiffness 3 - Use stress at beginning of increment but not in the last iteration 4 - Use only positive stresses in initial stress stiffness (faster than option 0 and is always stable for thin shell structures).
General Parameter	
STRAINS	Scale factor for strain increments. PARAMETERS(2,1) (Real $\geq 0$ ; Default = 1.0)
PENBOUN	Penalty value to enforce certain boundary conditions. PARAMETERS(2,2) (Real)

Table 9-30 Parameters (continued)

Name	Description, Type and Value Convergence Criteria
FSTRESS	Fraction of the hydrostatic pressure subtracted from the stress tensor in initial stress calculation. PARAMETERS(3,5) (Real)
<b>Load Step or Time Step Control</b>	
MAXTSC	Maximum number of allowable time step cuts. AUTO LOAD (2,3) (Integer $\geq 0$ ) 0 - No automatic restart from the previously converged step >1 - Maximum number of time step cutbacks allowed.
<b>Transient Analysis Damping Parameters</b>	
BETA	Beta parameter used by Newmark-beta procedure. PARAMETERS (2,5) (Real; Default = 0.25)
GAMMA	Gamma parameter used by Newmark-beta procedure. PARAMETERS(2,6) (Real; Default = 0.5)
GAMMA1	Gamma1 parameter used by Single Step Houbolt procedure. PARAMETERS (2,7) (Real; Default = 1.5)
GAMMA2	Gamma parameter used by Single Step Houbolt procedure. PARAMETERS (2,8) (Real; Default = -0.5)
<b>Solver-Related Parameters</b>	
ISOLVER	Type of solver (Integer $\geq 0$ ) SOLVER(2,1) 0 - Profile Direct Solver 2 - Sparse Iterative 4 - Sparse Direct 6 - Hardware provided direct sparse 8 - Multifrontal direct sparse (Default) 9 - The CASI iterative solver will be used 10 - The mixed direct/iterative solver will be used. The other NLSTRAT entries that apply to solvers 2 and 9 may also be used for solver 10 but are not required. 11 - Pardiso direct solver 12 - MUMPS parallel direct solver (Note: Solvers that do not require other NLSTRAT entries can be specified by PARAM,MARCSOLV. For solvers 11 or 12 please also see parameters <a href="#">MUMPSOLV</a> and <a href="#">MRTHREAD</a> )
ISYMM	Nonsymmetric solver option (Integer $\geq 0$ ; Default = 0) SOLVER (2,2) 0 - Symmetric solver 1 - Non symmetric solver
NONPOS	Nonpositive Definite solver option (Integer $\geq 0$ ; Default = 0) SOLVER (2,3) 0 - Error if system is nonpositive-definite 1 - Solve nonpositive definite systems if possible For jobs with multiple subcases, use IKNONPOS instead of NONPOS if some subcases should handle nonpositive-definite systems and other should not.

Table 9-30 Parameters (continued)

Name	Description, Type and Value Convergence Criteria
MBYTE	Solver type 6 or 8 memory option (Integer $\geq 0$ ) SOLVER (2,8). Enter the number of 4-byte words in millions to be used if solver type 6 (SGI only) or solver type 8 (all other systems) is to be used. For example, if 96MB is needed, enter 96.
MAXITER	Maximum number of iterations (Iterative solver only). (Integer; Default = 1000) Enter a negative value if program is to continue even though iterations have not fully converged. SOLVER (3,1)
PREVITER	Enter 1 if the previous solution is to be used as the initial trial value (Iterative solver only) (Integer $> 0$ ; Default = 0) SOLVER (3,2)
PRECOND	Preconditioner Option (Iterative solver only) (Integer $> 0$ ) SOLVER (3,3) For the CASI solver (solver 9): 1- CASI solver with standard preconditioner 0- CASI solver with primal preconditioner For the standard iterative solver (solver 2): 3 - Use diagonal preconditioner 4 - Use scaled-diagonal preconditioner 5 - Use incomplete Cholesky preconditioner
CJTOL	Enter Conjugate Gradient Convergence Tolerance (Iterative solver only) (Real; Default = 0.001) SOLVER (4,1)
<p>Note: Arc Length and Other Parameters for Marc's AUTO INCREMENT Option</p> <p>An NLPCI entry is needed in addition to the options below to trigger the AUTO INCREMENT option. It is usually used for post-buckling problems.)</p>	
AITYPE	Arc Length Method. AUTO INCREMENT (2,8) (Integer $\geq 0$ ; Default = 3) 0 standard load control 1 - Crisfield quadratic constraint method 2 - Riks/Ramm linear constraint method 3 - Modified Riks/Ramm (linear constrain method) 4 - Crisfield, switch to modified Riks/Ramm if no real root found
AIMAXCUT	Maximum number or time step cutbacks. AUTO INCREMENT (2,9) (Integer $\geq 0$ ; Default if not entered = 5) 0 - No automatic restart (cutbacks) from previous converged step are allowed >0 - Maximum number of load step cutbacks Note for shell buckling problems it is best to set this value to 5 or 10.
AIFRACT	Fraction of total load increment that is applied in the first cycle of the first increment. AUTO INCREMENT (2,1) (Real) Note this value is not set from NLPARM. It needs to be entered if AUTO INCREMENT is to be used for buckling problems.
AIMAXINC	Maximum number of increments. For most problems, this value should be entered and set to a large value such as 99999. AUTO INCREMENT (2,2) (Integer $> 0$ )

Table 9-30 Parameters (continued)

Name	Description, Type and Value Convergence Criteria
AINRECYC	Desired number of recycles per increment used to increase or decrease load steps. AUTO INCREMENT (2,3) (Integer > 0; Default = 3)
AIMAXF	Maximum fraction of the total load that can be applied in any increment. It is recommended that for most nonlinear problems, this value be 0.1 or smaller. AUTO INCREMENT (2,4) (Real; Default=0.05 if the model does not have contact and 0.01 if the model has contact). Note for shell buckling problems it is best not to set this value (i.e., leave it as default). If AIMAXF is set to a small value, the problem will probably diverge and/or get bad results.
AIARCM	Maximum arc length multiplier (norm of displacement vector to initial arc length). AUTO INCREMENT (2,5) (Real; Default is fraction of load divided by initial fraction of load)
AITOTT	Total Time period to be covered, used in conjunction with contact analysis. AUTO INCREMENT (2,6) (Real; Default = 1.0)
AIARC0	Fraction of the initial arc length to define a minimal arc length. AUTO INCREMENT (2,7) (Real; Default = 0.01)
<b>Fully Coupled Heat-Structural Analysis Controls</b>	
TCHANGE	Maximum nodal temperature change allowed. CONTROL(4,1) (Real; Default = 20.0)
TEVAL	Maximum nodal temperature change allowed before properties are re-evaluated and matrices reassembled. CONTROL(4,2) (Real; Default = 100.0)
TERROR	Maximum error in temperature estimates used for property evaluation. CONTROL(4,3) (Real; Default = 0.0; which bypasses the test)
<b>Contact-Related Parameters</b>	
ANG2D	Angle at which a node separates from a convex corner or becomes stuck in a concave corner in 2D contact (Real; Default = 8.625 degrees) PARAMETERS (3,1)
ANG3D	Angle at which a node separates from a convex corner or becomes stuck in a concave corner in 3D contact (Real; Default = 20.0 degrees) PARAMETERS (3,2)
<b>Other Parameters</b>	
DRILLF	The factor used to calculate the drilling mode for shell elements (types 22, 75, 138, 139, 140) DRILLF=1.0E-6*K6ROT. The default for DRILLF (0.0001) and K6ROT (100.0) produce the same results. If K6ROT is entered, it will be used for DRILLF unless DRILLF is also entered. DRILLF has precedence over K6ROT. (Real; Default = 0.0001) PARAMETERS (3,6)
REZONEF	Incremental displacement scale factor after a rezoning increment (Real; Default=1.0). Note that a value of 1.0 improves friction convergence but may result in an inside-out element. PARAMETERS (3,7)
UGAS	Universal Gas Constant (Real; Default = 8.314 J mol <sup>-1</sup> K <sup>-1</sup> ) PARAMETERS (4,1)

Table 9-30 Parameters (continued)

Name	Description, Type and Value Convergence Criteria
TOFSET	Offset temperature between user units and absolute zero temperature (Real; Default=273.15 which is correct for Centigrade). If temperature units are Kelvin (K) or Rankine (R), enter a negative value and the temperature offset is set to zero PARAMETERS (4,2)
TWEIGHT	Thermal properties evaluation weight (Real; Default = 0.5) PARAMETERS (4,3)
SPFACT	Surface projection factor for single step Houbolt method (Real; Default = 0.0) PARAMETERS (4,4)
STEFAN	Stefan Boltzman Constant (Real; Default = 5.67051E-8 W/m <sup>2</sup> K <sup>4</sup> PARAMETERS (4,5)
PLANKS	Planks second constant. (Real; Default = 14387.69 micro MK PARAMETERS (4,6)
CLIGHT	Speed of light in a vacuum. (Real; Default = 2.9979E14 micro M/s PARAMETERS (4,7)
RAPMAX	Maximum change in the incremental displacement in a Newton-Raphson iteration. (Real; Default = 1.0E30) PARAMETERS (4,8)
FISTIF	Initial friction stiffness for model 6 used in first cycle of an increment to define the friction stiffness matrix in cases where a touching node has a zero normal force and the amount of sliding does not exceed the elastic sticking limit. (Real; Default = 0.0 in which case the program calculates it.) PARAMETERS (5,1)
SNGMIN	Minimum value that indicates a singularity if a direct solver is used. (Real; Default = 0.0 in which case the value is set internally by the program.) PARAMETERS (5, 2)
RTMAX	Maximum change in temperature per iteration in radiation simulations. (Real; Default = 10 times the maximum error in temperature estimate or 100.0) PARAMETERS (5,3)
<b>New Items for Version 2005 r3 and Subsequent</b>	
IASMBL	Assembly flag. If set to 1, the stiffness matrix is assembled each iteration. Note that this switches off the modified Newton-Raphson procedure if chosen. (Integer)

Table 9-30 Parameters (continued)

Name	Description, Type and Value Convergence Criteria
INNER	For some material models, such as damage, cracking, and Chaboche, there is an inner iteration loop to insure accuracy. The maximum number of iterations allowed can be set here. (Integer; Default = 50)
RIGLNK	Rigid Link Rotation Tolerance: Maximum allowable value of the change in rotation increment at the retained nodes of RBE2, rigid link 80 or beam-shell offset nodes. Default is 0.0, in which case, no checking on rigid link rotations takes place. (Real)
RLROTT	Rigid Link Rotation Tolerance: Maximum allowable value of the change in rotation increment at the retained nodes of RBE2, rigid link 80 or beam-shell offset nodes. Default is 0.0, in which case, no checking on rigid link rotations takes place. (Real)  <b>Note:</b> If CONVTYPE is 4 or 5, the rigid link rotation tolerance entered here circumvents the corresponding value RIGLNK above. For all versions with PARAM, MARCVER less than 12, the rigid link rotation tolerance if left at 0, is reset to 0.001 radians to ensure backward compatibility for RBE2. In this case, the rigid link rotation tolerance should be set to a negative number to by-pass the check.
ENRGCH	Maximum allowable value of the change in energy increment. Enter only if CONVTYPE=2. (Real; Default = 0.1)

## Remarks:

1. This entry matches Marc's CONTROL, AUTO LOAD, DYNAMIC CHANGE, PARAMETERS, and SOLVER definitions.
2. NLSTRAT is recognized only when Marc is executed from SOL 600.
3. Correlation between NLSTRAT names and Marc CONTROL entry fields

2-1 MAXSTEP	3-1 RCK1	4-1 MAXDI	5-1 MAXENRG	6-1 TCHANGE
2-2 MAXREC	3-2 RCK2	4-2 MAXRI		6-2 TEVAL
2-3 MINREC	3-3 RCK3	4-3 MINDI		6-3 TERROR
2-4 CONVTYPE	3-4 RCK4	4-4 MINRI		6-4 VOLTMAX

2-7 GAMMA1	3-7 REZONEF	4-7 CLIGHT	
2-8 GAMMA2		4-8 RAPMAX	

5. Correlation between NLSTRAT names and Marc SOLVER entry fields

2-1 ISOLVER	3-1 MAXITER	4-1 CJTOL
2-2 ISYMM	3-2 PREVITER	
2-3 NONPOS	3-3 PRECOND	
2-8 MBYTE		

6. Correlation between NLSTRAT names and Marc AUTO INCREMENT entry fields

2-1 AIFRACT	2-6 AITOTT
2-2 AIMAXINC	2-7 AIARC0
2-3 AINRECYC	2-8 AITYPE
2-4 AIMAXF	2-9 AIMAXCUT
2-5 AIARCM	

7. Correlation between NLSTRAT names and Marc AUTO LOAD entry fields

2-2 IKUPD

2-3 MAXTSC

8. Correlation between NLSTRAT names and Marc DYNAMIC CHANGE entry fields

2-5 IKUPD

9. The ISOLVER must be the same for all load cases (and Phase 0) or Marc will abort. It is recommended that all other SOLVER items also be the same for the entire run. If ISOLVER is a value other than 8, NLSTART with ID=0 must be entered with the desired ISOLVER type. Multiply NLSTRAT entries with ID=1, 2, etc. may be used to change other values if desired.
10. ISYMM must be the same for all load cases. All discussions from note 10 apply to ISYMM.

**NOLIN1**

**Nonlinear Load as a Tabular Function**

Defines a forcing function for transient response or nonlinear harmonic response of the form

$$\text{Function of displacement: } P_i(t) = S \cdot T(u_j(t)) \text{ or } P_i(f) = S \cdot T(u_j(f)) \tag{9-26}$$

$$\text{Function of velocity: } P_i(t) = S \cdot T(\dot{u}_j(t)) \text{ or } P_i(f) = S \cdot T(\dot{u}_j(f)) \tag{9-27}$$

where  $t$  is time,  $f$  is frequency and  $u_j(t/f)$  and  $\dot{u}_j(t/f)$  are the displacement and velocity at point GJ in the direction of CJ.

Format:

1	2	3	4	5	6	7	8	9	10
NOLIN1	SID	GI	CI	S	GJ	CJ	TID		

Example:

NOLIN1	21	3	4	2.1	3	10	6		
--------	----	---	---	-----	---	----	---	--	--

Describer	Meaning
SID	Nonlinear load set identification number. (Integer > 0)
GI	Grid, scalar, or extra point identification number at which nonlinear load is to be applied. (Integer > 0)
CI	Component number for GI. (0 < Integer ≤ 6; blank or zero if GI is a scalar or extra point.)
S	Scale factor. (Real)
GJ	Grid, scalar, or extra point identification number. (Integer > 0)
CJ	Component number for GJ according to the following table:

Type of Point	Displacement	Velocity
Grid	1 ≤ Integer ≤ 6	11 ≤ Integer ≤ 16
Scalar	Blank or zero	Integer = 10
Extra	Blank or zero	Integer = 10

TID Identification number of a TABLEDi entry. (Integer > 0)

Remarks:

1. Nonlinear loads must be selected with the Case Control command NONLINEAR = SID.

2. Nonlinear loads may not be referenced on DLOAD entry.
3. All degrees-of-freedom referenced on NOLIN1 entries must be members of the solution set. This means the e-set (EPOINT entry) for modal formulation and the d-set for direct formulation.
4. Nonlinear loads as a function of velocity (9-27) are denoted by components ten greater than the actual component number; i.e., a component of 11 is component 1 (velocity). The velocity is determined by

$$\dot{u}_{j,t} = \frac{u_{j,t} - u_{j,t-1}}{\Delta t}$$

where  $\Delta t$  is the time step interval and  $u_{j,t-1}$  is the displacement of GJ-CJ for the previous time step.

5. The time step algorithm in transient solution sequences may lose unconditional stability when this load entry is used. In most practical cases, the time step size chosen to reach a certain accuracy is below the stability limit. It is recommended to decrease the time step if results diverge. Additional recommendations are outlined in the user guides.
6. RC network solver does not support NOLIN1 for thermal analysis.
7. When enforced motion is used, the NOLIN1 requires that PARAM,ENFMETH,ABS be specified because the generated loads are a function of total displacement and not relative displacement.
8. An alternate option for averaging nonlinear loads is available with DIAG 10, although it is *not* recommended.

**NOLIN2**

**Nonlinear Load as the Product of Two Variables**

Defines a forcing function for transient response or nonlinear harmonic response of the form

$$P_i(t) = S \cdot X_j(t) \cdot X_k(t) \text{ or } P_i(f) = S \cdot X_j(f) \cdot X_k(f)$$

where  $t$  is time,  $f$  is frequency and  $X_j(t/f)$  and  $X_k(t/f)$  can be either displacement or velocity at points GJ and GK in the directions of CJ and CK.

Format:

1	2	3	4	5	6	7	8	9	10
NOLIN2	SID	GI	CI	S	GJ	CJ	GK	CK	

Example:

NOLIN2	14	2	1	2.9	2	1	2		
--------	----	---	---	-----	---	---	---	--	--

Describer	Meaning
SID	Nonlinear load set identification number. (Integer > 0)
GI	Grid, scalar, or extra point identification number at which nonlinear load is to be applied. (Integer > 0)
CI	Component number for GI. (0 ≤ Integer ≤ 6; blank or zero if GI is a scalar or extra point.)
S	Scale factor. (Real)
GJ, GK	Grid, scalar, or extra point identification number. (Integer > 0)
CJ, CK	Component number for GJ, GK according to the following table:

Type of Point	Displacement	Velocity
Grid	1 ≤ Integer ≤ 6	11 ≤ Integer ≤ 16
Scalar	Blank or zero	Integer = 10
Extra	Blank or zero	Integer = 10

Remarks:

1. Nonlinear loads must be selected with the Case Control command NONLINEAR=SID.
2. Nonlinear loads may not be referenced on a DLOAD entry.
3. All degrees-of-freedom referenced on NOLIN2 entries must be members of the solution set. This means the e-set for modal formulation and the d-set for direct formulation.
4. GI-CI, GJ-CJ, and G  
K-CK may be the same point.

5. Nonlinear loads may be a function of displacement ( $X = u$ ) or velocity ( $X = \dot{u}$ ). Velocities are denoted by a component number ten greater than the actual component number; i.e., a component of 10 is component 0 (velocity). The velocity is determined by

$$\dot{u}_t = \frac{u_t - u_{t-1}}{\Delta t}$$

where  $\Delta t$  is the time step interval and  $u_{t-1}$  is the displacement of GJ-CJ or GK-CK for the previous time step.

6. The time step algorithm in transient solution sequences may lose unconditional stability when this load entry is used. In most practical cases, the time step size chosen to reach a certain accuracy is below the stability limit. It is recommended to decrease the time step if results diverge. Additional recommendations are outlined in the user guides.
7. RC network solver does not support NOLIN2 for thermal analysis.
8. When enforced motion is used, the NOLIN2 requires that PARAM,ENFMETH,ABS be specified because the generated loads are a function of total displacement and not relative displacement.
9. An alternate option for averaging nonlinear loads is available with DIAG 10, although it is *not* recommended.

**NOLIN3**

**Nonlinear Load as a Positive Variable Raised to a Power**

Defines a forcing function for transient response or nonlinear harmonic response of the form

$$P_i(t) = \begin{cases} S \cdot [X_j(t)]^A, & X_j(t) > 0 \\ 0, & X_j(t) \leq 0 \end{cases} \quad \text{or} \quad P_i(f) = \begin{cases} S \cdot [X_j(f)]^A, & X_j(f) > 0 \\ 0, & X_j(f) \leq 0 \end{cases}$$

where  $t$  is time,  $f$  is frequency and  $X_j(t/f)$  may be a displacement or a velocity at point GJ in the direction of CJ.

Format:

1	2	3	4	5	6	7	8	9	10
NOLIN3	SID	GI	CI	S	GJ	CJ	A		

Example:

NOLIN3	4	102		-6.1	2	15	-3.5		
--------	---	-----	--	------	---	----	------	--	--

Descriptor	Meaning
SID	Nonlinear load set identification number. (Integer > 0)
GI	Grid, scalar, or extra point identification number at which the nonlinear load is to be applied. (Integer > 0)
CI	Component number for GI. (0 ≤ Integer ≤ 6; blank or zero if GI is a scalar or extra point.)
S	Scale factor. (Real)
GJ	Grid, scalar, extra point identification number. (Integer > 0)
CJ	Component number for GJ according to the following table:

Type of Point	Displacement	Velocity
Grid	1 ≤ Integer ≤ 6	11 ≤ Integer ≤ 16
Scalar	Blank or zero	Integer = 10
Extra	Blank or zero	Integer = 10

A Exponent of the forcing function. (Real)

## Remarks:

1. Nonlinear loads must be selected with the Case Control command `NONLINEAR = SID`.
2. Nonlinear loads may not be referenced on a `DLOAD` entry.
3. All degrees-of-freedom referenced on `NOLIN3` entries must be members of the solution set. This means the e-set for modal formulation and the d-set for direct formulation.
4. Nonlinear loads may be a function of displacement ( $X_j = u_j$ ) or velocity ( $X_j = \dot{u}_j$ ). Velocities are denoted by a component number ten greater than the actual component number; e.g., a component of 16 is component 6 (velocity). The velocity is determined by

$$\dot{u}_{j,t} = \frac{u_{j,t} - u_{j,t-1}}{\Delta t}$$

where  $\Delta t$  is the time step interval and  $u_{j,t-1}$  is the displacement of GJ-CJ for the previous time step.

5. Use a `NOLIN4` entry for the negative range of  $X_j(t)$ .
6. The time step algorithm in transient solution sequences may lose unconditional stability when this load entry is used. In most practical cases, the time step size chosen to reach a certain accuracy is below the stability limit. It is recommended to decrease the time step if results diverge. Additional recommendations are outlined in the user guides.
7. RC network solver does not support `NOLIN3` for thermal analysis.
8. When enforced motion is used, the `NOLIN3` requires that `PARAM,ENFMETH,ABS` be specified because the generated loads are a function of total displacement and not relative displacement.
9. An alternate option for averaging nonlinear loads is available with `DIAG 10`, although it is *not* recommended.

**NOLIN4**

**Nonlinear Load as a Negative Variable Raised to a Power**

Defines a forcing function for transient response or nonlinear harmonic response of the form

$$P_i(t) = \begin{cases} -S \cdot [-X_j(t)]^A, & X_j(t) < 0 \\ 0, & X_j(t) \geq 0 \end{cases} \text{ or } P_i(f) = \begin{cases} -S \cdot [-X_j(f)]^A, & X_j(f) < 0 \\ 0, & X_j(f) \geq 0 \end{cases}$$

where *t* is time, *f* is frequency and *X<sub>j</sub>(t/f)* may be a displacement or a velocity at point GJ in the direction of CJ.

Format:

1	2	3	4	5	6	7	8	9	10
NOLIN4	SID	GI	CI	S	GJ	CJ	A		

Example:

NOLIN4	2	4	6	2.0	101		16.3		
--------	---	---	---	-----	-----	--	------	--	--

Descriptor	Meaning
SID	Nonlinear load set identification number. (Integer > 0)
GI	Grid, scalar, or extra point identification number at which nonlinear load is to be applied. (Integer > 0)
CI	Component number for GI. (0 < Integer ≤ 6; blank or zero if GI is a scalar or extra point.)
S	Scale factor. (Real)
GJ	Grid, scalar, or extra point identification number. (Integer > 0)
CJ	Component number for GJ according to the following table:

Type of Point	Displacement	Velocity
Grid	1 ≤ Integer ≤ 6	11 ≤ Integer ≤ 16
Scalar	Blank or zero	Integer = 10
Extra	Blank or zero	Integer = 10

A Exponent of forcing function. (Real)

## Remarks:

1. Nonlinear loads must be selected with the Case Control command `NONLINEAR = SID`.
2. Nonlinear loads may not be referenced on a `DLOAD` entry.
3. All degrees-of-freedom referenced on `NOLIN4` entries must be members of the solution set. This means the e-set for modal formulation and the d-set for direct formulation.
4. Nonlinear loads may be a function of displacement ( $X_j = u_j$ ) or velocity ( $X_j = \dot{u}_j$ ). Velocities are denoted by a component number ten greater than the actual component number; i.e., a component of 10 is component 0 (velocity). The velocity is determined by

$$\dot{u}_{j,t} = \frac{u_{j,t} - u_{j,t-1}}{\Delta t}$$

where  $\Delta t$  is the time step interval and  $u_{j,t-1}$  is the displacement of GJ-CJ for the previous time step.

5. Use a `NOLIN3` entry for the positive range of  $X_j(t)$ .
6. The time step algorithm in transient solution sequences may lose unconditional stability when this load entry is used. In most practical cases, the time step size chosen to reach a certain accuracy is below the stability limit. It is recommended to decrease the time step if results diverge. Additional recommendations are outlined in the user guides.
7. RC network solver does not support `NOLIN4` for thermal analysis.
8. When enforced motion is used, the `NOLIN4` requires that `PARAM,ENFMETH,ABS` be specified because the generated loads are a function of total displacement and not relative displacement.
9. An alternate option for averaging nonlinear loads is available with `DIAG 10`, although it is *not* recommended.

## NSM Non Structural Mass Entry by ID

Defines a set of non structural mass.

Format:

1	2	3	4	5	6	7	8	9	10
NSM	SID	TYPE	ID	VALUE	ID	VALUE	ID	VALUE	
	ID	VALUE	-etc.-						

Example:

NSM	3	PSHELL	15	.022					
-----	---	--------	----	------	--	--	--	--	--

Describer	Meaning
SID	Identification number of non structural mass set. (Integer > 0)
TYPE	Set points to either Property entries or Element entries. Properties are: PSHELL, PCOMP, PCOMPG, PBAR, PBARL, PBEAM, PBEAML, PBCOMP, PROD, CONROD, PBEND, PSHEAR, PTUBE, PCONEAX, and PRAC2D. ELEMENT list of individual element IDs of element that can have NSM. (Character)
ID	Property or Element ID. (Integer > 0)
VALUE	NSM value (Real)

Remarks:

1. Non structural mass sets must be selected with Case Control command NSM = SID.
2. For CCONEAX the element ID is  $1000 \cdot ID + i$ , where  $i = 1$  to number of harmonics.
3. The ELSUM Case Control command will give a summary of both structural and nonstructural mass by element or property type.

## NSM1

### Alternate Form for NSM Entry

Defines non structural mass entries by VALUE,ID list.

Format:

1	2	3	4	5	6	7	8	9	10
NSM1	SID	TYPE	VALUE	ID	ID	ID	ID	ID	
	ID	ID	ID	etc.	-				

Example:

NSM1	3	ELEMENT	.044	1240	1500	THRU	1600	BY	
	2	2440	THRU	2560					

Alternate Form and Example(s), applicable when NASTRAN SYSTEM(444)=0 (IFPSTAR=NO):

(All must be in FIELD 5 and non continuation is allowed)

NSM1	SID	TYPE	VALUE	ID	THRU	ID			
NSM1	SID	TYPE	VALUE	ALL					
NSM1	SID	TYPE	VALUE	ID	THRU	ID	BY	N	

Describer	Meaning
SID	Identification number of non structural mass set. (Integer > 0)
TYPE	Set points to either Property entries or Element entries. Properties are: PSHELL, PCOMP, PCOMPG, PBAR, PBARL, PBEAM, PBEAML, PBCOMP, PROD, CONROD, PBEND, PSHEAR, PTUBE, PCONEAX, and PRAC2D. ELEMENT list of individual element IDs of element that can have NSM. (Character)
VALUE	NSM value (Real)
ID	Property or Element ID. (Integer > 0 or "ALL" or "THRU" or "BY" or N (the BY increment))

Remarks:

1. Non structural mass sets must be selected with Case Control command NSM = SID.
2. For CCONEAX the element ID is  $1000 \cdot ID + i$ , where  $i = 1$  to number of harmonics.
3. PBEAML and PBCOMP are treated as PBEAM, PBARL is treated as PBAR, and PCOMP or PCOMPG is treated as PSHELL; therefore a command such as:

NSM1,12,PCOMP,0.045,ALL

would for example get all PSHELLs in the file. The converted PCOMPs or PCOMPGs plus any existing PSHELLs would have .045 added to their nonstructural mass.

4. The ELSUM Case Control command will give a summary of both structural and nonstructural mass by element or property type.

## NSMADD Non Structural Mass Set Combination

Defines non structural mass as the sum of the sets listed.

Format:

1	2	3	4	5	6	7	8	9	10
NSMADD	SID	S1	S2	S3	S4	S5	S6	S7	
	S8	S9	S10	etc.	-				

Example(s):

NSMADD	3	17	18	19	20	22	23	24	
	25	26	27	28					
NSMADD	3	29	40	50	55				

Describer	Meaning
SID	Identification number of non structural mass set. (Integer > 0)
Si	Identification numbers of non structural mass sets defined via NSM, NSML, NSM1, and NSML1 entries. (Integer > 0; SID ≠ Si)

Remarks:

1. The non structural mass sets must be selected with the Case Control command NSM = SID.
2. No Si may be the identification number of a non structural mass set defined by another NSMADD entry.
3. NSMADD entries take precedence over NSM, NSML, NSM1 or NSML1 entries. If both have the same set ID, only the NSMADD entry will be used.
4. The ELSUM Case Control command will give a summary of both structural and nonstructural mass by element or property type.

## NSML

## Lumped Non Structural Mass Entry by ID

Defines a set of lumped non structural mass.

Format:

1	2	3	4	5	6	7	8	9	10
NSML	SID	TYPE	ID	VALUE	ID	VALUE	ID	VALUE	
	ID	VALUE	-etc.-						

Example:

NSML	3	PSHELL	15	.66					
------	---	--------	----	-----	--	--	--	--	--

Describer	Meaning
SID	Identification number of non structural mass set. (Integer > 0)
TYPE	Set points to either Property entries or Element entries. Properties are: PSHELL, PCOMP, PCOMPG, PBAR, PBARL, PBEAM, PBEAML, PBCOMP, PROD, CONROD, PBEND, PSHEAR, PTUBE, PCONEAX, and PRAC2D. ELEMENT list of individual element IDs of element that can have NSM. (Character)
ID	Property or Element ID. (Integer > 0)
VALUE	A lumped mass value to be distributed. (Real)

Remarks:

1. If TYPE = ELEMENT is used, line element (CBAR, CBEAM, CBEND, CROD, CTUBE, and CONROD) IDs cannot be mixed with Area element (CQUAD4, CQUAD8, CQUADR, CTRIA3, CTRIA6, CTRIAR, CSHEAR, and CRAC2D) IDs.
2. For Area elements the calculation is  $NSM = VALUE / \sum_{elements} Area$  and for Line elements the calculation is  $NSM = VALUE / \sum_{elements} Length$ .
3. Non structural mass sets must be selected with Case Control command NSM = SID.
4. This entry is not allowed for the CCONEAX element.
5. This entry will cause an equivalent NSM entry to be generated using the computed value for NSM.
6. The ELSUM Case Control command will give a summary of both structural and nonstructural mass by element or property type.
7. Undefined property/element IDs are ignored.

## NSML1

## Alternate Form for NSML Entry

Defines lumped non structural mass entries by VALUE,ID list.

Format:

1	2	3	4	5	6	7	8	9	10
NSML1	SID	TYPE	VALUE	ID	ID	ID	ID	ID	
	ID	ID	ID	etc.	-				

Example:

NSML1	3	ELEMENT	.044	1240	1500				
-------	---	---------	------	------	------	--	--	--	--

Alternate Form and Example(s):

NSML1	SID	TYPE	VALUE	ID	THRU	ID	ID	THRU	
	ID	ID	THRU	ID	ID	THRU	ID	ID	
	THRU	ID	...						

NSML1	15	PSHELL	.067	1240	THRU	1760			
	2567	THRU	2568	35689	THRU	40998			
	76	THRU	300						

NSML1	SID	TYPE	VALUE	ID	THRU	ID	BY	N	
	ID	THRU	ID	BY	N	...			

NSML1	3	PSHELL	.067	1240	THRU	1760	1763	1764	
	2567	THRU	2568	35689	TO	40999	BY	2	
	76666	76668	79834						

(ALL must be in FIELD 5 and no continuation is allowed)

NSML1	SID	TYPE	VALUE	ALL					
-------	-----	------	-------	-----	--	--	--	--	--

NSML1	59	PTUBE	.0123	ALL					
-------	----	-------	-------	-----	--	--	--	--	--

Descriptor	Meaning
------------	---------

SID Identification number of non structural mass set. (Integer > 0)

TYPE Set points to either Property entries or Element entries. Properties are: PSHELL, PCOMP, PCOMPG, PBAR, PBARL, PBEAM, PBEAML, PBCOMP, PROD, CONROD, PBEND, PSHEAR, PTUBE, PCONEAX, and PRAC2D. ELEMENT list of individual element IDs of element that can have NSM. (Character)

Describer	Meaning
VALUE	A lumped mass value to be distributed (Real)
ID	Property or Element ID. (Integer > 0 or "ALL" or "THRU" or "TO" or "BY" or N (the BY increment))

#### Remarks:

1. If TYPE = ELEMENT is used, line element (CBAR, CBEAM, CBEND, CROD, CTUBE, and CONROD) IDs cannot be mixed with Area element (CQUAD4, CQUAD8, CQUADR, CTRIA3, CTRIA6, CTRIAR, CSHEAR, and CRAC2D) IDs.
2. For Area elements the calculation is  $NSM = VALUE / \sum_{elements} Area$  and for Line elements the calculation is  $NSM = VALUE / \sum_{elements} Length$ .
3. For NSML1 entries with multiple "THRU" and "THRU,BY" and "ID" lists or any such combination of entries, the  $NSM = VALUE / \sum_{elements} Area$  and for Line elements the calculation is  $NSM = VALUE / \sum_{elements} Length$  is based on the individual parent card plus all continuation entries. If an element appears more than once in these multiple combinations, its area or length will be used multiple times in the sum.
4. Nonstructural mass sets must be selected with Case Control command NSM=SID.
5. This entry is not allowed for the CCONEAX element.
6. PBEAML and PBCOMP are treated as PBEAM, PBARL is treated as PBAR, and PCOMP or PCOMPG is treated as PSHELL; therefore a command such as:  
`NSML1,12,PCOMP,1.35,ALL`  
would, for example, get all PSHELLs in the file. The converted PCOMPs or PCOMPGs plus any existing PSHELLs would have a mass of 1.35 added to their nonstructural mass.
7. The ELSUM Case Control command will give a summary of both structural and non structural mass by element or property type.
8. With the "THRU" and "THRU", "BY" forms, blanks fields are allowed for readability. Any combination of a list of IDs and "THRU" and "THRU", "BY" is allowed. The "THRU" and "BY" lists may have missing IDs. That is the list of IDs in a THRU range need not be continuous.
9. Undefined property/element IDs are ignored.

## NTHICK

## Nodal Thickness Values - SOL 600

Defines nodal thickness values for beams, plates and/or shells. This is the Marc's nodal thickness option used in SOL 600 only.

Format:

1	2	3	4	5	6	7	8	9	10
NTHICK	ID1	ID2	THICK						

Example:

NTHICK	151	180	0.255						
--------	-----	-----	-------	--	--	--	--	--	--

Describer	Meaning
ID1	First Nodal ID to which the thickness applies. (Integer > 0)
ID2	Last Nodal ID to which the thickness applies. (Integer; Default = EID1)
THICK	Thickness for all beam, plate or shell elements connecting the nodes specified. (Real > 0.0)

Remarks:

1. The option allows specification of beam, plate and/or shell thickness on a nodal basis. Thickness values specified on property entries overrides values specified by this entry.
2. For all elements including composite elements, nodal thickness is the total thickness.
3. Discontinuities must be modeled using property entries.

## OMIT Omitted Degrees-of-Freedom

Defines degrees-of-freedom to be excluded (o-set) from the analysis set (a-set).

Format:

1	2	3	4	5	6	7	8	9	10
OMIT	ID1	C1	ID2	C2	ID3	C3	ID4	C4	

Example:

OMIT	16	2	23	3516			1	4	
------	----	---	----	------	--	--	---	---	--

Describer	Meaning
ID <sub>i</sub>	Grid or scalar point identification number. (Integer > 0)
C <sub>i</sub>	Component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; zero or blank for scalar points.)

Remarks:

1. The degrees-of-freedom specified on this entry form members of the mutually exclusive o-set. They may not be specified on other entries that define mutually exclusive sets. See [“Degree-of-Freedom Sets”](#) for a list of these entries.
2. Up to 24 degrees-of-freedom may be specified on a single entry.
3. In many cases it may be more convenient to use OMIT1, ASET, or ASET1 entries.
4. In nonlinear analysis, degrees-of-freedom attached to nonlinear elements must be placed in the a-set. In other words, nonlinear degrees-of-freedom must not be specified on OMIT or OMIT1 entries.
5. SOL 400 does not support ASET<sub>i</sub>, OMIT<sub>i</sub>, BSET<sub>i</sub>, CSET<sub>i</sub>, SUPORT<sub>i</sub>, and QSET<sub>i</sub> except in the following situations:
  - a. Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
  - b. Linear perturbation with:
    - i. EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
    - ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
  - c. Superelements defined with BEGIN SUPER may contain ASET<sub>i</sub>, OMIT<sub>i</sub>, BSET<sub>i</sub>, CSET<sub>i</sub>, and QSET<sub>i</sub> entries.

## OMIT1 Omitted Degrees-of-Freedom, Alternate Form 1

Defines degrees-of-freedom to be excluded (o-set) from the analysis set (a-set).

Format:

1	2	3	4	5	6	7	8	9	10
OMIT1	C	G1	G2	G3	G4	G5	G6	G7	
	G8	G9	G10	-etc.-					

Example:

OMIT1	3	2	1	3	10	9	6	5	
	7	8							

Alternate Format and Example:

OMIT1	C	G1	“THRU”	G2					
OMIT1	0	17	THRU	109					

Describer	Meaning
C	Component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; zero or blank for scalar points.)
Gi	Grid or scalar point identification number. (Integer > 0; for “THRU” option, G1 < G2.)

Remarks:

- The degrees-of-freedom specified on this entry form members of the mutually exclusive o-set. They may not be specified on other entries that define mutually exclusive sets. See “[Degree-of-Freedom Sets](#)” for a list of these entries.
- If the alternate format is used, not all points in the range G1 through G2 have to be defined. Undefined points will collectively produce a warning message but will otherwise be ignored.
- In nonlinear analysis, degrees-of-freedom attached to nonlinear elements must be placed in the a-set. In other words, nonlinear degrees-of-freedom must not be specified on OMIT or OMIT1 entries.
- SOL 400 does not support ASETi, OMITi, BSETi, CSETi, SUPORTi, and QSETi except in the following situations:
  - Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
  - Linear perturbation with:
    - EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.

- ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark [21](#). under the ADAMSMNF Case Control command.
- c. Superelements defined with BEGIN SUPER may contain ASETi, OMITi, BSETi, CSETi, and QSETi entries.

## OMITAX

## Omitted Conical Shell Degrees-of-Freedom

Defines degrees-of-freedom to be excluded (o-set) from the analysis set (a-set).

Format:

1	2	3	4	5	6	7	8	9	10
OMITAX	RID1	HID1	C1	RID2	HID2	C2			

Example:

OMITAX	2	6	3	4	7	1			
--------	---	---	---	---	---	---	--	--	--

Describer	Meaning
RIDi	Ring identification number. (Integer > 0)
HIDi	Harmonic identification number. (Integer ≥ 0)
Ci	Component number(s). (Any unique combination of the Integers 1 through 6 with no embedded blanks.)

Remarks:

1. OMITAX is allowed only if an AXIC entry is also present.
2. Up to 12 degrees-of-freedom may be specified on this entry.
3. Degrees-of-freedom appearing on OMITAX entries may not appear on MPCAX, SUPAX, or SPCAX entries.
4. SOL 400 does not support OMITAX as well ASETi, OMITi, BSETi, CSETi, SUPORTi.

## Entries P

### PAABSF

### Frequency-Dependent Absorbers Element Property

#### Format:

1	2	3	4	5	6	7	8	9	10
PAABSF	PID	TZREID	TZIMID	S	A	B	K	RHOC	

#### Example:

PAABSF	44	38	47						
--------	----	----	----	--	--	--	--	--	--

Describer	Meaning
PID	Property identification number that matches the identification number of the corresponding CAABSF entry. (Integer > 0)
TZREID	Identification number of a TABLEDi entry that defines the resistance as a function of frequency. The real part of the impedance. See Remark 1. (Integer ≥ 0 or blank)
TZIMID	Identification number of a TABLEDi entry that defines the reactance as a function of frequency. The imaginary part of the impedance. See Remark 1. (Integer ≥ 0 or blank)
S	Impedance scale factor. (Real; Default = 1.0)
A	Area factor when 1 or 2 grid points are specified on the CAABSF entry. (Real > 0.0; Default = 1.0)
B	Equivalent structural damping coefficient. See Remark 1. (Real ≥ 0.0; Default = 0.0)
K	Equivalent structural stiffness coefficient. See Remark 1. (Real ≥ 0.0; Default = 0.0)
RHOC	Constant used in data recovery for calculating an absorption coefficient. RHO is the media density, and C is the speed of sound in the media. (Real; Default = 1.0)

#### Remarks:

- At least one of the four fields TZREID, TZIMID, B, or K must be specified.
- If only one grid point is specified on the CAABSF entry, then the impedance  $Z(f) = Z_R + iZ_I$  is the total impedance at the point. If two grids are specified, then the impedance is the impedance per unit length. If three or four points are specified, then the impedance is the impedance per unit area.  $Z_R(f) = \text{TZREID}(f) + B$  and  $Z_I(f) = \text{TZIMID}(f) - K/(2\pi f)$ .
- The resistance represents a damper quantity B. The reactance represents a quantity of the type  $(\omega M - K/\omega)$ . The impedance is defined as  $Z = p/\dot{u}$  where  $p$  is the pressure and  $\dot{u}$  is the velocity.
- The impedance scale factor S is used in computing element stiffness and damping terms as:

$$k = \frac{A}{S} \cdot \frac{2\pi f Z_I(f)}{Z_R^2 + Z_I^2} \int (\text{of shape functions})$$

$$b = \frac{A}{S} \cdot \frac{Z_R(f)}{Z_R^2 + Z_I^2} \int (\text{of shape functions})$$

The value of  $(Z_R^2 + Z_I^2)$  must be greater than machine epsilon--a machine dependent constant in the neighborhood of 1.E-15. The scale factor S can be used to ensure this constraint while retaining the same units.

- The output for the element is specified by the STRESS Case Control command and consists of the resistance, reactance, and absorption coefficient. The absorption coefficient is defined as:

$$a = \frac{4(Z_R/\rho c)}{(Z_R/\rho c + 1)^2 + (Z_I/\rho c)^2}$$

## PACABS Acoustic Absorber Property

Defines the properties of the acoustic absorber element.

### Format:

1	2	3	4	5	6	7	8	9	10
PACABS	PID	SYNTH	TID1	TID2	TID3		CUTFR	B	
	K	M							

### Example:

PACABS	12		1	2	3	3.5	500.0		
--------	----	--	---	---	---	-----	-------	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0)
SYNTH	Request the calculation of B, K, and M from the tables TIDi below. (Character = “YES” or “NO”; Default = “YES”)
TID1	Identification of the TABLEDi entry that defines the resistance. See Remark 2. (Integer > 0 or blank)
TID2	Identification of the TABLEDi entry that defines the reactance. See Remark 2. (Integer > 0 or blank)
TID3	Identification of the TABLEDi entry that defines the weighting function. See Remark 2. (Integer > 0 or blank)
CUTFR	Cutoff frequency for tables referenced above. (Real > 0.0)
B, K, M	Equivalent damping, stiffness and mass values per unit area. (Real ≥ 0.0)

### Remarks:

1. PACABS is referenced by a CHACAB entry only.
2. If SYNTH = “YES”, then TID1 and TID2 must be supplied (TID3 is optional) and the equivalent structural model will be derived from tables TIDi. If TID3 is blank, then the weighting function defaults to 1.0.
3. If SYNTH = “NO”, then the equivalent structural model will be derived from one of B, K, or M.
4. The continuation entry is optional.
5. All data defined in tables TIDi must be a function of frequency in cycles/unit time.

## PACBAR

## Acoustic Barrier Property

Defines the properties of the acoustic barrier element.

### Format:

1	2	3	4	5	6	7	8	9	10
PACBAR	PID	MBACK	MSEPTM	FRESON	KRESON				

### Example:

PACBAR	12	1.0	0.01	400.0					
--------	----	-----	------	-------	--	--	--	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0)
MBACK	Mass per unit area of the backing material. (Real > 0.0)
MSEPTM	Mass per unit area of the septum material. (Real > 0.0)
FRESON	Resonant frequency of the sandwich construction in hertz. (Real > 0.0 or blank)
KRESON	Resonant stiffness of the sandwich construction. (Real > 0.0 or blank)

### Remarks:

1. PACBAR is referenced by a CHACBR entry only.
2. Either FRESON or KRESON must be specified, but not both.

## PACINF Acoustic Conjugate Infinite Element Property

Defines the properties of acoustic conjugate infinite elements.

### Format:

1	2	3	4	5	6	7	8	9	10
PACINF	PID	MID	RIO	XP	YP	ZP			

### Example:

PACINF	100	10	5	0.	1.	2.			
--------	-----	----	---	----	----	----	--	--	--

Describer	Meaning
PID	Property Identification Number of PACINF entry. (Integer > 0)
MID	Material Identification Number of a MAT10 entry. (Integer > 0)
RIO	Radial Interpolation Order. (Integer > 0; no Default)
XP, YP, ZP	Coordinates of the Pole of the Infinite Elements (in the Basic Coordinate System).

### Remark:

1. The location of the pole together with the connecting grid points of the element, define the geometry of the element, see [Figure 9-104](#).

Figure 9-104 Geometry of Infinite Element

2. The radial interpolation order required depends on the directivity of the pressure field.

## PAERO1 Aerodynamic Panel Property

Defines associated bodies for the panels in the Doublet-Lattice method.

### Format:

1	2	3	4	5	6	7	8	9	10
PAERO1	PID	B1	B2	B3	B4	B5	B6		

### Example:

PAERO1	1	3							
--------	---	---	--	--	--	--	--	--	--

Describer	Meaning
PID	Property identification number referenced by a CAERO1 entry. (Integer > 0)
Bi	Identification number of CAERO2 entries for associated bodies. Embedded blanks are not allowed. (Integer ≥ 0 or blank)

### Remarks:

1. The associated bodies must be in the same aerodynamic group, as specified in the IGID field on CAERO2 entry.
2. If there are no bodies, the entry is still required (with Bi fields blank).
3. The Bi numbers above must appear on a CAERO2 entry to define these bodies completely.

**PAERO2****Aerodynamic Body Properties**

Defines the cross-sectional properties of aerodynamic bodies.

**Format:**

1	2	3	4	5	6	7	8	9	10
PAERO2	PID	ORIENT	WIDTH	AR	LRSB	LRIB	LTH1	LTH2	
	THI1	THN1	THI2	THN2	THI3	THN3			

**Example:**

PAERO2	2	Z	6.0	1.0	22	91	100		
	1	3							

Describer	Meaning
PID	Property identification number. (Integer > 0)
ORIENT	Orientation flag. Type of motion allowed for bodies. Refers to the aerodynamic coordinate system of ACSID. See AERO entry. (Character = "Z", "Y", or "ZY")
WIDTH	Reference half-width of body and the half-width of the constant width interference tube. (Real > 0.0)
AR	Aspect ratio of the interference tube (height/width). (Real > 0.0)
LRSB	Identification number of an AEFAC T entry containing a list of slender body half-widths at the end points of the slender body elements. If blank or zero, the value of WIDTH will be used. (Integer ≥ 0 or blank)
LRIB	Identification number of an AEFAC T entry containing a list of interference body half-widths at the end points of the interference elements. If blank or zero, the value of WIDTH will be used. (Integer ≥ 0 or blank)
LTH1, LTH2	Identification number of AEFAC T entries for defining $\theta$ arrays for interference calculations. (Integer ≥ 0)
THI <sub>i</sub> , THN <sub>i</sub>	The first and last interference element of a body to use the $\theta_1$ array; the others use the $\theta_2$ array. (Integer ≥ 0)

**Remarks:**

1. The half-widths (given on AEFAC T entries referenced in fields 6 and 7) are specified at division points. The number of entries on an AEFAC T entry used to specify half-widths must be one greater than the number of elements.
2. The half-width at the first point (i.e., the nose) on a slender body is usually 0.0; thus, it is recommended (but not required) that the LRSB data is supplied with a zero first value.
3. THI<sub>i</sub> and THN<sub>i</sub> are interference element numbers on a body. The first element is one for each body.

- A body is represented by a slender body surrounded by an interference tube. The slender body creates the downwash due to the motion of the body, while the interference tube represents the effects upon panels and other bodies.

Figure 9-105 Idealization of Aerodynamic Body

- The angles  $\theta_1$  and  $\theta_2$  are input in degrees using the aerodynamic element coordinate system as the reference coordinate system for defining the theta points.
- Distribution of the theta points need not be uniform. A theta point must be placed a finite distance from any aerodynamic box edge; preferably the box edge would be equidistant from any two theta points. This aerodynamic coordinate system is defined on the AERO Bulk Data entry.
- For half models, the theta arrays LTH1 and LTH2 should encompass a full 360 degree range.

**PAERO3****Aerodynamic Panel Property**

Defines the number of Mach boxes in the flow direction and the location of cranks and control surfaces of a Mach box lifting surface.

**Format:**

1	2	3	4	5	6	7	8	9	10
PAERO3	PID	NBOX	NCTRL		X5	Y5	X6	Y6	
	X7	Y7	X8	Y8	X9	Y9	X10	Y10	
	X11	Y11	X12	Y12					

**Example:**

PAERO3	2001	15	1		0.	65.			
	78.	65.	108.	65.	82.	97.5	112.	97.5	
	86.	130.	116.	130.					

Describer	Meaning
PID	Property identification number. (Integer > 0)
NBOX	Number of Mach boxes in the flow direction. (0 < Integer < 50)
NCTRL	Number of control surfaces. (Integer 0, 1, or 2)
X5 through Y12	Locations of points 5 through 12, which are in the aerodynamic coordinate system, to define the cranks and control surface geometry. (Real)

**Remarks:**

1. For an illustration of the geometry, see the CAERO3 entry description.
2. If  $Y5 \leq 0.0$ , there is no leading edge crank. Also, if  $Y6 \leq 0.0$ , there is no trailing edge crank.
3. If NCTRL = 0, no continuations are required. If NCTRL = 1 or 2, then NCTRL continuations are required.
4.  $Y7 \geq Y8$ ,  $Y9 \geq Y10$ , and  $Y11 \geq Y12$ .
5. The number of Mach boxes in the spanwise direction (NSB) may be found from the following formula:

$$NSB = \text{INT} \left[ \frac{\beta \cdot y_{max}}{\left( \frac{x_{max}}{NBOX + 0.5} \right)} + 0.5 \right]$$

where:

$$\beta = \sqrt{M^2 - 1}$$

$x_{max}$  = maximum chordwise direction

$y_{max}$  = maximum spanwise direction

NBOX = initial number of boxes specified in field 3

The number of Mach boxes in the streamwise direction may then be computed from:

$$NBOX = \text{INT} \left[ \frac{x_{max}}{\left( \frac{\beta \cdot y_{max}}{NSB - 0.5} \right)} + 0.999 \right]$$

The number of chordwise boxes specified by the user ( $NBOX \geq 50$ ) will be replaced by a floating point number (usually slightly higher than NBOX). The method contracts the mesh equally in both dimensions until a box edge lies on the surface tip. This mesh size is then used to compute the number of chordwise boxes.

**Note:** A minimum of seven Mach boxes in the flow direction (NBOX) is recommended.

**PAERO4**

**Aerodynamic Strip Properties**

Defines properties of each strip element for Strip theory.

**Format:**

1	2	3	4	5	6	7	8	9	10
PAERO4	PID	CLA	LCLA	CIRC	LCIRC	DOC1	CAOC1	GAPOC1	
	DOC2	CAOC2	GAPOC2	DOC3	CAOC3	GAPOC3	-etc.-		

**Example:**

PAERO4	6001	1	501	0	0	0.0	0.0	0.0	
	0.50	0.25	0.02	0.53	0.24	0.0			

Describer	Meaning
PID	Property identification number. (Integer > 0)
CLA	Select Prandtl-Glauert correction. (Integer = -1, 0, 1; Default = 0) -1 Compressibility correction made to lift curve slope data for a reference Mach number. 0 No correction and no list needed. (Default) +1 No correction and lift curve slope provided by a list as a function of strip location and Mach number.
LCLA	Identification number of the AEFACCT entry that lists the lift curve slope on all strips for each Mach number on the MKAEROi entry. See Remark 7(b.) below. (Integer = 0 if CLA = 0, > 0 if CLA ≠ 0)
CIRC	Select Theodorsen’s function $C(k)$ or the number of exponential coefficients used to approximate $C(k)$ . (Integer = 0, 1, 2, 3; Default = 0; Must be zero if CLA ≠ 0.) 0 Theodorsen function. 1, 2, 3 Approximate function with $b_0, b_1, \beta_1, \dots, b_n, \beta_n$ $n = 1, 2, 3$ .
LCIRC	Identification number of the AEFACCT entry that lists the $b, \beta$ values for each Mach number. See Remark 7c., 7d., and 7e. below; variable $b$ ’s and $\beta$ ’s for each mi on the MKAEROi entry. (Integer = 0 if CIRC = 0, > 0 if CIRC ≠ 0)
DOCi	$d/c$ distance of the control surface hinge aft of the quarter-chord divided by the strip chord. (Real ≥ 0.0)
CAOCi	$c_a/c$ control surface chord divided by the strip chord. (Real ≥ 0.0)
GAPOCi	$g/c$ control surface gap divided by the strip chord. (Real ≥ 0.0)

**Remarks:**

1. PAERO4 is required for Strip theory with three fields (DOCi, CAOCi, GAPOCi) specified per strip.

2. If CLA = -1, lift curve slope data at one Mach number are needed on the AEFACCT entry.
3. If CAOCi = 0.0, there is no control surface.
4. If GAPOCivb = 0.0, there is no slot flow.
5. If GAPOCi < 0.01, then 0.01 is used.
6. Embedded blank fields are not permitted.
7. Table 9-31 lists the lift curve slope or lag function selection and the AEFACCT entry formats used for Strip theory:

Table 9-31 Strip Theory Function Selections and AEFACCT Entry Formats

Theodorsen Function	Data Type Input	Parameter Combinations				Number of Words	Entry Format Index
		CLA	LCLA	CIRC	LCIRC		
Exact	Lift Curve Slope $c_{l_{ai}} = 2\pi$	0	0	0	0	No AEFACCT entry required	
	$c_{l_{ai}}$ Input, Uses Prandtl-Glauert Correction	-1	ID	0	0	(NSTRIPI+1)	a.
	$c_{l_{ai}}$ Input, for All m's on MKAERO Entry	1	ID	0	0	(NSTRIPI+1)*NMACH	b.
Approximate Coefficients	$b_{0i}, b_{1i}, \beta_{1i}$ , etc.	0	0	1	ID	4*NMACH	c.
		0	0	2	ID	6*NMACH	d.
		0	0	3	ID	8*NMACH	e.

Entry Format

- a. AEFACCT, ID,  $m_1, c_{l\alpha_1}, c_{l\alpha_2}, \dots, c_{l\alpha_{NSTRIPI}}$
  - b. AEFACCT, ID,  $m_1, c_{l\alpha_{11}}, c_{l\alpha_{21}}, \dots, c_{l\alpha_{NSTRIPI1}}, m_2, c_{l\alpha_{12}}, c_{l\alpha_{22}}, \dots, c_{l\alpha_{NSTRIPI1}}, c_{l\alpha_{NSTRIPI2}}$ , for all m on MKAEROi data entry
  - c. AEFACCT, ID,  $m_1, b_{01}, b_{11}, \beta_{11}, m_2, b_{02}, b_{12}, P_{12}, m_3$ , etc.
  - d. AEFACCT, ID,  $m_1, b_{01}, b_{11}, \beta_{11}, b_{21}, \beta_{21}, m_2$ , etc.
  - e. AEFACCT, ID,  $m_1, b_{01}, b_{11}, \beta_{11}, b_{21}, \beta_{21}, b_{31}, \beta_{31}, m_2$  etc.
8. A control surface rotation is positive when the trailing edge moves in the negative z-direction of the aerodynamic element coordinate system; see the *MSC Nastran: Aeroelastic Analysis User's Guide*.

## PAERO5 Aerodynamic Panel Property

Defines properties of each strip element for Piston theory.

### Format:

1	2	3	4	5	6	7	8	9	10
PAERO5	PID	NALPHA	LALPHA	NXIS	LXIS	NTAUS	LTAUS		
	CAOC1	CAOC2	CAOC3	CAOC4	CAOC5				

### Example:

PAERO5	7001	1	702	1	701	1	700		
	0.0	0.0	5.25	3.99375	0.0				

Describer	Meaning
-----------	---------

PID	Property identification number. (Unique Integer > 0)
NALPHA	Number of angle of attack ( $\alpha$ ) values to be input for each Mach number ( $m_i$ ) on the MKAERO1 or MKAERO2 entry. (Integer > 0)

NALPHA	Meaning
1	$\alpha$ is the same value for all strips; enter one value, in units of degrees, on the AEFACCT entry for each Mach number.
Number of Strips	$\alpha$ is different for each strip; enter $\alpha$ 's, in units of degrees, in the following order: $m_1, \alpha_1, \alpha_2, \dots, m_2, \alpha_1, \alpha_2, \dots$ , etc.

LALPHA	ID number of the AEFACCT entry that lists the $\alpha$ 's for the strips at each Mach number in the MKAERO1 or MKAERO2 entry. (Integer > 0)
NXIS	Number of dimensionless chord coordinates ( $\xi$ ) to be input. (Integer $\geq 0$ , Default = 0)

NXIS	Meaning
0	No $\xi$ 's are required. (Default)
1	$\xi$ 's are the same for all strips; enter values for one strip on the AEFACCT entry ( $\xi_h$ if NTHICK > 0, or $\xi_m$ and $\xi_h$ if NTHICK = 0)
Number of Strips	$\xi$ 's have to be input for each strip ( $\xi_{h1}, \xi_{h2}, \dots, \xi_{hNSPAN}$ , if NTHICK > 0, or $\xi_{m1}, \xi_{h1}, \xi_{m2}, \xi_{h2}, \dots, \xi_{mNSPAN}, \xi_{hNSPAN}, \beta_{hNSPAN}$ if NTHICK = 0)

- LXIS Identification number of AEFAC<sub>T</sub> entry that lists the  $\xi$  values for the strip in order indicated by values of NXIS and NTHICK. (Integer = 0 if  $c_a = 0$  and NTHICK > 0 or LXIS > 0 if  $c_a = 0$  and/or NTHICK = 0)
- NTAUS Parameter used to select the number of thickness ratio ( $\tau$ ) values to be input. (Integer  $\geq 0$ , Default = 0)

NTAUS	Meaning
0	No $\tau$ 's are required. (Default)
1	$\tau$ 's are the same for all strips; enter ( $\tau_1, \tau_{h1}, \tau_{t1}$ ) values for one strip on AEFAC <sub>T</sub> entry.
Number of Strips	$\tau$ 's must be input for each strip on an AEFAC <sub>T</sub> entry in the following order:  ( $\tau_1, \tau_{h1}, \tau_{t1}, \tau_2, \tau_{h2}, \tau_{t2}, \dots, \tau_{NSPAN}, \tau_{hNSPAN}, \tau_{tNSPAN}$ )

- LTAUS Identification number of AEFAC<sub>T</sub> entry that lists the  $\tau$  values for the strips. (Integer = 0 or blank if NTAUS = 0, LTAUS > 0 if NTAUS > 0)
- CAOCi  $c_a/c$  = control surface chord divided by the strip chord. (Real  $\geq 0.0$ )

**Remarks:**

1. The continuation entry is required for Piston theory with one entry (CAOCi) per strip.
2. Embedded blank fields are not allowed on the continuation entry.
3. If CAOCi = 0.0, there is no control surface.
4. [Table 9-32](#) lists the thickness data input and AEFAC<sub>T</sub> entry format used for Piston theory.

Table 9-32 Thickness Data Input and AEFACT Entry Format for Piston Theory

Type of Input	Parameter Combinations						Number of Words	Entry Format Index
	CAOG	NGHICK	NXIS	LXIS	NTAUS	LTAUS		
No control surfaces, Integrals input are same for all strips	0.	ID <sup>(a)</sup>	0	0	0	0	6	a.
With control surfaces, Integrals input, same hinge on all strips	≠ 0	ID <sup>(b)</sup>	1	ID <sup>(c)</sup>	0	0	12 1	b. c.
With control surfaces, Integrals input, variable hinge	≠ 0	ID <sup>(b)</sup>	NSTRIP	ID <sup>(d)</sup>	0	0	12 NSTRIP	b. d.
No control surfaces, thickness inputs are same for all strips	0.0	0	1	ID <sup>(f)</sup>	1	ID <sup>(e)</sup>	3 2	e. f.
With control surfaces, thickness inputs are same for all strips	≠ 0.0	0	1	ID <sup>(f)</sup>	1	ID <sup>(e)</sup>	3 2	e. f.
With control surfaces, thickness inputs vary for strips	≠ 0.0	0	NSTRIP	ID <sup>(h)</sup>	NSTRIP	ID <sup>(g)</sup>	3*NSTRIP 2*NSTRIP	g. h.

Entry Format

- a. AEFACT, ID,  $I_1, I_2, I_3, I_4, I_5, I_6$
- b. AEFACT, ID,  $I_1, \dots, I_6, J_1, \dots, J_6, I_1, I_2, I_3, I_4, I_5, I_6$
- c. AEFACT, ID,  $\xi_h$
- d. AEFACT, ID,  $\xi_{h1}, \xi_{h2}, \xi_{h3}, \dots, \xi_{hNSTRIP}$
- e. AEFACT, ID,  $\tau_m, \tau_h, \tau_t$
- f. AEFACT, ID,  $\xi_m, \xi_h$
- g. AEFACT, ID,  $\tau_{m1}, \tau_{h1}, \tau_{t1}, \tau_{m2}, \tau_{h2}, \tau_{t2}, \dots, \tau_{mNSTRIP}, \tau_{hNSTRIP}, \tau_{tNSTRIP}$   
 $\tau_{m1}, \tau_{h1}, \tau_{t1}, \tau_{m2}, \tau_{h2}, \tau_{t2}, \dots, \tau_{mNSTRIP}, \tau_{hNSTRIP}, \tau_{tNSTRIP}$
- h. AEFACT, ID,  $\xi_{m1}, \xi_{h1}, \xi_{m2}, \xi_{h2}, \dots, \xi_{mNSTRIP}, \xi_{hNSTRIP}$

5. The following table lists the angle-of-attack distribution and AEFACT entry formats used for Piston theory.

Type of Distribution	Parameter Combinations		Number of Words	Entry Format Index
	NALPHA	LALPHA		
Equal angle of attack on all strips	1	ID	2*NMACH	a.
Unequal angle of attack	NSTRIP	ID	(1 + NSTRIP) * NMACH	b.

Entry Format

- a. AEFACT, ID,  $m_1$ ,  $\alpha_1$ ,  $m_2$ ,  $\alpha_2$ , ... ,
- b. AEFACT, ID,  $m_1$ ,  $\alpha_{11}$ ,  $\alpha_{21}$ ,  $\alpha_{31}$ , ...,  $\alpha_{NSTRIP1}$ ,  $m_2$ ,  $\alpha_{12}$ ,  $\alpha_{22}$ , ...,  $\alpha_{NSTRIP2}$ ,  $m_2$ , etc., for all m on MKAEROi entry.
- c. A control surface rotation is positive when the trailing edge moves in the negative z-direction of the aerodynamic element coordinate system; see the *MSC Nastran: Aeroelastic Analysis User's Guide*.

## PANEL Panel Definition for Coupled Fluid-Structural Analysis

Defines one or more panels by referencing sets of grid points, elements or properties.

### Format:

1	2	3	4	5	6	7	8	9	10
PANEL	NAME1	SETID1	NAME2	SETID2	NAME3	SETID3	NAME4	SETID4	

### Example:

PANEL	BKDOOR	103							
-------	--------	-----	--	--	--	--	--	--	--

Descriptor	Meaning
NAMEi	Panel label. (Character)
SETIDi	Identification number of a SET1 or SET3 entry that lists the grid points, elements or properties of the panel. On this entry, the SET1 should only be used for grid definition. (Integer > 0)

### Remarks:

1. If a set of grid points is referenced, the set must list only structural grid points.
2. If an element is assigned to a panel, it is recommended that all of its connections points belong to the same panel.
3. If a set of elements is referenced, the set must list only structural elements. The panel will consist of all grid points that are connection points of these elements.
4. If a set of property identifiers is referenced, the properties must be referenced by structural elements. The panel will consist of all grid points that are connection points of elements referencing one of the properties contained in the set.
5. NAMEi is used only for labeling the output of the panel participation factors (cf. the description of the PFMODE and PFPANEL Case Control commands).

**PARAM**      Parameter

Specifies values for parameters used in solution sequences or user-written DMAP programs.

**Format:**

1	2	3	4	5	6	7	8	9	10
PARAM	N	V1	V2						

**Example:**

PARAM	IRES	1							
-------	------	---	--	--	--	--	--	--	--

Describer	Meaning
N	Parameter name (one to eight alphanumeric characters, the first of which is alphabetic).
V1, V2	Parameter value based on parameter type, as follows:

Type	V1	V2
Integer	Integer	Blank
Real, single-precision	Real	Blank
Character	Character	Blank
Real, double-precision	Double-precision real	Blank
Complex, single-precision	Real or blank	Real or blank
Complex, double-precision	Double-precision real	Double-precision real

**Remarks:**

1. See [Parameters](#) for a list of parameters used in solution sequences that may be set by the user on PARAM entries.
2. If the large field entry format is used, the second physical entry line must be present, even though fields 6 through 9 are blank except for SOL 700.
3. The first 8 characters of N must be unique. N with more than 8 characters is normally only used by SOL 700.
4. If the Bulk Data involves the use of part superelements or external superelements, the following points should be noted regarding the use of the PARAM Bulk Data entry:
  - a. PARAM entries specified in the Main Bulk Data portion of the input data apply *only to the residual and not to the part superelements or external superelements*.
  - b. PARAM entries specified in the BEGIN SUPER portion of the Bulk Data for a part superelement or an external superelement apply *only to that superelement*.

- c. The most convenient way of ensuring that PARAM entries apply not only to the residual, but also to all part superelements and external superelements is to specify such PARAM entries in Case Control, not in the Main Bulk Data. This is particularly relevant for such PARAMs as POST.
5. If Modules are present then this entry may only be specified in the main Bulk Data section.

## PARAMARC

## Parallel Domain Decomposition in Marc from SOL 600

Specifies parallel regions for domain decomposition in nonlinear analysis when Marc is executed from MSC Nastran. Used in SOL 600 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PARAMARC	ID	KIND	NPROC	IDSOLVE	ACCUR				
	IDP	ID1	ID2	ID3	ID4	ID5	ID6	ID7	
	IDP	ID8	ID9	etc.					

### Example: To create 4 parallel processes using Marc's single file input

PARAMARC	51		4	0	1.0E-4				
----------	----	--	---	---	--------	--	--	--	--

### Example: To create 2 parallel processes by specifying element numbers

PARAMARC	201	2	2						
	1	1	THRU	5000	BY	1			
	2	5001	5002	5005	5010	5012	5013	5015	
	2	5020	5030	5040	5050				

Describer	Meaning
ID	Identification number of the PARAMARC entry -- Not presently used. (Integer)
KIND	Designates how parallel domains are created. (Integer = 0 or Blank; Default = 0) 0 Parallel processing is accomplished using Marc's single file input. (Marc Version 2005 or subsequent must be used. The command line to execute Marc is changed from -np N (or -nproc N) to -nps N where N is the number of processors. The maximum number of processors for Marc is 256. Continuation lines may not be entered for KIND=0. 2 Parallel domains will be specified by the user and the continuation lines are required.
NPROC	Number of parallel processes requested. See Remark 11. (Integer; Default = 0)
IDSOLV	Inter-domain solution type. See Remark 11. (Integer; Default = 0) 0 Iterative Solver 1 Direct Solver
ACCUR	Inter-domain solve accuracy. See Remark 11. (Real; Default = 1.0E-2) For an accurate solution of difficult nonlinear models, ACCUR should be set to 1.0E-4.

Describer	Meaning
IDP	Parallel process ID for following group of elements or grid ID's. See Remark 5. (Integer > 0; Required)
ID(i)	Element number (if KIND=2). (Integer > 0; Required if KIND=2)
THRU	Enter THRU in field 4 (may be omitted if I2 and INC are not required. The word TO instead of THRU may also be used.)
ID2	Ending element number. (Integer > 0)
BY	Enter BY in field 6 (may be omitted in INC=1)
INC	Increment ID's. (Integer; Default = 1, may be negative but not zero)

**Remarks:**

1. The PARAMARC entry is recognized only when Marc is executed from within SOL 600.
2. Use of KIND=2 provides more control than does the automatic (KIND=0) option.
3. If parallel jobs are run on different computers across a network, as opposed to using multiple processors in the same box, a host file is normally needed. Consult MSC technical support to determine how to setup a host file for your computer system. Use of the host file is triggered by Bulk Data PARAM,MARHOST,Name.
4. Continuation lines should not be entered unless KIND=2.
5. The continuation entries should be entered as many times as necessary to completely define each parallel region for KIND=2.
6. The string TO may be substituted for THRU if so desired.
7. For PC Windows systems, the default type of MPI for SOL 600 is Intel MPI. The first time a parallel job is run, the user may be prompted for domain\user\_name and then for password. Since MSC Nastran is a batch process, the user will not normally see the prompts and the job may appear to hang. If the job appears to hang, carefully enter the following information in exactly the same way you enter it to login into your PC:
 

```
domain\user_name
password
```
8. If multiple computers are used across a network, all computers must normally be the same type of computer, run the same operating system, be in the same domain, have the same user name and passwords. Also, a host file is required to describe the machines to be used. Further details are provided in the *SOL 600 Parallel Processing User's Guide*.
9. See PARAM,MRPARALL for additional notes concerning SOL 600 parallel processing.
10. If running on a PC, see PARAM,MARCMPII for options to keep the small MPI service (for example, ismpd.exe for Intel MPI) running or not after the Marc portion of the job has completed.
11. Parallel processing for SOL 600 is accomplished using domain decomposition. A solution of each domain is performed using its own processor. When each of the individual processor solutions converge, the overall solution at each increment is put together from the domains and iterated until convergence occurs. Variables IDSOLV and ACCUR control how this final iteration is performed

and its accuracy. `IDSOLV=0` (iterative solver) will usually be faster than `IDSOLV=1` (direct solver), however it is sometimes necessary that `ACCUR` be reduced to `1.0E-3` or `1.0E-4` to obtain sufficient accuracy for difficult nonlinear models, particularly those with contact, post-buckling, or large strain plasticity.

**PAXISYM**

## Properties of Axisymmetric Line Element - SOL 400

Defines the properties of axisymmetric line elements.

**Format:**

1	2	3	4	5	6	7	8	9	10
PAXISYM	PID	MID		T1	T2	ANAL			

**Example:**

PAXISYM	98	17		0.1					
---------	----	----	--	-----	--	--	--	--	--

Describer	Meaning
PID	Property identification number of a CAXISYM entry. (Integer > 0)
MID	Identification number of a MAT1, MAT2, MAT3, MAT8, MATORT, or MATHE entry. Identification number of a MAT4 or MAT5 for heat transfer. See Remark 3. (Integer > 0)
T1	Thickness at G1. (Real > 0)
T2	Thickness at G2. (Real ≥ 0)
ANAL	Analysis type, IS=structural, IH=heat, ISH=structural-heat (CHAR Default=ISH)

**Remarks:**

1. PAXISYM identification entries should be unique with respect to all other property entries.
2. For elements with only two grids, only T1 is applicable. For elements with three grids, if T2 is blank or 0.0 then constant thickness is assumed.
3. The MID entry may point to MAT1, MAT2, MAT3, MAT8, MATORT, or MATHE entries for structures and MAT4 or MAT5 entries for heat transfer. The tables below show associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

Implicit Structural Materials					
MAT1	MAT2	MAT3	MAT8	MATORT	MATHE
MATVE	<MATVE>	<MATVE>	<MATVE>	<MATVE>	MATVE
MATVP	MATVP	MATVP		MATVP	
MATEP	MATEP	MATEP	MATEP	MATEP	
MATF	MATF	MATF	MATF	MATF	
MATS1		MATS3	MATS8	MATSORT	

<MATVE> refers to the ALTERNATE format for type ORTHO

### Heat Materials

MAT4

MAT5

MID for structure entries must follow the uniqueness rules of the MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, MATHP, MATHE, and MATG entries. MID for heat entries must follow the uniqueness rules of the MAT4 and MAT5 entries.

4. The CAXISYM element uses PLOADX1 for loading.
5. The element does not support composite materials, via PCOMP or PCOMPG.

## PAXSYMH

## Linear Axisymmetric Harmonic Element Properties

Defines the properties of a linear axisymmetric harmonic element.

### Format:

1	2	3	4	5	6	7	8	9	10
PAXSYMH	PID	MID	CID	NHARM	INT				

### Example:

PAXSYMH	100	10	5						
---------	-----	----	---	--	--	--	--	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0). See Remarks 1. and 5.
MID	Identification number of MAT1 or MAT9 entry. (Integer > 0).
CID	Identification number of element coordinate system. (Integer ≥ 0; Default = 0). See Remark 2..
NHARM	Harmonic index. (Integer ≥ 0; Default = 1). See Remark 3..
INT	Integration scheme. (Integer 0, 1, 2 or 3; Default = 0). See Remark 4.

### Remarks:

1. This entry is referenced by the CQUADX and CTRIAX entries.
2. The Y-axis of CID defines the axis of symmetry while its X-Y plane defines the two-dimensional plane of the axisymmetric harmonic element. The X-axis of CID thus defines the radial direction.
3. The gyroscopic matrix is generated for the element only for the case of NHARM = 1 (the default).
4. The integration scheme INT selects the number of Gauss points used for matrix generation as indicated below:

INT	Order	Gauss Points CQUADX	Gauss Points CTRIAX
1	1x1	1	1
2	2x2	4	3
3	3x3	9	7

INT=0 uses INT=2 (no mid-side nodes) or INT=3 (mid-side nodes). The default INT=0 is recommended. The use of INT=1 will produce a singular stiffness and is meant for experimental use only.

5. PAXSYMH is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PAXSYMH property entries have unique identification numbers with respect to all other property entries, else unexpected grouping results may occur. There must be uniqueness among PAXSYMH, PLPLANE and PSHELL entries.

## PBAR Simple Beam Property

Defines the properties of a simple beam element (CBAR entry).

### Format:

1	2	3	4	5	6	7	8	9	10
PBAR	PID	MID	A	I1	I2	J	NSM		
	C1	C2	D1	D2	E1	E2	F1	F2	
	K1	K2	I12						

### Example:

PBAR	39	6	2.9		5.97				
			2.0	4.0					

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number. See Remarks 2. and 3. (Integer > 0)
A	Area of bar cross section. (Real; Default = 0.0)
I1, I2, I12	Area moments of inertia. See Figure 9-106. (Real; $I1 \geq 0.0$ , $I2 \geq 0.0$ , $I1 * I2 \geq I12^2$ ; Default = 0.0)
J	Torsional constant. See Figure 9-106. (Real; Default = $\frac{1}{2}(I_1 + I_2)$ for SOL 600 and 0.0 for all other solution sequences)
NSM	Nonstructural mass per unit length. (Real)
Ci, Di, Ei, Fi	Stress recovery coefficients. (Real; Default = 0.0)
K1, K2	Area factor for shear. See Remark 5. (Real or blank)

### Remarks:

- Both continuation entries may be omitted.
- For structural problems, MID must reference a MAT1 material entry.
- For heat transfer problems, MID must reference a MAT4 or MAT5 material entry.
- See the CBAR entry description for a discussion of bar element geometry.
- The transverse shear stiffnesses times unit length in planes 1 and 2 are  $K1 * A * G$  and  $K2 * A * G$ , respectively, where G is the shear modulus. The default values for K1 and K2 are infinite; in other words, the transverse shear flexibilities are set equal to zero. K1 and K2 are ignored if  $I12 \neq 0$ . K1 and K2 must be blank if  $A = 0.0$ .

6. The stress recovery coefficients C1 and C2, etc., are the y and z coordinates in the bar element coordinate system of a point at which stresses are computed. Stresses are computed at both ends of the bar. For conventional element, only bending components of strain and stress are outputted at points C1 and C2, etc. Membrane components of strain and stress are outputted as axial value. For advanced nonlinear element, the bending and membrane components of strain and stress are superposed and outputted together at the points C1 and C2, etc., there is no axial value individually.
7. For response spectra analysis on stress recovery coefficients, the CBEAM element entry should be used because bar element results will be inaccurate.
8. [Figure 9-106](#) describes the PBAR element coordinate system.

where:

$$\begin{aligned}
 I1 &= I_{zz_{elem}} \\
 I2 &= I_{yy_{elem}} \\
 I12 &= I_{zy_{elem}} \\
 J &= I_{xx_{elem}}
 \end{aligned}$$

Figure 9-106 PBAR Element Coordinate System

9. For cross-sections that are not doubly symmetric, when a beam is loaded through the centroid, it may in addition to bending undergo rotation. The CBAR element, by default, does not represent this behavior because the shear center is not explicitly accounted for on a CBAR entry.

By definition, for the CBAR element, the load is applied at the centroid and not at the shear center. If load application at the shear center is desired, appropriately applied offsets can be used on the CBAR entry or the CBAR/PBAR element replaced by the CBEAM/PBEAM element which by default explicitly applies the load through the shear center.

If warping considerations and bi-moment calculations are important, the CBEAM/PBEAM element should be used.

10. Mass moment of inertial formulation has changed in Version 2003. System (398) may be used to select the formulation in pre-Version 2004 systems.
11. PBAR is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBAR property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBAR, PBARL, PBRSECT entries.

## PBARL

## Simple Beam Cross-Section Property

Defines the properties of a simple beam element (CBAR entry) by cross-sectional dimensions.

### Format:

1	2	3	4	5	6	7	8	9	10
PBARL	PID	MID	GROUP	TYPE					
	DIM1	DIM2	DIM3	DIM4	DIM5	DIM6	DIM7	DIM8	
	DIM9	-etc.-	NSM						

### Example:

PBARL	39	6		I					
	14.	6.	.5	.5	.5	.5	.2		

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number. (Integer > 0)
GROUP	Cross-section group. See Remarks 6. and 8. (Character; Default = "MSCBML0")
TYPE	Cross-section type. See Remarks 6. and 8. and Figure 9-107. (Character: "ROD", "TUBE", "TUBE2", "I", "CHAN", "T", "BOX", "BAR", "CROSS", "H", "T1", "I1", "CHAN1", "Z", "CHAN2", "T2", "BOX1", "HEXA", "HAT", "HAT1", "DBOX" for GROUP="MSCBML0")
DIMi	Cross-sectional dimensions. (Real > 0.0 for GROUP = "MSCBML0")
NSM	Nonstructural mass per unit length. NSM is specified after the last DIMi. (Default = 0.0)

### Remarks:

1. For structural problems, PBARL entries must reference a MAT1 material entry.
2. PBARL is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBARL property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBAR, PBARL, PBRSECT entries.
3. See CBAR entry for a discussion of bar element geometry.
4. For heat-transfer problems, the MID must reference a MAT4 or MAT5 material entry.
5. For response spectra analysis on stress recovery coefficients, the CBEAM element should be used because results for the CBAR element will not be accurate.

6. The GROUP is associated with an FMS CONNECT statement that specifies the evaluator. A reserved GROUP name is "MSCBML0". Users may create their own cross-section types. Each of the types will require one or more subroutines to convert DIMi information to geometric property information contained on a PBAR entry and optimization information. See [Building and Using the Sample Programs](#) in the *MSC Nastran Utilities Guide* for a discussion on how to include a user-defined beam library.
7. A function of this entry is to derive an equivalent PBAR entry. Any sorted echo request will also cause printout and/or punch of the derived PBAR.
8. For GROUP = "MSCBML0", the cross-sectional properties, shear flexibility factors, and stress recovery points (C, D, E, and F) are computed using the TYPE and DIMi as shown in [Figure 9-107](#) through [Figure 9-110](#). The figures show the origin of the cross section, but the PBARL does not account for differences between the shear center and the neutral axis and the properties are computed relative to the neutral axis. This results in approximations for section types 'I', 'CHAN', 'T', 'CHAN1', 'T1', 'CHAN2', 'T2', 'L' and 'BOX1'. The PBEAML provides a better representation of section properties in these cases and is recommended.

The PBARL does not account for offsets between the neutral axis and the shear center. Therefore, the CHAN, CHAN1 and CHAN2 cross-sections may produce incorrect results. The PBEAML is recommended.

9. For DBOX section, the default value for DIM5 to DIM10 are based on the following rules:
  - a. DIM5, DIM6, DIM7 and DIM8 have a default value of DIM4 if not provided.
  - b. DIM9 and DIM10 have a default value of DIM6 if not provided.

**Note:** The above default value rules for DIM5 to DIM10 are not applicable to design optimization property value update.

10. The finite element formulation (FEF) utilized for arbitrary beam cross section is selected as the default method for computing sectional properties for all supported cross section types of PBARL when GROUP=MSCBML0. The original beam equations which are based on thin-walled assumptions can be accessed via Bulk Data entry 'MDLPRM,TWBRBML,1'. Thus the shear stiffness factors K1 and K2 are calculated as in Remark 11. of the PBMSECT entry and the element will behave according to the Timoshenko beam theory by default. Thus the resulting CBAR will have non-infinite K1/K2 shear flexibility factors, and therefore will not behave as a Bernoulli-Euler.
11. For optimization, individual DIMx of PBARL can be selected as designed properties even with the finite element formulation.

## PBARN1

## Nonlinear Property Extensions for a PBAR or PBARL Entry

Specifies additional nonlinear properties for elements that point to a PBAR or PBARL entry in SOL 400.

### Format:

1	2	3	4	5	6	7	8	9	10
PBARN1	PID	MID		SECT					
	"C2"	BEH2	INT2						

### Example:

PBARN1	29	73							
--------	----	----	--	--	--	--	--	--	--

Descriptor	Meaning
PID	Property identification number of an existing PBAR entry. (Integer > 0,)
MID	Material ID. Remark 10.(Integer ≥ 0)
SECT	Section integration. SECT = "S" a smeared cross section is used for integration. SECT = "N" a numerically integrated cross section is used. See Remark 7. (Character Default S or blank)
C2	Keyword indicating that items following apply to elements with two end grids. (Character)
BEH2	Element structural behavior. See Remark 4. (Character Default BAR)
INT2	Integration scheme. See Remarks 4. and 5. (Character Default LC)

### Remarks:

1. The PID above must point to an existing PBAR or PBARL Bulk Data entry and is honored only in SOL 400.
2. MID if blank (or 0) use the MID value on the PBAR or PBARL entry. If > 0 it will override the MID value on the PBAR entry.
3. The MID entry may point to the MAT1 entry. The table below shows associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

Implicit Structural Materials
MAT1
MATVE
MATVP
MATEP

Implicit Structural Materials
MATF
MATS1
MATSMA

4. BEH2 refers to the nonlinear structural behavior of the BAR element. An underlined item delineates a default.

Structural Classification of Elements		
Element Structural Type	BEHAV CODE	Integration Code
Bar	BAR	<u>LC</u> LCC LS

5. Integration codes in Remark 4. are:

INT CODE	Integration Type
LC	Linear/Cubic
LCC	Linear/Cubic Closed section
LS	Linear-shear

6. Normal buckling modes for beams with nonlinear extensions can be computed through the ANALYSIS=BUCK step. The buckle modes can be evaluated through a linear perturbation step about a linear or nonlinear prestressed state. The current limitation is that lateral buckling mode computations (eg. Lateral-torsional buckling seen in compression flanges of open section beams) are not supported for these elements.

7. Smearred section support.

Primary BAR Property	INT CODE	SECT	Interpolation	Usage	COMMENTS
PBAR	LC	S	Linear Interpolation for axial displacement and Cubic Interpolation for transverse displacements	Both Thin-Walled and Solid Sections with elastic materials. Euler-Bernoulli Beam.	Smearred section properties only are supported. Only linear elastic materials via MAT1 card can be provided.
	LS	S	Linear Interpolation for axial, transverse displacements and rotations	Both Thin-Walled and Solid Sections with elastic materials. Captures transverse shear effects - useful for deep beams	Smearred section properties only are supported. Only linear elastic materials via MAT1 card can be provided.
	LC or LS	N			Not Supported
	LCC	S			Not Supported
	LCC	N			Not Supported
PBARL	LC or LS	S			Not Supported
	LC	N	Linear Interpolation for axial displacement and Cubic Interpolation for transverse displacements	Solid Sections. Euler-Bernoulli Beam	Numerically integrated sections are supported. Both linear and nonlinear materials can be provided. This includes MAT1, MATS1, MATEP, MATVE, MATVP, MATSMA materials are supported. MATHE/MATHP are not supported.

Primary BAR Property	INT CODE	SECT	Interpolation	Usage	COMMENTS
	LS	N	Linear Interpolation for axial displacements, transverse displacements and rotations	Solid Sections. Captures transverse shear effects - useful for deep beams	Numerically integrated sections are supported. Both linear and nonlinear materials can be provided. This includes MAT1, MATS1, MATEP, MATVE, MATVP, MATSMA materials. MATHE/MATHP are not supported.
	LCC	S			Not Supported
	LCC	N	Linear Interpolation for axial displacement and Cubic Interpolation for transverse displacements	Thin-Walled Sections. Euler-Bernoulli Beam.	Numerically integrated sections are supported. Both linear and nonlinear materials can be provided. This includes MAT1, MATS1, MATEP, MATVE, MATVP, MATSMA materials. MATHE/MATHP are not supported.

8. For creep material defined through MATVP, VALC=0 must be set on NLMOPTS, for explicit formulation.
9. For shape memory materials defined through MATSMA, only the thermo-mechanical model is available.
10. The structural element damping coefficient, GE, is not supported on elements which reference PBARN1.

## PBCOMP

## Beam Property (Alternate Form of PBEAM)

Alternate form of the PBEAM entry to define properties of a uniform cross-sectional beam referenced by a CBEAM entry. This entry is also used to specify lumped areas of the beam cross section for nonlinear analysis and/or composite analysis.

### Format:

1	2	3	4	5	6	7	8	9	10
PBCOMP	PID	MID	A	I1	I2	I12	J	NSM	
	K1	K2	M1	M2	N1	N2	SYMOPT		
	Y1	Z1	C1	MID1					
	Y2	Z2	C2	MID2					
	-etc.-								

### Example:

PBCOMP	39	6	2.9						
							1		
	-0.5	1.2	0.1	18					
	0.2	0.9	0.15						

Describer	Meaning
PID	Property identification number. See Remark 1. (Integer > 0)
MID	Material identification number. See Remarks 3. and 6. (Integer > 0)
A	Area of beam cross section. (Real > 0.0)
I1	Area moment of inertia in plane 1 about the neutral axis. See Remark 7. (Real > 0.0)
I2	Area moment of inertia in plane 2 about the neutral axis. See Remark 7. (Real > 0.0)
I12	Area product of inertia. See Remark 7. (Real; Default = 0.0, but $I1 \cdot I2 - (I12)^2 > 0.0$ )
J	Torsional stiffness parameter. See Remark 7. (Real > 0.0; Default = 0.0)
NSM	Nonstructural mass per unit length. (Real > 0.0; Default = 0.0)
K1, K2	Shear stiffness factor K in $K \cdot A \cdot G$ for plane 1 and plane 2. See Remark 5. (Real > 0.0; Default = 1.0)
M1, M2	The (y,z) coordinates of center of gravity of nonstructural mass. See the figure in the CBEAM entry description. (Real; Default = 0.0)
N1, N2	The (y,z) coordinates of neutral axis. See the figure in the CBEAM entry description. (Real; Default = 0.0)
SYMOPT	Symmetry option to input lumped areas for the beam cross section. See Figure 9-112 and Remark 8. ( $0 \leq \text{Integer} \leq 5$ ; Default = 0)

Describer	Meaning
Yi, Zi	The (y,z) coordinates of the lumped areas in the element coordinate system. See Remark 1. (Real)
Ci	Fraction of the total area for the i-th lumped area. (Real > 0.0; Default = 0.0)
MIDi	Material identification number for the i-th integration point. See Remark 6. (Integer > 0)

**Remarks:**

1. PBCOMP is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBCOMP property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBEAM, PBEAML, PBCOMP, PBMSECT, PBEAM3 entries.
2. The second continuation entry may be repeated 18 more times. If SYMOPT = 5 a maximum of 21 continuation entries is allowed; i.e., a maximum of 20 lumped areas may be input. If SYMOPT = 1 through 4, the total number of areas input plus the total number generated by symmetry must not exceed 20. If these are not specified, the program defaults, as usual, to the elliptically distributed eight nonlinear rods. See [Figure 9-111](#).

Figure 9-111 PBCOMP Entry SYMOPT Type Examples with 8 Lumped Areas

**Notes:** Integration points (lumped area) are numbered 1 through 8.

User-specified points are denoted by ● and the mirrored points are denoted by ○.

3. For structural problems, MID and MIDi must reference a MAT1 material entry. For material nonlinear analysis, the material should be perfectly plastic since the plastic hinge formulation is not valid for strain hardening. For heat transfer problems, MID and MIDi must reference a MAT4 or MAT5 material entry.
4. For the case where the user specifies I1, I2 and I12 on the parent entry, the stress-output location may also be specified on continuation entries. The (y,z) coordinates specified on these entries will serve as stress output locations with the corresponding Ci's set to 0. Stress output is provided at the first four lumped area locations only. If one of the symmetry options is used and fewer than four lumped areas are input explicitly, the sequence of output locations in the imaged quadrants is shown in [Figure 9-111](#). For one specific example in the model shown in Remark 8. ([Figure 9-112](#)), output can be obtained at points 1 and 2 and in the image points 3 and 4.
5. Blank fields for K1 and K2 are defaulted to 1.0. If a value of 0.0 is used for K1 and K2, the transverse shear stiffness becomes rigid and the transverse shear flexibilities are set to 0.0.
6. The values  $E_0$  and  $G_0$  are computed based on the value of MID on the parent entry. MID will follow the same symmetry rules as Ci depending on the value of SYMOPT. If the MIDi field on a continuation entry is blank, the value will be that of MID on the parent entry. MIDi values may be input on continuations without the corresponding Yi, Zi, and Ci values to allow different stress-strain laws.
7. If the lumped cross-sectional areas are specified, fields I1, I2, and I12 will be ignored. These and other modified values will be calculated based on the input data (Yi, Zi, Ci, MIDi) as follows:

$$y_{NA} = \frac{\sum_{i=1}^n Y_i C_i E_i}{\sum_{i=1}^n C_i E_i}$$

$$z_{NA} = \frac{\sum_{i=1}^n Z_i C_i E_i}{\sum_{i=1}^n C_i E_i}$$

$$\bar{A} = A \sum_{i=1}^n \frac{C_i E_i}{E_o}$$

$$\bar{I}_1 = A \sum_{i=1}^n \frac{C_i E_i (Y_i - y_{NA})^2}{E_o}$$

$$\bar{I}_2 = A \sum_{i=1}^n \frac{C_i E_i (Z_i - z_{NA})^2}{E_o}$$

$$\bar{I}_{12} = A \sum_{i=1}^n \frac{C_i E_i (Y_i - y_{NA})(Z_i - z_{NA})}{E_o}$$

$$J = J \sum_{i=1}^n \frac{C_i G_i}{G_o}$$

where n is the number of lumped cross-sectional areas specified.

- For a doubly symmetric section (SYMOPT = 1), if the lumped areas are specified on either axis, the symmetry option will double the areas. For example, for the section shown in [Figure 9-112](#), points 2 and 4 are coincident and so are points 6 and 8. In such cases, it is recommended that users input the value of area as half of the actual value at point 2 to obtain the desired effect.

Figure 9-112 Doubly Symmetric PBCOMP Section

9. For SYMOPT =0, 5, or blank at least three  $Y_i$  and one  $Z_i$  coordinates must be nonzero. All of the points (input plus mirrored) should not lie on a straight line. All of the points (input plus mirrored) should not lie on a straight line or a FATAL message will be issued.

## PBEAM

## Beam Property

Defines the properties of a beam element (CBEAM entry). This element may be used to model tapered beams.

### Format:

1	2	3	4	5	6	7	8	9	10
PBEAM	PID	MID	A(A)	I1(A)	I2(A)	I12(A)	J(A)	NSM(A)	
	C1 (A)	C2 (A)	D1 (A)	D2 (A)	E1 (A)	E2 (A)	F1 (A)	F2 (A)	

The next two continuations are repeated for each intermediate station as described in Remark 6. and SO and X/XB must be specified.

	SO	X/XB	A	I1	I2	I12	J	NSM	
	C1	C2	D1	D2	E1	E2	F1	F2	

The last two continuations are:

	K1	K2	S1	S2	NSI(A)	NSI(B)	CW(A)	CW(B)	
	M1(A)	M2(A)	M1(B)	M2(B)	N1(A)	N2(A)	N1(B)	N2(B)	

### Example:

Tapered beam with A=2.9 at end A and A=5.3 at end B.

PBEAM	39	6	2.9	3.5	5.97				
			2.0	-4.0					
	YES	1.0	5.3	56.2	78.6				
			2.5	-5.0					
			1.1		2.1		0.21		
					0.5		0.0		

Describer	Meaning	Default Values
PID	Property identification number. (Integer > 0)	Required
MID	Material identification number. See Remarks 1. and 3. (Integer > 0)	Required
A(A)	Area of the beam cross section at end A. (Real > 0.0)	Required
I1(A)	Area moment of inertia at end A for bending in plane 1 about the neutral axis. See Remark 10. (Real > 0.0)	Required
I2(A)	Area moment of inertia at end A for bending in plane 2 about the neutral axis. See Remark 10. (Real > 0.0)	Required

Describer	Meaning	Default Values
I12(A)	Area product of inertia at end A. See Remark 10. (Real, but $I1 \cdot I2 - (I12)^2 > 0.0$ )	0.0
J(A)	Torsional stiffness parameter at end A. See Remark 10. (Real $\geq 0.0$ but $> 0.0$ if warping is present)	Default = $\frac{1}{2}(I_1 + I_2)$ for SOL 600 and 0.0 for all other solution sequences
NSM(A)	Nonstructural mass per unit length at end A. (Real)	0.0
Ci(A), Di(A)	The y and z locations (i = 1 corresponds to y and i = 2 corresponds to z) in element coordinates relative to the shear center (see the diagram following the remarks) at end A for stress data recovery. (Real)	y = z = 0.0
Ei(A), Fi(A)		
SO	Stress output request option. See Remark 9. (Character)  "YES" Stresses recovered at points Ci, Di, Ei, and Fi on the next continuation.  "YESA" Stresses recovered at points with the same y and z location as end A.  "NO" No stresses or forces are recovered.	Required*
X/XB	Distance from end A in the element coordinate system divided by the length of the element See Figure 9-113 in Remark 10. (Real, $0.0 < x/xb \leq 1.0$ )	Required* See Remark 6.
A, I1, I2, I12, J, NSM Ci, Di, Ei, Fi	Area, moments of inertia, torsional stiffness parameter, and nonstructural mass for the cross section located at x. (Real; J > 0.0 if warping is present.)  The y and z locations (i = 1 corresponds to y and i = 2 corresponds to z) in element coordinates relative to the shear center (see Figure 9-113 in Remark 10.) for the cross section located at X/XB. The values are fiber locations for stress data recovery. Ignored for beam p-elements. (Real)	See Remark 7.
K1, K2	Shear stiffness factor K in $K \cdot A \cdot G$ for plane 1 and plane 2. See Remark 12. (Real)	1.0, 1.0
S1, S2	Shear relief coefficient due to taper for plane 1 and plane 2.	0.0, 0.0
NSI(A), NSI(B)	Nonstructural mass moment of inertia per unit length about nonstructural mass center of gravity at end A and end B. See Figure 9-113. (Real)	0.0, same as end A

Describer	Meaning	Default Values
CW(A), CW(B)	Warping coefficient for end A and end B. See Remark 11. (Real)	0.0, same as end A
M1(A), M2(A), M1(B), M2(B)	(y,z) coordinates of center of gravity of nonstructural mass for end A and end B. See Figure 9-113. (Real)	0.0 (no offset from shear center), same values as end A
N1(A), N2(A), N1(B), N2(B)	(y,z) coordinates of neutral axis for end A and end B. See Figure 9-113. (Real)	0.0 (no offset from shear center), same values as end A

### Remarks:

- For structural analysis, MID must reference a MAT1 material entry (SOL 600). The beam may be described by any valid stress-strain law. A plastic hinge is not used for SOL 600 and SOL 700; instead, a standard nonlinear analysis is performed
- For material nonlinear analysis, MID may also reference a MATS1 entry, but the material properties must be defined as elastic-perfectly plastic; for example, H = 0.0 on the MATS1 entry. Also, only one-eighth of the length at each end of the element abides by material nonlinear law; i.e., the element is modeled as a plastic hinge. Any other type of material property specification may yield inaccurate results.
- For heat transfer analysis, MID must reference a MAT4 or MAT5 material entry.
- If no stress data at end A is to be recovered and a continuation with the SO field is specified, then the first continuation entry, which contains the fields C1(A) through F2(A), may be omitted.
- If SO is “YESA” or “NO”, the third continuation entry, which contains the fields C1 through F2, must be omitted. If SO is “YES”, the continuation for Ci, Di, Ei, and Fi must be the next entry. The blank fields are defaulted to 0.0 on these continuations.
- The rules for the continuations entries are:
  - The second and third continuation entries, which contain fields SO through F2, may be repeated nine more times for intermediate X/XB values for linear beam elements. The order of these continuation pairs is independent of the X/XB value; however, one value of X/XB must be 1.0, corresponding to end B. The intermediate stress output requests will be ignored in the nonlinear solution sequences (SOLs 106 and 129).
  - The value of X/XB must be unique among the stations of a PBEAM. Duplication of X/XB is not permitted.
  - The fourth and fifth continuation entries, which contain fields K1 through N2(B), are optional and may be omitted if the default values are appropriate.
- If any fields 4 through 9 are blank on the continuation with the value of X/XB = 1.0, then the values for A, I1, I2, I12, J and NSM are set to the values given for end A. For the continuations that have intermediate values of X/XB between 0.0 and 1.0 and use the default option (any of the fields 4 through 9 are blank), a linear interpolation between the values at ends A and B is performed to obtain the missing section properties.

8. Blank fields for K1, K2 are defaulted to 1.0. If a value of 0.0 is used for K1 and K2, the transverse shear flexibilities are set to 0.0 and field G on the MAT1 entry selected by MID must be nonzero.
9. If end B forces are desired and station data are input, use “YES” or “YESA” in the SO field of the record with X/XB=1. If station data are not input you will get end B forces if forces are requested.
10. Figure 9-113 describes the PBEAM element coordinate system.

$I1 = I_{(zz)_{na}}$	$N1(A) = y_{na}$	$N1(B) = y_{nb}$
$I2 = I_{(yy)_{na}}$	$N2(A) = z_{na}$	$N2(B) = z_{nb}$
$I12 = I_{(zy)_{na}}$	$M1(A) = y_{ma}$	$M1(B) = y_{mb}$
$J = I_{(xx)_{na}}$	$M2(A) = z_{ma}$	$M2(B) = z_{mb}$

Figure 9-113 PBEAM Element Coordinate System

11. The warping coefficient  $CW$  is represented in the following differential equation for the torsion of a beam about the axis of the shear centers:

$$G \frac{d}{dx} \left( J \frac{d\theta}{dx} \right) - E \frac{d^2}{dx^2} \left( CW \frac{d^2\theta}{dx^2} \right) = m$$

where:

G = shear modulus  
 J = torsional stiffness  
 E = Young's modulus

$\theta$  = angle of rotation at any cross-section

$m$  = applied torsional moment per unit length

**Note:** CW has units of (length)<sup>6</sup>.

12. The shear stiffness factors  $K_1$  and  $K_2$  adjust the effective transverse shear cross-section area according to the Timoshenko beam theory. Their default values of 1.0 approximate the effects of shear deformation. To neglect shear deformation (i.e., to obtain the Bernoulli-Euler beam theory), the values of  $K_1$  and  $K_2$  should be set to 0.0.
13. In nonlinear analysis the location of the 8 plastic rods is the same on the PBEAM entry as it is on the SYMOPT field on the PBCOMP entry when SYMOPT = 0. Please see the [Figure 9-111](#) for more information on the SYMOPT field.
14. For SOL 600, for structural analysis, MID must reference a MAT1 material entry.
15. RC network solver only supports constant cross section beam for thermal analysis.
16. PBEAM is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBEAM property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBEAM, PBEAML, PBCOMP, PBMSECT, PBEAM3 entries.

**PBEAM3****Three-node Beam Property**

Defines the properties of a three-node beam element (CBEAM3 entry).

**Format:**

1	2	3	4	5	6	7	8	9	10

	0.9	1.0		1.5					
		1.0							

Descriptor	Meaning
PID	Property identification number. (Integer > 0; Required)
MID	Material identification number. See Remark 1. (Integer > 0; Required)
A(A)	Area of the beam cross-section at end A. (Real > 0.0; Required)
IZ(A)	Area moment of inertia at end A about local z-axis and the neutral axis. (Real > 0.0; Required)

Describer	Meaning
IY(A)	Area moment of inertia at end A about local y-axis and the neutral axis. (Real > 0.0; Required)
IYZ(A)	Area product of inertia at end A about local y- and z-axes and the neutral axis. If y- and z- axes are principal axes, then IYZ(A)=0.0. (Real, but $I_y \cdot I_z - I_{yz}^2 > 0.0$ ; Default = 0.0)
J(A)	Torsional stiffness parameter at end A. (Real > 0.0; Default = IZ+IY)
NSM(A)	Nonstructural mass per unit length at end A. (Real; Default = 0.0)
Ci(j), Di(j) Ei(j), Fi(j)	The local y and z coordinates ( $i=Y, Z$ ) at point $j$ ( $j=A, B, C$ ), used for stress output. (Real; Default = 0.0)
A(j), IZ(j), IY(j) IYZ(j), J(j), NSM(j)	Area, moments of inertia, torsional stiffness parameter and nonstructural mass for the cross-section at $j$ ( $j=B, C$ ). (Real; See Remark 2.)
SO(j)	Stress output request option at $j$ ( $j=B, C$ ). (Character; Default = "YESA") "YES"      Stresses are recovered at $C_i, D_i, E_i,$ and $F_i$ on the next continuation. "YESA"     Stresses are recovered at points with the same ( $y, z$ ) location at end A
KY, KZ	Shear effectiveness factors for local y- and z-directions. (Real > 0.0, Default = 1.0)
NY(j), NZ(j)	Local ( $y, z$ ) coordinates of neutral axis for $j$ ( $j=A, B, C$ ). (Real, Default = 0.0 at end A and same values as end A for $j = B, C$ )
MY(j), MZ(j)	Local ( $y, z$ ) coordinates of nonstructural mass center of gravity at $j$ ( $j=A, B, C$ ). (Real, Default = 0.0 at end A and same values as end A for $j=B,C$ )
NSIY(j), NSIZ(j)	Nonstructural mass moments of inertia per unit length about local y and z-axes, respectively, with regard to the nonstructural mass center of gravity at $j$ ( $j=A, B, C$ ). (Real, Default = 0.0 at end A and same values as end A for $j=B, C$ )
NSIYZ(j)	Nonstructural mass product of inertia per unit length about local y and z-axes, respectively, with regard to the nonstructural mass center of gravity at $j$ ( $j=A, B, C$ ). (Real, Default = 0.0 at end A and same values as end A for $j=B, C$ )
CW(j)	Warping coefficient at $j$ ( $j=A, B, C$ ). (Real $\geq 0.0$ ; Default = 0.0 at end A; same values as end A for $j = B, C$ )
STRESS	Location selection for stress, strain and force output. (Character; Default = "GRID"; See Remark 3.)
Wi(j)	Values of warping function at stress recovery points $i = C, D, E$ and $F$ , at location $j=A, B,$ and $C$ . (Real; Default = 0.0 at end A and same values as end A for $j=B, C$ )
WYi(j), WZi(j)	Gradients of warping function in the local ( $y, z$ ) coordinate system at stress recovery points $i=C, D, E,$ and $F$ , at location $j=A, B,$ and $C$ . (Real; Default = 0.0 at end A and same values as end A for $j=B, C$ .)

**Remarks:**

1. For structural analysis, MID must reference a MAT1, MAT2 or MAT8 material entry.
2. If any fields 4 through 9, for values of A, IZ, IY, IYZ, J and NSM at end B or C, are blank, then those values for end B or C are set to the values given for end A.
3. If STRESS="GRID", then the stresses, strains and forces are recovered at A, B and C. If STRESS="GAUSS", then the stresses, strains and forces are recovered at Gauss integration points,  $\xi = \{ 1/\sqrt{3}, 1/\sqrt{3}, 0 \}$ . The beam cross-section properties at these points are interpolated from those at A, B and C.
4. If all fields of  $W_i(j)$ ,  $WY_i(j)$  and  $WZ_i(j)$  ( $i=C, D, E, F$  and  $j=A, B, C$ ), are left blank, both stresses and strains due to the warping effect will not be recovered at the stress recovery points.
5. PBEAM3 is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBEAM3 property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBEAM, PBEAML, PBCOMP, PBMSECT, PBEAM3 entries.
6. When PBMSECT is used the resulting PBEAM3 image printed after the:

\*\*\* USER INFORMATION MESSAGE 4379 (IFP9B)

THE USER SUPPLIED PBMSECT BULK DATA ENTRIES ARE REPLACED BY THE FOLLOWING PBEAM3 ENTRIES.

contains special composite related data and will look different from the above entry description.

## PBEAMD

PBEAMD usage is no longer recommended and will be removed in a future version. Use PBEAM, PBDISCR, PBSPOT, PBEAM71 instead.

## PBEAML Beam Cross-Section Property

Defines the properties of a beam element by cross-sectional dimensions.

### Format:

(Note: n = number of dimensions and m = number of intermediate stations)

1	2	3	4	5	6	7	8	9	10
PBEAML	PID	MID	GROUP	TYPE					
	DIM1(A)	DIM2(A)	-etc.-	DIMn(A)	NSM(A)	SO(1)	X(1)/XB	DIM1(1)	
	DIM2(1)	-etc.-	DIMn(1)	NSM(1)	SO(2)	X(2)/XB	DIM1(2)	DIM2(2)	
	-etc.-	DIMn(2)	NSM(m)	-etc.-	SO(m)	X(m)/XB	DIM1(m)	-etc.-	
	DIMn(m)	NSM(m)	SO(B)	1.0	DIM1(B)	DIM2(B)	-etc.-	DIMn(B)	
	NSM(B)								

### Example:

PBEAML	99	21		T					
	12.	14.8	2.5	2.6		NO	0.4	6.	
	7.	1.2	2.6		YES	0.6	6.	7.8	
	5.6	2.3		YES					

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number. (Integer > 0)
GROUP	Cross-section group. (Character; Default = "MSCBML0")
TYPE	Cross-section shape. See Remark 4. (Character: "ROD", "TUBE", "TUBE2", "L", "I", "CHAN", "T", "BOX", "BAR", "CROSS", "H", "T1", "I1", "CHAN1", "Z", "CHAN2", "T2", "BOX1", "HEXA", "HAT", "HAT1", "DBOX" for GROUP = "MSCBML0")
DIMi(j)	Cross-section dimensions at end A, intermediate station j and end B. (Real > 0.0 for GROUP = "MSCBML0")
NSM(j)	Nonstructural mass per unit length. (Default = 0.0)
SO(j),SO(B)	Stress output request option for intermediate station j and end B. (Character; Default = "YES")
YES	Stresses and forces are recovered at all points shown under TYPE figures below at points labeled C, D, E, F

Describer	Meaning
	NO No stresses or forces are recovered.
X(j)/XB	Distance from end A to intermediate station j in the element coordinate system divided by the length of the element. (REAL, 0.0<x(j)/xb ≤1.0, default=1.0)

**Remarks:**

1. For structural problems, PBEAML entries must reference a MAT1 material entry.
2. PBEAML is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBEAML property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBEAM, PBEAML, PBCOMP, PBMSECT, PBEAM3 entries.
3. For heat-transfer problems, the MID must reference a MAT4 or MAT5 material entry.
4. See the PBEAM entry description for a discussion of beam-element geometry.
5. If any of the fields NSM(B), DIMi(B) are blank on the continuation entry for End B, the values are set to the values given for end A. For the continuation entries that have values of X(j)/XB between 0.0 and 1.0 and use the default option (blank field), a linear interpolation between the values at ends A and B is performed to obtain the missing field.
6. The GROUP is associated with a FMS CONNECT statement, which specifies the evaluator. A reserved GROUP name is "MSCBML0". Users may create their own cross-section types. Each of the types will require a one or more subroutines to convert DIMi information to geometric property information contained on a PBEAM entry. See [Building and Using the Sample Programs](#) in the *MSC Nastran Utilities Guide* for a discussion of how to include a user-defined beam library.
7. For GROUP = "MSCBML0", the cross-sectional properties, shear flexibility factors and stress recovery points are computed using the TYPE and DIMi as shown in [Figure 9-114](#). The element coordinate system is located at the shear center.
8. A function of this entry is to derive an equivalent PBEAM entry. Any sorted echo request will also cause printout and/or punch of the derived PBEAM.
9. Beams can have no more than 14 dimensions per station. The total number of dimensions at all stations must be less than 200. The transfer of data with the beam server is limited to 4000 words. None of these limits are exceeded with the MSC beam library, but a user defined beam library could.
10. The finite element formulation (FEF) utilized for the arbitrary beam cross section is selected as the default method for computing sectional properties for all supported cross section types of PBEAML when GROUP=MSCBML0. The original beam equations, which are based on thin-walled assumption can be accessed via Bulk Data entry 'MDLPRM,TWBRBML,1'.
11. For optimization, individual DIMx of PBEAML can be selected as designed properties even with finite element formulation.

12. The origin of the  $y_{elem}$  and  $z_{elem}$  coordinate system for the section types is at the shear center for all element types when using the FEF. For section types 'L', 'T', 'T1', 'T2' and 'HAT1', no shear center calculation is calculated with the original beam equations and the origins of these types are at the locations specified in the following figures. For these sections types, this can result in a difference in the stress recovery points and the neutral axis locations between the beam equations and the FEF. The FEF results are considered more exact. For the remaining types with the beam equation, the shear center is either computed or is obvious due to symmetry considerations.

## PBELT

## Belt Property- SOL 700

Defines the properties of a belt element referenced by a CROD entry. Used in SOL700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PBELT	PID	LOAD	UNLOAD	DENSITY	DAMP1	DAMP2	SLACK	PRESTRESS	

### Example:

PBELT	9	12	12	2.0E-5	0.1	0.1			

Field	Content
PID	Unique belt property number. (Integer > 0; required)
LOAD	TABLED1 ID defining the force as a function of strain during loading. The strain at time n is specified as engineering strain. (Integer > 0; required)  $\text{strain}(n) = (\text{length}(n) - \text{length}(0)) / \text{length}(0)$
UNLOAD	TABLED1 ID defining the force as a function of strain during unloading. The strain at time is specified as engineering strain. (Integer > 0; required)  $\text{strain}(n) = (\text{length}(n) - \text{length}(0)) / \text{length}(0)$
DENSITY	Density of the belt elements as mass per unit length. (Real > 0.0; required)

Field	Content
DAMP1	<p>A damping force is added to the internal force of the belt elements to damp out high frequency oscillations. (Real &gt; 0.0; default=0.1)</p> <p>The damping force is equal to:</p> $F_{\text{damp}} = \text{DAMP1.mass} \cdot (d\text{vel}/dt)$ <p>Where</p> <p><math>F_{\text{damp}}</math> = damping force</p> <p>DAMP1 = damping coefficient</p> <p>mass = mass of belt element</p> <p>dvel = velocity of elongation</p> <p>dt = time step</p>
DAMP2	<p>The maximum damping force: <math>\text{DAMP2} \cdot F_{\text{belt}}</math> (Real &gt; 0.0; default=0.1)</p> <p>Where</p> <p><math>F_{\text{belt}}</math> = Internal force in the belt element</p>
SLACK	<p>TABLED1 ID defining the slack as a function of time. (Integer &gt; 0; default=not used)</p> <p>The slack must be specified as engineering strain and will be subtracted from the element strain at time as:</p> $\text{strain}(n) = \text{strain}(n) - \text{SLACK}(n)$ <p>The force in the element is zero until the element strain exceeds the slack.</p>
PRESTRESS	<p>TABLED1 ID defining a prestress strain as a function of time. (Integer &gt; 0; default=not used)</p> <p>The prestress strain must be specified as engineering strain and will be added to the element strain at time as:</p> $\text{strain}(n) = \text{strain}(n) + \text{PRESTRESS}(n)$

**Remarks:**

1. The loading and unloading curves must start at (0.0, 0.0).

2. During loading, the loading curve is applied to determine the force in the belt element. At unloading, the unloading curve is shifted along the strain axis until it intersects the loading curve at the point from which unloading commences. The unloading table is applied for unloading and reloading, until the strain again exceeds the intersection point. Upon further loading, the loading table is applied. For subsequent unloading, the sequence is repeated.
3. Belt elements are tension only elements.
4. Instantaneous slack of an element can also be initialized per element using the TICEL entry with the keyword SLACK and a corresponding VALUE.

## PBEMN1

## Nonlinear Property Extensions for a PBEAM or PBEAML Entry

Specifies additional nonlinear properties for elements that point to a PBEAM or PBEAML entry in SOL 400.

### Format:

1	2	3	4	5	6	7	8	9	10
PBEMN1	PID	MID		SECT					
	"C2"	BEH2	INT2						

### Example:

PBEMN1	27	93							
--------	----	----	--	--	--	--	--	--	--

Describer	Meaning
PID	Property identification number of an existing PBEAM entry. (Integer > 0)
MID	Material ID. Remark 9.(Integer ≥ 0)
SECT	Section integration. SECT = "S" a smeared cross section is used for integration. SECT = "N" a numerically integrated cross section is used. See Remark 10. (Character Default S or blank)
C2	Keyword indicating that items following apply to elements with two end grids. (Character)
BEH2	Element structural behavior. See Remark 5. (Character Default BEAM)
INT2	Integration scheme. See Remarks 5. and 6. (Character Default LC)

### Remarks:

1. The PID above must point to an existing PBEAM or PBEAML Bulk Data entry and is honored only in SOL 400.
2. Tapering of the CBEAM is ignored. Only section properties at end A are used.
3. MID if blank (or 0) use the MID value on the PBEAM or PBEAML entry. If > 0 it will override the MID value on the PBEAM entry.
4. The MID entry may point to MAT1 entry. The following table shows associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

Implicit Structural Materials
MAT1
MATVE
MATVP

Implicit Structural Materials
MATEP
MATF
MATS1

5. BEH2 refers to the nonlinear structural behavior of the BEAM element. An underlined item delineates a default.

Structural Classification of Elements				
Element Structural Type	BEHAV CODE	Integration Code	Element Type	# Nodes
Beam	BEAM	<u>LC</u>	BEAM	2
		LCC	BEAM	2
		LCO	BEAM	2
		LS	BEAM	2

6. Integration codes in Remark 5. are:

INT CODE	Integration Type
LC	Linear/Cubic
LCC	Linear/Cubic Closed section
LCO	Linear/Cubic Open section
LS	Linear-shear

7. Integration code LCO requires appropriate scalar point SA and SB entries on the CBEAM entry or a fatal message will result.
8. Normal buckling modes for beams with nonlinear extensions can be computed through the ANALYSIS=BUCK step. The buckle modes can be evaluated through a linear perturbation step about a linear or nonlinear prestressed state. The current limitation is that lateral buckling mode computations (eg. Lateral-torsional buckling seen in compression flanges of open section beams) are not supported for these elements.
9. The structural element damping coefficient, GE, is not supported on elements which reference PBEMN1.

10. Smearing cross section support for integration codes are as follows:

Primary BEAM Property	INT CODE	SECT	Interpolation	Usage	COMMENTS
PBEAM	LC	S	Linear Interpolation for axial displacement and Cubic Interpolation for transverse displacements	Both Thin-Walled and Solid Sections with elastic materials. Euler-Bernoulli Beam	Smearing section properties only are supported. Only linear elastic materials via MAT1 card can be provided.
	LS	S	Linear Interpolation for axial displacements, transverse displacements and rotations	Both Thin-Walled and Solid Sections with elastic materials. Captures transverse shear effects - useful for deep beams.	Smearing section properties only are supported. Only linear elastic materials via MAT1 card can be provided.
	LC or LS	N			Not Supported
	LCC or LCO	S			Not Supported
	LCC or LCO	N			Not Supported
PBEAML	LC or LS	S			Not Supported
	LC	N	Linear Interpolation for axial displacement and Cubic Interpolation for transverse displacements	Solid Sections. Euler-Bernoulli Beam	Numerically integrated sections are supported. Both linear and nonlinear materials can be provided. This includes MAT1, MATS1, MATEP, MATVE, MATVP, MATSMA materials. MATHE/MATHP are not supported

Primary BEAM Property	INT CODE	SECT	Interpolation	Usage	COMMENTS
	LS	N	Linear Interpolation for axial displacements, transverse displacements and rotations	Solid Sections. Captures transverse shear effects - useful for deep beams.	Numerically integrated sections are supported. Both linear and nonlinear materials can be provided. This includes MAT1, MATS1, MATEP, MATVE, MATVP, MATSMA materials. MATHE/MATHP are not supported
	LCC or LCO	S			Not Supported
	LCC	N	Linear Interpolation for axial displacement and Cubic Interpolation for transverse displacements	Thin-Walled Closed Sections without warping. Euler-Bernoulli Beam	Numerically integrated sections are supported. Both linear and nonlinear materials can be provided. This includes MAT1, MATS1, MATEP, MATVE, MATVP, MATSMA materials. MATHE/MATHP are not supported
	LCO	N	Linear Interpolation for axial displacement and Cubic Interpolation for transverse displacements	Thin-Walled Open Sections with warping. Euler-Bernoulli Beam	Numerically integrated sections are supported. Both linear and nonlinear materials can be provided. This includes MAT1, MATS1, MATEP, MATVE, MATVP, MATSMA materials. MATHE/MATHP are not supported

## PBEND

## Curved Beam or Pipe Element Property

Defines the properties of a curved beam, curved pipe, or elbow element (CBEND entry).

### Format:

1	2	3	4	5	6	7	8	9	10
PBEND	PID	MID	A	I1	I2	J	RB	THETAB	
	C1	C2	DI	D2	E1	E2	F1	F2	
	K1	K2	NSM	RC	ZC	DELTA			

### Example:

PBEND	39	1	0.8	0.07	0.04	0.04	10.		
	0.5	0.4	-0.5	0.4					
	0.6	0.6				0.1			

### Alternate Format and Example for Elbows and Curved Pipes:

PBEND	PID	MID	FSI	RM	T	P	RB	THETAB	
			NSM	RC	ZC				
PBEND	39	1	1	0.5	0.02	10.	10.		
					0.1				

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number. See Remarks 1. and 2. (Integer > 0)
A	Area of the beam cross section. (Real > 0.0)
I1, I2	Area moments of inertia in planes 1 and 2. (Real > 0.0)
J	Torsional stiffness. (Real > 0.0)
FSI	Flag selecting the flexibility and stress intensification factors. See Remark 3. (Integer = 1, 2, or 3)
RM	Mean cross-sectional radius of the curved pipe. (Real > 0.0)
T	Wall thickness of the curved pipe. (Real ≥ 0.0; RM + T/2 < RB)
P	Internal pressure. (Real)
RB	Bend radius of the line of centroids. (Real. Optional, see CBEND entry.)
THETAB	Arc angle of element. (Real, in degrees. Optional, see CBEND entry.)
Ci, Di, Ei, Fi	The i, j, z locations from the geometric centroid for stress data recovery. See Remark 8. (Real)

Describer	Meaning
K1, K2	Shear stiffness factor K in $K \cdot A \cdot G$ for plane 1 and plane 2. (Real)
NSM	Nonstructural mass per unit length. (Real)
RC	Radial offset of the geometric centroid from points GA and GB. See <a href="#">Figure 9-116</a> . (Real)
ZC	Offset of the geometric centroid in a direction perpendicular to the plane of points GA and GB and vector v. See <a href="#">Figure 9-116</a> . See <a href="#">Remark 9</a> . (Real)
DELTAN	Radial offset of the neutral axis from the geometric centroid, positive is toward the center of curvature. See <a href="#">Figure 9-116</a> . See <a href="#">Remark 9</a> . (Real; Default is described in <a href="#">Remark 5</a> .)

**Remarks:**

1. For structural problems, MID must reference a MAT1 material entry.
2. For heat transfer problems, MID must reference a MAT4 or MAT5 material entry.
3. When the alternate PBEND entry with FSI is used the following options are available:  
Using the notation of Dodge and Moore from ORNL-TM-3658, 1972 we define:

The bend characteristic parameter  $\lambda$  as:

$$\lambda = \frac{R_B T}{R_M^2 \sqrt{(1 - \nu^2)}}$$

The internal loading parameter  $\Psi$  as

$$\Psi = \frac{P R_B^2}{E R_M T}$$

And the radius ratio parameter  $\gamma$  as

$$\gamma = \frac{R_B}{R_M}$$

For  $T \neq 0$

$$A = 2\pi R_M T$$

$$I_1 = I_2 = \frac{1}{2} A \left( R_M^2 + \frac{1}{4} T^2 \right)$$

For  $T = 0$

$$A = \pi R_M^2$$

$$I_1 = I_2 = \frac{1}{4} A R_M^2$$

For  $T \neq 0$

$$\Delta N = R_B \left\{ 1 - \frac{1}{2} \left[ \sqrt{\left(1 - \gamma^{-2} - \frac{1}{4} \left(\frac{T}{R_B}\right)^2 + \left(\frac{T}{R_B}\right) \gamma^{-1}\right)} + \sqrt{\left(1 - \gamma^{-2} - \frac{1}{4} \left(\frac{T}{R_B}\right)^2 - \left(\frac{T}{R_B}\right) \gamma^{-1}\right)} \right] \right\}$$

For  $T = 0$

$$\Delta N = \frac{1}{2} R_B \left[ 1 - \sqrt{(1 - \gamma^{-2})} \right]$$

#### Element flexibility calculations:

The shear stiffness factor represents a correction to the section area by computing an effective area  $A_s = KA$ . Here K is defined as:

$$K = \frac{1}{f_s}$$

$f_s$  is the form factor obtained here from the principal of complementary virtual work. There are many other ways to obtain this factor. By complementary virtual work it is defined as:

$$f_s = \frac{A}{I_1^2} \int \frac{Q^2}{b^2} dA$$

where Q is the first moment of area and b is the width of section cut.

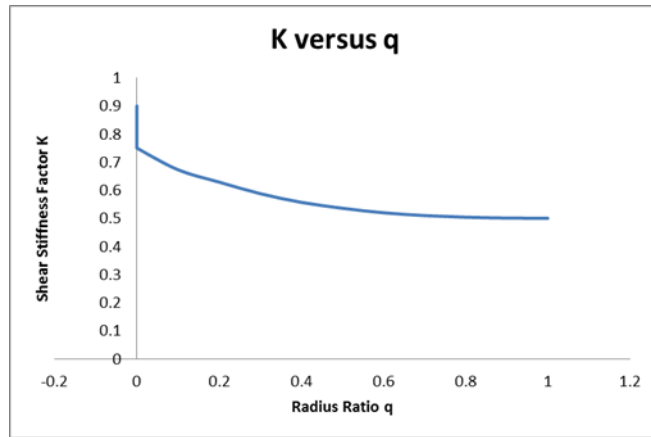

For a solid circular cross-section the above expressions yields a value of  $K = 0.9$ , and for very thin walled pipes the above integral evaluates as  $\pi T R_m^5$  and we get a value of  $K = 0.5$ .

For pipes with general thickness  $T > 0$  we define the radius ratio as:

$$q = \frac{R_i}{R_0} = \frac{1 - \frac{1}{2} \frac{T}{R_M}}{1 + \frac{1}{2} \frac{T}{R_M}}$$

where  $T = R_o - R_i$  and  $R_o$  is the outer radius of the pipe and  $R_i$  is the inner radius of the pipe. The above integral becomes a complicated function in terms of radicals and arc sine functions of  $q$  and its explicit integration form is not warranted in view of the approximate nature for  $f_s$ . We therefore approximate with the curve fit

$$K_1 = K_2 = \frac{0.75}{1 + \frac{q}{1 + q^2}}$$

The in and out of plane flexibility factors  $K_p$  used in computing the element flexibility are calculated as:

For FSI = 1

$$K_p = 1.0$$

For FSI = 2 (ASME code Section III, NB-3687.2, NB-3685.2, 1977)

$$K_p = \frac{1.65R_M^2}{R_B T} \left[ \frac{1}{1 + 6 \frac{PR_M}{TE} \left( \frac{R_M}{T} \right)^{\frac{4}{3}} \frac{1}{\gamma^{\frac{1}{3}}}} \right]$$

where it is recommended that  $\lambda \geq 0.2$

For FSI = 3 (Empirical factors from Welding Research Council Bulletin 179, Dodge and Moore)

$$K_p = \frac{1.73}{\lambda} \left[ \frac{1}{1 + 1.75\lambda^{\frac{4}{3}} \exp\left(-1.15\psi^{\frac{1}{4}}\right)} \right]$$

where it is recommended that  $0.05 \leq \lambda \leq 1.0$  and  $0.0 \leq \psi \leq 0.1$ . (Note in the cited Dodge and Moore the  $K_p$  coefficient has a value of 1.66 which was updated in 1991 to the current value of 1.73)

Also we must have  $K_p \geq 1.0$  for all FSI. Therefore, for FSI=2 or FSI=3, when  $K_p$  is computed as  $K_p < 1.0$ , it is set to  $K_p=1$ .

**Stress recovery stress intensification factor calculations:**

Define  $S_1$  as the in plane stress intensification factor and  $S_2$  as the out of plane stress intensification factor.

For FSI = 1

$$S_1 = \frac{I_1}{AR_B} \left[ \frac{1}{r_i} + \frac{R_B - \Delta N}{\Delta N(R_B + r_i)} \right]$$

$$S_2 = 1.0$$

If  $\Delta N = 0.0$ ,  $T = 0.0$ ,  $R_M = 0.0$  then  $S_1 = 1.0$ .

$r_i$  is the C1, D1, E1, F1 of the (r,z) recovery locations.

For FSI = 2 (ASME code Section III, NB-3687.2, NB-3685.2, 1977)

Define:

$$X_1 = 5.0 + 6\lambda^2 + 24\psi$$

$$X_2 = 17.0 + 600\lambda^2 + 480\psi$$

$$X_3 = X_1X_2 - 6.25$$

$$X_4 = (1 - \nu^2)(X_3 - 4.5X_2)$$

and

$$S_{1t} = \sin \phi + [(1.5X_2 - 18.75)\sin 3\phi + 11.25 \sin 5\phi]/X_4$$

$$S_{1n} = (\nu\lambda(9X_2 \cos 2\phi + 225 \cos 4\phi))/X_4$$

$$S_1 = S_{1t} + S_{1n}$$

$$S_{2t} = \cos \phi + [(1.5X_2 - 18.75)\cos 3\phi + 11.25 \cos 5\phi]/X_4$$

$$S_{2n} = (\nu\lambda(9X_2 \sin 2\phi + 225 \sin 4\phi))/X_4$$

$$S_2 = S_{2t} + S_{2n}$$

For data recovery the circumferential angle  $\phi$  is evaluated at 0 deg, 90 deg, 180 deg, and 270 deg. For FSI = 3 (Empirical factors from Welding Research Council Bulletin 179, Dodge and Moore)

$$S_1 = S_2 = \frac{2\lambda^{\frac{2}{3}}(1.0 + 0.25\gamma^{-1})}{1.0 + \lambda^{\frac{4}{3}} \exp\left(-\psi^{\frac{1}{4}}\right)}$$

4. The transverse shear stiffness in planes 1 and 2 are  $K1 \cdot A \cdot G$  and  $K2 \cdot A \cdot G$ , respectively. The default values for K1 and K2 on the first format are zero, which means the transverse shear flexibilities ( $1/Ki \cdot A \cdot G$ ) are set equal to zero. Transverse shear stiffness for the alternate format are automatically calculated for the curved pipe.
5. The neutral axis radial offset from the geometric centroid is default to the

$$\Delta N = \frac{I1}{A \cdot RB}$$

It is recommended that the default be used whenever

$$\frac{(RB)^2 A}{I1} < 15$$

in which case the default value of  $\Delta N$  is within 5% of the exact expression for circular or rectangular cross sections. For the alternate format, the neutral axis offset is calculated from an analytical expression for a hollow or solid circular cross section.

The user may compute an exact value for  $N$  as follows:

$$\Delta N = \frac{RB}{1 + \frac{(RB)^2 A}{Z}}$$

where

$$Z = \int \frac{r^2 dA}{1 + \frac{r}{RB}}$$

The integration is carried out over the cross section of the element.

6. If T is zero, a solid circular cross section of radius RM is assumed and FSI must be 1.
7. If the first format is used, third-order moments are neglected for the consistent mass matrix. These moments are zero whenever the cross section of the beam is symmetric about both the r and z axes.
8. If the circular cross-sectional property entry format is used, the stress points are automatically located at the points indicated in [Figure 9-115](#).
9. Offset vectors are treated like rigid elements and are therefore subject to the same limitations.
  - Offset vectors are not affected by thermal loads.
  - The specification of offset vectors is not recommended in solution sequences that compute differential stiffness because the offset vector remains parallel to its original orientation. (Differential stiffness is computed in buckling analysis provided in SOLs 105 and 200; SOLs 101,103 and 107 through 112 with STATSUB; and also nonlinear analysis provided in SOLs 106, 129, 153, and 159 with PARAM,LGDISP,1.)

Figure 9-115 PBEND Circular Cross Section

Figure 9-116 PBEND Element Coordinate System

Figure 9-117 PBEND Circular Cross Section Element Coordinate System

10. For RC network solver in thermal analysis, the DELTAN is ignored.
11. PBEND is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBEND property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBEND entries.
12. If GRAV or PLOAD1 loads are applied to a CBEND element, then it is recommended that the element should subtend an arc of 20 degrees or less degrees.

## PBMARB6

## Arbitrary Beam/Bar Cross Section in SOL 600

Defines arbitrary BEAM/BAR cross section for use in SOL 600.

### Format:

1	2	3	4	5	6	7	8	9	10
PBMARB6	PID	MID	Nseg	ORDx	ORDy	PreInt	POIS	IPRN	
	Px	Py	F1	F2	F3	F4	F5	F6	
	X1	Y1	X2	Y2	X3	Y3	X4	Y4	1st seg
	X1	Y1	X2	Y2	X3	Y3	X4	Y4	2nd seg

(more rectangular segments, if required)

	X1	Y1	X2	Y2	X3	Y3	X4	Y4	last seg
--	----	----	----	----	----	----	----	----	----------

### Example: (Remark 5)

PBMARB6	20	4	2	3	3			3	
	2.0	1.0							
	0.0	1.0	0.8	0.0	0.8	1.0	0.0	1.0	
	0.0	1.0	1.0	1.0	1.0	2.0	0.0	2.0	

Describer	Meaning
PID	Property identification number. Must be unique among all property ID's. (Integer > 0; no Default)
MID	Material identification number. (Integer > 0; no Default)
Nseg	Number of quadrilateral shaped segments. See Remark 2. (Integer; no Default)
ORDx	Order of the integration rule used for each quadrilateral shaped segment in parametric -direction. If the number is positive and odd, a Simpson rule is used. If the number is positive and even, a Newton-Cotes rule is used. If the number is negative, a Gauss rule is used. The default is 5 and the order cannot be larger than 10. (Integer; no Default)
ORDy	Order of the integration rule used for each quadrilateral shaped segment in parametric -direction. If the number is positive and odd, a Simpson rule is used. If the number is positive and even, a Newton-Cotes rule is used. If the number is negative, a Gauss rule is used. The default is the same rule and order as in parametric -direction and the order cannot be larger than 10. (Integer; no Default)
PreInt	Enter 1 to use a pre-integrated section or 0 to use numerical integration through the analysis. If PreInt=0, the section remains elastic. (Integer; Default = 0)
POIS	For a uniform change in cross section, enter the effective Poisson's ratio. This data is not used at this time and its value will be ignored. (Real; Default = 0.0)

Describer	Meaning
IPRN	<p>Enter 1 to have the principal axis associated with the largest area moment of inertia to be aligned with the local x-axis.</p> <p>Enter 2 to have the principal axis associated with the smallest area moment of inertia to be aligned with the local x-axis.</p> <p>Enter 3 to have the x-axis of the coordinate system for which the section is being defined to be aligned with the local x-axis of the element (element coordinates). (Integer; Default = 3)</p>
Px	<p>Enter the x-coordinate of a point that, when projected, lies on the positive side of the local x-axis. If the principal moments of inertia are equal, this defines the x-coordinate of a point on the positive local x-axis. This coordinate defaults to <math>X_{cg}+1</math>, where <math>X_{cg}</math> is the x-coordinate of the center of gravity of the section in the coordinate system in which the section was entered. The default is used when this field is blank or zero or when the user point coincides with the center of gravity.</p>
Py	<p>Enter the y-coordinate of a point that, when projected, lies on the positive side of the local x-axis. If the principal moments of inertia are equal, this defines the y-coordinate of a point on the positive local x-axis. This coordinate defaults to <math>Y_{cg}</math>, where <math>Y_{cg}</math> is the y-coordinate of the center of gravity of the section in the coordinate system in which the section was entered. The default is used when this field is blank or zero or when the user point coincides with the center of gravity.</p> <p>F1 Normal stiffness factor F1. (Real; Default = 1.0)</p> <p>F2 Bending stiffness factor for bending about local X axis. (Real; Default = 1.0)</p> <p>F3 Bending stiffness factor for bending about local Y Axis. (Real; Default = 1.0)</p> <p>F4 Shear stiffness factor for shear in local X direction. (Real; Default = 1.0)</p> <p>F5 Shear stiffness factor for shear in local Y direction. (Real; Default = 1.0)</p> <p>F6 Torsional stiffness factor. (Real; Default = 1.0)</p> <p><math>X_i, Y_i</math> Coordinates of the 4 corners of each rectangle. Enter Nseg sets of 4 coordinates each. See Remark 3. (Real; no Default)</p>

**Remarks:**

1. This option corresponds to Marc’s BEAM SECT Method D.
2. No more than 100 integration points can exist in any cross section. Pre-integrated sections do not allow stress and strain output in section integration points; only generalized stresses and strains can be requested for output. Non pre-integrated sections cannot have more than 100 segments using single point integration each. For pre-integrated sections, there is no limit on the number of segments
3. The corners are given in counterclockwise order with respect to the local x-y axis.
4. This option applies only to Marc element types 98 (SOL 600 default) and 52. The difference between types 98 and 52 is that 98 has transverse shear and 52 does not have transverse shear.

5. For the example, a section is made up of two rectangles as shown in the figure below. The input for the section defines one section with two quadrilateral segments using a 3x3 Simpson integration. The lower segment has size 0.8x1 and the upper segment has size 1x1. The first principal axis defines the local x-axis and the vector from the center of gravity (CG) to the projection of point P (2.0,1.0) onto this principal axis defines its positive direction. The coordinates of corner points of the segments and the coordinates of the point P have been entered with respect to the x,y-system.

6. If this entry is used, do not enter any other properties (such as pbeam, pbeam1, pbar, pbar1, etc.) for the elements using this property.
7. If this entry is used, the following parameters must be included in the bulk data:

PARAM,MARCBEAM,0

PARAM,MROUTLAY,N (where N is the number of integration layers, suggested values are N=5 if there is no plasticity and N=11 with plasticity)

PARAM,MARCSLHT,N (N should be the same as specified for MROUTLAY)

## **PBMNUM6** Four Specific Numerically Integrated BEAM/BAR Cross Section in SOL 600

Defines four specific numerically integrated BEAM/BAR cross section for use in SOL 600.

### **Format:**

1	2	3	4	5	6	7	8	9	10
PBMNUM6	PID	MID	ITYPE	ORDx	ORDy	PreInt	POIS		
	A	B	C						
	F1	F2	F3	F4	F5	F6			

### **Example:**

PBMNUM6	30	6	2	3	3				
	7.0	2.5							

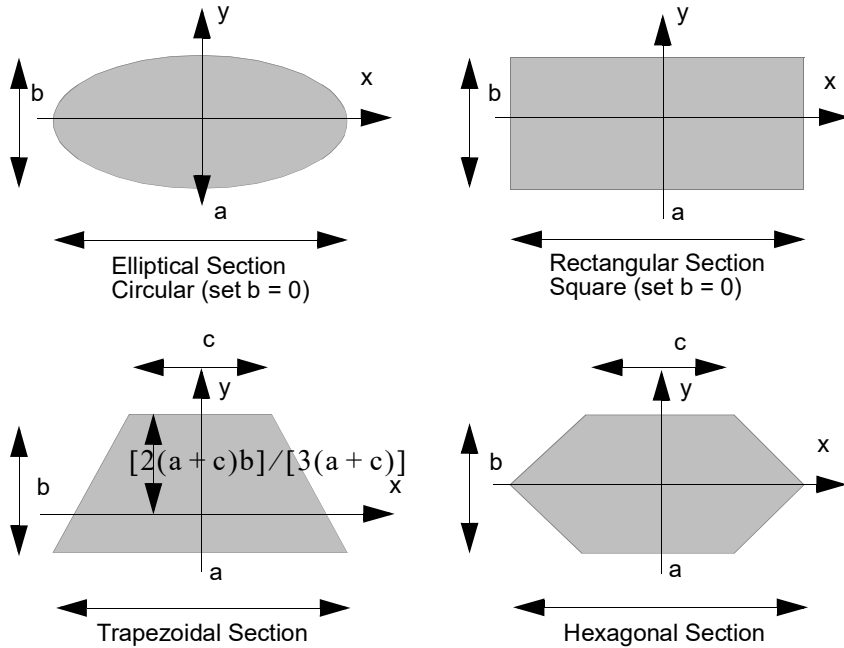

Describer	Meaning
PID	Property identification number. (Integer > 0; no Default) Must be unique among all property ID's
MID	Material identification number. (Integer > 0; no Default)
ITYPE	Type of section, see figure below. (Integer; no Default)
	1            Elliptical
	2            Rectangular
	3            Trapezoidal
	4            Hexagonal
ORDx	For an elliptical section, enter the number of subdivisions in radial direction. The default is 3.  For a rectangular or trapezoidal section, enter the order of the integration rule used in local x-direction. If the number is positive and odd, a Simpson rule is used. If the number is positive and even, a Newton-Cotes rule is used. If the number is negative, a Gauss rule is used. The default is 5 and the order cannot be larger than 10.  For a hexagonal section, enter the order of the integration rule used in local x-direction over each trapezoidal half. If the number is positive and odd, a Simpson rule is used. If the number is positive and even, a Newton-Cotes rule is used. If the number is negative, a Gauss rule is used. The default is 5 and the order cannot be larger than 10. (Integer; no Default)

Describer	Meaning
ORDy	<p>For an elliptical section, enter the number of subdivisions in circumferential direction of a 90° sector. The default is 2. For a rectangular or trapezoidal section, enter the order of the integration rule used in local y-direction. If the number is positive and odd, a Simpson rule is used. If the number is positive and even, a Newton-Cotes rule is used. If the number is negative, a Gauss rule is used. The default is what was entered in the first field and the order cannot be larger than 10.</p> <p>For a hexagonal section, enter the order of the integration rule used in local y-direction over each trapezoidal half. If the number is positive and odd, a Simpson rule is used. If the number is positive and even, a Newton-Cotes rule is used. If the number is negative, a Gauss rule is used. The default is half the order in x-direction plus 1 and the order cannot be larger than 10. For non-Gauss rules, the points in the top row of the lower trapezoid coinciding with the points in the bottom row of the upper trapezoid (i.e., the points coinciding at <math>y = 0</math>) are merged together.</p>
PreInt	Enter 1 to use a pre-integrated section or 0 to use numerical integration through the analysis. If PreInt=0, the section remains elastic. (Integer; Default = 0)
POIS	For a uniform change in cross section, enter the effective Poisson's ratio. This data is not used at this time and its value will be ignored. (Real; Default = 0.0)
A	<p>First dimension of the cross section (Real; no Default)</p> <p>Ellipse      A is the diameter of the circle or the length of the ellipse in local x.</p> <p>Rectangle    A is the length of the square or the rectangle in local x.</p> <p>Trapezoid    A is the width of the trapezoid in local x on minus local y side.</p> <p>Hexagon      A is the width of the hexagon in local x at <math>y = 0</math>.</p>
B	<p>Second dimension of the cross section (Real; Default B=A)</p> <p>Ellipse      B is the height of the ellipse in local y.</p> <p>Rectangle    B is the height of the rectangle in local y.</p> <p>Trapezoid    B is the height of the trapezoid in local y.</p> <p>Hexagon      B is the height of the hexagon in local y.</p>
C	<p>Third dimension of the cross section if required (Real; Default = 0.0)</p> <p>Ellipse      C is not used. Leave blank or enter 0.</p> <p>Rectangle    C is not used. Leave blank or enter 0.</p> <p>Trapezoid    C is the width of the trapezoid in local x on the plus local y side.</p> <p>Hexagon      C is the width of the hexagon in local x on either local y side.</p>
F1	Normal stiffness factor F1 (Real; Default = 1.0)
F2	Bending stiffness factor for bending about local X axis (Real; Default = 1.0)
F3	Bending stiffness factor for bending about local Y Axis (Real; Default = 1.0)
F4	Shear stiffness factor for shear in local X direction (Real; Default = 1.0)

Describer	Meaning
F5	Shear stiffness factor for shear in local Y direction (Real; Default = 1.0)
F6	Torsional stiffness factor. (Real; Default = 1.0)

**Remarks:**

1. This option corresponds to Marc's BEAM SECT Method C.
2. No more than 100 integration points can exist in any cross section. Pre-integrated sections do not allow stress and strain output in section integration points; only generalized stresses and strains can be requested for output. Non pre-integrated sections cannot have more than 100 segments using single point integration each. For pre-integrated sections, there is no limit on the number of segments
3. This option applies only to Marc element types 98 (SOL 600 default) and 52. The difference between types 98 and 52 is that 98 has transverse shear and 52 does not have transverse shear.
4. If this entry is used, do not enter any other properties (such as pbeam, pbeam1, pbar, pbar1, etc.) for the elements using this property.
5. The second continuation entry may be eliminated if F1 through F6 take the default values.
6. For the rectangle, if B=A or B=0.0 the cross section is a square.
7. For the Ellipse, if B=A or B=0.0, the cross section is a circle.

8. If this entry is used, the following parameters must be included in the bulk data:

PARAM,MARCBEAM,0

PARAM,MROUTLAY,N

(where N is the number of integration layers, suggested values are N=5 if there is no plasticity and N=11 with plasticity)

PARAM,MARCSLHT,N

(N should be the same as specified for MROUTLAY)

## PBMSECT

### Arbitrary Cross-Section for CBEAM

Defines the shape of arbitrary cross-section for CBEAM element.

**Format:**

1	2	3	4	5	6	7	8	9	10
PBMSECT	PID	MID	FORM						
Data description for arbitrary section									

**Example:**

PBMSECT	1	10	GS						
OUTP=10,INP=20									
PBMSECT	1	10	CP						
OUTP=10,BRP=20,T=1.0,T(11)=[1.2,PT=(123,204)], NSM=0.01									

Descriptor	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number. (Integer > 0)
FORM	Cross-section form. (Character) See Remark 1.

**Remarks:**

- Options for FORM are

GS	General Section
OP	Open Profile
CP	Closed Profile

- Keywords for describing the arbitrary cross-section:

For GS, OP and CP:

- OUTP = value(Integer > 0); points to ID of a SET1 or SET3 that defines the OUTER Perimeter for FORM=GS or the center line for FORM=CP (or OP) by traversing through all the POINTs in the SET.
- OUTM = value(Integer > 0), points to the ID of BEGIN BULK ARBMODEL. OUTM is designed specifically for arbitrary beam cross section with finite element discretization already available. Note that OUTM must not appear together with other keyword, such as OUTP or INP, on a PBMSECT.

For GS only:

INP(id) = value(Integer > 0); points to the ID of a SET1 or SET3 that defines a INner Perimeter by traversing through all the POINTs in the SET.

For OP and CP:

BRP(id) = value(Integer > 0); points to the ID of a SET1 or SET3 that specifies a BRanch. The rules for BRP are:

- BRP must start from and/or end on OUTP.
- Segment length, defined as distance between two neighboring points on BRP or OUTP, is preferably to be longer than the segment thickness. Closely spaced points creates denser mesh for the cross section and does not increase accuracy of properties significantly.

T(id) = [value(Real > 0.0),PT=(pid1,pid2)]; specifies the thickness of a segment in profile. PT=(pid1,pid2) defines the start and end points of line segment(s). The rules for T(id) are:

- For CP and OP, it is a requirement to have a T(id) without PT=(pid1,pid2) to serve as a default thickness for all segments which do not have its thickness specified. This requirement is valid even when the thickness for every segment is specified.
- pid1 and pid2 under PT=( ) do not need to be neighboring points of a SET. However, pid1 and pid2 must hold its position as in SETx for OUTP and/or BRP.
- Same segment may be covered by different T(id). T(id) are processed sequentially as specified. The thickness of the last T(id) for a segment is used as the thickness of a segment. Use 'PARAM,ARBMNOW,1' to turn off segment property overwrite.
- For CP, T(id) of segment that close the profile must have (pid1=ID of last point in OUTP, pid2=ID of first point in OUTP). Note that, if input for pid1 and pid2 are reversed, T(id) will cover all segments in OUTP except the one that close the profile.

- Core(id) = [PCID,PT=(pid1,pid2)]; specifies the composite layout for CORE part of composite. PCID is the ID of a PCOMPi/PCOMPG Bulk Data entry. PT=(pid1,pid2) defines the start and end points of line segment(s) which utilizes PCID.
- Core=PCID is acceptable input and is used as default which is applicable to all segments that are not specifically defined with Core(id).
  - Thickness continuity of a ply must be maintained. Thickness change from segment to segment is not allowed.
  - For CP, the closing segment should always use the default Core=pcid.
  - No ply should go over the profile line which is defined by OUTP and BRP. If situation arises, split a ply into two in such a way the no ply go over the profile line.
- Layer(id) = [PCID,SETID]; specifies the composite layout for additional Layer(s) that wraps around Core. PCID is the ID of a PCOMP/PCOMPG Bulk Data entry. SETID selects a SET1/SET3 with POINT IDs.
- NSM = value(Real > 0.0), specifies non-structural mass per unit length.
- (id) = integer (>0) identifies INP, BRP or T which is not required if a single entity appears in the PBMSECT entry. For T, the T(id) can be used to identify the particular thickness to be designed in SOL 200.

3. Stress data recovery points are selected automatically from all points of a PBMSECT with GS form. The points with maximum and/or minimum coordinates in X and Y axes are more likely to be picked. For PBMSECT with CP or OP form, the stress data recovery points are selected from points with computed coordinates that actually encircle the profile. Similar to GS form, the points with extreme coordinates are more likely to be selected.
4. Only the POINT entry ID should be listed under SET1 or SET3 entries which, in turn, are referenced by OUTP, INP and BRP. In addition, the POINT entry for defining an arbitrary beam cross section must have the CP and X3 fields left blank.

Figure 9-118 Arbitrary Cross-Section Definition

5. Current implementation of PBMSECT supports constant section beam only.
6. Note that keyword Core can be abbreviated as 'C'. Similarly, keyword Layer can be abbreviated as 'L'.
7. If Core and/or Layer appears in PBMSECT, the PBMSECT ID can not be referenced on CBEAM. Instead, it should be referenced on CBEAM3. Note, however, that a CBEAM3 cannot be used with any other of the above options except the Core and/or Layer option. The use of any other option results in a FATAL. In addition, it is recommended that CBEAM3 referencing composite PBMSECT has 3 nodes and 3 warping DOFs.'
8. If OUTM=arbid is utilized on PBMSECT, element connection, grid location, PSHELL and material Bulk Data entries must be provided after 'BEGIN ARBMODEL=arbid'.
9. Note that the 'arbid' used under 'BEGIN ARBMODEL' is considered global and can be referenced by PBMSECT with OUTM=arbid in different 'BEGIN SUPER' Bulk Data Section for Part Superelements (SE).
10. PBMSECT with Core or Layer must be utilized along with 'PARAM,ARB MSTYP,TIMOSHEN' in the Bulk Data Section.
11. The entry computes, based on an internally generated finite element analysis using a 2D mesh of the cross-section, the following:

$$A = \int dy dz$$

$$I1 = \int y^2 dy dz$$

$$I2 = \int z^2 dy dz$$

$$I12 = \int yz dy dz$$

where the above integrals are evaluated by numerical integration.

For a beam cross-section, the warping function,  $\phi$ , satisfies the equation

$$\frac{\partial^2 \phi}{\partial y^2} + \frac{\partial^2 \phi}{\partial z^2} = 0$$

with boundary

$$\left(\frac{\partial \phi}{\partial y} + z\right)n_y + \left(\frac{\partial \phi}{\partial z} - y\right)n_z = 0$$

where  $n_y$  and  $n_z$  are the direction cosine of the normal to the boundary.

Then, the torsion constant is defined as

$$J = I1 + I2 - \int \left[ \frac{\partial \phi}{\partial z} \frac{\partial \phi}{\partial y} \right] \begin{Bmatrix} -y \\ z \end{Bmatrix} dA$$

The load equilibrium of the beam cross-section can be resolved into two Poisson equations for the shear forces in the  $y$  and  $z$  direction as:

$$\nabla^2 f_y = -y/I1$$

$$\nabla^2 f_z = -z/I2$$

then, the shear stiffness factor is defined as

$$K1 = \left[ \frac{A}{I2} \int z f_z dA \right]^{-1}$$

$$K2 = \left[ \frac{A}{I1} \int y f_y dA \right]^{-1}$$

The warping constant is defined as

$$C_w = \int \phi^2 dA - \begin{bmatrix} y_{sc} & z_{sc} \end{bmatrix} [I] \begin{Bmatrix} y_{sc} \\ z_{sc} \end{Bmatrix}$$

The shear center is defined as

$$Q1 = \int z dA \quad Q2 = \int y dA$$

$$N1A = Q1/A \quad N2A = Q2/A$$

12. PBMSECT is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBMSECT property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBEAM, PBEAML, PBCOMP, PBMSECT, PBEAM3 entries.

## PBRSECT

## Arbitrary Cross-Section for CBAR

Defines the shape of arbitrary cross-section for CBAR element.

### Format:

1	2	3	4	5	6	7	8	9	10
PBRSECT	PID	MID	FORM	NSM					
Data description for arbitrary section									

### Example:

PBRSECT	1	10	GS						
OUTP=10,INP=20									
PBRSECT	1	10	CP						
OUTP=10,BRP=20,T=1.0,T(11)=[1.2,PT=(123,204)]									

Descriptor	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number. (Integer > 0)
FORM	Cross-section form. (Character) See Remark 1.
NSM	Non-structural mass per unit length. (Real $\geq$ 0.0; Default = 0.0)

### Remarks:

- Options for FORM are

GS	General Section
OP	Open Profile
CP	Closed Profile

- Keywords for describing the arbitrary cross-section:

For GS, OP and CP:

OUTP = value(Integer > 0); points to ID of a SET1 or SET3 that defines the OUTER Perimeter for FORM=GS or the center line for FORM=CP (or OP) by traversing through all the POINTs in the SET.

For GS only:

INP(id) = value(Integer > 0); points to the ID of a SET1 or SET3 that defines a INNER Perimeter by traversing through all the POINTs in the SET.

For OP and CP:

BRP(id) = value(Integer > 0); points to the ID of a SET1 or SET3 that specifies a BRanch.  
 The rules for BRP are:

- BRP must start from and/or end on OUTP.
- Segment length, defined as distance between two neighboring points on BRP or OUTP, is preferably to be longer than the segment thickness. Closely spaced points creates denser mesh for the cross section and does not increase accuracy of properties significantly.

T(id) = [value(real > 0.0),PT=(pid1,pid2)]; specifies the thickness of a segment in profile. PT=(pid1,pid2) defines the end points of a straight line segment. The rules for T(id) are:

- For CP and OP, it is a requirement to have a T(id) without PT=(pid1,pid2) to serve as a default thickness for all segments which do not have its thickness specified. This requirement is valid even when the thickness for every segment is specified.
- pid1 and pid2 under PT=( ) do not need to be neighboring points of a SET. However, pid1 and pid2 must hold its position as in SETx for OUTP and/or BRP.
- Same segment may be covered by different T(id). T(id) are processed sequentially as specified. The thickness of the last T(id) for a segment is used as the thickness of a segment. Use 'PARAM,ARBMNOW,1' to turn off segment property overwrite.
- For CP, T(id) of segment that close the profile must have (pid1=ID of last point in OUTP, pid2=ID of first point in OUTP). Note that, if input for pid1 and pid2 are reversed, T(id) will cover all segments in OUTP except the one that close the profile.

NSM = value(Real > 0.0), specifies non-structural mass per unit length.

(id) = integer (>0) identifies INP, BRP or T which is not required if a single entity appears in the PBRSECT entry. For T, the T(id) can be used to identify the particular thickness to be designed in SOL 200.

3. Stress data recovery points are selected automatically from all points of a PBRSECT with GS form. The points with maximum and/or minimum coordinates in X1 and/or X2 axes are more likely to be picked. For PBRSECT with CP or OP form, the stress data recovery points are selected from points with computed coordinates that actually encircle the profile. Similar to GS form, the points with extreme coordinates are more likely to be selected.
4. Only the POINT entry ID should be listed under SET1 or SET3 entries which, in turn, are referenced by OUTP, INP and BRP. In addition, the POINT entry for defining an arbitrary beam cross section must have the CP and X3 fields left blank.
5. See Remark 11. of the PBMSECT entry for the theory used to compute the cross-sectional properties.

Figure 9-119 Arbitrary Cross-Section Definition

6. PBRSECT is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBRSECT property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBAR, PBARL, PBRSECT entries.

**PBSH2DT****2-D Linear/Nonlinear Connection Properties using Table Lookup**

Defines frequency-dependent properties of a two-dimensional element (CBUSH2D) using TABLED1 lookup.

**Format:**

1	2	3	4	5	6	7	8	9	10
PBSH2DT	PID	“K”	K11	K22	K12	K21			
		“B”	B11	B22	B12	B21			
		“M”	M11	M22	M12	M21			

Describer	Meaning
PID	Property id of a PBUSH2D entry (see Remark 1.)
K11	TABLED1 used to define frequency-dependent stiffness in the T1 direction (Integer >0 or blank)
K22	TABLED1 used to define frequency-dependent stiffness in the T2 direction (Integer >0 or blank)
K12	TABLED1 used to define frequency-dependent cross coupling stiffness (Integer >0 or blank)
K21	TABLED1 used to define frequency-dependent cross coupling stiffness (Integer >0 or blank)
B11	TABLED1 used to define frequency-dependent damping in the T1 direction (Integer >0 or blank)
B22	TABLED1 used to define frequency-dependent damping in the T2 direction (Integer >0 or blank)
B12	TABLED1 used to define frequency-dependent cross coupling damping (Integer >0 or blank)
B21	TABLED1 used to define frequency-dependent cross coupling damping (Integer >0 or blank)
M11	TABLED1 used to define frequency-dependent mass in the T1 direction (Integer >0 or blank)
M22	TABLED1 used to define frequency-dependent mass in the T2 direction (Integer >0 or blank)
M12	TABLED1 used to define frequency-dependent cross coupling mass (Integer >0 or blank)
M21	TABLED1 used to define frequency-dependent cross coupling mass (Integer >0 or blank)

**Remarks:**

1. A PBUSH2D with the same PID must exist. The values from the PBUSH2D will be used as the nominal stiffness, damping, and mass. Linear statics, normal modes, reduction, and superelement processing will use the nominal values. The values from the selected TABLED1 entries will be used in any frequency-dependent loop.
2. Any field left blank indicates that the associated stiffness, damping, or mass is not frequency-dependent and the nominal values will be used for that term in the solution.
3. PBUSH2DT card will only work if there is rotor definition in the model. If PBUSH2DT is used on non-rotordynamics model, a FATAL message will be issued.

## PBUSH Generalized Spring-and-Damper Property

Defines the nominal property values for a generalized spring-and-damper structural element.

### Format:

1	2	3	4	5	6	7	8	9	10
PBUSH	PID	"K"	K1	K2	K3	K4	K5	K6	
		"B"	B1	B2	B3	B4	B5	B6	
		"GE"	GE1	GE2	GE3	GE4	GE5	GE6	
		"RCV"	SA	ST	EA	ET			
		"M"	M						
		"T"	ALPHA	TREF	COINL				

### Example 1:

Stiffness and structural damping are specified.

PBUSH	35	K	4.35	2.4				3.1	
		GE	.06						
		RCV	7.3	3.3					

### Example 2:

Damping force per unit velocity are specified.

PBUSH	35	B	2.3						
-------	----	---	-----	--	--	--	--	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0)
"K"	Flag indicating that the next 1 to 6 fields are stiffness values in the element coordinate system. (Character)
Ki	Nominal stiffness values in directions 1 through 6. See Remarks 2. and 3. (Real; Default = 0.0)
"B"	Flag indicating that the next 1 to 6 fields are force-per-velocity damping. (Character)
Bi	Nominal damping coefficients in direction 1 through 6 in units of force per unit velocity. See Remarks 2., 3., and 9. (Real; Default = 0.0)
"GE"	Flag indicating that the next fields, 1 through 6 are structural damping constants. See Remark 7. (Character)
GEi	Nominal structural damping constant in directions 1 through 6. See Remarks 2. and 3. and 9. (Real; GE1 default = 0.0, GE2-6, defaults described in Remark 9.)

Describer	Meaning
“RCV”	Flag indicating that the next 1 to 4 fields are stress or strain coefficients. See Remarks 4. and 5.(Character).
SA	Stress recovery coefficient in the translational component numbers 1 through 3. (Real; Default = 1.0)
ST	Stress recovery coefficient in the rotational component numbers 4 through 6. (Real; Default = 1.0)
EA	Strain recovery coefficient in the translational component numbers 1 through 3. (Real; Default = 1.0)
ET	Strain recovery coefficient in the rotational component numbers 4 through 6. (Real; Default = 1.0)
“M”	Flag indicating that the following entries are mass properties for the CBUSH element. If inertia properties ( Iij )are desired CONM2 should be used.
M	Lumped mass of the CBUSH. (Real≥0.0; Default=0.0)
“T”	Flag indicating that the following entries are thermal properties for the CBUSH element. See Remark 14.. (Character)
ALPHA	Thermal expansion coefficient for the CBUSH. (Real; Default=0.0)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0, See Remark 14.)
COINL	Length of a CBUSH with coincident grids. (Real; Default=0.0, COINL ≥ 0.0)

**Remarks:**

1. Ki, Bi, or GEi may be made frequency dependent for both direct and modal frequency response by use of the PBUSHT entry.
2. The nominal values are used for all analysis types except frequency response and nonlinear analysis. For modal frequency response, the normal modes are computed using the nominal Ki values. The frequency-dependent values are used at every excitation frequency.
3. If PARAM,W4 is not specified, GEi is ignored in transient analysis.
4. The element stresses are computed by multiplying the stress coefficients with the recovered element forces.  $\sigma_i = F_i \cdot SA$  or  $\sigma_i = M_i \cdot ST$
5. The element strains are computed by multiplying the strain coefficients with the recovered element displacements.  $\varepsilon_i = U_i \cdot EA$  or  $\varepsilon_i = \theta_i \cdot ET$
6. The “K”, “B”, “GE”, “RCV”, or “M” entries may be specified in any order.
7. To obtain the damping coefficient GE, multiply the critical damping ratio  $C/C_0$  by 2.0.
8. Applicable fields refer to directions in the element’s coordinate system.

9. For upward compatibility, if ONLY GE1 is specified on a PBUSH entry and GE<sub>i</sub>, i = 2 – 6 are all blank on the PBUSH entry, then the single structural damping GE1 is applied to all defined K<sub>i</sub> for the PBUSH entry. In this case, GE<sub>i</sub>, i = 2 - 6, blank is not equivalent to 0.0 but a special flag.

For any PBUSH entry that has any GE<sub>i</sub>, i = 2 – 6 numerically specified including a 0.0, the fields GE<sub>i</sub> are all treated separately and any GE<sub>i</sub>, i = 2 - 6 field with no entry specified is defaulted to 0.0. In this case, for any GE<sub>i</sub>, i = 2 – 6, blank is equivalent to 0.0 and the results are radically different from the no GE<sub>i</sub>, i = 2- 6 specified as described above.

Thus for the entry:

1	2	3	4	5	6	7	8	9	10
PBUSH	3303000	K	653.	4000.	460.	10.+3	10.+3	10.+3	
		GE	.05						

The GE=.05 will be replicated to fields 5 through 9.

While for the entry:

1	2	3	4	5	6	7	8	9	10
PBUSH	3303000	K	653.	4000.	460.	10.+3	10.+3	10.+3	
		GE	.05	0.0					

The element x-direction will have a GE=.05 while the other 5 directions will have an associated GE=0.0

The entry:

1	2	3	4	5	6	7	8	9	10
PBUSH	3303000	K	653.	4000.	460.	10.+3	10.+3	10.+3	
		GE	.05		.02				

is equivalent to the full entry:

1	2	3	4	5	6	7	8	9	10
PBUSH	3303000	K	653.	4000.	460.	10.+3	10.+3	10.+3	
		GE	.05	.0	.02	.0	.0	.0	

IFPSTAR introduced an incompatibility with the above rules in Nastran versions 2014 to 2017. For Nastran version 2018 IFPSTAR, the above original rules have been restored. However, the previous incompatible IFPSTAR results can be recovered with bulk data entry MDLPRM, GEV1417, 1 or NASTRAN, SYSTEM(754)=1 in which case the last example becomes equivalent to the full entry:

1	2	3	4	5	6	7	8	9	10
PBUSH	3303000	K	653.	4000.	460.	10.+3	10.+3	10.+3	
		GE	.05	.05	.02	.05	.05	.05	

10. For SOL 600, it is not necessary to enter PBUSH if a PBUSHT with the same ID is used in the model. Omitting the PBUSH entry if a PBUSHT with the same ID is entered.

11. For SOL 600, the defaults for SA, ST, EA and ET are 1.0E-10.

The mass properties are assumed located at the point defined by S (or S1, S2, S3 if OCID> -1) on the CBUSH entry. They are assumed to be in the element coordinate system. Define  $\alpha = S$  for the case OCID= -1 (default). See CBUSH entry. For the case OCID> -1, define  $r_A, r_B$  to be the vector from grid GA to (S1,S2,S3) and from grid GB to (S1,S2,S3) respectively, then

$$\alpha = \frac{|r_A|}{|r_A| + |r_B|}$$

$$|r_A| = \sqrt{(GA1 - S1)^2 + (GA2 - S2)^2 + (GA3 - S3)^2}$$

$$|r_B| = \sqrt{(GB1 - S1)^2 + (GB2 - S2)^2 + (GB3 - S3)^2}$$

Then the diagonal contribution to GA for the mass matrix in the element coordinate system is:

$$M11A= M22A=M33A= (1- \alpha)*M$$

The diagonal contribution to GB for the mass matrix in the element coordinate system is:

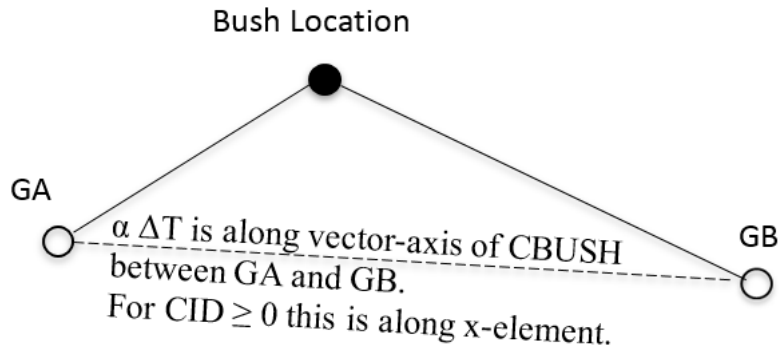

$$M11B= M22B=M33B=( \alpha)*M$$

12. PBUSH is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBUSH property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBUSH entries.
13. The CBUSH is a self-equilibrating element which means that for a CBUSH of finite length, its translational stiffness terms couple with rotational stiffness for rotational degrees of freedom. However, this coupling is dependent on the orientation of the CBUSH element. Thus there may be times when no explicit rotational stiffness is specified along a direction for which translational stiffness was specified that there is also no coupled rotational stiffness for that direction.

In modal analysis, a CBUSH of finite length having rotational degrees of freedom with no rotational stiffness (coupled or explicit) and no associated mass on the grids may cause massless mechanisms. A massless mechanism means the natural frequency for this rotational mode approaches the limit of zero rotational stiffness divided by zero mass, which is an undefined quantity. If the elements lie along a global coordinate axis, the mass term is identically zero, which leads to very large negative or positive eigenvalues and is usually beyond any reasonable search region. If the elements are skewed from the global axes, the eigenvalues may be computed at any value (including negative) because of the indeterminacy caused by numerical truncation.

14. The thermal expansion for the CBUSH will be calculated if the user supplies the thermal expansion coefficient ALPHA and TEMPERATURE(LOAD) is requested. See TEMPERATURE Case Control command for thermal loading rules. For a CBUSH with coincident grids, or a single grid, if COINL is provided, the thermal expansion is always just along the element x-axis.

## PBUSH1D

## Rod Type Spring-and-Damper Property

Defines linear and nonlinear properties of a one-dimensional spring and damper element (CBUSH1D entry).

### Format:

1	2	3	4	5	6	7	8	9	10
PBUSH1D	PID	K	C	M		SA	SE		
	"SHOCKA"	TYPE	CVT	CVC	EXPVT	EXPVC	IDTS		
			IDETS	IDECS	IDETSD	IDECSD			
	"SPRING"	TYPE	IDT	IDC	IDTDU	IDCDU			
	"DAMPER"	TYPE	IDT	IDC	IDTDV	IDCDV			
	"GENER"	TYPE	IDT	IDC	IDTDU	IDCDU	IDTDV	IDCDV	

### Example:

PBUSH1D	35	3000.	200.	300.					
	SHOCKA	TABLE	2.2	1.2	1.		200		

The continuation entries are optional. The four options, SHOCKA, SPRING, DAMPER, and GENER can appear in any order.

Describer	Meaning	Default
PID	Property identification number. (Integer > 0).	Required
K	Stiffness. (Real $\geq 0$ ).	See Remark 1.
C	Viscous damping. (Real $\geq 0$ ).	See Remarks 1. and 2.
M	Total mass of the element. (Real $\geq 0$ ).	Blank
SA	Stress recovery coefficient [1/area]. (Real $\geq 0$ ).	Blank
SE	Strain recovery coefficient [1/length]. (Real $\geq 0$ ).	Blank

Describer	Meaning	Default
SHOCKA	<p>Character string specifying that the next 10 fields are coefficients of the following force versus velocity/displacement relationship. (Character).</p> $F(u, v) = C_v \cdot S(u) \cdot \text{sign}(v) \cdot  v ^{\text{EXPV}}$ <p>The force F, the displacement u, and the velocity v, are in the axial direction of the damper. The axis of the damper is defined by the two connecting grid points GA and GB on the CBUSH1D Bulk Data entry. The displacement u and the velocity v, are the relative displacement and the relative velocity with respect to the grid point GA. The scale factor S(u) must be defined with a table or with an equation.</p>	
TYPE	<p>Character string indicating the type of definition. (Character). For TYPE = EQUAT, the fields IDETS, IDECS, IDETSD, and IDECSD are identification numbers of DEQATN entries. For TYPE = TABLE the field IDTS is an identification number of a TABLEDi entry. If no character string is provided (blanks), TYPE = TABLE is set.</p>	TABLE
CVT	<p>Viscous damping coefficient <math>C_V</math> for tension <math>v &gt; 0</math>, force per unit velocity. (Real).</p>	Required for SHOCKA
CVC	<p>Viscous damping coefficient <math>C_V</math> for compression <math>v &lt; 0</math>, force per unit velocity. (Real).</p>	CVT
EXPVT	<p>Exponent of velocity EXPV for tension <math>v &gt; 0</math>. (Real).</p>	1.
EXPVC	<p>Exponent of velocity EXPV for compression <math>v &lt; 0</math>. (Real).</p>	EXPVT
IDTS	<p>Identification number of a TABLEDi entry for tension and compression if TYPE = TABLE. The TABLEDi entry defines the scale factor S, versus displacement u.</p>	Required for SHOCKA and TYPE=TABLE
IDETS	<p>Identification number of a DEQATN entry for tension if TYPE = EQUAT. The DEQATN entry defines the scale factor S, versus displacement u, for tension <math>u &gt; 0</math>.</p>	Required for SHOCKA and TYPE=EQUAT
IDECS	<p>Identification number of a DEQATN entry for compression if TYPE = EQUAT. The DEQATN entry defines the scale factor S, versus displacement u, for compression <math>u &lt; 0</math>.</p>	IDETS
IDETSD	<p>Identification number of a DEQATN entry for tension if TYPE = EQUAT. The DEQATN entry defines the derivative of the scale factor S, with respect to the displacement u, for tension <math>u &gt; 0</math>.</p>	Required for SHOCKA and TYPE=EQUAT

Describer	Meaning	Default
IDECS	Identification number of a DEQATN entry for compression if TYPE = EQUAT. The DEQATN entry defines the derivative of the scale factor S, with respect to the displacement u, for compression u < 0.	IDETS
SPRING	Character string specifying that the next 5 fields define a nonlinear elastic spring element in terms of a force versus displacement relationship. (Character).  $F(u) = F_T(u)$ <p>Tension is u &gt; 0 and compression is u &lt; 0.</p>	
DAMPER	Character string specifying that the next 5 fields define a nonlinear viscous element in terms of a force versus velocity relationship. (Character).  $F(v) = F_T(v)$ <p>Tension is v &gt; 0 and compression is v &lt; 0.</p>	
GENER	Character string specifying that the next 7 fields define a general nonlinear elastic spring and viscous damper element in terms of a force versus displacement and velocity relationship. (Character). For this element, the relationship can only be defined with TYPE=EQUAT.  $F(u, v) = F_T(u, v)$ <p>Tension is u &gt; 0 and compression is u &lt; 0. For SPRING, DAMPER, and GENER, the remaining fields are</p>	
TYPE	Character string indicating the type of definition. (Character). For TYPE = EQUAT the following fields are identification numbers of DEQATN entries. For TYPE = TABLE the following field is an identification number of a TABLEDi entry. For "GENER", TYPE = blank or "EQUAT" is allowed..	Required for SPRING or DAMPER
IDT	Identification number of a DEQATN entry for tension if TYPE = EQUAT. Identification number of a TABLEDi entry for tension and compression if TYPE = TABLE.	Required for SPRING, DAMPER, and GENER
IDC	Identification number of a DEQATN entry for compression if TYPE = EQUAT. Is ignored for TYPE = TABLE.	IDT

Describer	Meaning	Default
IDTDU	Identification number of a DEQATN entry for tension if TYPE = EQUAT. The DEQATN entry defines the derivative of the force F with respect to the displacement u, for tension $u > 0$ . For SPRING and GENER only.	Required if TYPE=EQUAT
IDCDU	Identification number of a DEQATN entry for compression if TYPE = EQUAT. The DEQATN entry defines the derivative of the force F with respect to the displacement u, for compression $u < 0$ . For SPRING and GENER only.	IDTDU
IDTDV	Identification number of a DEQATN entry for tension if TYPE = EQUAT. The DEQATN entry defines the derivative of the force F with respect to the velocity v, for tension $v > 0$ . For DAMPER and GENER only.	Required if TYPE=EQUAT
IDCDV	Identification number of a DEQATN entry for compression if TYPE = EQUAT. The DEQATN entry defines the derivative of the force F with respect to the velocity v, for compression $v < 0$ . For DAMPER and GENER only.	IDCDT

### Remarks:

1. For a linear spring K a default value of 0.0 is allowed by not specifying the K entry. For a linear damper C a default value of 0.0 is allowed by not specifying the C entry. If any nonlinearity is specified (SHOCKA, SPRING, DAMPER, GENER)  $K > 0$  is required. If K is not provided in the presence of any nonlinearity, the element will behave as a linear element.
2. The damping C and mass M are ignored in static solution sequences.
3. The parameters defined on the continuation entries are used in nonlinear solution sequences only.
4. The linear parameters K and C are used in all solution sequences unless parameters on continuation entries are defined and a nonlinear solution sequence is used. Then, the parameters K and C are used for initial values in the first iteration of the first load step and the parameters from continuation entries overwrite the linear parameters thereafter. When SHOCKA, SPRING or GENER are specified, K is overwritten. When SHOCKA, DAMPER or GENER is specified, C is overwritten.
5. PBUSH1D may only be referenced by CBUSH1D elements in the residual structure which do not attach to omitted degrees-of-freedom.
6. The continuation entries SHOCKA, SPRING, DAMPER and GENER may be specified in any order. If more than one continuation entry is defined, then the forces of SHOCKA, SPRING, etc. are added. Multiple continuation entries of the same kind are not allowed, for example, multiple SPRING continuation entries.
7. For TYPE = TABLE, values on the TABLEDi entry are for tension and compression. If table values  $f(u)$  are provided only for positive values  $u > 0$ , then it is assumed that  $f(-u) = -f(u)$ .

8. For TYPE = EQUAT, the equations for tension and compression can be different. If the identification numbers for compression are left blank, it is assumed that the equation for tension is also valid for compression.
9. PBUSH1D is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBUSH1D property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBUSH1D entries.
10. The force output is:

```

F O R C E S   I N   B U S H 1 D   E L E M E N T S   ( C B U S H 1 D )

AXIAL      AXIAL      AXIAL      AXIAL      AXIAL      PLASTIC
FORCE      DISPLACEMENT VELOCITY   STRESS     STRAIN     STRAIN     STATUS
  
```

Where items in red are always output for linear analysis. The Stress output is:

```

S T R E S S E S   ( F O R C E S )   I N   B U S H 1 D   E L E M E N T S   ( C B U S H 1 D )

AXIAL      AXIAL      AXIAL      AXIAL      AXIAL      PLASTIC
FORCE      DISPLACEMENT VELOCITY   STRESS     STRAIN     STRAIN     STATUS
  
```

Where items in red are always output for linear analysis.

$$(\text{Axial stress}) = SA \times (\text{Axial Force}), (\text{Axial strain}) = SE \times (\text{Axial Displacement}).$$

In nonlinear dynamics, the element force is the sum of all springs and dampers.

In linear dynamic solution sequences, the damping forces are not included in the element force output.

Failed status is not currently used.

11. While computing Single Point Forces of Constraint (SPCFORCES), the constraint relationships exist in stiffness for linear spring. However, the nonlinear elements treat the constraints as loads on set. As a result, the SPCFORCES results are different between linear and nonlinear elements.

## PBUSH2D 2-D Linear/Nonlinear Connection Properties

Defines linear and nonlinear properties of a two-dimensional element (CBUSH2D entry).

### Format:

1	2	3	4	5	6	7	8	9	10
PBUSH2D	PID	K11	K22	B11	B22	M11	M22

PBUSH2D	PID	K11	K22	B11	B22	M11	M22		
	CROSS	K12	K21	B12	B21	M12	M21		

Descriptor	Meaning
PID	Property identification number (Integer > 0; Required).
K11	Nominal stiffness in T1 rectangular direction (Real; Required).
K22	Nominal stiffness in T2 rectangular direction (Real; Required).
B11	Nominal damping in T1 rectangular direction (Real; Default = 0.0).
B22	Nominal damping in T2 rectangular direction (Real; Default = 0.0).
M11	Nominal acceleration-dependent force in T1 direction (Real; Default = 0.0).
M22	Nominal acceleration-dependent force in T2 direction (Real; Default = 0.0).
'SQUEEZE'	Indicates that squeeze-film damper will be specified (Character; Required).
BDIA	Inner journal diameter. (Real > 0.0; Required)
BLEN	Damper length. (Real > 0.0; Required).
BCLR	Damper radial clearance (Real > 0.0; Required).
SOLN	Solution option: LONG or SHORT bearing (Character; Default = LONG).
VISCO	Lubricant viscosity (Real > 0.0; Required).
PVAPCO	Lubricant vapor pressure (Real; Required).
NPORT	Number of lubrication ports: 1 or 2 (Integer; no Default).
PRES1	Boundary pressure for port 1 (Real ≥ 0.0; Required if NPORT= 1 or 2).

Describer	Meaning
THETA1	Angular position for port 1 ( $0.0 \leq \text{Real} < 360.0$ ; Required if NPORT= 1 or 2). See Remark 2.
PRES2	Boundary pressure for port 2 ( $\text{Real} \geq 0.0$ ; Required if NPORT= 2).
THETA2	Angular position for port 2 ( $0.0 \leq \text{Real} < 360.0$ ; Required if NPORT= 2). See Remark 2.
OFFSET1	Offset in the SFD direction 1, see Remark 3. (Real; Default = 0.0).
OFFSET2	Offset in the SFD direction 2, see Remark 3. (Real; Default = 0.0)
CROSS	Indicates that cross coupling terms will be provided.
K12, K21	Cross coupling stiffness terms.
B12, B21	Cross coupling damping terms.
M12, M21	Cross coupling mass terms.

**Remarks:**

1. Either SQUEEZE or CROSS option can be used. Both options cannot be specified. SQUEEZE option will be supported only in SOL400. When SQUEEZE option is used, the squeeze film damper model force calculation is invoked using all the entries specified.
2. The angular measurement is counterclockwise from the displacement x-axis for the XY plane, the y-axis for the YZ plane, and the z-axis for the XZ plane.
3. Offsets are measured from GB relative to GA. For example, if direction 2 is in the vertical direction and a gravity load is placed on GA, OFFSET2 will be a positive value (GB ‘moves’ toward GA in the positive direction 2).
4. PBUSH2D is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PBUSH2D property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PBUSH2D entries.
5. PBUSH2D may be used in conjunction with THPAD obtained from ROMAC for rotordynamic applications. Also see ELEMUDS and THPAD bulk data entries.
6. The template used for specifying matrices using cross entries is:

$$[I]_{2 \times 2} = \begin{bmatrix} I_{11} & I_{12} \\ I_{21} & I_{22} \end{bmatrix}$$

where I=K,B or M

**PBUSHT**

Frequency Dependent or Nonlinear Force Deflection Spring and Damper Property

Defines the frequency dependent properties or the stress dependent properties for a generalized spring and damper structural element.

**Format:**

1	2	3	4	5	6	7	8	9	10
PBUSHT	PID	“K”	TKID1	TKID2	TKID3	TKID4	TKID5	TKID6	
		“B”	TBID1	TBID2	TBID3	TBID4	TBID5	TBID6	
		“GE”	TGEID1	TGEID2	TGEID3	TGEID4	TGEID5	TGEID6	
		“KN”	TKNID1	TKIND2	TKNID3	TKIND4	TKIND5	TKIND6	
			FDC	FUSE	DIR	OPTION	LOWER	UPPER	
			FSRS	LRGR					

**Example:**

PBUSHT	35	K	72						
		B	18						

Descriptor	Meaning
PID	Property identification number that matches the identification number on a PBUSH entry. (Integer > 0)
“K”	Flag indicating that the next 1 to 6 fields are stiffness frequency table identification numbers. (Character)
TKID <sub>i</sub>	Identification number of a TABLED <sub>i</sub> entry that defines the stiffness vs. frequency relationship in directions 1 through 6. (Integer ≥ 0; Default = 0)
“B”	Flag indicating that the next 1 to 6 fields are force per velocity frequency table identification numbers. (Character)
TBID <sub>i</sub>	Identification number of a TABLED <sub>i</sub> entry that defines the force per unit velocity damping vs. frequency relationship in directions 1 through 6. (Integer ≥ 0; Default = 0)
“GE”	Flag indicating that the next field is a structural damping frequency table identification number. (Character)
TGEID <sub>i</sub>	Identification number of a TABLED <sub>i</sub> entry that defines the non-dimensional structural damping vs. frequency relationship. (Integer ≥ 0; TGEID1 default = 0, for TGEID2-6 see defaults described in Remark 6.)
“KN”	Flag indicating that the next 1 to 6 fields are nonlinear force-deflection table identification numbers. (Character)
TKNID <sub>i</sub>	Identification number of a TABLED <sub>i</sub> entry that defines the force vs. deflection relationship in directions 1 through 6. (Integer ≥ 0; Default = 0)

Describer	Meaning
FDC	Force deflection curve rule. Specifies a dependence between displacement components. See Remark 16. for use with the FUSE option. (Character or blank default blank)
"NR" or blank	Implies there is no force deflection rule. T1-R6 directions are all independent of each other.
"TRXY"	A radial dependence exists between $u_x$ and $u_y$ element displacements. Either K1 or K2 may be specified on the PBUSH entry. If both are specified then K1 will be used. On the PBUSHT "KN" entry either TKNID1 or TKNID2 may be specified. If both are specified then TKNID1 is used. The expression $u_r = \sqrt{(u_x)^2 + (u_y)^2}$ is used for table lookup. Under the OPTION=ULTLD, the force used for the fuse calculation is computed using $u_r$ . Under the OPTION=RULTLD, the true forces $f_x$ and $f_y$ in the springs "x" and "y" are used for the fuse calculation. New K1 is returned from slope of load-deflection curve at slope at current $u_r$ .
"TRXZ"	A radial dependence exists between $u_x$ and $u_z$ element displacements. Either K1 or K3 may be specified on the PBUSH entry. If both are specified then K1 is used. On the PBUSHT "KN" entry either TKNID1 or TKNID3 may be specified. If both are specified then TKNID1 is used. The expression $u_r = \sqrt{(u_x)^2 + (u_z)^2}$ is used for table lookup. Under the OPTION=ULTLD, the force used for the fuse calculation is computed using $u_r$ . Under the OPTION=RULTLD, the true forces $f_x$ and $f_z$ in the springs "x" and "z" are used for the fuse calculation. New K1 is returned from slope of load-deflection curve at slope at current $u_r$ .
"TRYZ"	A radial dependence exists between $u_y$ and $u_z$ element displacements. Either K2 or K3 may be specified on the PBUSH entry. If both are specified then K2 is used. On the PBUSHT "KN" entry either TKNID2 or TKNID3 may be specified. If both are specified then TKNID2 is used. The expression $u_r = \sqrt{(u_y)^2 + (u_z)^2}$ is used for table lookup. Under the OPTION=ULTLD, the force used for the fuse calculation is computed using $u_r$ . Under the OPTION=RULTLD, the true forces $f_y$ and $f_z$ in the springs "y" and "z" are used for the fuse calculation. New K2 is returned from slope of load-deflection curve at slope at current $u_r$ .

Describer	Meaning
	<p>“TS”</p> <p>A spherical dependence exists between <math>u_x</math>, <math>u_y</math>, and <math>u_z</math> element displacements. Either K1, K2 or K3 may be specified on the PBUSH entry. If all three are specified K1 is used. If only K2 and K3 are specified then K2 is used. On the PBUSHT “KN” entry TKNID1, or TKNID2 or TKNID3 may be specified. If all three are specified then TKNID1 is used. If only TKNID2 and TKNID3 are specified then TKNID2 is used. The expression</p> $u_s = \sqrt{(u_x)^2 + (u_y)^2 + (u_z)^2}$ <p>is used for table lookup. Under the OPTION=ULTLD, the force used for the fuse calculation is computed using <math>u_p</math>. Under the OPTION=RULTLD, the true forces <math>f_x</math>, <math>f_y</math> and <math>f_z</math> in the springs "x", "y", and "z" are used for the fuse calculation. New K1 is returned from slope of load-deflection curve at slope at current <math>u_s</math></p>
FUSE	<p>0 The element remains active irrespective of failure level. (Integer 0, 1, or 2, Default = 0)</p> <p>1 The element is deactivated if maximum failure as specified in OPTION is reached. Elements remains for postprocessing.</p> <p>2 The element is deactivated if maximum failure as specified in OPTION is reached. Element is removed from postprocessing.</p>
DIR	<p>The fuse direction component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks; Default = 0)</p> <p>0 Any direction is allowed to fuse. Same if user entered 123456.</p> <p>1 through 6 may be placed in the field with no embedded blanks. See Remark 13. for use with FDC.</p>
OPTION	<p>Specifies a failure mode. (Character - Default="RELDIS")</p> <p>“ULTLD” The specified failure load in compression or tension will be used to define failure using load computed from the appropriate radial dependence of displacement relationship.</p> <p>“RELDIS” The specified max relative <math>\pm</math> displacement will be used to define failure.</p> <p>“RULTLD” The specified failure load in compression or tension will be used to define failure using the actual current physical load in each spring.</p>
LOWER	<p>Lower failure bound. (Real; Default=0.0)</p> <p>If OPTION = “ULTLD” then LOWER specifies a lower failure load</p> <p>If OPTION = “RELDIS” then LOWER specifies a minimum relative displacement before failure.</p>
UPPER	<p>Upper failure bound. (Real; Default=0.0)</p>

Describer	Meaning
	If OPTION = "ULTLD" then UPPER specifies an upper failure load. If OPTION = "RELDIS" then UPPER specifies a maximum relative displacement before failure.
FSRS	Fuse Stiffness Retention Factor is a factor which scales the stiffness so that the stiffness does not instantly drop to a zero value. (Real $\geq$ 0.0; Default = 1.-5)
LRGR	Specifies if large rotation is to occur at end A. (Integer $\geq$ 0; Default = 0). See Remark 14.

**Remarks:**

1. The "K", "B", and "GE" fields are associated with same entries on the PBUSH entry.
2. PBUSHT may only be referenced by CBUSH elements in the residual structure which do not attach to any omitted degrees-of-freedom of ASET and/or dependent DOFs of MPC/Rigid elements. Otherwise, the solution is an approximation based on nominal properties.
3. For nonlinear analysis the nominal values are used at the beginning of the analysis to compute initial loading of the CBUSH element and meaningful values should be supplied for stiffness. As the nonlinear analysis proceeds, the user supplied load deflection curves are used to compute new stiffness values. For frequency dependent modal frequency response the system modes are computed using the nominal Ki values. The frequency-dependent values are used at every excitation frequency.
4. The "K", "B", "GE" or "KN" fields may be specified in any order.
5. The PBUSHT is used in SOL 108 and SOL 111 when any "K", "B", or "GE" is specified. It is used in SOL 106, SOL 129 or SOL 400 when "KN" is specified. It is ignored in all other solution sequences.
6. For upward compatibility, if ONLY TGEID1 is specified on a PBUSHT entry and TGEID<sub>i</sub>, i = 2 – 6 are all blank on the PBUSHT entry, then the single structural damping table is applied to all defined GE<sub>i</sub> for the PBUSH entry. In this case, TGEID<sub>i</sub>, i = 2 – 6, blank is not equivalent to 0 but a special flag.

A PBUSHT entry that has any TGEID<sub>i</sub>, i = 2 – 6 numerically specified including a 0, all the fields TGEID<sub>i</sub> are then treated separately and any TGEID<sub>i</sub>, i=2 - 6 field with no entry specified is defaulted to a 0 value and the results are radically different from the no TGEID<sub>i</sub>, i=2 – 6 specified as described above.

Thus for the entry:

1	2	3	4	5	6	7	8	9	10
PBUSHT	3303000	K	33030001						
		GE	33030002						

The GE table ID 3303002 will be replicated to fields 5 through 9. While:

1	2	3	4	5	6	7	8	9	10

PBUSHT	3303000	K	33030001						
		GE	33030002	0					

The 0 in FIELD 5 of the above PBUSHT above negates table 3303002 being replicated, hence, fields 5 through 9 will not have any associated table lookup.

7. For nonlinear analysis, only the “KN” line and optionally its two continuation lines are used.
8. For frequency responses, only the “K”, “B” and/or “GE” fields are used.
9. The continuations entries to “KN” are optional.
10. When the FDC field specifies one of the optional radial or spherical rules, stiffness entries not involved in the rule may still have their own independent force-deflection curves.
11. If FUSE=0, the remaining entries are ignored. If FUSE > 0, the “OPTION”, “UPPER”, and “LOWER” fields must be specified.
12. UPPER > LOWER required.
13. The following relationships exists between FDC and DIR

FDC = “TRXY”	1 or 2 or 12 in the DIR field applies to the radial rule	a 3 in the DIR field will be ignored.
FDC = “TRXZ”	1 or 3 or 13 in the DIR field applies to the radial rule	a 2 in the DIR field will be ignored.
FDC = “TRYZ”	2 or 3 or 23 in the DIR field applies to the radial rule	a 1 in the DIR field will be ignored.
FDC = “TS”	Any unique combination of the integers 1 through 3 with no embedded blanks in the DIR field applies to the spherical rule	

14. LRGR = 0 (Default) the element coordinate system is rotated with the rotation of grid A for both the CID and the V vector. LRGR = 1 will suppress large rotation at end A. The initial CID and the V vector will remain unchanged. LRGR = 2 a mid-increment method is used to rotate the element system for the V vector. LRGR = 2 is deactivated if CID is not blank. When CID is blank, LRGR = 2 is recommended for SOL400 when large rotations are present as the mid-increment method “averages” the rotations at both ends of the CBUSH and allows rotation when end A might have a rotational constraint.
15. When the fuse criteria is reached in one of the stiffness components, the entire element is assumed to fail. The component stiffnesses are then computed to be  $K = K \cdot \text{FSRS}$  at initial failure.

16. The figures below depict, using FDC=TRYZ as a typical example, the OPTION="ULTLD" and OPTION="RULTLD". Under the OPTION="ULTLD" the resultant Fr load when FUSED will be

$$F_r = \sqrt{F_y^2 + F_z^2} \approx \text{LIMIT} .$$

Under the OPTION="RULTLD" the resultant Fr load when

FUSED will in general be  $F_r = \sqrt{F_y^2 + F_z^2} > \text{LIMIT}$  with one of the  $F_y$  or  $F_z \approx \text{LIMIT}$  . For FDC=TRYZ and DIR=123, the T1 direction is not included in the force direction curve rule, thus possible fusing in the T1 direction is always based on the actual T1 spring displacement and  $F_x$  if active will be  $F_x \approx \text{LIMIT}$  . For FDC=NR fusing is always calculated based on each individual spring displacement and the actual individual spring loading.

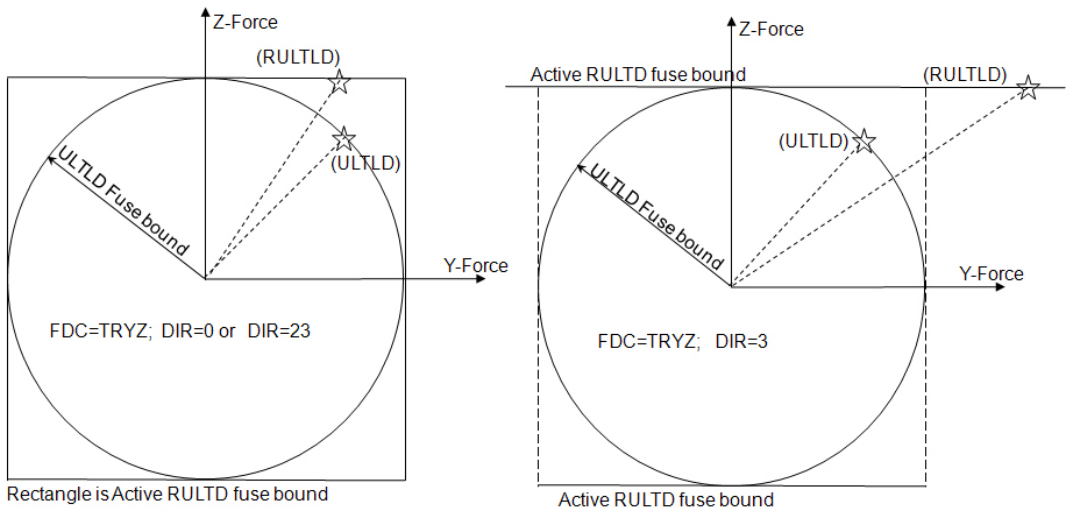

Figure 9-120 FUSE Models

## PCOHE

### Interface Cohesive Zone Modeling Element Properties

Defines the properties of a fully nonlinear element used to simulate the onset and progress of delamination in SOL 400.

#### Format:

1	2	3	4	5	6	7	8	9	10
PCOHE	PID	MID	INT	T	OUTPUT	SECANT			

#### Example:

PCOHE	700	701							
-------	-----	-----	--	--	--	--	--	--	--

Describer	Meaning
PID	Property identification. (Integer > 0)
MID	Identification number of a MCOHE entry. (Integer > 0)
INT	Integration scheme. 0 or blank Gauss integration, 1 for Newton-Coates/Lobatto integration. See Remark 3. (Integer 0 or 1; Default 0)
T	Thickness. See Remark 2. (Real > 0; Default = 1.0)
OUTPUT	Location selection for stress/strain output. If OUTPUT=GRID or blank, output is at the corner grid points. If OUTPUT=GAUSS output at the Gauss points. If INT=1, OUTPUT will be set to GRID. (Character or Blank; Default Grid)
SECANT	Tangent matrix scheme. 0 or blank a secant-type matrix is used to set up the element stiffness matrix, 1 a tangent-type matrix is used to set up the element stiffness matrix. (Integer 0 or 1; Default 0)

#### Remarks:

1. PCOHE can be referenced by CIFQUAD, CIFHEX, CIPENT, and CIFQDX entries.
2. The thickness T applies only to CIFQUAD elements.
3. For initially very stiff interface elements, the Newton-Coates/Lobatto integration scheme may be preferred.
4. PCOHE is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PCOHE property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PCOHE entries

## PCOMP Layered Composite Element Property

Defines the properties of an n-ply composite material laminate.

### Format:

1	2	3	4	5	6	7	8	9	10
PCOMP	PID	Z0	NSM	SB	FT	TREF	GE	LAM	
	MID1	T1	THETA1	SOUT1	MID2	T2	THETA2	SOUT2	
	MID3	T3	THETA3	SOUT3	-etc.-				

### Example of multiple plies per line format:

PCOMP	181	-0.224	7.45	10000.0	HOFF				
	171	0.056	0.	YES			45.		
			-45.				90.		

### Example of single ply per line format:

PCOMP	181	-0.224	7.45	10000.	HOFF				
	171	.056	0.	YES					
	171	.056	45.	YES					
	171	.056	-45.	YES					
	171	.056	90.	YES					

Descriptor	Meaning
PID	Property identification number. (0 < Integer < 10000000)
Z0	Distance from the reference plane to the bottom surface. See Remarks 10. and 11. (Real; Default = -0.5 times the element thickness.)
NSM	Nonstructural mass per unit area. (Real)
SB	Allowable shear stress of the bonding material (allowable interlaminar shear stress). Required if FT is also specified. (Real > 0.0)
FT	Failure theory. The following theories are allowed (Character or blank. If blank, then no failure calculation will be performed) See Remark 7. "HILL" for the Hill theory. "HOFF" for the Hoffman theory. "TSAI" for the Tsai-Wu theory. "STRN" for the Maximum Strain theory. "HFAIL" for the Hashin failure criterion "HTAPE" for the Hashin tape criterion "HFABR" for the Hashin fabric criterion
TREF	Reference temperature. See Remark 3. (Real; Default = 0.0)

Describer	Meaning
GE	Damping coefficient. See Remarks 4. and 12. (Real; Default = 0.0)
LAM	Laminate Options. (Character or blank, Default = blank). See Remarks 13. and 14.
	<p>“Blank” All plies must be specified and all stiffness terms are developed.</p> <p>“SYM” Only plies on one side of the element centerline are specified. The plies are numbered starting with 1 for the bottom layer. If an odd number of plies are desired, the center ply thickness (T1) should be half the actual thickness.</p> <p>“MEM” All plies must be specified, but only membrane terms (MID1 on the derived PSHELL entry) are computed.</p> <p>“BEND” All plies must be specified, but only bending terms (MID2 on the derived PSHELL entry) are computed.</p> <p>“SMEAR” All plies must be specified, stacking sequence is ignored MID1=MID2 on the derived PSHELL entry and MID3, MID4 and TS/T and 12I/T**3 terms are set as blanks).</p> <p>“SMCORE” All plies must be specified, with the last ply specifying core properties and the previous plies specifying face sheet properties. The stiffness matrix is computed by placing half the face sheet thicknesses above the core and the other half below with the result that the laminate is symmetric about the mid-plane of the core. Stacking sequence is ignored in calculating the face sheet stiffness.</p>
MIDi	Material ID of the various plies. The plies are identified by serially numbering them from 1 at the bottom layer. The MIDi must refer to MAT1, MAT2, MAT8, or MATDIGI Bulk Data entries. See Remarks 1. 15. and 18. For use with MAT4 and MAT5, see Remark 20. (Integer > 0 or blank, except MID1 must be specified.)
Ti	Thicknesses of the various plies. See Remarks 1. (Real or blank, except T1 must be specified.)
THETAi	Orientation angle of the longitudinal direction of each ply with the material axis of the element. (If the material angle on the element connection entry is 0.0, the material axis and side 1-2 of the element coincide.) The plies are to be numbered serially starting with 1 at the bottom layer. The bottom layer is defined as the surface with the largest -Z value in the element coordinate system. (Real; Default = 0.0)
SOUTi	Stress or strain output request. See Remarks 5. and 6. (Character: “YES” or “NO”; Default = “NO”)

**Remarks:**

1. The default for MID2, ..., MIDn is the last defined MIDi. In the example above, MID1 is the default for MID2, MID3, and MID4. The same logic applies to Ti.
2. At least one of the four values (MIDi, Ti, THETAi, SOUTi) must be present for a ply to exist. The minimum number of plies is one.
3. The TREF specified on the material entries referenced by plies are not used. Instead TREF on the PCOMP entry is used for all plies of the element. If not specified, it defaults to “0.0.”

If the PCOMP references temperature dependent material properties, then the TREF given on the PCOMP will be used as the temperature to determine material properties.

TEMPERATURE Case Control commands are ignored for deriving the equivalent PSHELL and MAT2 entries used to describe the composite element.

If for a nonlinear static analysis the parameter COMPMATT is set to YES, the temperature at the current load step will be used to determine temperature-dependent material properties for the plies and the equivalent PSHELL and MAT2 entries for the composite element. The TREF on the PCOMP entry will be used for the initial thermal strain on the composite element and the stresses on the individual plies. If the parameter EPSILON\_T is also set to INTEGRAL, TREF is not applicable.

4. GE given on the PCOMP entry will be used for the element and the values supplied on material entries for individual plies are ignored. The user is responsible for supplying the equivalent damping value on the PCOMP entry. If PARAM,W4 is not specified GE is ignored in transient analysis. When GE<sub>ij</sub> values are present on the MAT2 entry, Nastran will ignore the GE value given on the first continuation entry field (6) of the MAT2 and the GE entry given in field (8) of the PCOMP entry and use the given GE<sub>ij</sub> values.
5. Stress and strain output for individual plies are available in all superelement static, normal modes, buckling, frequency response (direct and modal), transient response (direct and modal) and nonlinear static analysis and requested by the STRESS and STRAIN Case Control commands. Composite lamina stress/strain are available in random analysis by XY PLOT command.
6. For Nastran conventional elements, if PARAM,NOCOMPS is set to -1, stress and strain output for individual plies will be suppressed and the homogeneous stress and strain output will be printed. See also Remark 10.
7. In order to get failure index output the following must be present:
  - a. STRESS or STRAIN Case Control commands,
  - b. SB, FT, and SOUT<sub>i</sub> on the PCOMP Bulk Data entry,
  - c. X<sub>t</sub>, X<sub>c</sub>, Y<sub>t</sub>, Y<sub>c</sub>, and S on all referenced MAT8 Bulk Data entries if stress allowables are used, or X<sub>t</sub>, X<sub>c</sub>, Y<sub>t</sub>, S, and STRN=1.0 if strain allowables are used.
  - d. -1 - failure in the fiber direction.  
-2 - failure in the matrix direction  
-12 - failure in the inplane shear
  - e. For Hashin Failure criterion, HFi (i=1,2,3,4,10,11) must be present in all referenced MAT8 bulk entry.
  - f. For Hashin Tape criterion, HTi (i=1,2,3,4,5,6,10,11,12) must be present in all referenced MAT8 bulk entry.
  - g. For Hashin Fabric criterion, HFBi (i=1,2,3,4,5,6,10,11,12) must be present in all referenced MAT8 bulk entry.

- h. Hashin failure theory output is captured with following code.
- 1 - failure in the tensile first fiber mode.
  - 1 - failure in the compressive first fiber mode.
  - 2 - failure in the tensile second fiber mode.
  - 2 - failure in the compressive second fiber mode.
  - 3 - failure in the tensile matrix mode.
  - 3 - failure in the compressive matrix mode.
8. A function of this entry is to derive equivalent internal PSHELL and MATi entries to describe the composite element. Any sorted echo request will also cause printout and/or punch of the derived PSHELL and MATi entries in User Information Message 4379 and/or the punch file. Use the NASTRAN system cell (361) PRTPCOMP=1 to print equivalent PSHELL/MAT2 Bulk Data entries to the .f06 file. Use the ECHO=PUNCH Case Control command to write them to the .pch file.
  9. The failure index for the bonding material is calculated as  $\text{Failure Index} = (\tau_{1z}, \tau_{2z})/SB$ .
  10. If the value specified for Z0 is not equal to -0.5 times the thickness of the element and PARAM,NOCOMPS,-1 is specified, then the homogeneous element stresses are incorrect, while element forces and strains are correct. For correct homogeneous stresses, use ZOFFS on the corresponding connection entry.
  11. Use of Z0 to offset a laminate does not change the reference plane. Z0 offsets the bottom of the plies from the reference plane. An unsymmetric layup or the use of Z0 to specify an unsymmetric layup, is not recommended in buckling analysis or the calculation of differential stiffness. Also, Z0 should not be used to specify an unsymmetric layup. The presence of coupling between bending and extension generally increases deflections. Hence, coupling decreases the effective stiffness of a laminate, reduces buckling loads and vibration frequencies significantly.
  12. To obtain the damping coefficient GE, multiply the critical damping ratio  $C/C_0$  by 2.0.
  13. The SYM option for the LAM option computes the complete stiffness properties while specifying half the plies. The MEM, BEND, SMEAR and SMCORE options provide special purpose stiffness calculations. SMEAR ignores stacking sequence and is intended for cases where this sequence is not yet known, stiffness properties are smeared. SMCORE allows simplified modeling of a sandwich panel with equal face sheets and a central core.
  14. Element output for the SMEAR and SMCORE options is produced using the PARAM NOCOMPS -1 methodology that suppresses ply stress/strain results and prints results for the equivalent homogeneous element.
  15. Temperature-dependent ply properties only available in SOL 106 and SOL 400. See PARAM,COMPMTT for details.
  16. For SOL 600, the default for SOUT is YES for the top and bottom layer and NO for all layers.

17. For SOL 600, LAM=BLANK if SMEAR is specified on the SOL 600 Executive Control statement. Other LAM options are not available using SOL 600. The default option for SOL 600 is to use complete through the thickness integration for all layers. This is achieved by not entering SMEAR on the SOL 600 entry. Options to speed up complete through the thickness integration by making certain assumptions such as no plasticity in the layers are available using the PCOMPF entry. Please note, the meaning of SMEAR for SOL 600 and for other MSC Nastran solution sequences is not the same.
18. PCOMP is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PCOMP property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PSHELL, PCOMP, PCOMPG entries.
19. For PCOMP, the non-default Zo option should not be used in conjunction with MEM, BEND, SMEAR or SMCORE as wrong results may occur. These four options provide special purpose stiffness calculations wherein stacking sequence effects are ignored (membrane-bending coupling terms are set to zero) at the preliminary design stage level. A better choice for offsets is to use the ZOFF option on the connectivity entries (CQUAD4, CTRIA3 etc). A User Fatal Message is issued if the user specifies a non-default value of Zo for any of the above smearing options. The fatal message may be changed to a User Warning Message by specifying a positive value for system cell 668 (e.g. nastran system(668)=1) to allow the program to continue.
20. In SOL400 only, this entry may refer to MAT4 or MAT5 entries. If it does, and the user has not supplied PSHLN1 entries, Nastran will internally generate a PSHLN1 entry. For details, the user should refer to Remark 7. of the PSHLN1 entry.
21. In layer composite output, the traditional element model outputs stress or strain separately by using STRESS or STRAN Case Control Command, respectively.  
  
The advanced element model does not recognize STRAIN Case Control Command. As long as user gives STRESS Case Control Command, both stress and strain are outputted together (similar to NLSTRESS).

**PCOMPA**

## Additional Data for Layered Composite Element Property - SOL 700

Defines additional properties of a multi-ply laminate composite material. Used in SOL 700 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
PCOMPA	PID	FORM	SHFACT	REF	STRDEF	DT1D	STRNOUT	CLT	
+	SPINCOR								

**Example:**

PCOMPA	1	BLT						1	
+	YES								

Describer	Meaning
PID	Unique property number referring to a PCOMP property number. (Integer > 0; Required)
FORM	Element formulation. (Character; See Remark 1.)
SHFACT	Shear correction factor, see Remark 4. (Real $\geq$ 0.0; default=0.83333)
REF	Reference surface. (Character; default=MID)
	TOP            Reference surface is the top of the surface.
	MID            Reference surface is the central surface.
	BOT            Reference surface is the bottom surface.
STRDEF	Definition in stress-strain output. (Character; default=FIBER)
	FIBER            Stresses defined in the fiber and matrix directions.
	ELEM            Stresses defined in the element coordinate system
DT1D	Time step skip for one-dimensional failure modes. See Remark 2. (Character; default=NO)
	YES            Skip one-dimensional failure modes.
	NO            Normal time-step calculation.
STRNOUT	Strain output option. See Remarks 3. and 4. (Character; default=YES)
	YES            Total strain is calculated.
	NO            No strain is stored in memory.
ICLT	Option to use Classical Lamination Theory. See Remark 4. (Integer > 0; default=0)
	1            Use the Classical Lamination Theory.
	0            Use the integration technique.
SPINCOR	Spin correction. See Remark 4. (Character; default=NO)

Describer	Meaning
NO	No SPINCOR applied
YES	SPINCOR applied

**Remarks:**

- For CQUAD4 elements, the default formulation is Key-Hoff. For CTRIA3 elements, the default formulation is C0-TRIA.
- If the failure mode is such that fiber and shear strength or matrix and shear strength are lost in all layers, the element is not included in the time-step calculation. If the element fails completely, the element is omitted from the time-step calculations, irrespective of the value entered in this field.
- If the STRNOUT field is NO, the strain cannot be output.
- If ICLT is set to 1, the analysis is performed with classical lamination theory. In this case, it is not possible to request the total strain output. The (transverse) shear correction factor input is ignored since it is calculated inside Nastran. There is no update of the cross-sectional properties due to failure. The failure flag only indicates that the failure condition is satisfied. Additional output for element variables is available, namely the stress resultants (NXX, NYY, NXY, MXX, MYY, MXY, QYZ, and QZX). Also the ABD-Q matrices of each element can be requested for output. These data are only stored in the first layer. The variable names are AijM, BijM, DijM, and QsijM for the components of the A-, B-, D- and Q-matrices, respectively. For example, to request the A11 of the A-matrix, the variable name is A11M01.
- The options for SPINCOR are:
 

NO	No SPINCOR correction is applied.
YES	A SPINCOR correction is applied.

When SPINCOR = NO, slight asymmetric forces are applied to the shell element's grid points. This approach is, in general, acceptable up to about 10° in plane shear angle.

The SPINCOR option is required for fabric models and is turned on by default to accurately keep track of the fiber directions.

**PCOMPF****Integration Procedure Used in Conjunction with PCOMP or PCOMPG**

Defines the integration procedure for through the thickness integration of composite shells in SOL 600 and SOL 400 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
PCOMPF	INT	PID1	THRU	PID2	BY	N			

**Alternate Formats (SOL 400):**

1	2	3	4	5	6	7	8	9	10
PCOMPF	INT	PID1	PID2	PID3	THRU	PID4	PID5	THRU	
	PID6	PID7	TO	PID8	PID9	PID10	PID11	PID12	
	THRU	PID13	BY	N					

1	2	3	4	5	6	7	8	9	10
PCOMPF	INT	ALL							

**Examples:**

PCOMPF	2	100	THRU	200	BY	10			
--------	---	-----	------	-----	----	----	--	--	--

**Example of Application to Single PID (SOL 400):**

PCOMPF	1		23	TO	25		33		
	44	THRU	54	BY	2				
	100								

Describer	Meaning
INT	1 Conventional through the thickness integration of each layer, allows all available material behavior through the thickness. (Default) 2 Linear elastic material, fast-integrated through the thickness - thermal strains and temperature dependent material properties are not allowed. 3 Linear elastic material, fast integrated through the thickness.
PIDi	Property identification number. (0 < Integer < 10000000) corresponds to a matching PCOMP or PCOMPG entry.
N	Property identification number increment. See Remark 7.. (Integer or blank)

### Remarks:

1. If nonlinear behavior is set on a MATS1 (or other option), but INT is  $> 1$ , then the nonlinear material behavior is ignored.
2. In SOL 600 only, if temperature dependent behavior is specified on a MATT1 or similar option and INT=2, the material values specified on the MATT1, MATT2, MATT8 option are ignored (the values on MAT1, MAT2 and MAT8 are used). In SOL 400, temperature loading or temperature dependent behavior should not be used with INT=2, a user fatal will be issued in this case. INT=3 can be used instead.
3. If more than one PCOMPF exists with different INT values, and there is an overlap in PID's, that is to say a given PID could have been assigned different values of INT, then a user fatal will be issued.
4. With the "THRU" and "THRU", "BY" forms, blank fields are allowed for readability. Any combination of a list of ID's and "THRU" and "THRU", "BY" is allowed. The "THRU" and "BY" lists may have missing ID's. That is the list of ID's in a THRU range need not be continuous.
5. In SOL 600 only, if all composite shells are to use the same INT value, it may be entered with PARAM,MFASTCMP instead of PCOMPF.
6. In SOL 600 only, if a "THRU" or "THRU", "BY" range is entered, all items associated with the range must be on the same line (or for large field a line and the continuation entry of that line).
7. For automatic generation of property identification numbers, the default increment value is 1 if property identification numbers are increasing or -1 if property identification numbers are decreasing (i.e., the user need not specify BY and the increment value).

## PCOMPFG      Frequency Dependent Composite structural damping Property

Defines the frequency dependent properties for a PCOMP/PCOMPG Bulk Data entry.

### Format:

1	2	3	4	5	6	7	8	9	10
PCOMPFG	PID						GE		

### Examples:

PCOMPFG	33						15		
---------	----	--	--	--	--	--	----	--	--

Describer	Meaning
PID	Property identification number that matches the identification number on PCOMP/PCOMPG entry. (Integer > 0)
GE	Identification number of a TABLEDi entry that defines the non-dimensional structural damping coefficient vs. frequency relationship. (Integer > 0; Default = 0)

### Remarks:

1. The Fields 8 of this entry corresponds to Field 8 of a PCOMP or PCOMG entry. The value in Field 8 of the PCOMP or PCOMPG entry is replaced by the table referenced in the corresponding field of this entry.
2. If the PCOMP/PCOMG MIDi fields point to MAT2 entries with the 2nd continuation fields containing GEij entries, then this entry is ignored for that MIDi entry and GE frequency dependency must be indicated by use of the MAT2F entry with same ID as the MIDi entry.
3. IF GE=0.0 on corresponding PCOMP or PCOMPG then GE table must be blank or 0.

## PCOMP

## Layered Composite Element Property (Alternate to PCOMP Entry)

Defines global (external) ply IDs and properties for a composite material laminate.

### Format:

1	2	3	4	5	6	7	8	9	10
PCOMP	PID	Z0	NSM	SB	FT	TREF	GE	LAM	
	GPLYID1	MID1	T1	THETA1	SOUT1	GEFLG			
	GPLYID2	MID2	T2	THETA2	SOUT2				

### Example of single ply per line format:

PCOMP	181	-0.224	7.45	10000.	HOFF				
	1001	171	.056	0.	YES				
	101	171	.07	45.	YES				
	2002	171	.056	-45.	YES				
	102	171	0.55	90.	YES				

Describer	Meaning
PID	Property identification number. (0 < Integer < 10000000)
Z0	Distance from the reference plane to the bottom surface. See Remark 11. (Real; Default = -0.5 times the element thickness.)
NSM	Nonstructural mass per unit area. (Real)
SB	Allowable shear stress of the bonding material (allowable interlaminar shear stress). Required if FT is also specified. (Real > 0.0)
FT	Failure theory. The following theories are allowed (Character or blank. If blank, then no failure calculation will be performed) See Remark 8. "HILL" for the Hill theory. "HOFF" for the Hoffman theory. "TSAI" for the Tsai-Wu theory. "STRN" for the Maximum Strain theory. "HFAIL" for the Hashin failure criterion "HTAPE" for the Hashin tape criterion "HFABR" for the Hashin fabric criterion
TREF	Reference temperature. See Remark 4. (Real; Default = 0.0)
GE	Damping coefficient. See Remark 5. (Real; Default = 0.0)
LAM	Laminate Options. (Character or blank, Default = blank). See Remarks 14. "Blank" All plies must be specified and all stiffness terms are developed.

Describer	Meaning
	<p>“MEM” All plies must be specified, but only membrane terms (MID1 on the derived PSHELL entry) are computed.</p> <p>“BEND” All plies must be specified, but only bending terms (MID2 on the derived PSHELL entry) are computed.</p> <p>“SMEAR” All plies must be specified, stacking sequence is ignored MID1=MID2 on the derived PSHELL entry and MID3, MID4 and TS/T and 12I/T**3 terms are set to zero).</p> <p>“SMCORE” All plies must be specified, with the last ply specifying core properties and the previous plies specifying face sheet properties. The stiffness matrix is computed by placing half the face sheet thicknesses above the core and the other half below with the result that the laminate is symmetric about the mid-plane of the core. Stacking sequence is ignored in calculating the face sheet stiffness.</p>
GPLYIDi	User-defined Global (External) Ply ID. See Remark 1. (Integer > 0)
MIDi	Material ID of the various plies. The plies are identified by serially numbering them from 1 at the bottom layer. The MIDs must refer to MAT1, MAT2, or MAT8 Bulk Data entries. See Remarks 2. and 15. For use with MAT4 and MAT5, see Remark 20. (Integer > 0 or blank, except MID1 must be specified.)
Ti	Thicknesses of the various plies. See Remark 2. (Real or blank, except T1 must be specified.)
THETAi	Orientation angle of the longitudinal direction of each ply with the material axis of the element. (If the material angle on the element connection entry is 0.0, the material axis and side 1-2 of the element coincide.) The plies are to be numbered serially starting with 1 at the bottom layer. The bottom layer is defined as the surface with the largest -Z value in the element coordinate system. (Real; Default = 0.0)
SOUTi	Stress or strain output request. See Remarks 6. and 7. (Character: “YES” or “NO”; Default = “NO”)
GEFLG	Ply structural damping flag may be only entered only once and if entered must be entered on the first ply. At least two layers are required else frequency dependency is ignored. For a one-layer PCOMPG use PCOMFQ entry for frequency dependency. (Integer -2, or -1; Default=0) See Remark 19.

### Remarks:

1. The global ply identification number must be unique with respect to other plies in the entry. The plies are defined in stacking sequence starting with the bottom layer.
2. The default for MID2, ..., MIDn is the last defined MIDi. In the example above, MID1 is the default for MID2, MID3, and MID4. The same logic applies to Ti.
3. The global ply ID (GPLYIDi) and at least one of the four values (MIDi, Ti, THETAi, SOUTi) must be present for a ply to exist. The minimum number of plies is one.

4. The TREF specified on the material entries referenced by plies are not used. Instead TREF on the PCOMPG entry is used for all plies of the element. If not specified, it defaults to “0.0.”

If the PCOMPG references temperature dependent material properties, then the TREF given on the PCOMPG will be used as the temperature to determine material properties.

TEMPERATURE Case Control commands are ignored for deriving the equivalent PSHELL and MAT2 entries used to describe the composite element.

If for a nonlinear static analysis the parameter COMPMATT is set to YES, the temperature at the current load step will be used to determine temperature-dependent material properties for the plies and the equivalent PSHELL and MAT2 entries for the composite element. The TREF on the PCOMPG entry will be used for the initial thermal strain on the composite element and the stresses on the individual plies. If the parameter EPSILONT is also set to INTEGRAL, TREF is not applicable.

5. GE given on the PCOMPG entry will be used for the element and the values supplied on material entries for individual plies are ignored. The user is responsible for supplying the equivalent damping value on the PCOMPG entry. If PARAM,W4 is not specified GE is ignored in transient analysis. When GEij values are present on the MAT2 entry, Nastran will ignore the GE value given on the first continuation entry field (6) of the MAT2 and the GE entry given in field (8) of the PCOMPG entry and use the given GEij values.
6. Stress and strain output for individual plies are available in all superelement static, frequency response (direct and modal), transient response (direct and modal) and normal modes analysis and requested by the STRESS and STRAIN Case Control commands. Composite lamina stress/strain are available in random analysis by XYLOT command.
7. For Nastran conventional elements, if PARAM,NOCOMPS is set to -1, stress and strain output for individual plies will be suppressed and the homogeneous stress and strain output will be printed. See also Remark 11.
8. In order to get failure index output the following must be present:
  - a. STRESS or STRAIN Case Control commands,
  - b. SB, FT, and SOUTi on the PCOMPG Bulk Data entry,
  - c. Xt, Xc, Yt, Yc, and S on all referenced MAT8 Bulk Data entries if stress allowables are used, or Xt, Xc, Yt, S, and STRN=1.0 if strain allowables are used.
  - d. -1 - failure in the fiber direction  
-2 - failure in the matrix direction  
-12 - failure in the inplane shear.
  - e. For Hashin Failure criterion, HFi (i=1,2,3,4,10,11) must be present in all referenced MAT8 bulk entry.
  - f. For Hashin Tape criterion, HTi (i=1,2,3,4,5,6,10,11,12) must be present in all referenced MAT8 bulk entry.
  - g. For Hashin Fabric criterion, HFBi (i=1,2,3,4,5,6,10,11,12) must be present in all referenced MAT8 bulk entry.

- h. Hashin failure theory output is captured with following code.
- 1 - failure in the tensile first fiber mode.
  - 1 - failure in the compressive first fiber mode.
  - 2 - failure in the tensile second fiber mode.
  - 2 - failure in the compressive second fiber mode.
  - 3 - failure in the tensile matrix mode.
  - 3 - failure in the compressive matrix mode.
9. A function of this entry is to derive equivalent internal PSHELL and MATi entries to describe the composite element. Any sorted echo request will also cause printout and/or punch of the derived PSHELL and MATi entries in User Information Message 4379 and/or the punch file. Use the NASTRAN system cell (361) PRTPCOMP=1 to print equivalent PSHELL/MAT2 Bulk Data entries to the .f06 file. Use the ECHO=PUNCH Case Control command to write them to the .pch file.
  10. The failure index for the bonding material is calculated as  $\text{Failure Index} = (\tau_{1z}, \tau_{2z})/SB$ .
  11. If the value specified for Z0 is not equal to -0.5 times the thickness of the element and PARAM,NOCOMPS,-1 is specified, then the homogeneous element stresses are incorrect, while lamina stresses and element forces and strains are correct. For correct homogeneous stresses, use ZOFFS on the corresponding connection entry. Use of Z0 to offset a laminate does not change the reference plane. Z0 offsets the bottom of the plies from the reference plane.
  12. An unsymmetric layup or the use of Z0 to specify an unsymmetric layup, is not recommended in buckling analysis or the calculation of differential stiffness. Also, Z0 should not be used to specify an unsymmetric layup. The presence of coupling between bending and extension generally increases deflections. Hence, coupling decreases the effective stiffness of a laminate, reduces buckling loads and vibration frequencies significantly.
  13. To obtain the damping coefficient GE, multiply the critical damping ratio  $C/C_0$  by 2.0.
  14. Element output for the SMEAR and SMCORE options is produced using the PARAM NOCOMPS -1 methodology that suppresses ply stress/strain results and prints results for the equivalent homogeneous element.
  15. Temperature-dependent ply properties only available in SOL 106 and SOL400. See PARAM,COMPMMAT for details.
  16. For SOL 600, the default for SOUT is YES for the top and bottom layer and NO for all layers.
  17. For SOL 600, LAM=BLANK if SMEAR is specified on the SOL 600 Executive Control statement. Other LAM options are not available using SOL 600. The default option for SOL 600 is to use complete through the thickness integration for all layers. This is achieved by not entering SMEAR on the SOL 600 entry. Options to speed up complete through the thickness integration by making certain assumptions such as no plasticity in the layers are available using the PCOMP entry. Please note, the meaning of SMEAR for SOL 600 and for other MSC Nastran solution sequences is not the same.

18. PCOMPG is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PCOMPG property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PSHELL, PCOMP, PCOMPG entries.
19. Defines structural damping matrix data for composites. This entry if used MUST appear on the first ply entry ONLY and all subsequent plies follows depending if -1 or -2 described below

GEFLG Value	Meaning
0	The GE value specified in Field 8 of the PCOMPG parent entry is used for computation of all structural damping.
-1	The GE <sub>i</sub> value associated with the MID1 of this ply and the MID <sub>i</sub> with MID( <i>i</i> > 1) for all subsequent plies will be used in computing the K4 structural damping properties for the composite. For any MID <sub>i</sub> for which there is no associated GE value on the MAT1, MAT2, or MAT8 entry, the GE value specified in Field 8 of the PCOMPG parent entry will be used. The resulting smeared value GE will be placed in field 8 of the PCOMPG and used for computing structural damping.
-2	The GE <sub>i</sub> value associated with the MID1 of this ply and the MID <sub>i</sub> with MID( <i>i</i> > 1) for all subsequent plies will be used in computing the K4 structural damping properties for the composite. For any MID <sub>i</sub> for which there is no associated GE value on the MAT1, MAT2, or MAT8 entry then that ply will not contribute to the computation of the K4 structural damping of the composite. The resulting smeared value GE will be placed in field 8 of the PCOMPG and used for computing structural damping.
When GEFLG is used, the smeared GE value will appear in the second continuation entry field (6) of the four internally generated equivalent MAT2 entries	
<b>If GEFLG appears with extended MAT2 entries the GEFLG is ignored for that PCOMPG: See Remark of MAT2 entry.</b>	

20. In SOL400 only, this entry may refer to MAT4 or MAT5 entries. If it does, and the user has not supplied PSHLN1 entries, Nastran will internally generate a PSHLN1 entry. For details, the user should refer to Remark 7. of the PSHLN1 entry.

## PCOMPLS

## Layered Solid Composite Element Property

Defines global (external) ply IDs and properties for a composite material laminate in SOL 600, SOL 400, all linear solution sequences between SOL 101 and SOL 112, and analysis only for SOL 200.

### Format:

1	2	3	4	5	6	7	8	9	10
PCOMPLS	PID	DIRECT	CORDM	SB	ANAL				
	"C8"	BEH8	INT8	BEH8H	INT8H				
	"C20"	BEH20	INT20	BEH20H	INT20H				
	ID1	MID1	T1	THETA1					
	ID2	MID2	T2	THETA2					

### Example:

PCOMPLS	782	1							
	1001	171	.3	12.3					
	100	175	.7	77.7					

Describer	Meaning
PID	Property identification number. (Integer > 0)
DIRECT	The layer direction for BEHi = SLCOMP. See Remark 5. for direction definition. A positive value implies that the composite layer inputs is a fractional percent of the total element thickness in the ply direction and is recommended. A negative value implies that the composite layer input is the actual thickness of that ply. (Integer ± 1, ±2, or ±3; Default +1)
CORDM	Identification number of the material coordinate system. See Remark 10. (Integer; Default = 0, which is basic)
SB	Allowable shear stress of the bonding material (allowable interlaminar shear stress). (Real ≥ 0.0)
ANAL	Analysis type. ANAL='IS' - Implicit structural elements are being referred to. ANAL='IH' - Implicit heat analysis elements are being referred to. ANAL='ISH' - Implicit structural and heat elements are being referred to. (Character Default ISH)
C8	Keyword indicating that two items following apply to elements with eight corner grids. (Character)
C20	Keyword indicating that two items following apply to elements with eight corner grids and twelve mid-side grids. (Character)
BEHi	Element structural behavior. See Remarks 4. and 7. (Character default: SLCOMP for BEH8 and BEH20)
INTi	Integration scheme. See Remark 9. (Character default: L for INT8, Q for INT20)

BEHiH	Element heat behavior. See Remarks 4. and 8. (Character Default: SLCOMP for BEH8H and BEH20H)
INTiH	Integration scheme. See Remark 9. (Character Default: L for INT8H, Q for INT20H)
IDi	Global Ply ID. Must be unique with respect to other plies in this entry. See Remark 2. (Integer > 0)
MIDi	Material ID for the ply. See Remark 3. (Integer > 0)
Ti	Either fractional percent of the total element thickness or actual thickness of that ply depending on $\pm$ value of DIRECT. See Remarks 5. and 6.. (Real > 0.0)
THETAi	Orientation angle of the ply in the plane of the plies. Measured relative to the projection z-axis defined by CORDM on the plane defined by DIRECT. See Remark 1. (Real; Default = 0.0)

**Remarks:**

1. The PCOMPLS can only be referenced by a CHEXA entry. To view the composite results of large models using solid composite elements in PATRAN or SimXpert, the following environment variable setting is required when starting the session: DRANAS\_NAST\_MEM=2048MB.
2. Global Ply ID is intended as a unique ply identifier for ply alignment across all PCOMP, PLCOMP, and PCOMPLS entries.
3. The MIDi entry may point to MAT1, MAT9, MATORT, MATHE, MATUSR or MATDIGI entries. The following table shows associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

Implicit Structural Materials					
MAT1	MAT9	MATORT	MATHE	MATUSR	MATDIGI
MATVE	<MATVE>	<MATVE>	MATVE		
MATVP	MATVP	MATVP			
MATEP	MATEP	MATEP			
MATF	MATF	MATF			
MATS1		MATSORT			
<MATVE> refers to the ALTERNATE format for type ORTHO.					

Heat Materials	
MAT4	MAT5

If heat analysis is being performed and the user wishes to override standard MSC Nastran heat elements, the ANAL entry must be set to IH or ISH.  
 If ISH is specified then the MAT1 and MAT4 or MAT1 and MAT5 must have the same ID.  
 MID for structure entries must follow the uniqueness rules of the MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, MATHP, MATHE, MATG and MATDIGI entries.  
 If MATDIGI is being used, the ANAL field must be set to IS.  
 MID for heat entries must follow the uniqueness rules of the MAT4 and MAT5 entries.

4. The keyword entries, between themselves, may occur in any order or not at all. If a keyword entry is missing, its defaults are assumed.
5. The following table describes layer orientation for BEHi=SLCOMP.

For INT8=L and INT20=Q, a total of 510 layers are allowed for any one element.

For INT8=ASTN, a total of 2040 layers are allowed for any one element.

Note the ply numbering starts from the bottom to the top parallel to the positive thickness direction.

Layer orientation			
DIRECT	Normal to Layer Plane	Layers run parallel from face (ply numbering starts here)	to face (ends here)
1	Element T direction	G1-G2-G3-G4	G5-G6-G7-G8
2	Element R direction	G1-G4-G8-G5	G2-G3-G7-G6
3	Element S direction	G1-G2-G6-G5	G4-G3-G7-G8

6. The ply thickness of the element is computed using isoparametric coordinates of the element in the DIRECT direction and the element nodes are mapped between -1 and +1. The ply thickness is entered in one of two ways:
  - a. Relative thickness where the numbers entered, are a fractional percent of the total thickness. This is the preferred method. For this method, the sum of all the fractional percents of thickness must sum to 1.0.
  - b. Absolute thickness where the layer thickness is entered directly. Using this option, the code sums the total user input thickness across all plies and then figures the fractional percent of each individual ply as in method 6a.

7. In the following table, BEHi refers to the structural behavior of 3D-solid elements. An underlined item delineates a default.

Structural Classification of Elements				
Element Structural Type	BEHi CODE	Integration Code	Element Type	# Nodes
Solid continuum composite	SLCOMP	<u>L</u>	HEX	8
		ASTN*	HEX	8
		Q	HEX	20
*Only DIRECT=1 or -1 is allowed				

8. In the following table, BEHiH refers to the heat behavior of 3D-solid elements. An underlined item delineates a default.

Heat Classification of Elements				
Element Heat Type	BEHiH CODE	Integration Code	Element Type	# Nodes
Solid continuum composite	SLCOMP	<u>L</u>	HEX	8
		Q	HEX	20

9. Integration codes in Remark 7. and 8. are:

INT CODE	Integration Type
L	Linear
ASTN	Assumed STRaiN enhanced formulation solid shell
Q	Quadratic

10. The material coordinate system CORDM may be the basic system (0 or blank) or the element coordinate system (-1) or any defined coordinate system (> 0) (Default = 0).

THETAi in conjunction with CORDM is used to define the ply orientation.

- a. For BEH = SLCOMP and INT = ASTN, the X axis of the CORDM system is projected onto the layer plane to form the local X axis. The normal direction of the element (thickness direction = local Z axis) is crossed with the local X axis to yield the local Y axis. THETAi is then measured positive counter-clockwise about the local Z axis. If the X axis of the CORDM is in the same direction as the thickness direction, then the analysis will stop with an error.
- b. For BEH = SLCOMP and INT = L or Q, the Material Coordinate System is a function of how NLMOPTS, INLAM, CPROJ is set.

If CPROJ is ON then the projection scheme (see Figure 9-121) is activated. With the activation of projection scheme the X axis of the CORDM system is projected onto the layer plane to form the local X axis. The normal direction of the element (thickness direction = local Z axis) is crossed with the local X axis to yield the local Y axis. THETA<sub>i</sub> is then measured positive counter-clockwise about the local Z axis. If the X axis of the CORDM is in the same direction as the thickness direction, then the analysis will stop with an error.

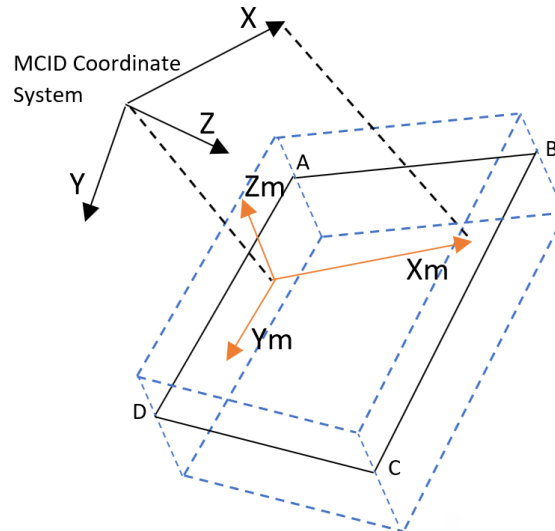

Figure 9-121 Projection Scheme

In Figure 9-121, plane ABCD is the layer plane of interest.  $Z_m$  is normal to the layer plane (or is the thickness direction).  $X_m$  is the projection of the X axis of the MCID coordinate system on the layer plane.  $Z_m \times X_m$  gives the  $Y_m$ . Angle theta is measured counter-clockwise from  $X_m$  axis about the  $Z_m$  axis.

If CPROJ is OFF (default), THETA<sub>i</sub> is then measured positive counter-clockwise about the local Z axis. The local Z is perpendicular to layer plane defined by the layup direction via DIRECT describer.

11. DIRECT, SB, ANAL, “C8” and “C20” are not supported in SOL 600 will be ignored if entered.
12. For SOL 600, PCOMPLS is made into PSOLID and PCOMP internally. Existing PSOLID and PCOMP entries with the same PID may be overwritten. The combination PSOLID and PCOMP is preferred over PCOMPLS for SOL 600, either option (but not both) may be used.
13. PCOMPLS is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PCOMPLS property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PSOLID, PCOMPLS, PLCOMP, PCOMPG entries.

## PCONEAX Conical Shell Element Property

Defines the properties of a conical shell element described on a CCONEAX entry.

### Format:

1	2	3	4	5	6	7	8	9	10
PCONEAX	ID	MID1	T1	MID2	I	MID3	T2	NSM	
	Z1	Z2	PHI1	PHI2	PHI3	PHI4	PHI5	PHI6	
	PHI7	PHI8	PHI9	PHI10	PHI11	PHI12	PHI13	PHI14	

### Example:

PCONEAX	2	4	1.0	6	16.3	8	2.1	0.5	
	0.001	-0.002	23.6	42.9					

### Describer

### Meaning

ID	Property identification number. (Unique Integer > 0)
MID <sub>i</sub>	Material identification number for membrane, bending, and transverse shear. (Integer ≥ 0)
T1	Membrane thickness. (Real > 0.0 if MID1 = 0)
T2	Transverse shear thickness. (Real > 0.0 if MID3 = 0)
I	Moment of inertia per unit width. (Real)
NSM	Nonstructural mass per unit area. (Real)
Z1, Z2	Fiber distances from the middle surface for stress recovery. (Real)
PHI <sub>i</sub>	Azimuthal coordinates (in degrees) for stress recovery. (Real)

### Remarks:

1. PCONEAX is allowed only if an AXIC entry is also present.
2. PCONEAX entries may reference MAT1 or MAT2 material entries. However, only orthotropic material properties are consistent with axisymmetry. Therefore, G13 and G23 values on the MAT2 entry referenced by MID1 or MID2 and the G12 value on the MAT2 entry referenced by MID3 should be set to 0.0. In addition, the MID3 entry, if it references a MAT2 material matrix, should be of size 2 x 2.
3. If either MID1 = 0 or blank or T1 = 0.0 or blank, then both must be zero or blank.
4. If either MID2 = 0 or blank or I = 0.0 or blank, then both must be zero or blank.
5. If either MID3 = 0 or blank or T2 = 0.0 or blank, then both must be zero or blank.
6. A maximum of 14 azimuthal coordinates (PHI<sub>i</sub>) for stress recovery may be specified.
7. For a discussion of the conical shell problem, see Section 5.3.3 of the *MSC Nastran Reference Guide*.

8. The following elastic relationships are assumed:

- In-plane forces per unit width

$$\{F\} = T1[G_1]\{\varepsilon\}$$

where  $\{\varepsilon\}$  is the vector of strains in the middle surface.

- Bending moments per unit width

$$\{M\} = I[G_2]\{\chi\}$$

where  $\{\chi\}$  is the vector of curvatures.

- Transverse shear forces per unit width

$$\{V\} = T2[G_3]\{\gamma\}$$

where  $\{\gamma\}$  is the vector of transverse shear strains.

$[G_1]$ ,  $[G_2]$  and  $[G_3]$  are the stress-strain matrices defined by MID1, MID2, and MID3, respectively.

## PCONV Convection Property Definition

Specifies the free convection boundary condition properties of a boundary condition surface element used for heat transfer analysis.

### Format:

1	2	3	4	5	6	7	8	9	10
PCONV	PCONID	MID	FORM	EXPF	FTYPE	TID			
	CHLEN	GIDIN	CE	E1	E2	E3			

### Examples:

PCONV	53	2	0	.25					
PCONV	4				1	101			
PCONV	38	21			2	54			
	2.0	235	0	1.0	0.0	0.0			

### Alternate Format and Examples:

1	2	3	4	5	6	7	8	9	10
PCONV	PCONID	MID	FORM	EXPF	"3"	H1	H2	H3	
	H4	H5	H6	H7	H8				
PCONV	20				3	10.0			
PCONV	7				3	10.32	10.05	10.09	
	10.37								

Descriptor	Meaning
PCONID	Convection property identification number. (Integer > 0)
MID	Material property identification number. See Remarks 2. (Integer > 0)
FORM	Type of formula used for free convection. (Integer 0, 1, 10, 11, 20, or 21; Default = 0)
EXPF	Free convection exponent as implemented within the context of the particular form that is chosen. See Remark 3. (Real ≥ 0.0; Default = 0.0)
FTYPE	Formula type for various configurations of free convection. See Remarks 2. and 5. (Integer ≥ 0; Default = 0)
TID	Identification number of a TABLEHT entry that specifies the two-variable tabular function of the free convection heat transfer coefficient or Nusselt number. See Remark 5. (Integer ≥ 0 or blank)
CHLEN	Characteristic length. See Remarks 6. and 8. (Real > 0.0 or blank)

Describer	Meaning
GIDIN	Grid ID of the referenced inlet point. See Remarks 7. and 8. (Integer > 0 or blank)
CE	Coordinate system for defining the direction of boundary-layer flow. See Remarks 7. and 8. (Integer ≥ 0; Default = 0)
Ei	Component of the vector for defining the direction of boundary-layer flow in coordinate system CE. See Remarks 7. and 8. (Real or blank)
Hi	Free convection heat transfer coefficient. See Remark 5. (Real for H1 and Real or blank for H2 through H8; Default for H2 through H8 is H1)

### Remarks:

- Every surface to which free convection is to be applied must reference a PCONV entry. PCONV is referenced on the CONV Bulk Data entry.
- MID is used to supply the convection heat transfer coefficient (H) for FTYPE=0, or the thermal conductivity (K) for FTYPE=2. MID is ignored for FTYPE=1 and FTYPE=3 and may be blank.
- EXPF is the free convection temperature exponent.

- If FORM = 0, 10, or 20, EXPF is an exponent of (T - TAMB), where the convective heat transfer is represented as

$$q = H \cdot u_{\text{CNTRLND}} \cdot (T - \text{TAMB})^{\text{EXPF}} \cdot (T - \text{TAMB}).$$

- If FORM = 1, 11, or 21,

$$q = H \cdot u_{\text{CNTRLND}} \cdot (T^{\text{EXPF}} - \text{TAMB}^{\text{EXPF}})$$

where T represents the elemental grid point temperatures and TAMB is the associated ambient temperature.

- FORM specifies the formula type and the reference temperature location used in calculating the convection film coefficient if FLMND = 0.
  - If FORM = 0 or 1, the reference temperature is the average of element grid point temperatures (average) and the ambient point temperatures (average).
  - If FORM = 10 or 11, the reference temperature is the surface temperature (average of element grid point temperatures).
  - If FORM = 20 or 21, the reference temperature is the ambient temperature (average of ambient point temperatures).
- FTYPE defines the formula type used in computing the convection heat transfer coefficient *h*.
  - If FTYPE = 0, *h* is specified in the MAT4 Bulk Data entry referenced by MID.
  - If FTYPE = 1, *h* is computed from  $h = f(T_w, T_a)$ , where *f* is a two-variable tabular function specified in the TABLEHT Bulk Data entry referenced by TID,  $T_w$  is the wall temperature, and  $T_a$  is the ambient temperature.
  - If FTYPE = 2, the program computes *h* from Nusselt number  $Nu = f(T_w, T_a)$ , where *f* is a two-variable tabular function specified in the TABLEHT Bulk Data entry referred by TID,  $T_w$  is the wall temperature, and  $T_a$  is the ambient temperature.

- a. For average heat transfer coefficient  $\bar{h}$ , specify the tabular data of the average Nusselt number  $\overline{Nu}_L = \bar{h} L / K$  and CHLEN for the characteristic length L (See Remarks 6. and 8.).
  - b. For local spatial dependent heat transfer coefficient  $h_x$ , define the tabular function of local Nusselt number  $Nu_x = h_x x / K$  along with GIDIN, CE, and Ei to calculate the distance x from the leading edge of heat transfer. (See Remarks 7. and 8.)
- If FTTYPE = 3, h is the free convection heat transfer coefficient applied to grid point Gi of the referenced HBDY surface element.
6. CHLEN specifies the characteristic length used to compute the average heat transfer coefficient  $\bar{h}$ . The following table lists typical values of CHLEN for various convection configurations.

Convection Configuration	Characteristic Length CHLEN
Free convection on a vertical plate or cylinder	Height of the plate or cylinder
Free convection from horizontal tubes	Diameter of the pipes
Free convection from horizontal square plates	Length of a side
Free convection from horizontal rectangular plates	Average length of four sides
Free convection from horizontal circular disks	0.9d, where d is the diameter of the disk.
Free convection from horizontal unsymmetric plates	A/P, where A is the surface area and P is the perimeter of the surface.

7. GIDIN, CE and Ei are used to define the distance from the leading edge of heat transfer. GIDIN specifies the referenced grid ID where heat transfer starts. CE and Ei define the direction of boundary-layer flow. If CE field is blank, the default is CE=0 for basic coordinate system. If E1, E2, and E3 fields are blank, the defaults are Ei = < 1.0, 0.0, 0.0 >, i.e. the flow is in the x direction. The distance x from the leading edge of heat transfer is computed as follows.

$$x = \overrightarrow{AB} \bullet \vec{e}$$

Where A is the location of GIDIN, B is the centroid of the convection element, and  $\vec{e}$  is the unit vector in the direction of boundary-layer flow.

8. CHLEN, GIDIN, CE, and Ei are required only for free convection from flat plates with FTYPE = 2. In this case, if the heat transfer coefficient is spatial dependent, GIDIN must be specified. Otherwise, CHLEN has to be defined for the computation of average heat transfer coefficient  $\bar{h}$ . For free convection from tubes (CHBDYP elements with TYPE="ELCY", "TUBE" or "FTUBE"), CHLEN, GIDIN, CE, and Ei need not be specified, because MSC Nastran will use the average diameter of tubes as the characteristic length while computing Nu. CHLEN, GIDIN, CE, and Ei are ignored for FTYPE ≠ 2 .
9. For RC network solver in thermal analysis, the FORM, EXPF, FTYPE, TID, CHLEN, GIDIN, CE, E1, E2 and E3 are ignored.

## PCONVM Forced Convection Property Definition

Specifies the forced convection boundary condition properties of a boundary condition surface element used for heat transfer analysis.

### Format:

1	2	3	4	5	6	7	8	9	10
PCONVM	PCONID	MID	FORM	FLAG	COEF	EXPR	EXPPI	EXPPO	

### Example:

PCONVM	3	2	1	1	.023	0.80	0.40	0.30	
--------	---	---	---	---	------	------	------	------	--

Describer	Meaning
PCONID	Convection property identification number. (Integer > 0)
MID	Material property identification number. (Integer > 0)
FORM	Type of formula used for convection. (Integer = 0, 1, 10, 11, 20, or 21; Default = 0)
FLAG	Flag for mass flow convection. (Integer = 0 or 1; Default = 0)
COEF	Constant coefficient used for forced convection. (Real > 0.0)
EXPR	Reynolds number convection exponent. (Real ≥ 0.0; Default = 0.0)
EXPPI	Prandtl number convection exponent for heat transfer into the working fluid. (Real ≥ 0.0; Default = 0.0)
EXPPO	Prandtl number convection exponent for heat transfer out of the working fluid. (Real ≥ 0.0; Default = 0.0)

### Remarks:

- Every surface to which forced convection is applied must reference a PCONVM entry. PCONVM is referenced on the CONVM entry.
- MID specifies material properties of the working fluid at the temperature of the point FLMND. FLMND is specified on the CONVM entry.
- The material properties are used in conjunction with the average diameter and mass flow rate (mdot). MID references the material properties and supplies the fluid conductivity (k), heat capacity (cp), and viscosity (μ) needed to compute the Reynolds (Re) and Prandtl (Pr) numbers as follows:

$$Re = 4 \cdot |\text{mdot}| / (\pi \cdot \text{diameter} \cdot \mu)$$

$$Pr = cp \cdot \mu / k$$

- FORM controls the type of formula used in determination of the forced convection film coefficient h. There are two cases:

- If FORM = 0, 10, or 20 than  $h = \text{coef} \cdot Re^{EXPR} \cdot Pr^{EXPPI}$ .

- If FORM = 1, 11, or 21 then the above h is multiplied by k and divided by the average hydraulic diameter.
  - FORM also specifies the reference temperature used in calculating material properties for the fluid if FLMND = 0.
  - If FORM = 0 or 1, the reference temperature is the average of element grid point temperatures (average) and the ambient point temperature (average).
  - If FORM = 10 or 11, the reference temperature is the surface temperature (average of element grid point temperatures).
  - If FORM = 20 or 21, the reference temperature is the ambient temperature (average of ambient point temperature).
5. In the above expression, EXPP is EXPPI or EXPPO, respectively, for heat flowing into or out of the working fluid. This determination is performed internally.
  6. FLAG controls the convective heat transfer into the downstream point (the second point as identified on the CHBDYi statement is downstream if mdot is positive).
    - FLAG = 0, no convective flow (stationary fluid).
    - FLAG = 1, convective energy flow that is consistent with the Streamwise Upwind Petrov Galerkin (SUPG) element formulation.
  7. No phase change or internal heat generation capabilities exist for this element.
  8. For RC network solver in thermal analysis, the FORM, FLAG, COEF, EXPR, EXPPI and EXRPO are ignored.

## PCONV1

## Thermal Convection Calculation Properties

Defines the properties required to calculate convective heat transfer. Can exist in a simple mode with convection coefficient defined in the MID or in advanced mode where the H value is calculated using the geometric parameters and referenced material.

### Format:

1	2	3	4	5	6	7	8	9	10
PCONV1	PID		CorrID	MID	Mdot	Velocity	Length or Diameter	Flow Cross Section	
			Length function type	Flow Cross Sec type	Mdot f	Velocity f	Length or Diameter f	Flow Cross Sec f	
	C1	C2	C3	C4	C5	C6	C7	C8	
	C9	C10	C11	C12	C13	C14	C15	C16	
	C17	C18	C19	C20	C21	C22	C23	C24	

### Example:

PCONV1	2		701	2			1.0		
--------	---	--	-----	---	--	--	-----	--	--

### Describer

### Meaning

PID	Property identification number, referenced by CHBDYP and/or CONV. (Integer > 0)
Corr ID	ID of convection type in correlation library (Integer ≥ 0; Default 0)
MID	Material identification number for convection calculation (Integer > 0)
Mdot	Mass flow rate (Real; Default 0.0)
Velocity	Fluid velocity (Real ≥ 0.0; Default 0.0)
Length or Diameter	Geometry, based on Corr ID (Real ≥ 0.0; Default 0.0)
Flow Cross Section	Flow Cross Section (Real ≥ 0.0; Default 0.0)
Length function type	Geometry function type, 1=time 2=temperature (Integer > 0; Default 2)
Flow Cross Sec type	Flow Cross Section function type, 1=time 2=temperature (Integer > 0; Default 2)
Mdot f	Mass flow rate TABLEDj table ID (Integer ≥ 0; Default 0)
Velocity f	Fluid velocity TABLEDj table ID (Integer ≥ 0; Default 0)
Length or Diameter f	Geometric function TABLEMj or TABLEDj table ID (Integer ≥ 0; Default 0)
Flow Cross Sec f	Flow Cross Section function TABLEMj or TABLEDj table ID (Integer ≥ 0; Default 0)
C1 thru C24	Geometric properties based on chosen convection correlation (Real; Default 0.0)

**Remarks:**

1. This entry is for RC Network solver only.
2. The PCONV1 entry contains the properties for a CONV and CHDBYP, and can be used for connecting with a PRJCON. PID must be unique to both the PCONVID in PCONV and the PID in PHBDY. This will be the ID referenced by CONV, PRJCON, and CHBDYP.
3. MATID must reference a MAT4 fluid material.
4. For Corr. ID and C1 thru C24, please reference *MSC SINDA User's Guide and Library Reference* or *P/Thermal User's Guide*.

## PDAMP Scalar Damper Property

Specifies the damping value of a scalar damper element using defined CDAMP1 or CDAMP3 entries.

### Format:

1	2	3	4	5	6	7	8	9	10
PDAMP	PID1	B1	PID2	B2	PID3	B3	PID4	B4	

### Example:

PDAMP	14	2.3	2	6.1					
-------	----	-----	---	-----	--	--	--	--	--

Describer	Meaning
PID <sub>i</sub>	Property identification number. (Integer > 0)
B <sub>i</sub>	Force per unit velocity. (Real)

### Remarks:

1. Damping values are defined directly on the CDAMP2 and CDAMP4 entries, and therefore do not require a PDAMP entry.
2. A structural viscous damper, CVISC, may also be used for geometric grid points.
3. Up to four damping properties may be defined on a single entry.
4. For a discussion of scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
5. PDAMP is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PDAMP property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PDAMP entries.

## PDAMP5 Scalar Damper Property for CDAMP5

Defines the damping multiplier and references the material properties for damping. CDAMP5 is intended for heat transfer analysis only.

### Format:

1	2	3	4	5	6	7	8	9	10
PDAMP5	PID	MID	B						

### Example:

PDAMP5	2	3	4.0						
--------	---	---	-----	--	--	--	--	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number of a MAT4 or MAT5 entry. (Integer > 0)
B	Damping multiplier. (Real > 0.0)

### Remarks:

1. B is the mass that multiplies the heat capacity CP on the MAT4 or MAT5 entry.
2. RC network solver does not support PDAMP5 for thermal analysis.

**PDAMPT**

## Frequency-Dependent Damper Property

Defines the frequency-dependent properties for a PDAMP Bulk Data entry.

**Format:**

1	2	3	4	5	6	7	8	9	10
PDAMPT	PID1	TBID1							

**Example:**

PDAMPT	12	34							
--------	----	----	--	--	--	--	--	--	--

**Describer****Meaning**

PID

Property identification number that matches the identification number on a PDAMP entry. (Integer > 0)

TBID1

Identification number of a TABLEDi entry that defines the damping force per-unit velocity versus frequency relationship. (Integer  $\geq$  0; Default = 0)

**Remarks:**

1. PDAMPT may only be referenced by CDAMP1 or CDAMP3 elements in the residual structure, which do not attach to any omitted degrees-of-freedom.
2. The PDAMPT entry is ignored in all solution sequences except frequency response analysis.

## PDISTB Element property distributions.

Defines element distributions of property data.

### Format:

1	2	3	4	5	6	7	8	9	10
PDISTB	ID	TYPE	PID	PNAME	LOCNUM	SMULT	DELTA		
	EID1	V1	EID2	V2	EID3	V3	EID4	V4	
	EID5	V5	EID6	V6	EID7	V7	EID8	V8	
	-etc.-	-etc.-	-etc.-	-etc.-	-etc.-	-etc.-			

### Example:

PDISTB	7008	PCOMP G	700	GE		.9			
	205	.013	224	.015	362	.135			
PDISTB	70014	PCOMP G	700	T	1				
	205	.013	224	.015	362	.135			
PDISTB	70034	PCOMP G	700	T	3				
	205	.013	224	.015	362	.135	400	.067	

### Descriptor      Meaning

ID	Unique identification number. (Integer > 0, no default)
TYPE	Name of a property entry, PBAR, PBEAM, PBEAM3, PCOMP, PCOMPG, PROD, PSHEAR, PSHELL, PSOLID and PTUBE (Character-Required).
PID	Property identification number that matches the identification number of an existing Property entry. (Integer > 0, no default)
PNAME	Property name, such as "T", "I12" (Character). See Remark 8.
LOCNUM	The Numerical order of Ply in PCOMP or PCOMPG. The Station number on a PBEAM or PBEAM3. (Integer ≥ 0).
SMULT	Scale factor of distribution entries. (Real, Default=1.0)
DELTA	Delta value of distribution entries. (Real, Default=0.0)
EID <sub>i</sub>	Element ID associated with Property PID. (Integer > 0, no default)
V <sub>i</sub>	The value of item to be changed. (Real for not PSOLID, Integer ≥ -2 for PSOLID)

### Remarks:

1. The ID of the PDISTB is for user convenience of grouping identification and is not used for case control selection.

2. The PID must point to an existing “Property” entry as shown in the Table of Remark 8. entry below. If this entry is used, Nastran will check that all elements have a unique element ID across all element types. If a non-unique element ID is found a fatal message will be issued.
3. If no distribution is given, the value associated with the named property entry will be used.
4. If an EID occurs on this entry for an element not associated with referred to property the EID is ignored.
5. If an EID is referred to twice on this entry or another PDISTB entry with the same PID and PNAME, Or in the case of a PCOMP or PCOMPG with same PID, PNAME, and LOCNUM referral a fatal message will be issued.
6.  $VALUE_i = SMULT * V_i + DELTA$
7. The PID referred to may not have an associated PCOMPFQ entries. A fatal message will be issued if there is such an association.
8. For most Primary property entries, the QRG symbol is used for valid PNAME. See values in table below. For more difficult entries such as a PCOMP the PNAME for example of the thickness of PLY 3 would be entered as PNAME=T and LOCNUM=3. Note on PCOMPG it is the numerical PLY listed not the GPLYID. Thus for example if the second ply listed on a PCOMPG entry had GPLYID=4 and the thickness is to be changed then PNAME=T and LOCNUM=2 not 4.

Property	PNAME	Corresponding QRG Description
<b>Current Supported Items are:</b>		
PSHELL	T	T - Membrane thickness
	I12	12I/T**3 Bending moment of inertia ratio
	TS	TS/T Transverse shear thickness ratio
	NSM	Nonstructural mass.
	Z1, Z2	Fiber distances for stress calculations
PCOMP (G)	Z0	Distance from the reference plane to the bottom surface
	NSM	Nonstructural mass.
	SB	Allowable shear stress of the bonding material
	TREF	Reference temperature
	GE	Damping coefficient
	T	Thicknesses of the various plies (Ply Identified by LOCNUM)
	THETA	Orientation angle of the various ply. (Ply Identified by LOCNUM)
PBEAM	LOCNUM=1 corresponds to END A; LOCNUM=12 corresponds to END B; LOCNUM=2-11 Intermediate stations left to right.	
	A	Area of bar cross section (Identified by LOCNUM)

Property	PNAME	Corresponding QRG Description
<b>Current Supported Items are:</b>		
	I1, I2, I12	Area moments of inertia (Identified by LOCNUM)
	J	Torsional constant (Identified by LOCNUM)
	NSM	Nonstructural mass. (Identified by LOCNUM)
	K1, K2	Shear stiffness factor K in $K^*A^*G$ for plane 1 and plane 2.
PROD	A	Area of bar cross section
	J	Torsional constant
	NSM	Nonstructural mass.
PBAR	A	Area of bar cross section
	I1, I2, I12	Area moments of inertia
	J	Torsional constant
	NSM	Nonstructural mass.
	K1, K2	Area factor for shear
PTUBE	OD	Outside diameter of tube
	T	Thickness of tube
	NSM	Nonstructural mass.
	OD2	Diameter of tube at second grid point
PSHEAR	T	Thickness of shear panel.
	NSM	Nonstructural mass.
	F1, F2	Effectiveness factor for extensional stiffness along edges 2-3 and 1-4.
PBEAM3	LOCNUM=1 corresponds to END A; LOCNUM=2 corresponds to END B; LOCNUM=3 "middle" station C	
	A	Area of the beam cross-section (Identified by LOCNUM)
	IZ, IY, IYZ	Area moments of inertia (Identified by LOCNUM)
	J	Torsional constant (Identified by LOCNUM)
	NSM	Nonstructural mass. (Identified by LOCNUM)
	KY, KZ	Shear effectiveness factors for local y- and z-directions.
	CW	Warping coefficient (Identified by LOCNUM).
PSOLID	CORDM	Identification number of the material coordinate system. Leave SMULT and DELTA fields blank.

## PDISTBM Element property material distributions.

Defines element distributions of property data.

### Format:

1	2	3	4	5	6	7	8	9	10
PDISTBM	ID	TYPE	PID	MIDNUM					
	EID1	MIDV1	EID2	MIDV2	EID3	MIDV3	EID4	MIDV4	
	EID5	MIDV5	EID6	MIDV6	EID7	MIDV7	EID8	MIDV8	
	-etc.-	-etc.-	-etc.-	-etc.-	-etc.-	-etc.-			

### Example:

PDISTBM	70013	PSHELL	700	2					
	205	16							

### Descriptor Meaning

ID	Unique identification number. (Integer > 0, no default)
TYPE	Name of a property entry, PBAR, PBEAM, PBEAM3, PCOMP, PCOMPG, PROD, PSHEAR, PSHELL, PSOLID, and PTUBE (Character-Required).
PID	Property identification number that matches the identification number of an existing Property entry. (Integer > 0, no default)
MIDNUM	MID <sub>i</sub> name (Integer ≥ 0, Default=1) See Remark 6.
EID <sub>i</sub>	Element ID associated with Property PID. (Integer > 0, no default)
MIDV <sub>i</sub>	The replacement value of the MID <sub>i</sub> . (Integer>0, no default)

### Remarks:

1. The PID must point to an existing “PSHELL”, “PCOMPG”, “PCOMP”, and “PSOLID”, entry. If this entry is used, Nastran will check that all elements have a unique element ID across all element types. If a non-unique element ID is found a fatal message will be issued.
2. If no distribution is given, the value associated with the named property entry will be used.
3. If an EID occurs on this entry for an element not associated with referred to property entry the EID is ignored.
4. If an EID is referred to twice on this entry or another PDISTBM entry with the same PID and MIDNUM referral a fatal message will be issued.
5. The MIDV<sub>i</sub> the user supplies must be a valid MAT<sub>i</sub> entry unique across all existing MAT<sub>i</sub> entries. The MAT<sub>i</sub> may have associated MAT<sub>i</sub>F entries, however, TABLED5 (Frequency as a function of temperature) entry is not currently supported with spatial entries.

6. The MIDNUM is property dependent. For example a PSHELL has MID1 through MID4, so a MIDNUM=3 means that the MID3 field of the PSHELL is being changed. For PCOMP or PCOMPG the MIDNUM refers to the MIDi of the Numerical order of ply.

## PDUMi Dummy Element Property

Defines the properties of a dummy element ( $3 \leq i \leq 7$ ). Referenced by the CDUMi entry.

### Format:

1	2	3	4	5	6	7	8	9	10
PDUMi	PID	MID	A1	A2	A3	A4	A5	A6	
	A7	-etc.-							

### Example:

PDUM3	108	2	2.4	9.6	1.E4	15.		3.5	
	5		2						

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number. (Integer > 0)
Aj	Additional fields. (Real or Integer)

### Remark:

1. The additional fields are defined in the user-written element subroutines.
2. The fields on this entry are required to be defined on the corresponding ADUMi entry. This entry requires a license for "USER MODIFIABLE Nastran" Other than the PID field, all field checking is the responsibility of the user supplied code.

## PELAS Scalar Elastic Property

Specifies the stiffness, damping coefficient, and stress coefficient of a scalar elastic (spring) element (CELAS1 or CELAS3 entry).

### Format:

1	2	3	4	5	6	7	8	9	10
PELAS	PID1	K1	GE1	S1	PID2	K2	GE2	S2	

### Example:

PELAS	7	4.29	0.06	7.92	27	2.17	0.0032		
-------	---	------	------	------	----	------	--------	--	--

Describer	Meaning
PIDi	Property identification number. (Integer > 0)
Ki	Elastic property value. (Real)
GEi	Damping coefficient, $g_e$ . See Remarks 5. and 6. (Real)
Si	Stress coefficient. (Real)

### Remarks:

1. Be careful using negative spring values.
2. Spring values are defined directly on the CELAS2 and CELAS4 entries, and therefore do not require a PELAS entry.
3. One or two elastic spring properties may be defined on a single entry.
4. For a discussion of scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPI\)](#) in the *MSC Nastran Reference Guide*.
5. If PARAM,W4 is not specified, GEi is ignored in transient analysis. See [Parameters](#).
6. To obtain the damping coefficient GE, multiply the critical damping ratio  $C/C_0$  by 2.0.
7. If PELAS is used in conjunction with PELAST,  $K_i > 0$ , and the initial slope of the nonlinear force-displacement relationship defined by the PELAST should agree with  $K_i$ .
8. PELAS is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PELAS property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PELAS entries.

## PELAS1

Defines a spring property designated by a force-deflection curve for SOL 700. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PELAS1	PID	TID							

### Example:

PELAS1	22	33							
--------	----	----	--	--	--	--	--	--	--

### Describer

### Meaning

PID

Property identification number. (Integer, no Default, > 0)

TID

Identification number of a TABLED1 entry which defines the force deflection curve. (Integer, no Default, > 0)

### Remarks:

1. Unlike PELAST, when PELAS1 is used, no PELAS entry is made.
2. All PELAS and PELAS1 ID's must be unique.
3. This entry may only be referenced by a CELAS1D entry.

## PELAST Frequency Dependent or Nonlinear Elastic Property

Defines the frequency dependent or nonlinear properties for a PELAS Bulk Data entry.

### Format:

1	2	3	4	5	6	7	8	9	10
PELAST	PID	TKID	TGEID	TKNID					

### Example:

PELAST	44	38							
--------	----	----	--	--	--	--	--	--	--

Describer	Meaning
PID	Property identification number that matches the identification number on a PELAS entry. (Integer > 0)
TKID	Identification number of a TABLEDi entry that defines the force per unit displacement vs. frequency relationship. (Integer > 0; Default = 0)
TGEID	Identification number of a TABLEDi entry that defines the nondimensional structural damping coefficient vs. frequency relationship. (Integer > 0; Default = 0)
TKNID	Identification number of a TABLEDi entry that defines the nonlinear force vs. displacement relationship. (Integer > 0; Default = 0)

### Remarks:

1. The PELAST entry may only be referenced by CELAS1 or CELAS3 elements in the residual structure which do not attach to any omitted degrees-of-freedom.
2. For frequency dependent modal frequency response the modes are computed using the nominal Ki values as specified on the PELAS entry.
3. The nominal values are used for all analysis types except frequency response and nonlinear analyses. For frequency dependent modal frequency response the system modes are computed using the nominal Ki values. The frequency-dependent values are used at every excitation frequency. For nonlinear analysis the nominal values for Ki should agree with the initial slope of the nonlinear force-displacement relationship defined by the PELAST, or the results will be unpredictable.
4. The following table summarizes the usage PELAST entry in various solution sequences

Field	Frequency Response	NONLINEAR (See Remark 6)	Linear (Non-Frequency Response)
TKID	Used	Ignored	Ignored
TGEID	Used	Ignored	Ignored
TKNID	Ignored	Used	Ignored

5. PELAST is used in SOL 108 and SOL 111 when TKID or TGEID is specified. It is used in SOL 106, SOL 129 and SOL 400 when TKIND is specified. It is ignored in all other solution sequences.
6. This entry is not available in SOL 600 and if entered will cause the job to terminate. If PARAM,MRPELAST,1 is entered this entry will be ignored in SOL 600.
7. The CELAS1/3 elements linear force computation  $F=K(U1-U2)$ , conflicts with the below figure, in that an obvious tension loading produces a compressive force.

The PELAST, TKNID option, for this loading, internally uses the  $F=K(U2-U1)$  when computing the element tangent matrix. This allows for tension only loading, the use of a single sided load-deflection curve to compute the element stiffness.

For element material nonlinear force and stress output, the default PELAST, TKNID option, the sign convention used is  $F=K(U2-U1)$ .

For a user desiring that the material nonlinear force and strain output, be consistent with the linear CELAS1/3 elements, the Nastran system cell NASTRAN DELTAU=1 is provided.

The tangent stiffness is still computed using  $F=K(U2-U1)$ , but for nonlinear force and stress output the convention is  $F= - K(U2-U1)$ .

While the PELAST, TKNID default option is more consistent with the figure above, in general for  $U1>U2$ , a compressive force will result. When tension or compression may occur, then the load deflection curves must be two sided curves as shown in the above figure.

## PERMEAB

## Air Bag Permeability

Defines the permeability of a COUPLE and/or GBAG (sub)surface.

Permeability is the velocity of gasflow through a (sub)surface and is defined as a linear or tabular function of the pressure difference over the surface. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PERMEAB	PID	PERMC	PERMT	FLOW	PENV	RHOENV	SIEENV	CP	

### Example:

PERMEAB	201	0.5		OUT	1.E5	1.128	2.21E5	1001.	
---------	-----	-----	--	-----	------	-------	--------	-------	--

Describer	Meaning
PID	Unique identification number of a PERMEAB entry. (Integer > 0, Required)
PERMC	Permeability is a linear function of the pressure difference. $\text{permeability} = \text{PERM} - C * \text{abs}(\text{Pinside} - \text{PENV})$ For Pinside > PENV: outflow For Pinside < PENV: inflow See Remark 3. (Real ≥ 0)
PERMT	Permeability is a tabular function of the pressure difference: table contains: permeability versus  Pinside – PENV  For Pinside > PENV: outflow For Pinside < PENV: inflow See Remark 3. (Integer ≥ 0)
FLOW	Defines the allowed directions of the flow. (Character, Default = BOTH) BOTH      In- and outflow are allowed. IN          Only inflow allowed. OUT        Only outflow allowed.
PENV	Environmental pressure. (Real > 0, Required)
RHOENV	Environmental density. (Real > 0, Required)
SIEENV	Environmental specific internal energy. (Real > 0, Required)
CP	Environmental specific heat at constant pressure. See Remark 5. (Real > 0)

### Remarks:

1. The PERMEAB entry can be referenced from a LEAKAGE entry.
2. When used with Euler, the entry can only be used with the single material hydrodynamic Euler solver or Roe solver using an EOSGAM (ideal gas) equation of state.

3. Either PERM-C or PERM-T must be specified.
4. The values for the environment  $p_{env}$  (PENV),  $\rho_{env}$  (RHOENV),  $e_{env}$  (SIEENV) must be defined consistent with an ideal-gas equation of state:

$$p_{env} = (\gamma_{env} - 1)\rho_{env}e_{env}$$

The  $\gamma_{env}$  is calculated and is used when inflow occurs. Inflow occurs when  $p_{env} > p_{inside}$ .

5. CP is only required if updating of Euler or gasbag gas constants is done, for example if hybrid inflators are defined.

## PERMGBG

## Air Bag Permeability

Defines a permeable area of a COUPLE and/or GBAG surface, connected to another GBAG.

The velocity of the gas flow through the surface is defined as a linear or tabular function of the pressure difference. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PERMGBG	PID	PERMC	PERMT	FLOW	GBID				

### Example:

PERMGBG	12		10		2				
---------	----	--	----	--	---	--	--	--	--

Describer	Meaning						
PID	Unique identification number of a PERMEAB entry. It can be referenced from either a LEAKAGE to model the flow between GBAGs, or from a LEAKAGE to model the flow between an Eulerian air bag and a GBAG. (Integer > 0; Required)						
PERMC	Permeability is a linear function of the pressure difference. permeability = PERM – C*abs (Pinside – Pgbid) The gas flow is from the higher to the lower pressure. See Remark 3. (Real > 0)						
PERMT	Permeability is a tabular function of the pressure difference: table contains: permeability versus  Pinside – Pgbid  The gas flow is from the higher to the lower pressure. See Remark 3. (Integer > 0)						
FLOW	Defines the allowed directions of the flow. (Character; Default = BOTH)  <table border="0"> <tr> <td>BOTH</td> <td>In- and outflow are allowed.</td> </tr> <tr> <td>IN</td> <td>Only inflow allowed into the GBAG or the coupling surface that references this entry.</td> </tr> <tr> <td>OUT</td> <td>Only outflow allowed into the GBAG or the coupling surface that references this entry.</td> </tr> </table>	BOTH	In- and outflow are allowed.	IN	Only inflow allowed into the GBAG or the coupling surface that references this entry.	OUT	Only outflow allowed into the GBAG or the coupling surface that references this entry.
BOTH	In- and outflow are allowed.						
IN	Only inflow allowed into the GBAG or the coupling surface that references this entry.						
OUT	Only outflow allowed into the GBAG or the coupling surface that references this entry.						
GBID	Number of a GBAG entry. This GBAG is the one that is connected to the GBAG or coupling surface that references this entry. (Integer > 0; Required)						

### Remarks:

1. The PERMGBG entry can be referenced from a LEAKAGE entry.
2. When used with Euler, the entry can only be used with the single material hydrodynamic Euler solver, using an EOSGAM (ideal gas) equation of state.

3. Either PERMC or PERMT must be specified.

## PEULER

## Eulerian Element Properties

Defines the properties of Eulerian element. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PEULER	PID	MID	TYPE						

### Example:

PEULER	100	25							
--------	-----	----	--	--	--	--	--	--	--

### Describer

### Meaning

PID	Unique property number. (Integer > 0, Required)
MID	Number of a MATDEUL entry defining the constitutive model. (Integer ≥ 0, Required)
TYPE	The type of Eulerian material being used. (Character, Default = HYDRO)
HYDRO	Hydrodynamic material with no shear strength + void.
1STORDER	Single material, 1 <sup>st</sup> order accurate Riemann solution-based fluids- & gases Euler solver.
2NDORDER	Single material, 2 <sup>nd</sup> order accurate Riemann solution-based fluids- & gases Euler solver.
STRENGTH	Structural material with shear strength + void.
MMHYDRO	Multimaterial hydrodynamic material with no shear strength + void.
MMSTREN	Structural multimaterial with shear strength + void.

### Remarks:

1. Make the property number unique with respect to all other property numbers.
2. The elements that reference this property use the Eulerian formulation.
3. If TYPE is set to HYDRO, only one material number for all the Eulerian elements of TYPE is used and a hydrodynamic yield model is chosen.
4. If the TYPE is set to either 1st Order or 2nd Order, only one material for all Eulerian elements of TYPE is used and the Riemann solution-based solver is chosen.
5. If TYPE is set to STRENGTH, only one material number for all the Eulerian elements of TYPE is used and a nonhydrodynamic yield model is chosen.
6. If TYPE is set to MMHYDRO, different material numbers for all Eulerian elements of TYPE are used and a hydrodynamic behavior is chosen for each material.
7. If TYPE is set to MMSTREN, different material numbers for all Eulerian elements of TYPE are used and a yield model is chosen for each material.

8. In a multimaterial Euler calculation, the options MMSTREN and MMHYDRO cannot be mixed; they are mutually exclusive.
9. If the material number is blank or zero, the corresponding elements are void. Note that this is not allowed in the Riemann solution-based Euler solvers, as they will not handle void elements. If you define void elements and select either the 1st Order or 2nd Order scheme, an error message will be issued and the analysis will stop.
10. Initial conditions are defined on the TICEL Bulk Data entry.

## PEULER1

## Eulerian Element Properties

Eulerian element properties. The initial conditions of these elements are defined in geometric regions. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PEULER1	PID		TYPE	SID	SID2				

### Example:

PEULER1	100		HYDRO	300					
---------	-----	--	-------	-----	--	--	--	--	--

### Describer

### Meaning

PID	Unique property number. (Integer > 0; Required)
TYPE	They type of Eulerian material(s) being used. (Character; Default = HYDRO)
HYDRO	Hydrodynamic material + void.
1STORDER	Single material, 1 <sup>st</sup> order accurate Riemann solution-based fluids- & gases solver.
2NDORDE R	Single material, 2 <sup>nd</sup> order accurate Riemann solution-based fluids- & gases solver.
STRENGTH	Structural material with shear strength + void.
MMHYDRO	Multimaterial hydrodynamic material with no shear strength + void.
MMSTREN	Structural multimaterial with shear strength + void.
SID	Number of a TICEUL1 entry specifying the materials and geometric grouping criteria. (Integer > 0; Required)
SID2	Number of a EULFOR1 entry defining acceleration field. (Integer>=0 Default=0)

### Remarks:

1. Remarks 1 through 6 of the PEULER definition apply also here.
2. Initial conditions and/or material assignments are defined on the TICEUL1 Bulk Data entry.

## PFAST

## CFAST Fastener Property

Defines the CFAST fastener property values.

### Format:

1	2	3	4	5	6	7	8	9	10
PFAST	PID	D	MCID	MFLAG	KT1	KT2	KT3	KR1	
	KR2	KR3	MASS	GE	ALPHA	TREF	COINL		

### Example:

PFAST	7	1.1	70		100000.	46000.	12300.		
-------	---	-----	----	--	---------	--------	--------	--	--

### Describer

### Meaning

PID	Property identification number. (Integer > 0)
D	Diameter of the fastener. See Remark 2. (Real > 0)
MCID	Specifies the element stiffness coordinate system. See Remark 1. (Integer ≥ -1 or blank; Default = -1)
MFLAG	Defines if the coordinate system defined by MCID is absolute or relative. See Remark 1. (Integer 0 or 1; Default = 0) If MFLAG = 0, MCID defines a relative coordinate system. See Remark 1a. If MFLAG = 1, MCID defines an absolute coordinate system. See Remark 1c.
KT <sub>i</sub>	Stiffness values in directions 1 through 3. (Real)
KR <sub>i</sub>	Rotational stiffness values in directions 1 through 3. (Real; Default = 0.0)
MASS	Lumped mass of fastener. (Real; Default = 0.0)
GE	Structural damping. (Real; Default = 0.0)
ALPHA	Thermal expansion coefficient for the CFAST. (Real; Default=0.0)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0, See Remark 8.)
COINL	Length of a CFAST with coincident grids. (Real; Default=0.0, COINL ≥ 0.0)

### Remarks:

1.
  - a. If  $MCID \geq 0$  and  $MFLAG = 0$  (Default), then the  $KT_1$  stiffness will be applied along the  $x_{elem}$  axis direction of the fastener defined as

$$\vec{e}_1 = \frac{\vec{x}_B - \vec{x}_A}{\|\vec{x}_B - \vec{x}_A\|}$$

The T2 direction defined by MCID will be used to define the orientation vector  $\vec{v}$  of the fastener. Then the element  $z_{elem}$  axis will be defined as

$$\vec{e}_3 = \frac{\vec{e}_1 \times \vec{v}}{\|\vec{e}_1 \times \vec{v}\|}$$

The KT3 stiffness will lie along the  $z_{elem}$  axis. The element  $y_{elem}$  axis is defined as

$$\vec{e}_2 = \vec{e}_3 \times \vec{e}_1$$

The KT2 stiffness will lie along the  $y_{elem}$  axis

This option allows the user to define orthotropic material properties normal to the axis of the fastener that will “slide” with the curve of the patches.

- b. If MCID = -1, MFLAG is ignored, and the following element system is defined: the  $x_{elem}$  axis direction of the fastener defined as

$$\vec{e}_1 = \frac{\vec{x}_B - \vec{x}_A}{\|\vec{x}_B - \vec{x}_A\|}$$

Relative to the basic system, find the smallest component  $j$  of the element  $x_{elem}$  axis unit vector. If two such components are equal, take the first one. Form a unit vector in the basic system. For example, assuming the  $j = 3$  component of  $\vec{e}_1$  was the smallest.

$$b_j = b_3 = \begin{Bmatrix} 0 \\ 0 \\ 1 \end{Bmatrix}$$

Form the following orthogonal vector:

$$\hat{e}_2 = \vec{b}_j - \frac{\vec{e}_1 \cdot \vec{b}_j}{\vec{e}_1 \cdot \vec{e}_1} \vec{e}_1$$

$$\vec{e}_2 = \frac{\hat{e}_2}{\|\hat{e}_2\|}$$

Form  $\vec{e}_3$  as

$$\vec{e}_3 = \vec{e}_1 \times \vec{e}_2$$

- c. If MCID  $\geq 0$  and MFLAG = 1, then the MCID will be used to compute stiffness. KT1 will be applied along the MCID T1 axis, KT2 along the MCID T2 axis, and KT3 along the MCID T3 axis. The element forces will be computed in the coordinate system defined in Remark 1b.

- d. If the length of GA - GB is zero, then the element  $x_{elem}$  axis is defined to lie along the projected normal to patch A.
2. The diameter D is used along with the piercing points of GA and GB to determine the location of fictitious grid points to form a fictitious hexa volume that determines the elements and physical grids used for the fastener element. Four points are positioned at  $\pm a$  positions parallel to the element axis where  $a = f(D)$ . The stiffness contribution of the fastener depends on both the stiffness values specified and the diameter D. It is a function of D, because the  $\pm a$  positions are used along with the surface shape functions of the fictitious hexa to weight the contribution of the physical grids used to the grids GA and GB of the fastener element.
3. The CFAST element (see Figure 9-122), for stiffness and structural damping calculations, is designed to satisfy rigid body equilibrium requirements. When  $\vec{x}_B - \vec{x}_A$  has finite length, internal rigid links connect grids GA and GB. This may result in coupling between translational and rotational degrees-of-freedom even when no rotational stiffness (KR1-KR3) are specified.  
For mass calculations, half the specified mass value is placed directly onto the projected grid A and grid B translational degrees-of-freedom.

Figure 9-122 CFAST Element

4. The CFAST element lies midway between GA and GB.
5. Values for  $KTi$  and  $KRi$  are specified at the user's discretion. Assuming a short stubby beam where shear is dominate, possible values might be:

$$KT1 = \frac{EA}{L}$$

$$KT2 = \frac{G_2 A_s}{L}$$

$$KT3 = \frac{G_3 A_s}{L}$$

$$KR1 = \frac{GJ}{L}$$

$$KR2 = \frac{EI}{L} + \frac{G_2 A_s L}{3}$$

$$KR3 = \frac{EI}{L} + \frac{G_3 A_s L}{3}$$

where:

$$A = \pi D^2 / 4$$

$$I = \pi D^4 / 64$$

$$J = \pi D^4 / 32$$

$$L = |\vec{x}_B - \vec{x}_A|$$

$$A_s = A_s = A / \alpha_s$$

$$\alpha_s = 4/3$$

$E$ ,  $G_2$ ,  $G_3$ , and  $G$  are the material properties of the fastener.

The fastener stiffness is not, however, independent of the surrounding structure. The values of stiffness specified should not overwhelm the stiffness of the local structure or max ratio's will occur.

One possible way to estimate the local stiffness  $S$  is by the relationship.

$$S = \frac{t_p E_p E}{E_p + E}$$

where  $t_p$  is a shell thickness and  $E_p$  is the modulus of the shell.

6. The element force and strain are computed as follows:

$$\{f_e\} = [K_e] \{u_e\} \text{ for statics}$$

$$\{f_e\} = ([K_e] + i(g + g_e)[K_e])(\{u_e\}_{\text{real}} + i\{u_e\}_{\text{imag}}) \text{ for frequency}$$

$$\{f_e\} = [K_e] \{u_e\} + \left( \frac{g}{w3} + \frac{g_e}{w4} \right) [K_e] \{v_e\} \text{ for transient}$$

where  $[K_e]$  is the 6 x 6 element stiffness matrix,  $\{u_e\} = \{u_b\} - \{u_a\}$  relative displacement in the element coordinate system, and  $\{v_e\} = \{v_b\} - \{v_a\}$  relative velocity in the element coordinate system. The subscripts  $a$  and  $b$  stand for end A and end B of the fastener.  $g$  is defined by param,g;  $w3$  is defined by param,w3;  $w4$  is defined by param,w4; and  $g_e$  is the GE entry of the PFAST.  $\{u_e\}$  is the strain output. Stress output is the same as force output.

7. PFAST is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PFAST property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PFAST entries.
8. The thermal expansion for the CFAST will be calculated if the user supplies the thermal expansion coefficient ALPHA and TEMPERATURE(LOAD) is requested. See TEMPERATURE Case Control command for thermal loading rules. For a CFAST with coincident grids, if COINL is provided, the thermal expansion is always just along the element x-axis.

## PFASTT

### Frequency Dependent and material nonlinear CFAST Property

Defines the frequency dependent and material nonlinear properties for a PFAST Bulk Data entry.

**Format:**

1	2	3	4	5	6	7	8	9	10
PFASTT	PID	“K”	TKID1	TKID2	TKID3	TKID4	TKID5	TKID6	
		“GE”	TGEID						
		“KN”	TKNID1	TKNID2	TKNID3	TKNID4	TKNID5	TKNID6	
			FDC	FUSE	DIR	OPTION	LOWER	UPPER	
			FSR	LRGR					

**Examples:**

PFASTT	33	“GE”	158						
--------	----	------	-----	--	--	--	--	--	--

Describer	Meaning						
PID	Property identification number that matches the identification number on PFAST entry. (Integer > 0)						
“K”	Flag indicating that the next 1 to 6 fields are stiffness frequency table identification numbers. (Character)						
TKID <sub>i</sub>	Identification number of a TABLED <sub>i</sub> entry that defines the stiffness vs. frequency relationship in directions 1 through 6. (Integer ≥ 0; Default = 0)						
“GE”	Flag indicating that the next field is a structural damping frequency table identification number. (Character)						
TGEID	Identification number of a TABLED <sub>i</sub> entry that defines the nondimensional structural damping coefficient vs. frequency relationship. (Integer ≥ 0; Default = 0)						
“KN”	Flag indicating that the next 1 to 6 fields are nonlinear force-deflection table identification numbers. (Character)						
TKIND <sub>i</sub>	Identification number of a TABLED <sub>i</sub> entry that defines the force vs. deflection relationship in directions 1 through 6. (Integer ≥ 0; Default = 0)						
FDC	Force deflection curve rule. Specifies dependence between displacement components. See PBUSHT FDC entry of detail of rules.						
FUSE	<table style="width: 100%; border: none;"> <tr> <td style="width: 10%; text-align: center; vertical-align: top;">0</td> <td style="padding-left: 20px;">The element remains active irrespective of failure level. (Integer 0, 1, or 2, Default = 0)</td> </tr> <tr> <td style="text-align: center; vertical-align: top;">1</td> <td style="padding-left: 20px;">The element is deactivated if maximum failure as specified in OPTION is reached. Elements remains for post processing.</td> </tr> <tr> <td style="text-align: center; vertical-align: top;">2</td> <td style="padding-left: 20px;">The element is deactivated if maximum failure as specified in OPTION is reached. Element is removed from post processing.</td> </tr> </table>	0	The element remains active irrespective of failure level. (Integer 0, 1, or 2, Default = 0)	1	The element is deactivated if maximum failure as specified in OPTION is reached. Elements remains for post processing.	2	The element is deactivated if maximum failure as specified in OPTION is reached. Element is removed from post processing.
0	The element remains active irrespective of failure level. (Integer 0, 1, or 2, Default = 0)						
1	The element is deactivated if maximum failure as specified in OPTION is reached. Elements remains for post processing.						
2	The element is deactivated if maximum failure as specified in OPTION is reached. Element is removed from post processing.						

Describer	Meaning
DIR	The fuse direction. ( $0 < \text{Integer} < 6$ ; Default = 0). 0 or 123456 imply any direction may fuse. Values of 1 through 6 may be placed in the field with no embedded blanks. See Remark 13. of PBUSHT.
OPTION	Specifies a failure mode. (Character - Default="RELDIS") "ULTLD" The specified failure load in compression or tension will be used to define failure using load computed from the appropriate radial dependence of displacement relationship. "RELDIS" The specified max relative + displacement will be used to define failure. "RULTLD" The specified failure load in compression or tension will be used to define failure using the actual current physical load in each spring.
LOWER	Lower failure bound. (Real; Default=0.0) If OPTION = "ULTLD" then LOWER specifies a lower failure load If OPTION = "RELDIS" then LOWER specifies a minimum relative displacement before failure.
UPPER	Upper failure bound. (Real; Default=0.0) If OPTION = "ULTLD" then UPPER specifies an upper failure load. If OPTION = "RELDIS" then UPPER specifies a maximum relative displacement before failure.
FSR	Fuse Stiffness Retention Factor is a factor which scales the stiffness so that the stiffness does not instantly drop to a zero value. (Real > 0.0; Default = 1.-5)
LRGR	Specifies if large rotation is to occur at end A. (Integer > 0; Default = 0). Remark 14. of the PBUSHT.

**Remarks:**

1. For frequency dependent modal frequency response the modes are computed using the nominal  $K_i$  values as specified on the PFAST entry.
2. The nominal values are used for all analysis types except frequency response. For frequency dependent modal frequency response the system modes are computed using the nominal  $K_i$  values. The frequency-dependent values are used at every excitation frequency.
3. The PFASTT entry may only be referenced by CFAST elements in the residual structure of SOL400 which do not attach to any omitted degrees-of-freedom.
4. For nonlinear analysis the nominal values for  $K_i$  on the PFAST should agree with the initial slope of the nonlinear force-displacement relationship defined by the PFASTT, or the results will be unpredictable.

## PFTG Fatigue Properties.

Defines fatigue properties of elements.

### Format:

1	2	3	4	5	6	7	8	9	10
PFTG	ID		FINISH	KFINISH	KF	SCALE	OFFSET		
	SHAPE	KTREAT	DIAM	T1	T2	SPTFLG			

### Examples:

PFTG	3		POLISH			1.2			
------	---	--	--------	--	--	-----	--	--	--

Describer	Meaning
ID	Unique ID referenced by a FTGDEF bulk data entry. (Integer>0)
FINISH	Material Surface Finish. This is a result of manufacturing process. Value can be NONE, POLISH, GROUND, MACHINE, POOR, ROLLED, CAST, KROUGH, KSURFC (Character; Default=NONE). See Remark 1.
KFINISH	Roughness factor for FINISH = KROUGH (0.0 < Real < 1.0, no Default). Surface roughness in microns for FINISH = KSURFC (Real > 0.0; no Default; 0.0 ≤ Real ≤ 1.0 for materials not listed in Remark 2).
KF	Fatigue strength reduction factor. (Real ≥ 0.0, Default=1.0). See Remark 3.
SCALE	Factor used to scale the resulting FE stresses of entities associated to this property set (Real; Default=1.0).
OFFSET	Offset used to offset the resulting FE stresses of entities associated to this property set (Real; Default=0.0).
SHAPE	Shape factor (Real ≥ 1.0; No default). See Remark 4.
KTREAT	Treatment factor (Real ≥ 0.0; Default = 1.0).
DIAM	Spot weld nugget diameter. Used in the fatigue analysis of spot welds only. (Real > 0.0 or blank, No Default). See Remark 5. and 6.
T1/T2	Top (T1) and bottom (T2) thickness of shells connecting spot welds. Used in the fatigue analysis of spot welds only. (Real > 0.0 or blank, No Default). Both should be left blank if either one is left blank. See Remark 5.
SPTFLG	Flag to indicate that a lookup table is to be used to define the spot weld nugget diameter. 0 or 1, Default = 0, no lookup). Only used if CWELD elements are used to define spot welds. See Remark 6.

**Remarks:**

1. The KF field can be used in lieu of or in addition to the FINISH & KTREAT field to modify the fatigue limit by multiplying the original fatigue limit by this value. POOR = Poor Machined. ROLLED = As Rolled. CAST = As Cast. KROUGH and KSURFC require that a KFINISH be entered. A material CODE on the MATFTG entry must be supplied to use anything other than NONE or POLISH, otherwise an error is issued.
2. If KFINISH = KSURFC, the user should enter a value for surface roughness  $R_z$  in  $\mu\text{m}$ . This is the average surface roughness according to the German standard DIN 4768. The Surface Roughness Factor  $K_r$  will then be calculated based on the strength and type of material (for example stronger materials are in general more sensitive to surface finish, and cast materials less so). The method for calculating  $K_r$  is taken from the FKM guideline *Analytical Strength Assessment of Components in Mechanical Engineering*.

If  $R_z \leq 1\mu\text{m}$ ,  $K_r = 1$ .

Otherwise:

$$K_r = 1 - a_r \log(R_z) \log(2R_m/R_{m,N,\min})$$

$R_m$  is the UTS in MPa

$R_{m,N,\min}$  and  $a_r$  are constants.

Table 9-33 Constants for Derivation of Surface Roughness Factor  $K_r$  from Roughness  $R_z$

Material	Steel	GS*	GGG†	GT‡	GG**	Wrought Al Alloys	Cast Al alloys
CODE from MATFTG	13,15,16-99	9-12, 15	5-8	2-4	1	100-105	106
$a_r$	0.22	0.20	0.16	0.12	0.06	0.22	0.20
$R_{m,N,\min}$	400	400	400	350	100	133	133

\*GS = cast steel and heat treatable cast steel, for general purpose

†GG = cast iron with lamellar graphite (grey cast iron)

‡GGG = nodular cast iron

\*\*GT = malleable cast iron

3. Fatigue strength reduction factor can take into account notch effects, size effects, and loading type influence.  $K_f = C_{\text{notch}} \cdot C_{\text{size}} \cdot C_{\text{loading}}$  where the latter three are correction factors for each effect, respectively.
4. Setting the shape factor activates the Seeger Heuler plastic limit load correction. Leave this field blank if no plastic limit load correction is required.
5. If T1, T2, and DIAM are specifically supplied, they are used directly in the fatigue analysis of spot welds. If either T1 or T2 are blank, the thicknesses are automatically determined from the PSHELL entries that connect the spot welds.

When performing optimization using SOL 200, it is necessary to leave T1 and T2 blank if the connecting shell thicknesses are being used as design variable, otherwise the fatigue analysis of the spot welds will not use correct thicknesses from one design cycle to another.

6. If DIAM is left blank, the following rule is used:
  - The diameter is derived based on the minimum thickness of the two sheets either side of the weld by performing a lookup on a table. An example table is provided in the `spotweld.sys` file in the `msc20xx/util` directory of a standard MSC Nastran installation. This is true for element types CBAR/CBEAM and CHEXA used to define spot welds. If using CWELD elements the diameter is automatically extracted from the PWELD entry, if SPTFLG=0. If SPTFLG=1, then the lookup table is used for CWELDS. The `spotweld.sys` file is specified by including the `spotweld=<path>/spotweld.sys` on the Nastran command line or defining it in the Nastran RC file as is done with other keywords. See [Executing MSC Nastran](#) (Ch. 1). If not specified, the default table is used as given in the example file mentioned.

In the case of a table lookup to determine DIAM, the thicknesses of the top and bottom sheets must be within the range of the lookup table, which is up to 3mm by default. Otherwise a fatal error is issued. Also the diameter is set as a function of the thickness of the thinnest sheet joined by the spot weld. No interpolation between the data points in the `spotweld.sys` file is done; rather, the thickness of the thinnest sheet from each spot weld is compared to the table, and the value of thickness that is nearest to but less than or equal to the thickness of the sheet is identified. The corresponding diameter from the table is assigned to that spot weld.

Example `spotweld.sys` file:

```
SPOT WELD DEFINITION FILE
NUGGET DIAMETER=BY_THICKNESS
0.3,3.5
0.8,4.0
1.2,5.0
2.0,5.5
3.0,6.0
```

Note that there may be rounding errors in the extraction of sheet thicknesses, so when defining a `spotweld.sys` file, it may be a good idea to reduce the sheet thickness values by a small tolerance in order to avoid anomalous results

## PGAP Gap Element Property

Defines the properties of the gap element (CGAP entry).

### Format:

1	2	3	4	5	6	7	8	9	10
PGAP	PID	U0	F0	KA	KB	KT	MU1	MU2	
	TMAX	MAR	TRMIN						

### Example:

PGAP	2	.025	2.5	1.E6		1.E6	0.25	0.25	
------	---	------	-----	------	--	------	------	------	--

Describer	Meaning
PID	Property identification number. (Integer > 0)
U0	Initial gap opening. See <a href="#">Figure 9-124</a> . (Real; Default = 0.0)
F0	Preload. See <a href="#">Figure 9-124</a> . (Real ≥ 0.0; Default = 0.0)
KA	Axial stiffness for the closed gap; i.e., $U_a - U_b > U0$ . See <a href="#">Figure 9-124</a> . (Real > 0.0)
KB	Axial stiffness for the open gap; i.e., $U_a - U_b < U0$ . See <a href="#">Figure 9-124</a> . See <a href="#">Remark 2</a> . (Real ≥ 0.0; Default = $10^{-14} \cdot KA$ )
KT	Transverse stiffness when the gap is closed. See <a href="#">Figure 9-125</a> . It is recommended that $KT \geq (0.1 \cdot KA)$ . (Real ≥ 0.0; Default = $MU1 \cdot KA$ )
MU1	Coefficient of static friction ( $\mu_s$ ) for the adaptive gap element or coefficient of friction in the y transverse direction ( $\mu_y$ ) for the nonadaptive gap element. See <a href="#">Remark 3</a> . and <a href="#">Figure 9-125</a> . (Real ≥ 0.0; Default = 0.0)
MU2	Coefficient of kinetic friction ( $\mu_k$ ) for the adaptive gap element or coefficient of friction in the z transverse direction ( $\mu_z$ ) for the nonadaptive gap element. See <a href="#">Remark 3</a> . and <a href="#">Figure 9-125</a> . (Real ≥ 0.0 for the adaptive gap element, $MU2 \leq MU1$ ; Default = $MU1$ )
TMAX	Maximum allowable penetration used in the adjustment of penalty values. The positive value activates the penalty value adjustment. See <a href="#">Remark 4</a> . (Real; Default = 0.0)
MAR	Maximum allowable adjustment ratio for adaptive penalty values KA and KT. See <a href="#">Remark 5</a> . ( $1.0 < Real < 10^6$ ; Default = 100.0)
TRMIN	Fraction of TMAX defining the lower bound for the allowable penetration. See <a href="#">Remark 6</a> . ( $0.0 \leq Real \leq 1.0$ ; Default = 0.001)

### Remarks:

- [Figure 9-123](#), [Figure 9-124](#), and [Figure 9-125](#) show the gap element and the force-displacement curves used in the stiffness and force computations for the element.

2. For most contact problems,  $K_A$  (penalty value) should be chosen to be three orders of magnitude higher than the stiffness of the neighboring grid points. A much larger  $K_A$  value may slow convergence or cause divergence, while a much smaller  $K_A$  value may result in inaccurate results. The value is adjusted as necessary if  $TMAX > 0.0$ .
3. When the gap is open, there is no transverse stiffness. When the gap is closed and there is friction, the gap has the elastic stiffness ( $K_T$ ) in the transverse direction until the friction force is exceeded and slippage starts to occur.
4. There are two kinds of gap elements: adaptive gap and nonadaptive gap. If  $TMAX \geq 0.0$ , the adaptive gap element is selected by the program. When  $TMAX = 0.0$ , penalty values will not be adjusted, but other adaptive features will be active (i.e., the gap-induced stiffness update, gap-induced bisection, and subincremental process). The value of  $TMAX = -1.0$  selects the nonadaptive (old) gap element. The recommended allowable penetration  $TMAX$  is about 10% of the element thickness for plates or the equivalent thickness for other elements that are connected to the gap.
5. The maximum adjustment ratio  $MAR$  is used only for the adaptive gap element. Upper and lower bounds of the adjusted penalty are defined by

$$\frac{K^{init}}{MAR} \leq K \leq K^{init} \cdot MAR$$

where  $K^{init}$  is either  $K_A$  or  $K_T$ .

6.  $TRMIN$  is used only for the penalty value adjustment in the adaptive gap element. The lower bound for the allowable penetration is computed by  $TRMIN \cdot TMAX$ . The penalty values are decreased if the penetration is below the lower bound.

Figure 9-123 The CGAP Element Coordinate System

Figure 9-124 CGAP Element Force-Deflection Curve for Nonlinear Analysis

Figure 9-125 Shear Force for CGAP Element

7. If  $U_0$  is specified negative and  $G_A$  and  $G_B$  are not coincident, then the direction for closing must be controlled by the use of the CID field on the CGAP entry.
8. PGAP is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PGAP property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PGAP entries.

## PHBDY

## CHBDYP Geometric Element Definition

A property entry referenced by CHBDYP entries to give auxiliary geometric information for boundary condition surface elements.

### Format:

1	2	3	4	5	6	7	8	9	10
PHBDY	PID	AF	D1	D2					

### Example:

PHBDY	2	.02	1.0	1.0					
-------	---	-----	-----	-----	--	--	--	--	--

### Describer

### Meaning

PID	Property identification number. (Unique Integer among all PHBDY entries). (Integer > 0)
AF	Area factor of the surface used only for CHBDYP element TYPE = "POINT", TYPE = "LINE", TYPE = "TUBE", or TYPE = "ELCYL". For TYPE = "TUBE", AF is the constant thickness of the hollow tube. (Real > 0.0 or blank)
D1, D2	Diameters associated with the surface. Used with CHBDYP element TYPE = "ELCYL", "TUBE", and "FTUBE". (Real > 0.0 or blank; Default for D2 = D1)

### Remarks:

- The PHBDY entry is used with CHBDYP entries.
- AF
  - For TYPE = "POINT" surfaces, AF is the area.
  - For TYPE = "LINE" or TYPE = "ELCYL" surfaces, AF is the effective width:  $\text{area} = \text{AF} \cdot (\text{length})$ .
  - For TYPE = "FTUBE" and outer TYPE = "TUBE" surfaces

$$\text{area} = \pi \cdot \left( \frac{D1 + D2}{2} \right) \cdot \sqrt{(\text{LGTH})^2 + \left( \frac{D1 - D2}{2} \right)^2}$$

- D1 and D2 are used only with TYPE = "ELCYL", TYPE = "TUBE", and TYPE = "FTUBE" surfaces.
  - For TYPE = "ELCYL" surfaces, D1 and D2 are the two diameters associated with the ellipse.
  - For TYPE = "FTUBE" and outer TYPE = "TUBE" surfaces, D1 and D2 are the diameters associated with the first and second grid points, respectively.
  - For inner TYPE = "TUBE" surfaces, the diameters are reduced by twice the thickness ( $2 \cdot \text{AF}$ ).

**PLCOMP**

## Plane Strain or Axisymmetric Composite Element Property

Defines global (external) ply IDs and properties for a composite material laminate.

**Format:**

1	2	3	4	5	6	7	8	9	10
PLCOMP	PID	DIRECT	THICKOP	SB	ANAL				
	"C4"	BEH4	INT4	BEH4H	INT4H				
	"C8"	BEH8	INT8	BEH8H	INT8H				
	ID1	MID1	T1	THETA1					
	ID2	MID2	T2	THETA2					

**Example:**

PLCOMP	782	1							
	1001	171	.3	12.3					
	100	175	.7	77.7					

Describer	Meaning
PID	Element property identification number. (Integer > 0)
DIRECT	The layer direction for BEHi=COMPS or AXCOMP. See Remark 5. for direction definition. A positive value implies that the composite layer input is a fractional percent of the total element thickness in the ply direction and is recommended. A negative value implies that the composite layer input is the actual thickness of that ply. (Integer $\pm 1$ or $\pm 2$ ; Default + 1)
THICKOP	An out-of-plane thickness. (Real, Default = 1.0)
ANAL	Analysis type. ANAL='IS' - Implicit structural elements are being referred to. ANAL='IH' - Implicit heat analysis elements are being referred to. ANAL= "ISH" - Implicit structural and heat elements are being referred to. (Character Default ISH).
SB	Allowable shear stress of the bonding material (allowable interlaminar shear stress). (Real $\geq 0.0$ )
C4	Keyword indicating that two items following apply to elements with four corner grids. (Character)
C8	Keyword indicating that two items following apply to elements with four corner grids and four mid-side grids. (Character)
BEHi	Element structural behavior. See Remarks 4. and 7. (Character default: COMPS for BEH4 and BEH8)
INTi	Integration scheme. See Remark 9. (Character Default: L for INT4H, Q for INT8H and INT8H)

Describer	Meaning
BEHiH	Element heat behavior. See Remark 8. (Character Default: COMPS for BEH4H and BEH8H)
INTiH	Integration scheme. See Remark 9. (Character Default: L for INT4H, Q for INT8H, Q for INT8H)
IDI	Global Ply ID. Must be unique with respect to other plies in this entry. See Remark 2. (Integer > 0)
MIDI	Material ID for the ply. See Remark 3. (Integer > 0)
Ti	Either fractional percent of the total element thickness or actual thickness of that ply depending on $\pm$ value of DIRECT. See Remarks 5. and 6. (Real > 0.0)
THETAi	Orientation angle of the ply in the plane of the plies. These angles are measured about the thickness direction of the element. (Real; Default = 0.0)

**Remarks:**

1. The PLSIMP can only be referenced by a CQUAD, CQUAD4, CQUAD8, or CQUADX entry. Currently it should be used ONLY in SOL400. Erroneous results will occur in other Solution sequences.
2. Global Ply ID is intended as a unique ply identifier for ply alignment across ALL PCOMP, PLSIMP, and PLSIMPLS entries.
3. The MIDI entry may point to MAT1, MAT3, MATHORT, MATHE, MATUSR or MATDIGI entries. The following table shows associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

The MID entry for nonlinear heat may point to MAT4 or MAT5 entries.

Implicit Structural Materials					
MAT1	MAT3	MATORT	MATHE	MATUSR	MATDIGI
MATVE	<MATVE>	<MATVE>	MATVE		
MATVP	MATVP	MATVP			
MATEP	MATEP	MATEP			
MATF	MATF	MATF			
MATS1		MATSORT			
<MATVE> refers to the ALTERNATE format for type ORTHO					

Heat Materials	
MAT4	MAT5

If heat analysis is being performed and the user wishes to override standard MSC Nastran heat elements, the ANAL entry must be set to IH or ISH.  
 If ISH is specified then the MAT1 and MAT4 or MAT1 and MAT5 must have the same ID. MID for structure entries must follow the uniqueness rules of the MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, MATHP, MATHE, and MATG entries.  
 MID for heat entries must follow the uniqueness rules of the MAT4 and MAT5 entries.

4. The keyword entries may occur, between themselves, in any order or not at all. If a keyword entry is missing, its defaults are assumed.
5. The following table describes layer orientation for BEHi=COMPS or AXCOMP. A total of 1026 plys are allowed for any one element.

Note the ply numbering starts from the bottom to the top parallel to the positive thickness direction.

Layer Orientation			
DIRECT	Normal to Layer edge	Layers run parallel from edge (ply numbering starts here)	to edge (ends here)
1	Element Y direction	G1-G2	G4-G3
2	Element X direction	G1-G4	G2-G3

6. The ply thickness of the element is computed using isoparametric coordinates of the element in the DIRECT direction and the element nodes are mapped between -1 and + 1. The ply thickness is entered in one of two ways:
  - a. Relative thickness where the numbers are a fractional percent of the total thickness. This is the preferred method. For this method, the sum of all the fractional percentages of thickness must sum to 1.0.
  - b. Absolute thickness where the layer thickness is entered directly. Using this option, the code sums the total user input thickness across all plys and then figures the fractional percent of each individual ply as in method 6a.
7. In the following table, BEHi refers to the structural behavior of 2D-solid elements. An underlined item delineates a default.

Implicit Structural Classification of Elements				
Element Structural Type	BEHi CODE	Integration Code	Element Type	# Nodes
Plane Strain composite	COMPS	<u>L</u>	QUAD	4
		<u>Q</u>	QUAD	8
Axisymmetric composite	AXCOMP	L	QUAD	4
		Q	QUAD	8

8. In the following table, BEHiH refers to the heat behavior of 2D-solid elements. An underlined item delineates a default.

Heat Classification of Elements				
Element Structural Type	BEHi CODE	Integration Code	Element Type	# Nodes
Plane Strain composite	COMPS	<u>L</u>	QUAD	4
		<u>Q</u>	QUAD	8
Axisymmetric composite	AXCOMP	L	QUAD	4
		Q	QUAD	8

9. Integration codes in Remark 7 are:

INT CODE	Integration Type
L	Linear
Q	Quadratic

10. P<sub>L</sub>COMP is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the P<sub>L</sub>COMP property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between P<sub>S</sub>SOLID, P<sub>C</sub>COMPLS, P<sub>L</sub>COMP, P<sub>C</sub>COMPG, P<sub>S</sub>SHELL, P<sub>L</sub>PLANE entries.

## PLOAD Static Pressure Load

Defines a uniform static pressure load on a triangular or quadrilateral surface comprised of surface elements and/or the faces of solid elements.

### Format:

1	2	3	4	5	6	7	8	9	10
PLOAD	SID	P	G1	G2	G3	G4			

### Example:

PLOAD	1	-4.0	16	32	11				
-------	---	------	----	----	----	--	--	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
P	Pressure. (Real)
Gi	Grid point identification numbers. (Integer > 0; G4 may be zero or blank.)

### Remarks:

- In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- The grid points define either a triangular or a quadrilateral surface to which a pressure is applied. If G4 is blank, the surface is triangular.
- In the case of a triangular surface, the assumed direction of the pressure is computed according to the right-hand rule using the sequence of grid points G1, G2, G3 illustrated in [Figure 9-126](#).

Figure 9-126 Pressure Convention for Triangular Surface of Surface Elements and/or the Faces of Solid Elements

The total load on the surface (see [Figure 9-127](#)),  $AP$ , is divided into three equal parts and applied to the grid points as concentrated loads. A minus sign in field 3 reverses the direction of the load.

4. In the case of a quadrilateral surface, the grid points  $G1$ ,  $G2$ ,  $G3$ , and  $G4$  should form a consecutive sequence around the perimeter. The right-hand rule is applied to find the assumed direction of the pressure. Four concentrated loads are applied to the grid points in approximately the same manner as for a triangular surface. The following specific procedures are adopted to accommodate irregular and/or warped surfaces:
  - The surface is divided into two sets of overlapping triangular surfaces. Each triangular surface is bounded by two of the sides and one of the diagonals of the quadrilateral.
  - One-half of the pressure is applied to each triangle, which is then treated in the manner described in [Remark 2](#).

Figure 9-127 Pressure Convention for Quadrilateral Surface of Surface Elements and/or the Faces of Solid Elements

5. The follower force effects due to loads from this entry are included in the stiffness in all linear solution sequences that calculate a differential stiffness. The solution sequences are SOLs 103, 105, 107 to 112, 115 and 116 (see also the parameter [FOLLOWK, 835](#)). In addition, follower force effects are included in the force balance in the nonlinear static and nonlinear transient dynamic solution sequences, SOLs 106, 129, 153, 159, 400 and 600 if geometric nonlinear effects are turned on with `PARAM,LGDISP,1`. The follower force stiffness is included in the nonlinear static solution sequences (SOLs 106, 153, 400 and 600) but not in the nonlinear transient dynamic solution sequences (SOLs 129 and 159).

## PLOAD1

### Applied Load on CBAR, CBEAM or CBEND Elements

Defines concentrated, uniformly distributed, or linearly distributed applied loads to the CBAR or CBEAM elements at user-chosen points along the axis. For the CBEND element, only distributed loads over an entire length may be defined.

#### Format:

1	2	3	4	5	6	7	8	9	10
PLOAD1	SID	EID	TYPE	SCALE	X1	P1	X2	P2	

#### Example:

PLOAD1	25	1065	MY	FRPR	0.2	2.5E3	0.8	3.5E3	
--------	----	------	----	------	-----	-------	-----	-------	--

#### Describer

#### Meaning

SID	Load set identification number. (Integer > 0)
EID	CBAR, CBEAM, or CBEND element identification number. (Integer > 0)
TYPE	Load type. (Character: "FX", "FY", "FZ", "FXE", "FYE", "FZE", "MX", "MY", "MZ", "MXE", "MYE", "MZE")
SCALE	Determines scale factor for X1, X2. (Character: "LE", "FR", "LEPR", "FRPR")
X1, X2	Distances along the CBAR, CBEAM, or CBEND element axis from end A. (Real; X2 may be blank; $0 \leq X1 \leq X2$ )
P1, P2	Load factors at positions X1, X2. (Real or blank)

#### Remarks:

- In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- If  $X2 \neq X1$ , a linearly varying distributed load will be applied to the element between positions X1 and X2, having an intensity per unit length of bar equal to P1 at X1 and equal to P2 at X2, except as noted in Remarks 8. and 9.
- If X2 is blank or equal to X1, a concentrated load of value P1 will be applied at position X1.
- If  $P1 = P2$  and  $X2 \neq X1$ , a uniform distributed load of intensity per unit length equal to P1 will be applied between positions X1 and X2 except as noted in Remarks 8. and 9.
- Load TYPE is used as follows to define loads:  
"FX", "FY" or "FZ": Force in the x, y, or z direction of the basic coordinate system.  
"MX", "MY" or "MZ": Moment in the x, y, or z direction of the basic coordinate system.

- “FXE”, “FYE” or “FZE”: Force in the x, y, or z direction of the element’s coordinate system.  
 “MXE”, “MYE” or “MZE”: Moment in the x, y, or z direction of the element’s coordinate system.
- If SCALE = “LE” (length), the xi values are actual distances along the element axis, and, if  $X1 \neq X2$ , then  $P_i$  are load intensities per unit length of the element.
  - If SCALE = “FR” (fractional), the xi values are ratios of the distance along the axis to the total length, and (if  $X2 \neq X1$ )  $P_i$  are load intensities per unit length of the element.
  - If SCALE = “LEPR” (length projected), the xi values are actual distances along the element axis, and (if  $X2 \neq X1$ ) the distributed load is input in terms of the projected length of the element.

Figure 9-128 PLOAD1 Convention on Beam or Bar Elements

If SCALE = “LE”, the total load applied to the bar is  $P1 (X2 - X1)$  in the y-basic direction.

If SCALE = “LEPR”, the total load applied to the bar is  $P1 (X2 - X1) \cos\alpha$  in the y-basic direction.

- If SCALE = “FRPR” (fractional projected), the Xi values are ratios of the actual distance to the length of the bar (CBAR entry), and if  $X1 \neq X2$ , then the distributed load is specified in terms of the projected length of the bar.
- Element identification numbers for CBAR, CBEAM, and CBEND entries must be unique.
- For the CBEND element, the following coordinate equivalences must be made for the element coordinates

$$R_{elem} \equiv X_{elem}$$

$$\theta_{elem} \equiv Y_{elem}$$

12. Only distributed loads applied over the entire length of the CBEND element may be applied.
13. Projected loads are not applicable to the CBEND element.
14. Loads on CBEAM elements defined with PLOAD1 entries are applied along the line of the shear centers.
15. If a CBARAO or PLOAD1 entry is specified and stress and/or force output is requested, then the stresses and/or forces will be calculated at each location  $X_i$  and output as a separate line. The force and stress locations  $X_i=0$  and  $X_i = l$  will always be output. This output format will be used for all beam and bar elements.
16. If on the TYPE field of the PLOAD1 entry, the element coordinate system direction (e.g. TYPE = FYE) option is selected, then the projection (i.e. SCALE = FRPR or LEPR) option is ignored and the result is the same as the SCALE = FR (or LE) option.

## PLOAD2

### Uniform Normal Pressure Load on a Surface Element

Defines a uniform static pressure load applied to CQUAD4, CSHEAR, or CTRIA3 two-dimensional elements.

#### Format:

1	2	3	4	5	6	7	8	9	10
PLOAD2	SID	P	EID1	EID2	EID3	EID4	EID5	EID6	
	EID7	EID8	-etc.-						

#### Example:

PLOAD2	21	-3.6		4	16		2		
--------	----	------	--	---	----	--	---	--	--

#### Alternate Format and Example:

PLOAD2	SID	P	EID1	“THRU”	EID2				
PLOAD2	1	30.4	16	THRU	48				

#### Describer

#### Meaning

SID	Load set identification number. (Integer > 0)
P	Pressure value. (Real)
EID <sub>i</sub>	Element identification number. (Integer ≥ 0 or blank; for the “THRU” option, EID1 < EID2.)

#### Remarks:

- In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOAD<sub>i</sub> or TLOAD<sub>i</sub> entry.
- At least one positive EID must be present on each PLOAD2 entry.
- If the alternate form is used, all elements EID1 through EID2 must be two-dimensional.
- The direction of the pressure is computed according to the right-hand rule using the grid point sequence specified on the element entry. Refer to the PLOAD entry.
- All referenced elements must exist (closed list) for residual only runs and are not required to exist (open list) for superelement runs; and they cannot be hyperelastic for either.
- The follower force effects due to loads from this entry are included in the stiffness in all linear solution sequences that calculate a differential stiffness. The solution sequences are SOLs 103, 105, 107 to 112, 115 and 116 (see also the parameter [FOLLOWK, 835](#)). In addition, follower force effects are included in the force balance in the nonlinear static and nonlinear transient dynamic solution

sequences, SOLs 106, 129, 153, 159, 400 and 600, if geometric nonlinear effects are turned on with `PARAM,LGDISP,1`. The follower force stiffness is included in the nonlinear static solution sequences (SOLs 106, 153, 400 and 600) but not in the nonlinear transient dynamic solution sequences (SOLs 129 and 159).

## PLOAD4

### Pressure Load on Surface and Faces of Solid Elements

Defines a pressure load on a face of a CHEXA, CPENTA, CPYRAM, CTETRA, CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, or CQUADR element. See Remark 17.

#### Format:

1	2	3	4	5	6	7	8	9	10
PLOAD4	SID	EID	P1	P2	P3	P4	G1	G3 or G4	
	CID	N1	N2	N3	SORL	LDIR			

#### Example:

PLOAD4	2	1106	10.0	8.0	5.0		48		
	6	0.0	1.0	0.0					

#### Alternate Format and Example (See Remark 8.):

PLOAD4	SID	EID1	P1	P2	P3	P4	“THRU”	EID2	
	CID	N1	N2	N3	SORL	LDIR			

PLOAD4	2	1106	10.0	8.0	5.0		THRU	1143	
	6	0.0	1.0	0.0					

Describer	Meaning
SID	Load set identification number. (Integer > 0)
EID EID1 EID2	Element identification number. (Integer > 0; for the “THRU” option, EID1 < EID2)
P1, P2, P3, P4	
G1	
G3	
G4	Identification number of the CTETRA grid point located at the corner; this grid point may not reside on the face being loaded. This is required data and is used for CTETRA elements only. (Integer > 0)

Describer	Meaning
CID	Coordinate system identification number. See Remark 2. (Integer $\geq 0$ ; Default = 0)
N1, N2, N3	Components of vector measured in coordinate system defined by CID. Used to define the direction (but not the magnitude) of the load intensity. See Remark 2. (Real)
SORL	The character string SURF or LINE. SURF means the surface load acting on the surface of the element and LINE means the consistent edge loads acting on the edges of the element. The default is SURE. See Remark 13.
LDIR	Denote the direction of the line load (SORL=LINE), character string X, Y, Z, TANG, or NORM. The default is NORM. See Remark 14.

### Remarks:

- In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- The continuation entry is optional. If fields 2, 3, 4, and 5 of the continuation entry are blank, the load is assumed to be a pressure acting normal to the face. If these fields are not blank, the load acts in the direction defined in these fields. Note that if CID is a curvilinear coordinate system, the direction of loading may vary over the surface of the element. The load intensity is the load per unit of surface area, not the load per unit of area normal to the direction of loading.
- For the faces of solid elements, the direction of positive pressure (defaulted continuation) is inward. For triangular and quadrilateral faces, the load intensity P1 acts at grid point G1 and load intensities P2, P3, (and P4) act at the other corners in a sequence determined by applying the right-hand rule to the outward normal.
- For plate elements, the direction of positive pressure (defaulted continuation) is in the direction of positive normal, determined by applying the right-hand rule to the sequence of connected grid points. The load intensities P1, P2, P3, (and P4) act respectively at corner points G1, G2, G3, (and G4) for triangular and quadrilateral elements. (See plate connection entries.)
- If P2, P3, and P4 are blank fields, the load intensity is uniform and equal to P1. P4 has no meaning for a triangular face and may be left blank in this case.
- Equivalent grid point loads are computed by linear or bilinear interpolation of load intensity followed by numerical integration using isoparametric shape functions. Note that a uniform load intensity will not necessarily result in equal equivalent grid point loads.
- G1 and G3 are ignored for CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, and CQUADR elements.
- The alternate format is available only for CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, and CQUADR elements. The continuation entry may be used in the alternate format.

9. For triangular faces of CPENTA elements, G1 is an identification number of a corner grid point that is on the face being loaded and the G3 or G4 field is left blank. For faces of CTETRA elements, G1 is an identification number of a corner grid point that is on the face being loaded and G4 is an identification number of the corner grid point that is not on the face being loaded. Since a CTETRA has only four corner points, this point G4 will be unique and different for each of the four faces of a CTETRA element.
10. For the CQUADR and CTRIAR element, only pressure that acts normal to the element is computed properly. Surface tractions are not resolved into moments normal to the element.
11. All referenced elements must exist (closed list) for residual only runs and are not required to exist (open list) for superelement runs; and they cannot be hyperelastic for either.
12. If fields 3 through 5 of the continuation entry are not blank, the load is assumed to have a fixed direction. If fields 2 through 5 of the continuation entry are left blank, the load is assumed to be a pressure load. In this case, follower force effects are included in the stiffness in all linear solution sequences that calculate a differential stiffness. The solution sequences are SOLs 103, 105, 107 to 112, 115 and 116 (see also the parameter [FOLLOWK, 835](#)). In addition, follower force effects are included in the force balance in the nonlinear static and nonlinear transient dynamic solution sequences, SOLs 106, 129, 153, 159, 400 and 600, if geometric nonlinear effects are turned on with `PARAM,LGDISP,1`. The follower force stiffness is included in the nonlinear static solution sequences (SOLs 106, 153, 400 and 600) but not in the nonlinear transient dynamic solution sequences (SOLs 129 and 159).
13. The SORL field is ignored by all elements except QUADR and TRIAR. For QUADR or TRIAR only, if `SORL=LINE`, the consistent edge loads are defined by the PLOAD4 entry. P1, P2, P3 and P4 are load per unit length at the corner of the element. If all four Ps are given, then the line loads along all four edges of the element are defined. If any P is blank, then the line loads for only two edges are defined. For example, if P1 is blank, the line loads of the two edges connecting to G1 are zero. If two Ps are given, then the line load of the edge connecting to the two grid points is defined. If only one P is given, the second P value default to the first P value. For example, P1 denotes that the line load along edge G1 and G2 has the constant value of P1.
14. The direction of the line load (`SORL=LINE`) is defined by either (CID, N1, N2, N3) or LDIR. Fatal error will be issued if both methods are given. TANG denotes that the line load is in tangential direction of the edge, pointing from G1 to G2 if the edge is connecting G1 and G2. NORM denotes that the line load is in the mean plan, normal to the edge, and pointing outward from the element. X, Y, or Z denotes the line load is in the X, Y, or Z direction of the element coordinate system. If both (CID, N1, n2, N3) and LDIR are blank, then the default is `LDIR=NORM`.
15. For SOL 600, the SORL field may also be used by CQUAD4 and CTRIA3 in addition to CQUADR and CTRIAR.
16. For SOL 600, the LDIR field must be blank or a fatal error will occur. SOL 600 line loads must use the CID, N1, N2, N3 fields.
17. For SOL 400, with large displacement (`PARAM,LGDISP`), higher-order 6-node triangles (CTRIA6), 8-node quadrilateral (CQUAD8), 20-node hexagonal (CHEXA), or 15-node pentahedral (CPENTA), the load is not calculated correctly. Use lower-order elements if distributed loads are required in a large displacement analysis.

**PLOADB3**

## Applied distributed load on CBEAM3 elements

Defines a distributed load to a CBEAM3 element over entire length of the beam axis.

**Format:**

1	2	3	4	5	6	7	8	9	10
PLOADB3	SID	EID	CID	N1	N2	N3	TYPE	SCALE	
	P(A)	P(B)	P(C)						

**Example:**

PLOADB3	10	1002	LOCAL	1.0			MOMENT		
	100.	90.	70.						

**Describer****Meaning**

SID	Load set identification number. (Integer > 0; Required)
EID	CBEAM3 element identification number. (Integer > 0, Required)
CID	Coordinate system for load definition. (Character or Integer; Default = "BASIC") "LOCAL"            Local coordinate system; "ELEMENT"        Element coordinate system; "BASIC" or 0       Basic coordinate system;
n (n>0):	Any user-specified coordinate system identification number.
N1, N2, N3	Load vector components measured in coordinate system specified by CID. (Real; at least one $N_i \neq 0.0$ )
TYPE	Type of applied load. (Character = "FORCE", "MOMENT" or "BIMOMENT"; Required)
SCALE	Load vector scale factor. (Real; Default = 1.0)
P(j)	Magnitudes of load at j (j=A, B and C). (Real; Default = 0.0)

**Remarks:**

- In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- The load vector is defined by  $\vec{P}_j = SCALE \cdot P_j \cdot \vec{N}$ , ( $j = A, B, C$ ). The orientation of load  $\vec{P}$  is determined by vector  $\vec{N}$  and the magnitude is equal to  $SCALE \cdot P$  times magnitude of vector  $\vec{N}$ .

3. The distributed load is applied over the entire length of the beam axis, along the line of the shear center.

## PLOADX1

### Pressure Load on Axisymmetric Element

Defines surface traction to be used with CAXISYM, CQUADX, CTRIAX, and CTRIAX6 axisymmetric elements.

#### Format:

1	2	3	4	5	6	7	8	9	10
PLOADX1	SID	EID	PA	PB	GA	GB	THETA		

#### Example:

PLOADX1	200	35	3.5	10.5	10	30	20.		
---------	-----	----	-----	------	----	----	-----	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
EID	Element identification number. (Integer > 0)
PA	Surface traction at grid point GA. (Real)
PB	Surface traction at grid point GB. (Real; Default = PA)
GA, GB	Corner grid points. GA and GB are any two adjacent corner grid points of the element. (Integer > 0)
THETA	Angle between surface traction and inward normal to the line segment. (Real; Default = 0.0)

#### Remarks:

1. In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
2. PLOADX1 is intended only for the CAXISYM, CQUADX, CTRIAX, and CTRIAX6 elements.
3. The surface traction is assumed to vary linearly along the element side between GA and GB.
4. The surface traction is input as force per unit area. MSC Nastran converts this traction into equivalent nodal loads by integration over the surface. For AXISYM and hyperelastic QUADX and TRIAX elements this integration is over one radian. For TRIAX6 and axisymmetric harmonic QUADX and TRIAX elements this integration is over two pi radians.
5. THETA is measured counter-clockwise from the inward normal of the straight line between GA and GB, to the vector of the applied load, as shown in [Figure 9-129](#), [Figure 9-130](#), and [Figure 9-131](#). Positive pressure is in the direction of inward normal to the line segment.

For the axisymmetric shell element (CAXISYM), the inward normal is established from the cross product  $\hat{k} \times (\vec{GB} - \vec{GA})$ , where  $\hat{k}$  is the unit out-of-plane vector and  $(\vec{GB} - \vec{GA})$  is the in-plane line segment from GA to GB (see Figure 9-131).

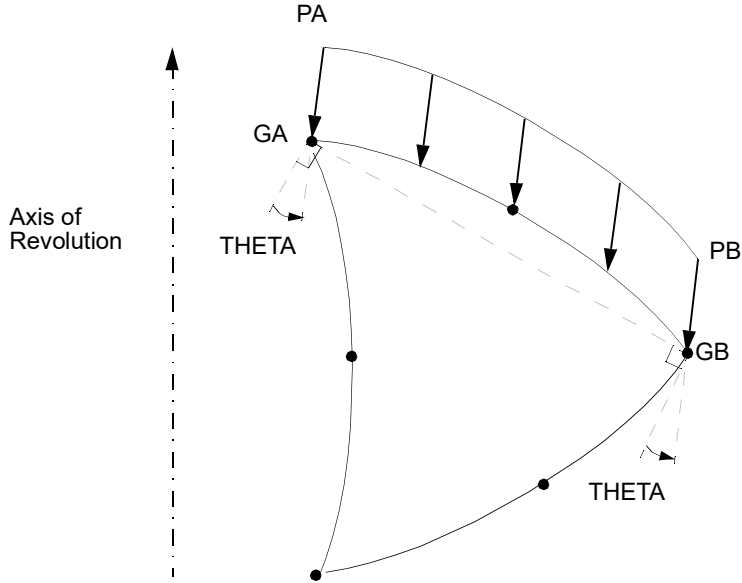

Figure 9-129 Pressure Load on CTRIAX6 or CTRIAX Element

Figure 9-130 Pressure Load on CQUADX Element

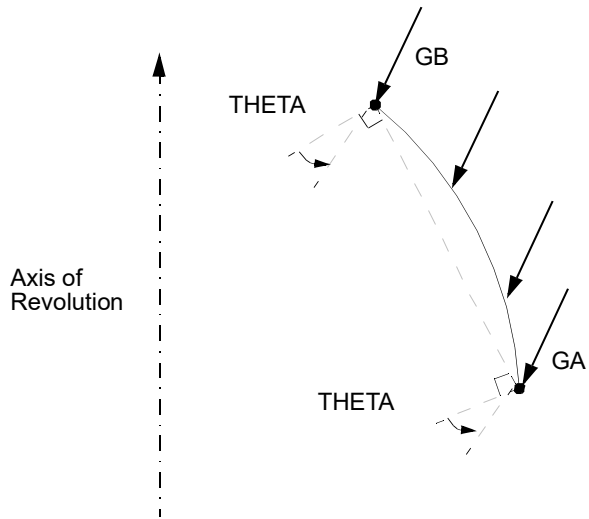

Figure 9-131 Pressure Load on CAXISYM Element

6. Axisymmetric harmonic elements may have Harmonic "N" greater than zero. For this case the "PA" and "PB" fields of the PLOADX1 entry are coefficients of  $\text{COS}(N \cdot \text{theta})$ . The PLOADX1 cannot supply azimuthal tractions on axisymmetric harmonic elements.

## PLOTEL Dummy Plot Element Definition

Defines a one-dimensional dummy element for use in plotting.

### Format:

1	2	3	4	5	6	7	8	9	10
PLOTEL	EID	G1	G2						

### Example:

PLOTEL	29	35	16						
--------	----	----	----	--	--	--	--	--	--

Describer	Meaning
EID	Element identification number. (Integer > 0)
G1, G2	Grid point identification numbers of connection points. (Integer > 0; G1 ≠ G2)

### Remarks:

1. This element is not used in the model during any of the solution phases of a problem. It is used to simplify plotting of structures with large numbers of colinear grid points, where the plotting of each grid point along with the elements connecting them would result in a confusing plot.
2. Element identification numbers should be unique with respect to all other element identification numbers.
3. Only one PLOTEL element may be defined on a single entry.
4. In superelement analysis, PLOTELS, as well as other elements such as CBAR, CQUAD4, etc., will affect the formation of the superelement tree. The PLOTEL EIDs will also appear in the superelement map output; see the description of PARAM,SEMAPPRT in [Parameters](#).
5. Only grid points connected by structural elements appear on structure plots. This does not include points connected only by rigid or general elements or MPCs. A plot element in parallel with elements that do not plot will cause these points to be present.

## PLPLANE

### Fully Nonlinear Plane Element Properties

Defines the properties of a fully nonlinear (i.e., large strain and large rotation, etc.) plane strain, plane stress, or axisymmetric element. Please refer to PSHLN2.

#### Format:

1	2	3	4	5	6	7	8	9	10
PLPLANE	PID	MID	CID	STR					

#### Example:

PLPLANE	203	204	-2	GRID					
---------	-----	-----	----	------	--	--	--	--	--

#### Describer

#### Meaning

PID	Element property identification number. (Integer > 0)
MID	Identification number of a MATHP entry for Nastran conventional elements, or MATHE and other linear or nonlinear material entries for Nastran advanced nonlinear elements. (Integer > 0). See Remarks 7.
CID	Identification number of a coordinate system defining the plane of deformation. See Remarks 2. and 3. (Default = 0)
STR	Location of stress and strain output. (Character: "GAUS" or "GRID", Default = "GRID")

#### Remarks:

1. PLPLANE can be referenced by a CQUAD, CQUAD4, CQUAD8, CQUADX, CTRIA3, CTRIA6, or CTRIAX entry.
2. Plane strain hyperelastic elements must lie on the x-y plane of the CID coordinate system. Stresses and strains are output in the CID coordinate system.
3. Axisymmetric hyperelastic elements must lie on the x-y plane of the basic coordinate system. CID may not be specified and stresses and strains are output in the basic coordinate system.
4. Negative values of CID will indicate an axes combination for axisymmetric elements. The following table describes the value and axes. Inside one model, only one CID value is allowed.

Axial	Radial	CID Value
X	Y	-2
X	Z	-3
Y	X	-4

Axial	Radial	CID Value
Y	Z	-5
Z	X	-6
Z	Y	-7

- CID = 0 is the default value which equal to CID = -2.
- PLPLANE is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PLPLANE property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness among PLPLANE, PAXSYMH, and PSHELL entries.
- When using Enhanced materials (SOL400), the MID field may point to additional Material entries such as a MAT1. For a full list see the PSHLN2 entry. If a material type other than the MATHP or MATHE entry is used in solution sequences other than SOL400, wrong results will occur. Note linear stress recovery is not available for any element using the PLPLANE.

## PLSOLID Fully Nonlinear Solid Element Properties

Defines a fully nonlinear (i.e., large strain and large rotation) hyperelastic solid element.

### Format:

1	2	3	4	5	6	7	8	9	10
PLSOLID	PID	MID	STR						

### Example:

PLSOLID	20	21							
---------	----	----	--	--	--	--	--	--	--

Describer	Meaning
PID	Element property identification number. (Integer > 0)
MID	Identification number of a MATHP entry. (Integer > 0)
STR	Location of stress and strain output. (Character: "GAUS" or "GRID", Default = "GRID")

### Remarks:

1. PLSOLID can be referenced by a CHEXA, CPENTA, or CTETRA entry.
2. Stress and strain are output in the basic coordinate system.
3. PLSOLID is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PLSOLID property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PSOLID, PLSOLID entries.

## PLTSURF

## Surface plot mesh definition

Defines the surface plot mesh.

### Format:

1	2	3	4	5	6	7	8	9	10
PLTSURF	EID	GID1	GID2	GID3	GID4	GID5	GID6	GID7	
	GID8								

### Describer

### Meaning

EID	Identification number of element.
GIDi	Grid identification number of structure/cavity models or trim component surface element.

### Remarks:

1. This element is used only to describe the surface mesh of 3D model. The connection can be 3, 4, 6 or 8 nodes and the connection sequence mirrors those of CTRIA3, CQUAD4, CTRIA6 and CQUAD8.
2. PLTSURF can be utilized to describe surface mesh on ACPEMCP for trim component coupling in PEM job.
3. For trim component, PLTSURF ID must be referenced on SET3,id,ELEM. If SET1 entry is used with PLTSURF ID, fatal error or unexpected results may be the results.
4. PLTSURF entry can also be used to define surface mesh for structure/cavity models and it behaves similarly as PLOTTEL and does not participate in analysis.

## PMARKER

## Property Definition of a Marker Element

Defines the behavior of the marker element in the EULER domain. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PMARKER	ID	TYPE							

### Example:

PMARKER	7	FIXED							
---------	---	-------	--	--	--	--	--	--	--

### Describer

### Meaning

ID	Marker property ID, referred by CMARKB2 and CMARKN1 entries. (Integer > 0, Required)
TYPE	Behavior of the marker grid points in the Euler domain: (Character, Default = FIXED)
	FIXED                      The marker will not move in the Euler domain.
	MOVING                     The marker will be moved by velocities in the Euler domain.

### Remarks:

1. The PMARKER entry will be ignored for elements that are referring to structural grid points. These structural grid points will move with the structure and the Euler velocities do not change their velocity.
2. TYPE = FIXED. This means that the marker is stationary through out the simulation and it is therefore not moving with the Euler velocity. If the marker grid is located outside the Eulerian domain(s), the Marker will still be allowed to exist. It means, however, that no variables are recorded and that the variables will appear as zero on the Time History plots.
3. TYPE = MOVING. The marker is moving along with the Eulerian material. When the grid point approaches a coupling surface there is no mechanism that prevents the marker from passing through the coupling surface. When this happens the marker enters an element that is covered and motion of the grid point will stop. It is allowed that the grid point moves from one Euler domain to the other through a porous hole or a coupling surface with interactive failure.

## PMASS Scalar Mass Property

Specifies the mass value of a scalar mass element (CMASS1 or CMASS3 entries).

### Format:

1	2	3	4	5	6	7	8	9	10
PMASS	PID1	M1	PID2	M2	PID3	M3	PID4	M4	

### Example:

PMASS	7	4.29	6	13.2					
-------	---	------	---	------	--	--	--	--	--

Describer	Meaning
PIDi	Property identification number. (Integer > 0)
Mi	Value of scalar mass. (Real)

### Remarks:

1. Mass values are defined directly on the CMASS2 and CMASS4 entries, and therefore do not require a PMASS entry.
2. Up to four mass values may be defined by this entry.
3. For a discussion of scalar elements, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.
4. PMASS is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PMASS property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PMASS entries.

## PMINC

## Constant Spallation Model

Defines a spallation model where the minimum pressure is constant. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PMINC	PID	VALUE	FVTOL	FVTOL2					

### Example:

PMINC	220	-370							
-------	-----	------	--	--	--	--	--	--	--

Describer	Meaning
PID	Unique PMINC number. Referenced from MATDEUL. (Integer > 0, Required)
VALUE	The value of the minimum pressure. (Real $\leq$ 0.0, Default = 0.0)
FVTOL	Volume cutoff tolerance. (Real > 0, 1.E-4)
FVTOL2	Maximum void fraction that is permissible under tension. (Real $\geq$ 0; Default = 0.0)

### Remarks:

1. If the pressure in an element falls below the minimum pressure, the element spalls. The pressure and yield stress are set to zero.

2. The default for the volume cutoff tolerance is 1.E-4. This value should be decreased in case of large mass increase of material without any reason.
3. If an element spalls a void is created. In order to prevent getting void fractions that are too small, a void fraction is put to zero if it is smaller than FVTOL. The default for FVTOL is 1.E-4 and works only for Eulerian elements. This value should be decreased in case of large mass increase of material without any reason. Voids can be created during transport of material, because of a material failure and by unloading.

4. With  $FVTOL2 = 0$ , any void fraction in an element will lead to failure, and then no tensile stresses are possible. In simulations in which tensile conditions are present, it can be required to allow for tensile stresses in the presence of a small void fraction not exceeding a threshold. This threshold is given by  $FVTOL2$ . A good value for  $FVTOL2 = 2 * FVTOL = e.E-4$ .  $FVTOL 2$  is only used for Eulerian materials.  $FVTOL 2$  should be larger than  $FVTOL$ .

## PMREBAI Defines Rebar Property Information for CMREBAI Elements in SOL 600

In some cases, particularly for modeling of concrete or tires, it is beneficial to add rebar or cord material to a matrix. The resulting combined material is similar to a composite but it is sometimes easier to postprocess the stresses of the rebar and matrix separately to determine failure conditions. SOL 600 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PMREBAI	IP	TOL	IFILE	X1	X2	X3	MICRO	FACTOR	
	IM1	POS1	AREA1	SSS1	ANG1	IPOST1	IORI1		
	IM2	POS2	AREA2	SSS2	ANG2	IPOST2	IORI2		
	IM3	POS3	AREA3	SSS3	ANG3	IPOST3	IORI3		
	IM4	POS4	AREA4	SSS4	ANG4	IPOST4	IORI4		
	IM5	POS5	AREA5	SSS5	ANG5	IPOST5	IORI5		
	"HEXA"	ID1	THRU	ID2	IHE3	THRU	IHE4		
	"HEXA"	ID5	THRU	ID6	etc.				

### Example (two rebar layers through matrix CHEXA elements 100-120):

PMREBAI	20		1	1.0	0.0	0.0	1	0.01	
	100	0.25	0.075	3.0	45.0	2000	1		
	101	0.275	0.050	32.0	4 -30.0	2001	1		
	HEXA	100	THRU	120					

Describer	Meaning
IP	Rebar property ID. (Integer, Required, no Default)
TOL	Exterior tolerance. A rebar grid is considered within a matrix CHEXA element if the distance between the element and the grid is smaller than the tolerance times the average edge length of the element unless the grid is actually inside another matrix CHEXA element. (Real, Default = 0.05)
IFILE	Option to create a file for rebar verification. (Integer, Default = 0). If IFILE=1, a file named jid.marc_rebar.mfd will be created for use by Mentat.
X1	First direction cosine of reference axis. (Real, Required, no Default)
X2	Second direction cosine of reference axis. (Real, Required, no Default)
X3	Third direction cosine of reference axis. (Real, Required, no Default)
MICRO	Option to activate "micro buckling" behavior. (Integer, Default = 0) If MICRO=0 micro buckling is not activated, if MICRO=1 micro buckling is activated.
FACTOR	Factor to use to reduce rebar stiffness in compression if MICRO=1. (Real, Default = 0.02)

IMi	Material identification number. (Integer, Required, no Default)
POSi	Relative position of rebar layer at edge 1 (pr/t) - the ratio of the distance between the reference surface and the rebar layer to the distance across the element. (Real, Required, no Default)
AREAi	Rebar cross sectional area. (Real, Required, no Default)
SSSi	Number of rebars per unit length in each layer. (Real, Required, no Default)
ANGi	Angle (degrees) between the rebar and the projection of the reference axis on the rebar layer plane (see the following figure). (Real, Default = 0.0, must be between -90.0 and 90.0), see <a href="#">Figure 9-132</a> .
IPOSTi	Global identification number of the rebar layer used for postprocessing. (Integer, Default = 0)
IORIi	Rebar layer orientation type, see <a href="#">Figure 9-133</a> . (Integer, Required, no Default) 1 = Thickness direction is from the 1,2,3,4 face to the 5,6,7,8 face 2 = Thickness direction is from the 1,4,8,5 face to the 2,3,7,6 face 3 = Thickness direction is from the 2,1,5,6 face to the 3,4,8,7 face
HEXA	Enter the string HEXA to indicate the line that contains matrix CHEXA element ID's through which the rebar passes. (Character, Required)
ID1, ID3, etc.	Starting matrix CHEXA element ID. (Integer ID1 is Required)
THRU	Enter string THRU to indicate that more than one matrix CHEXA element with these rebar properties apply.
ID2, ID4, etc.	Ending matrix CHEXA element ID. (Integer, ID2 is Required)

### Remarks:

1. This entry is the property entry for CMREBAI elements and makes use of Marc's REBAR and INSERT capabilities for rebar membrane element types 147 and 148. Entries CMREBAR and PMREBAR makes use of Marc's REBAR only capability and use rebar elements 23 and 146.
2. If rebar layers i are not desired, the lines 2-5 may be omitted. The line for i=1 is required.
3. See the following two figures for a definition of ANG and IORI.
4. Any material valid for SOL 600 may be used to define IM.
5. For each rebar layer, the user is required to define cord material identification number, cross section area of the cords, density of the cords, and an angle (defining spatial orientation of the cords).  $\alpha$  is the angle between the cord and the projection of a predefined reference axis on the rebar layer plane as shown in the next figure.

Figure 9-132 Description of rebar orientation on a single rebar layer

### 3-D

Figure 9-133 Rebar numbering and orientation type (IORI value) - only 3D supported.

**PMREBAR****Defines Rebar Property Information for CMREBAR Elements in SOL 600**

In some cases, particularly for modeling of concrete or tires, it is beneficial to add rebar or cord material to a matrix. The resulting combined material is similar to a composite but it is sometimes easier to postprocess the stresses of the rebar and matrix separately to determine failure conditions. Enter lines 2 through 6 below to describe up to 5 “rebar layers”. If only the structure only contains two rebar layers, only enter lines 1-3 as shown in the example. SOL 600 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
PMREBAR	IP		IFILE	X1	X2	X3	MICRO	FACTOR	
	IM1	POS1	AREA1	SSS1	ANG1	IPOST1	IORI1		
	IM2	POS2	AREA2	SSS2	ANG2	IPOST2	IORI2		
	IM3	POS3	AREA3	SSS3	ANG3	IPOST3	IORI3		
	IM4	POS4	AREA4	SSS4	ANG4	IPOST4	IORI4		
	IM5	POS5	AREA5	SSS5	ANG5	IPOST5	IORI5		

**Example (two rebar layers):**

PMREBAR	20		1	1.0	0.0	0.0	1	0.01	
	100	0.25	0.075	3.0	45.0	2000	1		
	101	0.275	0.050	32.0	4 -30.0	2001	1		

**Describer****Meaning**

IP	Rebar property ID. (Integer; Required; no Default)
IFILE	Option to create a file for rebar verification. (Integer; Default = 0). If IFILE=1, a file named jid.marc_rebar.mfd will be created for use by Mentat.
X1	First direction cosine of reference axis. (Real; Required; no Default)
X2	Second direction cosine of reference axis. (Real; Required; no Default)
X3	Third direction cosine of reference axis. (Real; Required; no Default)
MICRO	Option to activate “micro buckling” behavior. (Integer; Default = 0) If MICRO=0 micro buckling is not activated, if MICRO=1 micro buckling is activated.
FACTOR	Factor to use to reduce rebar stiffness in compression if MICRO=1. (Real; Default = 0.02)
IMi	Material identification number. (Integer; Required; no Default)
POSi	Relative position of rebar layer at edge 1 (p/r/t) - the ratio of the distance between the reference surface and the rebar layer to the distance across the element. (Real; Required; no Default)
AREAi	Rebar cross sectional area. (Real; Required; no Default)

SSSi	Number of rebars per unit length in each layer. (Real; Required; no Default)
ANGi	Angle (degrees) between the rebar and the projection of the reference axis on the rebar layer plane (see the following figure). (Real; Default = 0.0, must be between -90.0 and 90.0), see <a href="#">Figure 9-134</a> .
IPOSTi	Global identification number of the rebar layer used for postprocessing. (Integer; Default = 0)
IORIi	Rebar layer orientation type, see <a href="#">Figure 9-135</a> . (Integer; Required; no Default) 1 = Thickness direction is from the 1,2,3,4 face to the 5,6,7,8 face 2 = Thickness direction is from the 1,4,8,5 face to the 2,3,7,6 face 3 = Thickness direction is from the 2,1,5,6 face to the 3,4,8,7 face

**Remarks:**

1. This entry is the property entry for CMREBAR elements and makes use of Marc’s REBAR capability for element types 23 and 146. Entries CMREBAI and PMREBAI makes use of Marc’s REBAR and INSERT capabilities and use membrane rebar elements 147 and 148.
2. See [Figure 9-134](#) and [Figure 9-135](#) for a definition of ANG and IORI.
3. Any material valid for SOL 600 may be used to define IM.
4. For each rebar layer, the user is required to define cord material identification number, cross section area of the cords, density of the cords, and an angle (defining spatial orientation of the cords).  $\alpha$  is the angle between the cord and the projection of a predefined reference axis on the rebar layer plane as shown in the [Figure 9-134](#).

Figure 9-134 Description of rebar orientation on a single rebar layer

Figure 9-135 Rebar numbering and orientation type (IORI value) - only 3D supported

## POINT Geometric Point Entry

Define edge point for SELOC entries or profile PBMSECT entries.

### Format:

1	2	3	4	5	6	7	8	9	10
POINT	ID	CP	X1	X2	X3				

### Example:

POINT	12	1	1.	2.	5.				
-------	----	---	----	----	----	--	--	--	--

Describer	Meaning	Type	Default
ID	Point identification number.	Integer $\geq 0$	Required
CP	Identification number of coordinate system in which the location of point is defined.	Integer $\geq 0$	0
X1, X2, X3	Location of the point in coordinate system CP.	Real	0.0

### Remarks:

1. SELOC entries can refer to POINT entries in the residual or part superelements.
2. ID of POINTs must be unique with respect to ID of GRID entries.
3. POINT entries can be referenced on SET1/SET3 for defining arbitrary beam cross section, ABCS, via PBRSECT/PBMSECT. Note that CP and X3 must be left blank for POINT entries used for ABCS.

**POINTAX**

## Conical Shell Point

Defines the location of a point on an axisymmetric shell ring at which loads may be applied via the FORCE or MOMENT entries and at which displacements may be requested. These points are not subject to constraints via MPCAX, SPCAX, or OMITAX entries.

**Format:**

1	2	3	4	5	6	7	8	9	10
POINTAX	ID	RID	PHI						

**Example:**

POINTAX	2	3	30.0						
---------	---	---	------	--	--	--	--	--	--

Describer	Meaning
ID	Point identification number. (Unique Integer > 0)
RID	Identification number of a RINGAX entry. (Integer > 0)
PHI	Azimuthal angle in degrees. (Real)

**Remarks:**

1. This entry is allowed only if an AXIC entry is also present.
2. POINTAX identification numbers must be unique with respect to all other POINTAX, RINGAX, and SECTAX identification numbers.
3. For a discussion of the conical shell problem, see [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide*.

## PORFCPL

## Flow Between Two Coupling Surfaces Through a Hole

Defines an interaction between two coupling surfaces through a hole. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PORFCPL	PID	SIZE		FLOW	CSID	MID			

### Example:

PORFCPL	1	SMALL		BOTH	1				
---------	---	-------	--	------	---	--	--	--	--

### Describer

### Meaning

PID	Unique PORFCPL identification number. (Integer > 0; Required)
SIZE	Defines the type of flow method that is used for mass leaving or entering the airbag volume. (Character; Default = SMALL)
	SMALL The size of the hole in the surface is the same or smaller than the size of the Euler mesh used. The velocity of the gasflow through the hole is based on the theory of one-dimensional gas flow through a small orifice, and depends on the pressure difference. This is the method that is used if the PORHOLE is used on a GBAG entry.
	LARGE The size of the hole in the surface is larger than the Euler mesh used. The velocity of the gasflow through the hole is based on the velocity method for an Eulerian air bag. If the PORHOLE is used on a GBAG entry, it will default back to method used for SIZE=SMALL.
FLOW	Defines the allowed directions of the flow. (Character; Default = BOTH)
	BOTH In- and outflow are allowed.
	IN Only inflow allowed into the COUPLE that references this entry.
	OUT Only outflow allowed into the COUPLE that references this entry.
CSID	The ID of the COUPLE entry. This COUPLE is the one that is connected to the coupling surface that references this entry. (Integer > 0; Required)
MID	MATDEUL ID number of the transported gas. Only used when connecting to a GBAG and Euler solver uses the multi-material and SIZE=LARGE. See Remark 2. (Integer > 0)

### Remarks:

1. The PORFCPL entry can only be referenced from LEAKAGE entry.

2. For SIZE=LARGE: once gas from a GBAG flows into an Eulerian domain it is treated as Eulerian material. For the single material Euler solver only one Eulerian material is present and the material number MID can be left blank. Since GBAG material is an ideal gas it is required that Eulerian material also uses an EOSGAM (ideal gas) equation of state. When using the multi-material solver the Material number MID has to point to one of the Eulerian materials and the equation of state of that material has to be of type EOSGAM.

## PORFGBG

## Flow Between Two Air Bags Through a Hole

Defines a hole in a couple and/or GBAG (sub)surface, connected to another GBAG. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PORFGBG	FID	SIZE		FLOW	GBID	MID			

### Example:

PORFGBG	1	SMALL		BOTH	1				
---------	---	-------	--	------	---	--	--	--	--

### Describer

### Meaning

FID	Unique number of a PORFGBG entry. It can be referenced from either a LEAKAGE to model the flow between GBAGs, or between Eulerian air bag and a GBAG or between Eulerian air bags. (Integer > 0; Required)
SIZE	Defines the type of flow method that is used for mass leaving or entering the air bag volume. (Character; Default = SMALL)  SMALL      The size of the hole in the surface is the same or smaller than the size of the Euler mesh used. The velocity of the gasflow through the hole is based on the theory of one-dimensional gas flow through a small orifice, and depends on the pressure difference. This is the method that is used if the PORHOLE is used on a GBAG entry.  LARGE      The size of the hole in the surface is larger than the Euler mesh used. The velocity of the gasflow through the hole is based on the velocity method for an Eulerian air bag. If the PORHOLE is used on a GBAG entry, it will default back to method used for SIZE=SMALL.
FLOW	Defines the allowed directions of the flow. (Character; Default = BOTH)  BOTH      In- and outflow are allowed.  IN      Only inflow allowed into the GBAG or the coupling surface that references this entry.  OUT      Only outflow allowed into the GBAG or the coupling surface that references this entry.
GBID	Number of a GBAG entry. This GBAG is the one that is connected to the GBAG or coupling surface that references this entry. (Integer > 0; Required)
MID	MATDEUL ID number of the GBAG gas. Only used when connecting a GBAG to an Eulerian air bag that uses the multi-material Euler solver and SIZE=LARGE. See Remark 3. (Integer > 0)

**Remarks:**

1. The PORFGBG entry can be referenced from a LEAKAGE entry.
2. When used with Euler and SIZE=SMALL, this entry can only be used with the single material hydrodynamic Euler solver, using an EOSGAM (ideal gas) equation of state.
3. For SIZE=LARGE: once gas from a GBAG enters an Eulerian domain it is treated as Eulerian material. For the single material Euler solver only one Eulerian material is present and the material number MID can be left blank. Since GBAG material is an ideal gas it is required that Eulerian material also uses an EOSGAM (ideal gas) equation of state. When using the Multi-material solver the Material number MID has to point to one of the Eulerian materials and the equation of state of that material has to be of type EOSGAM.

## PORFLOW

## Porous Flow Boundary

Defines the material properties for the in- or outflow of an Eulerian mesh through a porous area of the couple surface. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PORFLOW	FID		TYPE1	VALUE1	TYPE2	VALUE2	TYPE3	VALUE3	
	TYPE4	VALUE4	-etc.-						

### Example:

PORFLOW	120		XVEL	100.0	1				

### Describer

### Meaning

FID	Unique number of a PORFLOW entry. (Integer > 0; Required)
TYPE	The properties on the flow boundary. (Character, Required)
MATERIAL	MATDEUL ID number.
XVEL	Velocity in the x-direction.
YVEL	Velocity in the y-direction.
ZVEL	Velocity in the z-direction.
PRESSURE	Pressure.
DENSITY	Density.
SIE	Specific internal energy.
FLOW	The type of flow boundary required.
METHOD	The method used for the material transport.
VALUE <sub>i</sub>	The value of the property specified in the TYPE field. (Real or Character, Required) For TYPE <sub>i</sub> set to FLOW, the value is a character entry: either IN, OUT or BOTH, indicating that the flow boundary is defined as an inflow, outflow, or possibly an in- or outflow boundary. The default is BOTH. See Remark 4. For TYPE <sub>i</sub> set to METHOD, the value is a character entry: either VELOCITY or PRESSURE, indicating that the material transport is based on the velocity method or the pressure method. The default is VELOCITY. See Remark 4.

### Remarks:

1. Reference FID by a LEAKAGE entry.
2. Any material properties not specifically defined have the same value as the element that the (SUB)SURFACE segment is intersecting.

3. The SURFACE can be only a general coupling surface (see the COUPLE entry).
4. The different methods used to calculate the material transport through a porous (sub)surface are described in General Coupling.
5. METHOD=VELOCITY is valid for all equation of state models.  
 METHOD=PRESSURE is valid for EOSGAM (ideal gas) in combination with the single material hydrodynamic Euler solver.
6. Alternative methods are available to define holes and permeable sections in an air bag. See the entries: LEAKAGE, PORHOLE, PERMEAB, PORFGBG and PERMGBG.
7. In the case of material flow into a multi-material Euler mesh, the material number, the density and specific energy have to be set. On the other hand when material flows out of a multi-material Euler mesh it is assumed that each of the materials present in the outflow Euler element contributes to the out flow of mass. The materials are transported in proportion to their relative volume fractions
8. Prescribing both pressure and velocity may lead to the instabilities.

## PORFLWT

## Time Dependent Porous Flow Boundary

Defines a time dependent flow through a porous area of the couple surface. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PORFLWT	FID	TYPE							
	VELTYPE	VELOCITY	PRESTYP	PRES					
	MID	DENSTYP	DENSITY	SIETYP	SIE				

### Example:

PORFLWT	2	IN							
	TABLE	101	TABLE	102					
	91	TABLE	105	TABLE	107				

### Describer

### Meaning

FID	Unique number of a PORFLWT entry. (Integer > 0; Required)
TYPE	Type of flow boundary. (Character; Default = BOTH)
	IN                      Inflow boundary (see Remarks 2. and 3.). Only inflow is allowed. The inflow velocity and pressure can be optionally specified. If not given, the values in the adjacent Euler element will be used. The same holds for the density and sie.
	OUT                     Only outflow is allowed. The outflow velocity and pressure can be optionally specified. If not given, the values in the adjacent Euler element will be used. The outflow boundary will always use the material mixture as present in the adjacent Euler element.
	BOTH                   Material is allowed to flow in or out. The switch between inflow and outflow is based on the direction of the velocity in the adjacent Euler element. Only pressure can be left unspecified. If not given the pressure in the adjacent Euler element will be taken.
VELTYPE	Type of velocity definition. (Character; Default = ELEMENT)
	ELEMENT            Value of Euler element.
	CONSTANT          Value is constant in time.
	TABLE                Value varies in time.
VELOCITY	Value of inflow or outflow velocity. If VELTYPE = TABLE it refers to a TABLED1. The velocity direction is normal to the coupling surface or subsurface. A positive velocity corresponds with inflow. See Remark 6. (Integer or Real)
PRESTYP	Type of pressure definition. See Remark 6. (Character)

	ELEMENT	Value of Euler element.
	CONSTANT	Value is constant in time.
	TABLE	Value varies in time.
PRES		Value of inflow or outflow pressure. If PRESTYPE = TABLE it refers to a TABLED1. (Integer or Real)
MID		MATDEUL ID of inflowing material. Input is not allowed for TYPE = OUT. When MID is specified, it is required to also define density and SIE for the inflowing material. (Integer; Default = 0)
DENSTYP		Type of density definition: (Character, Required when MID > 0.)
	ELEMENT	Value of Euler element
	CONSTANT	Value is constant in time
	TABLE	Value varies in time
DENSITY		Value of density. If DENSTYP = TABLE, it refers to a TABLED1 ID. (Integer or Real, Required when MID is given.)
SIETYPE		Type of density definition. Required when MID is given. (Integer or Real)
	ELEMENT	Value of Euler element.
	CONSTANT	Value is constant in time.
	TABLE	Value varies in time.
SIE		Value of specific internal energy. If SIETYPE = TABLE it refers to a TABLED1. Required when MID is given. (Integer or Real)

**Remarks:**

1. Reference FID by a LEAKAGE entry.
2. Any material properties not specifically defined have the same value as the element that the segment of the coupling surface is intersecting.
3. The surface can be only a general coupling surface (see the COUPLE entry).
4. Alternative methods are available to define holes and permeable sections in an air bag. See the entries: LEAKAGE, PORHOLE, PERMEAB, PORFGBG and PERMGBG.
5. In the case of material flow into a multi-material Euler mesh, the material number, the density and specific energy have to be set. On the other hand when material flows out of a multi-material Euler mesh it is assumed that each of the materials present in the outflow Euler element contributes to the out flow of mass. The materials are transported in proportion to their relative volume fractions

6. The boundary condition initiates/determines a wave in compressible material like gas and water. This can be either an outgoing or an ingoing wave. For stability it is important that the waves created are compatible with the flow type near the boundary. Relevant flow types are subsonic inflow, subsonic outflow, supersonic inflow and supersonic outflow. For example for subsonic inflow prescribing both pressure and velocity would initiate outgoing waves. Outgoing waves for an inflow boundary condition is known to be instable. However, for supersonic inflow one can specify both pressure and velocity since there are no outgoing waves at a supersonic inflow boundary.

## PORHOLE

## Holes in Air Bag Surface

Defines a hole in a COUPLE and/or GBAG surface. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PORHOLE	FID	SIZE		FLOW	PENV	RHOENV	SIEENV	CP	
	MID								

### Example:

PORHOLE	301								

Describer	Meaning
PID	Unique number of a PORHOLE entry. (Integer > 0; Required)
SIZE	Defines the type of flow method that is used for mass leaving or entering the airbag volume. (Character; Default = SMALL) <ul style="list-style-type: none"> <li>SMALL      The size of the hole in the surface is the same or smaller than the size of the Euler mesh used. The velocity of the gasflow through the hole is based on the theory of one-dimensional gas flow through a small orifice, and depends on the pressure difference. This is the method that is used if the PORHOLE is used on a GBAG entry.</li> <li>LARGE      The size of the hole in the surface is larger than the Euler mesh used. The velocity of the gasflow through the hole is based on the velocity method for an Eulerian air bag. If the PORHOLE is used on a GBAG entry, it will default back to method used for SIZE=SMALL.</li> </ul>
FLOW	Defines the allowed directions of the flow. (Character; Default = BOTH) <ul style="list-style-type: none"> <li>BOTH      In- and outflow are allowed.</li> <li>IN          Only inflow allowed.</li> <li>OUT        Only outflow allowed.</li> </ul>
PENV	Environmental pressure. (Real > 0.0; Required)
RHOENV	Environmental density. (Real > 0.0; Required)
SIEENV	Environmental specific internal energy. (Real > 0.0; Required)
CP	Environmental specific heat at constant pressure. See Remark 4. (Real > 0.0)
MID	MATDEUL ID number of the environment gas. Only used for an Eulerian air bag that uses the multi-material Euler solver and SIZE=LARGE. See Remark 6. (Integer > 0)

**Remarks:**

1. The PORHOLE entry can be referenced from a LEAKAGE entry.
2. When used with Euler, this entry can only be used with the single material hydrodynamic Euler solver, using an EOSGAM (ideal gas) equation of state.
3. The values for the environment  $p_{env}$  (PENV),  $\rho_{env}$  (RHOENV),  $e_{env}$  (SIEENV) must be defined consistent with an ideal-gas equation of state:

$$p_{env} = (\gamma_{env} - 1)\rho_{env}e_{env}$$

The  $\gamma_{env}$  is calculated and is only used when inflow occurs. Inflow occurs when  $p_{env} > p_{inside}$ .

4. CP is only required if updating of Euler or gasbag gas constants is done, for example if hybrid inflators are defined.
5. For in and out flow of an uniform pressure air bag (GBAG), the material transport is based on the theory of one-dimensional gas flow through a small orifice, and depends on the pressure difference. This is equivalent to the PORHOLE entry.
6. When used in combination with the single material hydrodynamic Euler solver, an EOSGAM (ideal gas) equation of state is required. In that case, the material number, MID, can be left blank. When using the multi-material solver, the material number, MID, has to point to one of the Eulerian materials and the equation of state of that material has to be of type EOSGAM.

## PORHYDS

### Porous Flow Boundary with a Hydrostatic Pressure Profile

Prescribes a hydrostatic pressure profile on a porous BSURE. Used in SOL 700 only.

#### Format:

1	2	3	4	5	6	7	8	9	10
PORHYDS	PID								

#### Example:

PORHYDS	120								
---------	-----	--	--	--	--	--	--	--	--

Describer	Meaning
-----------	---------

PID	Unique number of a PORHYDS entry. (Integer > 0; Required)
-----	---

#### Remarks:

1. Reference PID by a LEAKAGE entry.
2. The surface can be only a general coupling surface (see the COUPLE entry).
3. It is required that the coupling surface refers to a HYDSTAT entry. This HYDSTAT entry will be used to prescribe a hydrostatic pressure profile on the subsurface. For example, the water level and atmospheric pressure are taken from the HYDSTYAT entry. This defines the pressure and the inflow density.
4. In contributions of the surface to the Euler elements the pressure gradient across the surface is taken into account. Therefore splitting up of the surface and creating new PORHYDS entries does not increase the accuracy of prescribed pressures. If the water level and atmospheric pressure are the same in the whole region outside the coupling surface using one PORHYDS entry is sufficient.
5. The atmospheric pressure is prescribed on those parts of the surface that are above the water level.

## PORUDS

User-defined Porosity Model Specified by a User Defined Service.

Defines a porosity model of a COUPLE surface through a user-written subroutine. Use in SOL700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PORUDS	PID	GROUP	UNAME						

### Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE mypor 'SCA.MDSolver.Obj.Uds.Dytran.Flow'
```

*In Bulk Data:*

1	2	3	4	5	6	7	8	9	10
PORUDS	12	mypor	EXPOR						

Describer	Meaning
PID	Unique porosity model ID. (Integer > 0; Required)
GROUP	The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default)
UNAME	User subroutine name associated with the entry. (Character; default=EXPOR)

### Remarks:

1. Only can be used for SOL 700.
2. The porosity ID (PID) must be referenced by a LEAKAGE entry.
3. UNAME can be:

Subroutine Name	Function
EXPOR	Standard user defined flow boundary on the coupling

## PRAC2D

## CRAC2D Element Property

Defines the properties and stress evaluation techniques to be used with the CRAC2D structural element.

### Format:

1	2	3	4	5	6	7	8	9	10
PRAC2D	PID	MID	T	IPLANE	NSM	GAMMA	PHI		

### Example:

PRAC2D	108	2	0.10	0	.17	.50	180.		
--------	-----	---	------	---	-----	-----	------	--	--

### Describer

### Meaning

PID	Property identification number. (Integer > 0)
MID	Material identification number. (Integer > 0)
T	Element thickness. (Real > 0.0)
IPLANE	Plane strain or plane stress option. Use 0 for plane strain; 1 for plane stress. (Integer = 0 or 1, Default = 0)
NSM	Non-structural mass per unit area. (Real $\geq$ 0.0; Default = 0)
GAMMA	Exponent used in the displacement field. See Remark 4. (Real; Default = 0.5)
PHI	Angle (in degrees) relative to the element x-axis along which stress intensity factors are to be calculated. See Remark 4. (Real; Default = 180.0)

### Remarks:

1. PRAC2D is a primary property entry. Primary property entries are grouping entities for many applications in Nastran. Therefore it is highly recommended that the PRAC2D property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PRAC2D entries.
2. PRAC2D entry may refer to MAT1, MAT2, or MAT8 material property entries.
3. For plane strain analysis, only MAT1 type data should be used.
4. Nondefault values for GAMMA and PHI have not been tested. Therefore, the default value should be used.

**PRAC3D****CRAC3D Element Property**

Defines the properties of the CRAC3D structural element.

**Format:**

1	2	3	4	5	6	7	8	9	10
PRAC3D	PID	MID	GAMMA	PHI					

**Example:**

PRAC3D	108	2	.50	180.					
--------	-----	---	-----	------	--	--	--	--	--

**Describer****Meaning**

PID	Property identification number. (Integer > 0)
MID	Material identification number. (Integer > 0)
GAMMA	Exponent used in the displacement field. See Remark 3. (Real; Default = 0.5)
PHI	Angle (in degrees) relative to the element x axis along which stress intensity factors are to be calculated. See Remark 3. (Real; Default = 180.0)

**Remarks:**

1. PRAC3D is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PRAC3D property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PRAC3D entries.
2. Either isotropic (MAT1) or anisotropic (MAT9) material entries may be referenced.
3. Nondefault values for GAMMA and PHI have not been tested. Therefore, the default value should be used.

## PRESAX Conical Shell Pressure Load

Defines the static pressure loading on a conical shell element.

### Format:

1	2	3	4	5	6	7	8	9	10
PRESAX	SID	P	RID1	RID2	PHI1	PHI2			

### Example:

PRESAX	3	7.92	4	3	20.6	31.4			
--------	---	------	---	---	------	------	--	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
P	Pressure value. (Real)
RID1, RID2	Ring identification numbers. See RINGAX entry. (Integer > 0)
PHI1, PHI2	Azimuthal angles in degrees. (Real; PHI2 > PHI1)

### Remarks:

1. PRESAX is allowed only if an AXIC entry is also present.
2. Load sets must be selected with the Case Control command LOAD = SID.
3. For a discussion of the conical shell problem, see [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide*.
4. For axisymmetric loading over 360 degrees, use PHI1 = 0.0 and PHI2 = 360.0.

**PRESPT** Fluid Pressure Point

Defines the location of pressure points in the fluid for recovery of pressure data.

**Format:**

1	2	3	4	5	6	7	8	9	10
PRESPT	IDF	IDP1	PHI1	IDP2	PHI2	IDP3	PHI3		

**Example:**

PRESPT	14	141	0.0			142	90.0		
--------	----	-----	-----	--	--	-----	------	--	--

<b>Describer</b>	<b>Meaning</b>
IDF	Fluid point (RINGFL entry) identification number. (Integer > 0)
IDPi	Pressure point identification number. (Integer > 0)
PHIi	Azimuthal position on fluid point referenced by IDF in fluid coordinate system. (Real)

**Remarks:**

1. PRESPT is allowed only if an AXIF entry is also present.
2. All pressure point identification numbers must be unique with respect to other scalar, structural, and fluid points.
3. The pressure points are used primarily for the identification of output data. They may also be used as points at which to measure pressure for input to control devices.
4. One, two, or three pressure points may be defined per entry.
5. Output requests for velocity and acceleration of these degrees-of-freedom will result in derivatives of pressure with respect to time.

## PRIMx

### Thermal Geometric Primitives for RC Radiation

Specifies the properties of geometric primitives to be used in radiation calculations in place of elements.

#### Format (GEOM2):

1	2	3	4	5	6	7	8	9	10
PRIM1	PRIMID	IVIEWF	IVIEWB	RADMIDF	RADMIDB	SET3ID			
	P1(1)	P1(2)	P1(3)	P2(1)	P2(2)	P2(3)			
	P3(1)	P3(2)	P3(3)	A_mesh	B_mesh				

#### Example:

PRIM1	11	101	102	3	4	2			
	0.	0.	0.	1.	0.	0.			
	0.	1.	0.	3	4				

#### Format:

1	2	3	4	5	6	7	8	9	10
PRIM2	PRIMID	IVIEWF	IVIEWB	RADMIDF	RADMIDB	SET3ID			
	P1(1)	P1(2)	P1(3)	P2(1)	P2(2)	P2(3)			
	P3(1)	P3(2)	P3(3)	P4(1)	P4(2)	P4(3)	A_mesh	B_mesh	

#### Example:

PRIM2	12	102	103	3	4	2			
	0.	0.	0.	1.	0.	0.			
	0.	1.	0.	1.	1.	0.	3	4	

#### Format:

1	2	3	4	5	6	7	8	9	10
PRIM3	PRIMID	IVIEWF	IVIEWB	RADMIDF	RADMIDB	SET3ID			
	P1(1)	P1(2)	P1(3)	P2(1)	P2(2)	P2(3)			
	P3(1)	P3(2)	P3(3)	A_mesh	B_mesh				

#### Example:

PRIM3	13	103	104	3	4	2			
	0.	0.	0.	1.	0.	0.			
	0.	1.	0.	3	4				

**Format:**

1	2	3	4	5	6	7	8	9	10
PRIM4	PRIMID	IVIEWF	IVIEWB	RADMIDF	RADMIDB	SET3ID			
	P1(1)	P1(2)	P1(3)	P2(1)	P2(2)	P2(3)			
	P3(1)	P3(2)	P3(3)	Diam1	Diam2	Angle1	Angle2		
	A_mesh	B_mesh							

**Example:**

PRIM4	14	104	105	3	4	2			
	0.	0.	0.	0.0	1.0	0.			
	0.	0.	1.	1.	0.	60.	180.		
	3	4							

**Format:**

1	2	3	4	5	6	7	8	9	10
PRIM5	PRIMID	IVIEWF	IVIEWB	RADMIDF	RADMIDB	SET3ID			
	P1(1)	P1(2)	P1(3)	P2(1)	P2(2)	P2(3)			
	P3(1)	P3(2)	P3(3)	Diam1	Angle1	Angle2	A_mesh	B_mesh	

**Example:**

PRIM5	15	105	106	3	4	2			
	0.	0.	0.	0.	1.	0.			
	0.	0.	1.	1.	60.	180.	3	4	

**Format:**

1	2	3	4	5	6	7	8	9	10
PRIM6	PRIMID	IVIEWF	IVIEWB	RADMIDF	RADMIDB	SET3ID			
	P1(1)	P1(2)	P1(3)	P2(1)	P2(2)	P2(3)			
	P3(1)	P3(2)	P3(3)	Diam1	Diam2	Angle1	Angle2		
	A_mesh	B_mesh							

**Example:**

PRIM6	16	106	107	3	4	2			
	0.	0.	0.	0.	1.	0.			
	0.	0.	1.	1.	0.	60.	80.		
	3	4							

**Format:**

1	2	3	4	5	6	7	8	9	10
PRIM7	PRIMID	IVIEWF	IVIEWB	RADMIDF	RADMIDB	SET3ID			
	P1(1)	P1(2)	P1(3)	P2(1)	P2(2)	P2(3)			
	P3(1)	P3(2)	P3(3)	Diam1	Angle1	Angle2	Trunc1	Trunc2	
	A_mesh	B_mesh							

**Example:**

PRIM7	17	107	108	3	4	2			
	0.	0.	0.	0.	1.	0.			
	0.	0.	1.	1.	60.	180.	-0.5	0.5	
	3	4							

**Format:**

1	2	3	4	5	6	7	8	9	10
PRIM8	PRIMID	IVIEWF	IVIEWB	RADMID F	RADMID B	SET3ID			
	P1(1)	P1(2)	P1(3)	P2(1)	P2(2)	P2(3)			
	P3(1)	P3(2)	P3(3)	Diam1	Angle1	Angle2	Trunc1	Trunc2	
	A_mesh	B_mesh							

**Example:**

PRIM8	18	108	109	3	4	2			
	0.	0.	0.	0.	1.	0.			
	0.	0.	1.	1.	60.	180.	0.5	1.	
	3	4							

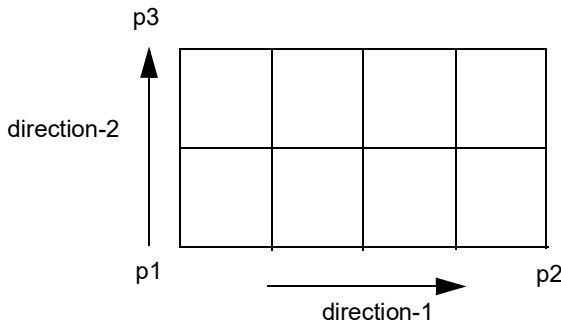

Describer	Meaning
PRIMID	Primitive identification number, unique to all other PRIMx (Integer > 0; Required)
IVIEWF	A VIEW entry identification number for the front face of surface element. (Integer > 0).
IVIEWB	A VIEW entry identification number for the back face of surface element. (Integer > 0).
RADMIDF	RADM identification number for front face of surface element. (Integer > 0).
RADMIDB	RADM identification number for back face of surface element. See Remark 2.. For default. (Integer > 0).

Describer	Meaning
SET3ID	ID of the element collection to which this primitive describes. This collection acts as the elements that will exist in the thermal model, but the collection will be absent from the radiation model. Instead, the primitive will be used to calculate radiation, and be redistributed back onto the elements. All radiation properties for the primitive will be applied to the element collection, and must be consistent across. (Integer > 0; Required)
Pi(a)	The position of point i in the a axis, as described in the correlating picture. For example P2(2) denotes the y coordinate of the second point. Position is always described in global coordinates. (Real; Required)
Diamx	Diameter x of the primitive, if applicable and as described in the correlating picture. (Real ≥ 0.0; Required)
Anglex	Angle x of the primitive in degrees, if applicable and as described in the correlating picture. (0 ≤ Real ≤ 360.0; Required)
Truncx	Truncation x of the primitive, if applicable and as described in the correlating picture. (For PRIM8, Real ≥ 0; Required). (For PRIM7, -0.5*Diam1 ≤ Real ≤ 0.5*Diam1)
A_mesh	Number of mesh spaces in parametric direction-1, as described in the correlating picture. (Integer > 0; Required)
B_mesh	Number of mesh spaces in parametric direction-2, as described in the correlating picture. (Integer > 0; Required)

**Remarks:**

1. This entry is for RC Network solver only.
2. Set 3 should include all the elements which belong to this primitive. It will cause wrong results if only partial of the elements are included.
3. About the primitives

Prim1: Rectangle

Prim2: Quad

Prim3: Triangle

Prim4: Disc

Prim5: Cylinder

Prim6: Cone

Prim7: Sphere

Prim8: Parabolic

**PRJCON** Thermal RC Element Contact

Specifies a thermal connection between two regions of elements. The connection is automatically determined geometrically as a projection of the secondary region on to the primary, and the strength of the connection is calculated based on the properties given.

**Format: (HEAT1)**

1	2	3	4	5	6	7	8	9	10
PRJCON	BID								
	"HEAT1"	SET3 PRIMARY	SET3 SECNDRY	h					

**Example:**

PRJCON	1								
	HEAT1	1	2	1.2					

**Format: (HEAT2)**

1	2	3	4	5	6	7	8	9	10
PRJCON	BID								
	"HEAT2"	SET3 PRIMARY	SET3 SECNDRY	ID					

**Example:**

PRJCON	1								
	HEAT2	1	2	1001					

**Format: (HEAT3)**

1	2	3	4	5	6	7	8	9	10
PRJCON	BID								
	"HEAT3"	SET3 PRIMARY	SET3 SECNDRY	F	Emis Primary	Emis Secndry			

**Example:**

PRJCON	1								
	HEAT3	1	2	1.	0.85	0.5			

**Format: (HEAT4)**

1	2	3	4	5	6	7	8	9	10
PRJCON	BID								
	"HEAT4"	SET3 PRIMARY	SET3 SECNDRY	F	RADC ID Primary	RADC ID Secndry			

**Example:**

PRJCON	1								
	HEAT4	1	2	1.	1001	1002			

Describer	Meaning
BID	BCBODY identification number (Integer > 0; Required)
HEATx	Indicates the start of HEAT elements (Character)
SET3 Primary	ID of the primary element collection for connection (Integer > 0; Required)
SET3 Secondary	ID of the secondary element collection for connection (Integer > 0; Required)
h	Convection correlation (Real $\geq 0.0$ ; Required for HEAT1)
PCONID	PCONID of the property to be used for h value. (Integer > 0; Required for HEAT2)
F	View factor between parts ( $0.0 \leq \text{Real} \leq 1.0$ ; Required for HEAT3 & HEAT4)
Emis Primary	Emissivity of primary collection (Real $\geq 0.0$ ; Required for HEAT3)
Emis Secndry	Emissivity of secondary collection (Real $\geq 0.0$ ; Required for HEAT3)
RADC id Primary	RADMID of the material to be used for primary emissivity value. (Integer > 0; Required)
RADC id SECNDRY	RADMID of the material to be used for secondary emissivity value. (Integer > 0; Required)

**Remarks:**

1. This “HEATx” and the later parameters are for RC Network solver only.
2. For HEAT2, PCONID must refer to a PCONV1 type and not a PCONV or PCONVM.
3. RC Network Solver uses a projection method to determine the connection (not the “nearest neighbor method”. In most of the cases, the projection method is more accurate than the nearest neighbor method.

**PROD**

## Rod Property

Defines the properties of a rod element (CROD entry).

**Format:**

1	2	3	4	5	6	7	8	9	10
PROD	PID	MID	A	J	C	NSM			

**Example:**

PROD	17	23	42.6	17.92	4.2356	0.5			
------	----	----	------	-------	--------	-----	--	--	--

**Describer****Meaning**

PID	Property identification number. (Integer > 0)
MID	Material identification number. See Remarks 2. and 3. (Integer > 0)
A	Area of the rod. (Real)
J	Torsional constant. (Real)
C	Coefficient to determine torsional stress. (Real; Default = 0.0)
NSM	Nonstructural mass per unit length. (Real)

**Remarks:**

1. PROD is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PROD property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PROD entries.
2. For structural problems, MID must reference a MAT1 material entry.
3. For heat transfer problems, MID must reference a reference MAT4 or MAT5 entry.
4. The formula used to calculate torsional stress is

$$\tau = \frac{CM_{\theta}}{J}$$

where  $M_{\theta}$  is the torsional moment.

## PRODN1

## Nonlinear Property Extensions for a PROD Entry

Specifies additional nonlinear properties for elements that point to a PROD entry in SOL 400.

### Format:

1	2	3	4	5	6	7	8	9	10
PRODN1	PID	MID			ANAL				
	"C2"	BEH2	INT2	BEH2H	INT2H				

### Example:

PRODN1	22	98							
--------	----	----	--	--	--	--	--	--	--

### Describer

### Meaning

PID	Property identification number of an existing PROD entry. (Integer > 0)
MID	Material identification number. Remarks 7. (Integer ≥ 0)
ANAL	Analysis type. ANAL='IS' - Implicit structural elements are being referred to. ANAL='IH' - Implicit heat analysis elements are being referred to. ANAL='ISH' - Implicit structural and heat elements are being referred to. (Character Default ISH).
C2	Keyword indicating that items following apply to elements with two end grids. (Character)
BEH2	Element structural behavior. See Remark 4. (Character Default ROD)
INT2	Integration scheme. See Remarks 4. and 5. (Character Default L)
BEH2H	Element heat behavior. See Remark 4. (Character Default ROD)
INT2H	Integration scheme. See Remarks 4. and 5. (Character Default L)

### Remarks:

1. The PID above must point to an existing PROD Bulk Data entry and is honored only in SOL 400.
2. MID if blank (or 0) use the MID value on the PROD entry. If > 0 it will override the MID value on the PROD.
3. The MID entry may point to the MAT1 entry. The following table shows associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

**Caution:** The MATVE, MATVP, MATEP, and MATF entries are only associated with a CROD element if the CROD element refers to a PRODN1 entry.

The MID entry for nonlinear heat may point to MAT4 or MAT5 entries.

Implicit Structural Materials
MAT1
MATVE
MATVP
MATEP
MATF
MATS1

Heat Materials	
MAT4	MAT5

If heat analysis is being performed and the user wishes to override standard Nastran heat elements, the ANAL entry must be set to IH or ISH.  
 If ISH is specified then the MAT1 and MAT4 or MAT1 and MAT5 must have the same ID.  
 MID for structure entries must follow the uniqueness rules of the MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, MATHP, MATHE, and MATG entries.  
 MID for heat entries must follow the uniqueness of the MAT4 and MAT5 entries.

4. BEH2/BEH2H refers to the nonlinear structural/heat behavior of the ROD element. An underlined item delineates default.

Structural/Heat Classification of Elements				
Element Structural/Heat Type	BEH2/BEH2H CODE	Integration Code	Element Type	# Nodes
Rod	ROD	<u>L</u>	ROD	2

5. Integration codes in Remark 4. are:

INT CODE	Integration Type
L	Linear

6. Any J, C, or NSM value on the PROD will be ignored.
7. The structural element damping coefficient, GE, is not supported on elements which reference PRODN1.

## PSEAM

## CSEAM Property

Defines the PSEAM property values.

### Format:

1	2	3	4	5	6	7	8	9	10
PSEAM	PID	MID	TYPE	W	T	IN			

### Example:

PSEAM	7	1		16.					
-------	---	---	--	-----	--	--	--	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number. (Integer > 0)
TYPE	“KEYWORD” type of Seam Weld generated. (Character; Default = LINE)
W	Width of the SEAM. See Remark 1. (Real > 0.)
T	Thickness of the SEAM. See Remark 2. (Real > 0. or blank)
IN	Integration scheme. See Remark 6. of PSOLID entry. (Integer 0 or 2; Default = 2) If IN = 0, 2x2x2 reduced shear integration with bubble functions. If IN = 2, 2x2x2 reduced shear integration.

### Remarks:

1. The length of the SEAM is the distance between GS and GE. The width  $W$  of the SEAM is measured perpendicular to the length and lies in the plane of the patches A and B (see [Figure 9-136](#)). The width is also used to find the projection of the SEAM on the two patches A and B.

Figure 9-136 Dimensions of a CSEAM Element

2. If left blank, the thickness will be computed as  $T = (T_A + T_B)/2$  where  $T_A$  is the thickness of patch A and  $T_B$  is the thickness of patch B.

3. PSEAM is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PSEAM property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PSEAM entries.

## PSHEAR Shear Panel Property

Defines the properties of a shear panel (CSHEAR entry).

### Format:

1	2	3	4	5	6	7	8	9	10
PSHEAR	PID	MID	T	NSM	F1	F2			

### Example:

PSHEAR	17	23	42.6	17.92	4.236	0.5			
--------	----	----	------	-------	-------	-----	--	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Material identification number of a MAT1 entry. (Integer > 0)
T	Thickness of shear panel. (Real ≠ 0.0)
NSM	Nonstructural mass per unit area. (Real)
F1	Effectiveness factor for extensional stiffness along edges 1-2 and 3-4. See Remark 2. (Real ≥ 0.0; Default = 0.0)
F2	Effectiveness factor for extensional stiffness along edges 2-3 and 1-4. See Remark 2. (Real ≥ 0.0; Default = 0.0)

### Remarks:

1. PSHEAR is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PSHEAR property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PSHEAR entries.
2. The effective extensional area is defined by means of equivalent rods on the perimeter of the element. If  $F1 \leq 1.01$ , the areas of the rods on edges 1-2 and 3-4 are set equal to  $(F1 \cdot T \cdot PA) / (L12 + L34)$  where PA is the panel surface area-half the vector cross product area of the diagonals-and L12, L34 are the lengths of sides 1-2 and 3-4. Thus, if  $F1 = 1.0$ , the panel is fully effective for extension in the 1-2 direction. If  $F1 > 1.01$ , the areas of the rods on edges 1-2 and 3-4 are each set equal to  $0.5 \cdot F1 \cdot T^2$ .

Figure 9-137 Extensional Area for Shear Panel

Thus, if  $F1 = 30$ , the effective width of skin contributed by the panel to the flanges on edges 1-2 and 3-4 is equal to  $15T$ . The significance of  $F2$  for edges 2-3 and 1-4 is similar.

3. Poisson's ratio coupling for extensional effects is ignored.
4. The parameter entry MDLPRM,SHEARP,GARVEY(default) selects the standard Garvey shear panel. MDLPRM,SHEARP,HARDER selects the Harder shear panel: See Remark 4. of the CSHEAR entry.

## PSHEARN

## Nonlinear Property Extensions for a PSHEAR Entry

Specifies nonlinear properties for elements that point to a PSHEAR entry in SOL 400.

### Format:

1	2	3	4	5	6	7	8	9	10
PSHEARN	PID	MID			ANAL				
	"C4"	BEH4	INT4						

### Example:

PSHEARN	22	18							
---------	----	----	--	--	--	--	--	--	--

### Describer

### Meaning

PID	Property identification number of an existing PSHEAR entry. (Integer > 0)
MID	Material identification number. Remark 9. (Integer ≥ 0 or blank)
ANAL	Analysis type. ANAL = 'IS' - Implicit structural elements are being referred to. (Character: Default IS)
C4	Keyword indicating that two items following apply to elements with four corner grids. (Character)
BEH4	Element structural behavior. See Remark 5. (Character Default MB)
INT4	Integration scheme. See Remarks 4. and 6. (Character Default L)

### Remarks:

1. The PID must point to an existing PSHEAR Bulk Data entry and is honored only in SOL 400.
2. Only large membrane rotation is supported. Stringer effectiveness is ignored and only membrane action is considered.
3. MID if blank (or 0) use the MID value on the PSHEAR entry. If > 0 is will override the MID value on the PSHEAR.
4. The MID entry for nonlinear structures may point to the MAT entry. The following table shows associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

Caution: The MATVE, MATVP, MATEP, MATF and MATSMA entries are only associated with a CSHEAR element if the CSHEAR element refers to a PSHEARN entry.

Implicit Structure Materials
MAT1
MATVE
MATVP
MATEP
MATF
MATS1
MATSMA

5. BEH4 refers to the nonlinear structural behavior of the SHEAR element. An underlined item delineates default.

Structural Classification of Elements				
Element Structural Type	BEH2/BEH2H CODE	Integration Code	Element Type	# Nodes
SHEAR	MB	<u>L</u>	SHEAR	4

6. Integration codes in Remark 4. are:

INT CODE	Integration Type
L	Linear

7. For creep material defined through MATVP, VALC=0 must be set on NLMOPTS, for explicit formulation.
8. For shape memory materials defined through MATSMA, only the thermo-mechanical model is available.
9. The structural element damping coefficient, GE, is not supported on elements which reference PSHEARN.

## PSHELL Shell Element Property

Defines the membrane, bending, transverse shear, and coupling properties of thin shell elements.

### Format:

1	2	3	4	5	6	7	8	9	10
PSHELL	PID	MID1	T	MID2	12I/T**3	MID3	TS/T	NSM	
	Z1	Z2	MID4						

### Example:

PSHELL	203	204	1.90	205	1.2	206	0.8	6.32	
	+.95	-.95							

### Describer

### Meaning

PID	Property identification number. (Integer > 0)
MID1	Material identification number for the membrane. (Integer ≥ 0 or blank)
T	Default membrane thickness for Ti on the connection entry. If T is blank then the thickness must be specified for Ti on the CQUAD4, CTRIA3, CQUAD8, and CTRIA6 entries. (Real or blank) Average thickness if TFLAG = 1 ( $T_i = T_i \cdot T$ ).
MID2	Material identification number for bending. (Integer ≥ -1 or blank)
12I/T**3	Bending moment of inertia ratio, $12I/T^3$ . Ratio of the actual bending moment inertia of the shell, $I$ , to the bending moment of inertia of a homogeneous shell, $T^3/12$ . The default value is for a homogeneous shell. (Real > 0.0; Default = 1.0)
MID3	Material identification number for transverse shear. If MID2 is blank or -1, then MID3 must be blank. (Integer > 0 or blank)
TS/T	Transverse shear thickness ratio, $T_s/T$ . Ratio of the shear thickness, ( $T_s$ ), to the membrane thickness of the shell, $T$ . The default value is for a homogeneous shell. (Real > 0.0; Default = .833333)
NSM	Nonstructural mass per unit area. (Real)
Z1, Z2	Fiber distances for stress calculations. The positive direction is determined by the right-hand rule, and the order in which the grid points are listed on the connection entry. See Remark 11. for defaults. (Real or blank)
MID4	Material identification number for membrane-bending coupling. See Remarks. (Integer > 0 or blank, must be blank unless MID1 > 0 and MID2 > 0, may not equal MID1 or MID2.)

**Remarks:**

1. PSHELL is a primary property entry. Primary properties are used to internally group entities. Therefore it is highly recommended that PSHELL entries use unique identification numbers (PIDs) with respect to all other property entries to avoid unexpected grouping results. PSHELL, PCOMP, and PCOMPG entries must have unique PIDs.
2. The structural mass is calculated from the density using the membrane thickness and membrane material properties. If MID1 is blank, then the density is obtained from the MID2 material.
3. The results of leaving an MID<sub>i</sub> field blank (or MID2 = -1) are:

MID1	No membrane or coupling stiffness
MID2	No bending, coupling, or transverse shear stiffness
MID3	No transverse shear flexibility
MID4	No bending-membrane coupling unless ZOFFS is specified on the connection entry. See Remark 6.
MID2=-1	See Remark 12.

**Note:** MID1 and MID2 must be specified if the ZOFFS field is also specified on the connection entry.

4. The continuation entry is not required.
5. The structural damping (GE on the MAT<sub>i</sub> entry) is obtained from the MID1 material. If MID1 is blank, then it is obtained from the MID2 material. If PARAM,SHLDAMP,DIFF is set or is anything other than SAME, then the structural damping  $K^4$  matrix is computed using the GE entries on the MAT<sub>i</sub> entries according to rules in the following table (Table 28). If a single PSHELL corresponds to row eight (8) of Table 28, then all PSHELLs in the model will follow the rule of row eight (8). Rows 1-7 is an attempt to maintain upward compatibility, if a user inadvertently places a SHLDAMP,DIFF in the model.

**Note:** Large values of damping associated with an MID4 entry, when using PARAM,SHLDAMP,DIFF, can cause structural instability in transient dynamics.

Table 28 SHELL Structural Damping Rules

SHELL Structural Damping Rules					
Row	MID1	MID2	MID3	MID4	$K^4$ based on
1*	v	v			GE on MID1
2	v				
3	v	-1			
4	v	v			
5		v			GE on MID2
6		v	v		GE on MID1 if  $n = m$ and $ge_i = ge_2 = \dots = ge_m$ or $m = 1$ and $ge_1 \neq 0$ or $m = 0$  where: $n$ is total number of non blank MIDi (vi) $m$ is total number of non zero $ge_i$
7	v1	v2	v3	v4	
8	v1	v2	v3	v4	Otherwise:  $GE = ge_1 \cdot \text{membrane-stiff} +$ $ge_2 \cdot \text{bending-stiff} +$ $ge_3 \cdot \text{transverse shear-stiff} +$ $ge_4 \cdot \text{bending-membrane-stiff}$
* v $\rightarrow$ MIDi values the same; vi $\rightarrow$ MIDi values different or blank $ge_i \rightarrow$ GEvalue from a MATj entry associated with MIDi					
If for row eight (8), a $ge_i = 0$ , it is replaced by $ge_i = 1.0E-8$					

PSHELL rules with extended MAT2 entries
The PSHELL has four MIDi entries: MID1-Membrane; MID2-Bending; MID3-Transverse Shear; MID4-Membran-Bending Coupling.
The Damping for shell elements is determined by the GE value associated to the material entry specified by MID1 (or MID2 if MID1 is blank).
PSHELL allows any of its MIDi fields to use any combination of MAT1, MAT2, or MAT8 material entries.
The MAT2 entry has a feature consisting of six (6) structural damping coefficients called GE11, GE12, GE13, GE22, GE23, and GE33 in a <i>second continuation entry</i> . When any one or more of these GEij entries are non-zero, the GE entry in field six (6) of the first continuation entry is ignored for that material.

PSHELL rules with extended MAT2 entries	
<p>MAT2 entries with any GEij are called <i>extended</i> MAT2 entries. The damping is computed for such a material as <math>G_{ij} = G_{ij} * GE_{ij}</math> where <math>G_{ij}</math> are the elastic material coefficients on the parent MAT2 entry. An element structural damping matrix is then generated using these scaled <math>G_{ij}</math>.</p> <p>Any PSHELL with an <i>extended</i> MAT2 in the MID1 field assumes that every MID2 and MID4 present will performs a <math>G_{ij} = G_{ij} * GE_{ij}</math> calculation to form the appropriate structural damping matrix. The MID3 calculation is of the form <math>J_{11} = J_{11} * GE_{11}</math>, <math>J_{12} = J_{12} * GE_{12}</math>, and <math>J_{22} = J_{22} * GE_{22}</math>.</p>	
1	<p>For the case where MID1 is <i>extended</i> (is a reference to a MAT2 with GEij defined) but MID2, MID3, and/or MID4 contain a MAT1, a non-<i>extended</i> MAT2, or a MAT8 entry the calculation is of the form <math>G_{ij} = G_{ij} * GE</math> where GE is the structural damping coefficient of the associated MAT1, MAT2, or MAT8 entry.</p>
2	<p>For the case where MID1 is a MAT1, a non-<i>extended</i> MAT2, or a MAT8, but any one of the MID2, MID3, or MID4 fields have <i>extended</i> MAT2 entries, the structural damping coefficient GE of the MATi entry is used to simply scale the element stiffness as <math>K4</math> matrix contribution <math>? GE * K</math>.</p>
3	<p>For case two (2) above, the user has the option of using PARAM,SHLDAMP,DIFF in which case any MID2, MID3, or MID4 containing an <i>extended</i> MAT2 entry force the use or the extended fields. HOWEVER, remember the PARAM,SHLDAMP,DIFF is global – meaning EVERY PSHELL scales each of its MIDi material by the appropriate GEij or GE to form an element structural damping matrix.</p>

6. The following should be considered when using MID4.
  - The MID4 field should be left blank if the material properties are symmetric with respect to the middle surface of the shell. If the element centerline is offset from the plane of the grid points but the material properties are symmetric, the preferred method for modeling the offset is by use of the ZOFFS field on the connection entry. Although the MID4 field may be used for this purpose, it may produce ill-conditioned stiffness matrices (negative terms on factor diagonal) if done incorrectly.
  - Only one of the options MID4 or ZOFFS should be used; if both methods are specified the effects are cumulative. Since this is probably not what the user intends, this may results in unexpected answers. Note that the mass properties are not modified to reflect the existence of the offset when the ZOFFS and MID4 methods are used. If the weight or mass properties of an offset plate are to be used in an analysis, the RBAR method must be used to represent the offset. See [Shell Elements \(CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, CQUADR\)](#) in the *MSC Nastran Reference Guide*.
  - The effects of MID4 are not considered in the calculation of differential stiffness. Therefore, it is recommended that MID4 be left blank in buckling analysis.
7. This entry is referenced by the CTRIA3, CTRIA6, CTRIAR, CQUAD4, CQUAD8, and CQUADR entries via PID.
8. For structural problems, MIDi must reference a MAT1, MAT2, or MAT8 material property entry

9. If the transverse shear material MID3 or the membrane-bending coupling term MID4 references a MAT2 entry, then G33 must be zero. If MID3 references a MAT8 entry, then G1Z and G2Z must not be zero.
10. For heat transfer problems, MIDi must reference a MAT4 or MAT5 material property entry.
11. The default for Z1 is  $-T/2$ , and for Z2 is  $+T/2$ . T is the local plate thickness defined either by T on this entry or by membrane thicknesses at connected grid points, if they are input on connection entries.
12. For plane strain analysis, set MID2=-1 and set MID1 to reference a MAT1 entry. In-plane loads applied to plain strain elements are interpreted as line-loads with a value equal to the load divided by the thickness. Thus, if a thickness of "1.0" is used, the value of the line-load equals the load value. Pressure can be approximated with multiple line loads where the pressure value equals the line-load divided by the length between the loads. For SOL 600, plain strain models must be in the basic coordinate system X-Y plane.
13. For a material nonlinear property, MID1 must reference a MATS1 entry and be the same as MID2, unless a plane strain (MID2 = -1) formulation is desired. Also, MID3 cannot reference a MATS1 entry.
14. If transverse shear flexibility is specified for a model with curved shells where the loading is dominated by twist and shell normals are turned off (e.g., PARAM,SNORM,-1), then results may be inaccurate and may diverge when the mesh is refined. PARAM,SNORM should be set for this unique model condition.
15. For 3D contact analysis, MID2 must be non-zero and for 2D contact analysis, MID1 must be non-zero.

## PSHELL1

### Properties of shell elements for SOL 700 only

Defines the properties of shell elements with variable shell thickness for SOL 700 only.

#### Format:

1	2	3	4	5	6	7	8	9	10
PSHELL1	PID	MID	FORM	QUAD	NUMB	SHFACT	REF	SPINCOR	
+	T1	T2	T3	T4	TRANSHR	SHRLCK			

#### Example:

PSHELL1	7	2	BLT	GAUSS	5	0.9			
	10.0	10.0	10.0	10.0					

Describer	Meaning
PID	Unique property number. (Integer; Required)
MID	Material number. See Remark 2. (Integer; Required)
FORM	Shell formulation. See Remark 2. (Character; Required)
	HUGHES     Hughes-Liu
	BLT             Belytschko-Lin-Tsay
	KEYHOFF     Key-Hoff
	C0-TRIA     C0 triangle
	MEMB         Membrane element (no bending)
	DUMMY        Dummy element (only applicable for FSI coupling)
QUAD	Type of quadrature. (Character; Default = GAUSS)
	GAUSS         Gauss quadrature
	LOBATTO     Lobatto quadrature
NUMB	The number of integration points through the thickness. (Integer; Default = 3 for quadrature). 1 for membrane element. Maximum value is 5.
SHFACT	Shear factor. (Real; Default = 0.83333)
REF	Reference surface. (character, default=MID)
	TOP            Reference surface is the top surface.
	MID            Reference surface is the central surface.
	BOT            Reference surface is the bottom surface.
SPINCOR	Spin correction. See Remark 5. (Character; default=NO)
	NO              No SPINCOR applied

Describer	Meaning
	YES            SPINCOR is applied
T1 toT4	Element thickness at the grid points. See Remark 4. (Real; Default = 0.0)
TRANSHR	Method of transverse-shear calculation. (Character; See Remark 6.)
	LINEAR        Linear transverse shear
	CONSTANT    Constant transverse shear
	CONAPX        Approximated constant transverse shear
SHRLCK	Shear-lock avoidance. (Character; See Remark 6.)
	AVOID         Avoid shear lockup
	NOAVOID      No avoid

**Remarks:**

1. For constant thickness shell element with three-point Gauss integration, PSHELL entry is recommended.
2. For CQUAD4 elements, the default of FORM for formulation is KEYHOFF. For CTRIA3 elements, the default of FORM for formulation is CO-TRIA.
3. Property identification number (PID) must be unique.
4. If the thickness T1 is set to blank or 0.0, the thickness of the shell must be defined on the CTRIA3 and CQUAD4 entry.
5. The options for SPINCOR are:

NO                No SPINCOR correction is applied.  
 YES                SPINCOR correction is applied.

When SPINCOR = NO, slight asymmetric forces are applied to the shell element's grid points. This approach is, in general, acceptable up to about 10° in plane shear angle.

6. The following defaults apply:

	BLT	HUGHES	KEYHOFF
TRANSHR	Not Available	Not Available	LINEAR
SHRLCK	NOAVOID	Not Available	AVOID

## PSHLN1

## Nonlinear Property Extensions for a PSHELL or PCOMP(G) Entry

Specifies additional nonlinear properties for shell elements that point to a PSHELL or PCOMP(G) entry in SOL 400.

### Format:

1	2	3	4	5	6	7	8	9	10
PSHLN1	PID	MID1	MID2		ANAL				
	"C3"	BEH3	INT3	BEH3H	INT3H				
	"C4"	BEH4	INT4	BEH4H	INT4H				
	"C6"	BEH6	INT6	BEH6H	INT6H				
	"C8"	BEH8	INT8	BEH8H	INT8H				

### Example:

PSHLN1	22	98							
--------	----	----	--	--	--	--	--	--	--

Descriptor	Meaning
PID	Property identification number of an existing PSHELL or PCOMP(G) entry. (Integer > 0)
MID1	Membrane material identification number. See Remark 17. (Integer $\geq 0$ or blank)
MID2	Bending material identification number. See Remark 17. (Integer $\geq 0$ or blank)
ANAL	Analysis type. ANAL = 'IS' - Implicit structural elements are being referred to. ANAL = 'IH' - Implicit heat analysis elements are being referred to. ANAL = 'ISH' - Implicit structural and heat elements are being referred to. (Character Default ISH)
C3	Keyword indicating that two items following apply to elements with three corner grids. (Character)
C4	Keyword indicating that two items following apply to elements with four corner grids. (Character)
C6	Keyword indicating that items following apply to elements with three corner grids and three midside grids. (Character)
C8	Keyword indicating that two items following apply to elements with four corner grids and four midside grids. (Character)
BEHi	Element structural behavior. See Remark 12. (Character Default: DCTN for BEH3, DCT for BEH4, and DCT for BEH8, MB for BEH6)
INTi	Integration scheme. See Remarks 11. and 13. (Character Default: LDK for INT3, L for INT4, QRI for INT8, Q for INT6)

Describer	Meaning
BEHiH	Element heat behavior. See Remark 12. (Character Default: DCT for BEH3H, BEH4H, and BEH8H, MB for BEH6H)
INTiH	Integration scheme. See Remarks 11. and 13. (Character Default: L for INT3H, L for INT4H, Q for INT8H and INT6H)

**Remarks:**

- The PID must point to an existing PSHELL, PCOMP, or PCOMPG Bulk Data entry and is honored only in SOL 400.
- The keyword entries may occur in any order or not at all. If a keyword entry is missing, its defaults are assumed.
- MID1 if blank (or 0) use the MID1 value on the PSHELL. If > 0 it will override the MID1 value on the PSHELL. MID1 is ignored for PCOMP/PCOMPG.
- MID2:
  - If BEHi = DCT or DCTN: If blank (or 0) use the MID2 value on the PSHELL. If > 0 it will override the MID2 value on the PSHELL. If MID2 = -1 on the PSHELL entry it must be replaced with a positive value MID2 entry or the PSHELL should be replaced with a PLPLANE entry and a PSHLN2 entry should be used instead of a PSHLN1 entry.
  - If BEHi = MB: MID2 on both the PSHELL and PSHLN1 entries are ignored. MID2 is ignored for PCOMP/PCOMPG.
- The MID1 or MID2 entries, were applicable, may point to MAT1, MAT2, MAT8, MATHE and MATSMA entries. The table below shows associated nonlinear entries. The association is established through the material entries having the same values as the MID1 or MID2 entries.

Caution: The primary MATHE and the secondary MATVE, MATVP, MATEP, MATF, and MATS8 entries are only associated with a Shell (CQUAD4, CQUADR, CQUAD8, CTRIA3, CTRIAR, or CTRIA6) element if the Shell element refers to a PSHLN1 entry.

The MID entry for nonlinear heat may point to MAT4 or MAT5 entries.

Implicit Structural Materials			
MAT1	MAT2	MAT8	MATHE
MATVE	<MATVE>	<MATVE>	MATVE
MATVP	MATVP		
MATEP	MATEP	MATEP	
MATF	MATF	MATF	
MATS1		MATS8	
<MATVE> refers to the ALTERNATE format for type ORTHO			

6. If MID3 is not specified on the PSHELL, BEH4 = DCTN with INT4 = LDK should be used and any CQUAD8 elements using this PSHELL should have a new PSHELL with MID3 specified. If not a fatal message will be issued. MID3 is not used for PCOMP/PCOMPG.
7. If MID2 is not specified on the PSHELL or overridden with a nonzero value on the PSHLN1, BEH4 = MB. and BEH8 = MB. If not, a fatal message will be issued.

Heat Materials	
MAT4	MAT5

If heat analysis is being performed and the user wishes to override standard Nastran heat elements, the ANAL entry must be set to IH or ISH.  
 If ISH is specified then the MAT1 and MAT4 or MAT1 and MAT5 must have the same ID. MID for structure entries must follow the uniqueness rules of the MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, MATHP, MATHE, and MATG entries.  
 MID for heat entries must follow the uniqueness rules of the MAT4 and MAT5 entries.

8. NSM is not currently supported when this entry is used.
9. When this entry points to a PCOMP or a PCOMPG, special restrictions should be noted for some of the PCOMP/PCOMPG entries:
  - NSM, FT and GE are not supported. If a failure theory for any ply defined on the PCOMP/PCOMG entry is required, a MATF entry should be specified for the associated material.
  - The allowable inter-laminar bond strength SB is supported. When used in conjunction with the parabolic shear option (NLMOPTS, TSHEAR), the provided value of SB is used to calculate the ply shear bond index for thick shells using the relation - Bond index = max(inter-laminar shear stress)/SB.
  - LAM=BLANK and LAM=SYM (only for PCOMP) are supported. No smearing i.e., conversion of PCOMP/PCOMG into equivalent PSHELL is supported. Conventional integration through the thickness and across all layers is used. LAM=MEM, BEND, SMEAR and SMCORE are treated in a manner similar to LAM=BLANK, i.e., the sequence of the plies and the data given for each ply is used to carry out the conventional thickness integration.
  - SOUTi is not supported for individual plies. If STRESS output is requested for a particular shell element, then integration point stresses and elastic strains in the material coordinate system for all plies of the element are printed. If the parabolic shear option is used, then integration point values of the inter-laminar stresses and the bond index are also printed.
  - Layer Composite (PCOM/PCOMG) is not supported to CTRAI6 by PSHLN1.
10. If BEHi = MB is selected on PSHLN1, any ZOFF entry on the element connection entry will be ignored with a user warning.
11. In the following table, BEHi refers to the nonlinear structural behavior of shell elements. An underlined item delineates a default.

Implicit Structural Classification of Elements				
Element Structural Type	BEHi CODE	Integration Code	Element Type	# Nodes
Doubly-curved thick shell	DCT	<u>L</u>	QUAD	4
		<u>QRI</u>	QUAD	8
		LRIH	QUAD	4
Doubly-curved thin shell	DCTN	<u>LDK</u>	TRIA	3
		LDK	QUAD	4
Membrane three-dimensional	MB	L	QUAD	4
		Q	QUAD	8
		L	TRIA	3
		<u>Q</u>	TRIA	6

12. In the following table, BEHiH refers to the nonlinear heat behavior of shell elements. An underlined item delineates a default.

Heat Classification of Elements				
Element Heat Type	BEHiH CODE	Integration Code	Element Type	# Nodes
Doubly-curved thick shell	DCT	L	QUAD	4
		Q	QUAD	8
		L	TRIA	3
Membrane three-dimensional	MB	L	QUAD	4
		Q	QUAD	8
		L	TRIA	3
		<u>Q</u>	TRIA	6

13. Integration codes in Remark 11. are:

INT CODE	Integration Type
L	Linear
LRIH	Linear Reduced Integration Hourglass control (assumed strain)
Q	Quadratic
QRI	Quadratic Reduced Integration
LDK	Linear Discrete Kirchhoff

14. Smear shell formulation will be used in case MID1 and MID2 are different from one another or different from MID3 used on the corresponding PSHELL entry. Smear shell formulation allows membrane, bending and transverse shear properties to be defined independently, however, it is limited to linear elastic material behavior only.
15. For creep material defined through MATVP, VALC=0 must be set on NLMOPTS, for explicit formulation if BEH=PSTRS.
16. For shape memory materials defined through MATSMA, only the thermo-mechanical model is available if BEH=PSTRS.
17. Structural damping is supported for elements which reference PSHLN1. The structural damping coefficient, GE, is supported for elements using the MAT1 entries.

**PSHLN2****Nonlinear Property Extensions for a PLPLANE Entry**

Specifies additional nonlinear properties for plane strain, plane stress, or axisymmetric elements that point to a PLPLANE entry in SOL 400.

**Format:**

1	2	3	4	5	6	7	8	9	10
PSHLN2	PID	MID	DIRECT	T	ANAL				
	"C3"	BEH3	INT3	BEH3H	INT3H				
	"C4"	BEH4	INT4	BEH4H	INT4H				
	"C6"	BEH6	INT6	BEH6H	INT6H				
	"C8"	BEH8	INT8	BEH8H	INT8H				

**Example:**

PSHLN2	22	98							
--------	----	----	--	--	--	--	--	--	--

Descriptor	Meaning
PID	Property identification number of an existing PLPLANE entry. (Integer > 0)
MID	Material identification number. Remarks 13. (Integer > 0)
DIRECT	The layer direction for BEHi=COMPS or AXCOMP. See Remark 6. (Integer = 1 or 2; Default = 1)
T	A thickness. (Real; Default = 1.0)
ANAL	Analysis type. ANAL = 'IS' - Implicit structural elements are being referred to. ANAL = 'IH' - Implicit heat analysis elements are being referred to. ANAL = 'ISH' - Implicit structural and heat elements are being referred to. (Character Default ISH)
C3	Keyword indicating that two items following apply to elements with three corner grids. (Character)
C4	Keyword indicating that two items following apply to elements with four corner grids. (Character)
C6	Keyword indicating that two items following apply to elements with three corner grids and three midside grids. (Character)
C8	Keyword indicating that two items following apply to elements with four corner grids and four midside grids. (Character)
BEHi	Element structural behavior. See Remark 7. (Character Default: PLSTRN for BEH3, BEH4, BEH6, and BEH8)
INTi	Integration scheme. See Remarks 7. and 10. (Character Default: L for INT3, INT4, Q for INT6 and INT8)

Describer	Meaning
BEHiH	Element heat behavior. See Remark 9. (Character Default: PLSTRN for BEH3H, BEH4H, BEH6H, and BEH8H.
INTiH	Integration scheme. See Remarks 9. and 10. (Character Default: L for INT3H, L for INT4H, Q for INT6H and INT8H)

**Remarks:**

1. The PID must point to an existing PLPLANE Bulk Data entry and is honored only in SOL 400. Since these are additional nonlinear properties to the PLPLANE, the PLPLANE must still have an associated MATHP.
2. It is REQUIRED to override the MID value on the PLPLANE entry.
3. The element must lie in the x-y plane of the basic system. The CID field of the PLPLANE entry is not valid for this entry.
4. The MID entry may point to MAT1, MAT3, MATHORT, MATHE, MATG or MATSMA entry and MUST be used to override the MID field on a PLPLANE entry. The following table shows associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

Caution: The primary MAT1, MAT3, MAT8, MATORT, MATHE, and MATG entries and the secondary MATVE, MATVP, MATEP, MATF, MATS1, MATS3, MATS8, and MATSORT entries are only associated with a 2D or axisymmetric (CQUAD4, CQUAD, CQUAD8, CTRIA3, or CTRIA6) or (CTRIAX or CQUADX) element if the element refers to a PSHLN2 entry.

Implicit Structural Materials							
MAT1	MAT2	MAT3	MAT8	MATORT	MATHE	MATG	MATHP
MATVE	<MATVE>	<MATVE>	<MATVE >	<MATVE>	MATVE		
MATVP	MATVP	MATVP		MATVP			
MATEP	MATEP	MATEP	MATEP	MATEP			
MATF	MATF	MATF	MATF	MATF			
MATS1		MATS3	MATS8	MATSORT			

<MATVE> refers to the ALTERNATE format for type ORTHO  
 MAT1 applicable to all BEHi codes of 7 below, except COMPS and AXCOMP.

MAT3 axisymmetric orthotropic applicable only to BEHi=AXSOLID code of 7 below.

MAT8 orthotropic applicable only to BEHi=PSTRS code of 7 below.

MATG for BEH4=COMPS or AXCOMP; INT4=L only.  
 MATG has an associated field IDMEM that points to a MAT1.

With MATHE, MATHP, and MAT1 (with MATS1 or MATEP) BEH3=IPS or IAX with INT3=L is recommended.

### Heat Materials

MAT4	MAT5
------	------

If heat analysis is being performed and the user wishes to override standard Nastran heat elements, the ANAL entry must be set to IH or ISH.

If ISH is specified then the MAT1 and MAT4 or MAT1 and MAT5 must have the same ID. MID for structure entries must follow the uniqueness rules of the MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, MATHP, MATHE, and MATG entries.

MID for heat entries must follow the uniqueness rules of the MAT4 and MAT5 entries. The CTRIAX6 remains a valid nonlinear heat transfer element BUT cannot be used in conjunction with this entry because it lies in an x-z plane and not an x-y plane.

- The keyword entries may occur in any order or not at all. If a keyword entry is missing, its defaults are assumed.
- The following table describes layer orientation for BEHi=COMPS or AXCOMP.

Layer Orientation			
DIRECT	Normal to Layer edge	Layers run parallel from edge	to edge
1	Element Y direction	G1-G2	G4-G3
2	Element X direction	G1-G4	G2-G3

- In the following table, BEHi refers to the nonlinear structural behavior of 2D-solid elements. An underlined item delineates a default.

Structural Classification of Elements				
Element Structural Type	BEHi CODE	Integration Code	Element Type	# Nodes
Plane Stress	PSTRS	L	QUAD	4
		Q	QUAD	8
		QRI	QUAD	8
		LRIH	QUAD	4
		Q	TRIA	6
Plane Strain	PLSTRN	L	QUAD	4
		L	TRIA	3
		Q	QUAD	8
		QRI	QUAD	8
		LRIH	QUAD	4
		Q	TRIA	6
Plane Strain composite	COMPS	L	QUAD	4
Axisymmetric Solid	AXSOLID	L	QUAD	4
		L	TRIA	3
		LT	QUAD	4
		Q	QUAD	8
		QRI	QUAD	8
		QT	QUAD	8
		LRIH	QUAD	4
		Q	TRIA	6
Axisymmetric Composite	AXCOMP	L	QUAD	4
Incompressible Plane Strain	IPS	L	TRIA	3
Incompressible Axisymmetric	IAX	L	TRIA	3

Only BEH4 = COMPS or AXCOMP with INT4 = L may use the MATG, additionally they should not use a MAT1, MAT2, MAT3, MAT8, MATORT, or MATHE as they will suffer from hourglassing.

- Note for this entry with a BEHi=COMPS or AXCOMP, the THETA/MCID value on the element connection entry will be ignored.
- In the table below, BEHiH refers to the nonlinear heat behavior of 2D-solid elements. An underlined item delineates a default.

Heat Classification of Elements				
Element Heat Type	BEHiH CODE	Integration Code	Element Type	# Nodes
Planar Solid	PLSTRN	L	QUAD	4
		L	TRIA	3
		Q	QUAD	8
		Q	TRIA	6
		Q	TRIA	6
Axisymmetric Solid	AXSOLID	L	QUAD	4
		L	TRIA	3
		Q	QUAD	8
		Q	QUAD	8
		Q	TRIA	6

10. Integration codes in Remarks 7. and 9. are:

INT CODE	Integration Type
L	Linear
LRIH	Linear Reduced Integration Hourglass Control (assumed strain)
Q	Quadratic
QRI	Quadratic Reduced Integration
QT	Quadratic with Twist
LT	Linear with Twist

11. For creep material defined through MATVP, VALC=0 must be set on NLMOPTS, for explicit formulation.
12. For shape memory materials defined through MATSMA, only the thermo-mechanical model is available.
13. The structural element damping coefficient, GE, is not supported on elements which reference PSHLN2.

## PSHLPF

## Property of Perforated Shell Element

Specifies properties for perforated shell of trim component, TRMC, in porous elastic material.

### Format:

1	2	3	4	5	6	7	8	9	10
PSHLPF	PID	MID	T	SPACEG	RADIUS	TOPOLOGY	FRHO	FVIS	
	HOMG								

### Example:

PSHLPF	1	2	8.1-4	1.132-2	1.245-3	SQUARE	1.225	1.71-5	
--------	---	---	-------	---------	---------	--------	-------	--------	--

Describer	Meaning
MID	Identification number of MAT1. (Integer>0)
T	Thickness. (Real>0.0)
SPACEG	Spacing of perforation holes (Real>0.0)
RADIUS	Radius of perforation holes (Real>0.0)
TOPOLOGY	Hole pattern: SQUARE, TRIA or HEXA
FRHO	Fluid density (Real>0.0)
FVIS	Fluid viscosity (Real>0.0)
HOMG	Homogenization flag (Integer=0 or 1; default=1)

### Remarks:

1. PSHLPF should be used for PEM modelling under 'BEGIN TRMC=trmid' only.
2. Finer mesh of the holes or around the holes should be avoided. The computation of an equivalent transfer admittance allows to reduce meshing effort and CPU time.
3. With default HOMG, stiffness and density are varying with porosity. With HOMG set to 0, stiffness provided is utilized as is.

**PSLDN1****Nonlinear Property Extensions for a PSOLID Entry**

Specifies additional nonlinear properties for solid elements that point to a PSOLID entry in SOL 400.

**Format:**

1	2	3	4	5	6	7	8	9	10
PSLDN1	PID	MID	DIRECT		ANAL				
	"C4"	BEH4	INT4	BEH4H	INT4H				
	"C5"	BEH5	INT5	BEH5H	INT5H				
	"C6"	BEH6	INT6	BEH6H	INT6H				
	"C8"	BEH8	INT8	BEH8H	INT8H				
	"C10"	BEH10	INT10	BEH10H	INT10H				
	"C13"	BEH13	INT13	BEH13H	INT13H				
	"C15"	BEH15	INT15	BEH15H	INT15H				
	"C20"	BEH20	INT20	BEH20H	INT20H				

**Example:**

PSLDN1	22	55	2						
--------	----	----	---	--	--	--	--	--	--

Describer	Meaning
PID	Property identification number of an existing PSOLID entry. (Integer > 0)
MID	Material identification number. Remark 8.(Integer ≥ 0)
DIRECT	The layer direction for BEHi=SLCOMP. See Remark 5. (Integer, 1, 2, OR 3; Default = 1)
ANAL	Analysis type. ANAL = 'IS' - Implicit structural elements are being referred to. ANAL = 'IH' - Implicit heat analysis elements are being referred to. ANAL = 'ISH' - Implicit structural and heat elements are being referred to. (Character Default ISH)
C4	Keyword indicating that two items following apply to elements with four corner grids. (Character)
C5	Keyword indicating that two items following apply to elements with five corner grids. (Character)
C8	Keyword indicating that two items following apply to elements with eight corner grids. (Character)
C10	Keyword indicating that two items following apply to elements with four corner grids and six midside grids. (Character)
C13	Keyword indicating that two items following apply to elements with five corner grids and eight midside grids. (Character)
C15	Keyword indicating that items following apply to elements with six corner and nine midside grids. (Character)

Describer	Meaning
C20	Keyword indicating that two items following apply to elements with eight corner grids and twelve midside grids. (Character)
BEHi	Element structural behavior. See Remark 6. (Character default: SOLID for BEH4, BEH6, BEH8, BEH10, BEH15, and BEH20)
INTi	Integration scheme. See Remark 7. (Character default: L for INT4, INT6, and INT8; Q for INT10, INT15, and INT20)
BEHiH	Element heat behavior. See Remark 6. (Character Default: SOLID for BEH4H, BEH6H, BEH8H, BEH10H, BEH15, and BEH20H)
INTiH	Integration scheme. See Remark 7. (Character Default: L for INT4H, INT6H, and INT8H; Q for INT10H, INT15H, and INT20H)

**Remarks:**

1. The PID must point to an existing PSOLID Bulk Data entry and is honored only in SOL 400.
2. The MID entry may point to MAT1, MAT9, MATORT, MATHE, or MATG entries and can be used to override the MID field on a PSOLID entry. The following table shows associated nonlinear entries. The association is established through the material entries having the same values as the MID entry.

Caution: The primary MATORT, MATHE, and MATG entries and the secondary MATVE, MATVP, MATEP and MATF entries are only associated with a 3D Solid (CHEXA, CPENTA, CPYRAM and CTETRA) element if the Solid element refers to a PSLDN1 entry.

The MID entry for nonlinear heat may point to MAT4 or MAT5 entries.

Implicit Structure Materials					
MAT1	MAT9	MATORT	MATHE	MATG	MATHP
MATVE	<MATVE>	<MATVE>	MATVE		
MATVP	MATVP	MATVP			
MATEP	MATEP	MATEP			
MATF	MATF	MATF			
MATS1		MATSORT			
<MATVE> refers to the ALTERNATE format for type ORTHO MATG for BEH8=SLCOMP, INT8=L only. MATG has an associated field IDMEM that points to a MAT1 BEH4 = ISOL, INT4 = L is currently limited to MAT1 (with possible association with MATS1 or MATEP), MATHE and MATHP					

Heat Materials	
MAT4	MAT5

If heat analysis is being performed and the user wishes to override standard Nastran heat elements, the ANAL entry must be set to IH or ISH.

If ISH is specified then the MAT1 and MAT4 or MAT1 and MAT5 must have the same ID. MID for structure entries must follow the uniqueness rules of the MAT1, MAT2, MAT3, MAT8, MAT9, MATORT, MATHP, MATHE, and MATG entries.

MID for heat entries must follow the uniqueness rules of the MAT4 and MAT5 entries.

- The keyword entries may occur in any order or not at all. If a keyword entry is missing, its defaults are assumed.
- The following table describes layer orientation for BEH8=SLCOMP, INT8=L.

Layer Orientation			
DIRECT	Normal to Layer plane	Layers run parallel from face	to face
1	Element T direction	G1-G2-G3-G4	G5-G6-G7-G8
2	Element R direction	G1-G4-G8-G5	G2-G3-G7-G6
3	Element S direction	G1-G2-G6-G5	G4-G3-G7-G8

- In the following table, BEHi refers to the nonlinear structural behavior of the solid element. An underlined item delineates a default.

Structural Classification of Elements				
Element Structural Type	BEHi CODE	Integration Code	Element Type	# Nodes
SOLID	SOLID	L	HEX	8
		<u>Q</u>	HEX	20
		QRI	HEX	20
		LRIH	HEX	8
		<u>Q</u>	TET	10
		LRIH	TET	10
		L	TET	4
		<u>L</u>	PEN	6
		<u>Q</u>	PEN	15
		L	PYR	5
		<u>LRIH</u>	PYR	5
		<u>Q</u>	PYR	13
		3D Solid Gasket	SLCOMP	L

Structural Classification of Elements				
Element Structural Type	BEHi CODE	Integration Code	Element Type	# Nodes
Solid Shell	SLCOMP	ASTN*	HEX	8
Incompressible solid	ISOL	L	TET	4
Only BEH8=SLCOMP,INT=L may use a MATG, additionally it should not use a MAT1, MAT9, MATORT, or MATHE as it will suffer from hour-glassing. It is recommended that for BEH4 = ISOL, INT4 = L that NLMOPTS,LRGSTRN,2 be flagged				
*Only DIRECT=1 is allowed.				

6. In the following table, BEHiH refers to the heat behavior of the solid element. An underlined item delineates a default.

Heat Classification of Elements				
Element Heat Type	BEHiH CODE	Integration Code	Element Type	# Nodes
SOLID	SOLID	<u>L</u>	HEX	8
		<u>Q</u>	HEX	20
		<u>Q</u>	TET	10
		<u>L</u>	TET	4
		<u>L</u>	PEN	6
		<u>Q</u>	PEN	15
		<u>L</u>	PYR	5
		<u>Q</u>	PYR	13

7. Integration codes in Remark 5 are:

INT CODE	Integration Type
L	Linear
LRIH	Linear Reduced Integration Hourglass control (assumed strain)
ASTN	Assumed STraiN enhanced formulation solid shell
Q	Quadratic
QRI	Quadratic Reduced Integration

8. Structural damping is supported for elements which reference PSLDN1.
- The structural damping coefficient, GE, is supported for elements using the MAT1 or MAT9 entries.
  - Extended damping coefficients GEij are supported for elements using the MAT9 entries.

## PSOLID Properties of Solid Elements

Defines the properties of solid elements (CHEXA, CPENTA, CPYRAM and CTETRA entries).

### Format:

1	2	3	4	5	6	7	8	9	10
PSOLID	PID	MID	CORDM	IN	STRESS	ISOP	FCTN		

### Example:

PSOLID	2	100	6	TWO	GRID	REDUCED	PORO		
--------	---	-----	---	-----	------	---------	------	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0)
MID	Identification number of a MAT1, MAT4, MAT5, MAT9, MAT10, MATHP, MATPE1, or MATHE entry. (Integer > 0)
CORDM	Identification number of the material coordinate system. See Remarks 3. and 4. (Integer; Default = 0, which is the basic coordinate system; see Remark 3.)
IN	Integration network. See Remarks 6., 7., 8., and 10. (Integer; Character, or blank)
STRESS	Location selection for stress output. See Remarks 9. and 10. (Integer; Character, or blank)
ISOP	Integration scheme. See Remarks 6., 7., 8., and 10. (Integer; Character, or blank)
FCTN	Fluid element flag. (Character: “FFLUID” indicates a fluid element with frequency dependent rigid absorber properties, “PFLUID” indicates a fluid element, “SMECH” indicates a structural element, “PORO” indicates an element of poroelastic medium, see Remark 12. , “PSLDSHL” indicates an element of solid shell of poroelastic medium, see Remark 13; Default = “SMECH.”)

### Remarks:

1. PSOLID is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PSOLID property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PSOLID, PCOMPLS entries.
2. Isotropic (MAT1 or MAT4), anisotropic (MAT5 or MAT9), or fluid (MAT10) material properties may be referenced. If FCTN = “PFLUID” or “FFLUID”, then MID must reference a MAT10 entry. PFLUID and FFLUID are not available for SOL 600 and SOL 700.

3. See the CHEXA, CPENTA, or CTETRA entry for the definition of the element coordinate systems. The material coordinate system (CORDM) may be the basic system (0 or blank), any defined system (Integer > 0), or the standard internal coordinate system of the element based on eigenvalue techniques to insure non bias in the element formulation designated as element coordinate system (-1) or the element system (-2). The default value for CORDM is zero unless it is overridden by the NASTRAN statement with the CORDM keyword. When MAT9 entry is used, the coordinate system used effects the stiffness calculation of the element.
4. For the CPYRAM entry the element coordinate system is the same as the basic coordinate system. CORDM values of 0, -1, -2 or blank are treated to be identical to the basic coordinate system.
5. Advanced nonlinear solid elements identified through an additional PSLDN1 entry, or SPROPMAP > -1 in NLMOPTS, or IDAMP>0 in NLSTEP, and so on, in SOL 400 do not support: IN, ISOP, and FCTN. Also, in this case, CORDM=-1 is only supported for CHEXA elements. Fatal error is issued if CORDM < 0 is used for CPENTA and CTETRA.

**The following Remarks, DO NOT APPLY TO SOL 600 or SOL 700.**

6. For CHEXA and CPENTA elements with no midside nodes, reduced shear integration with bubble functions (ISOP = blank or "REDUCED" and IN = blank or "BUBBLE") is the default. This is recommended because it minimizes shear locking and Poisson's ratio locking and does not cause modes of deformation that lead to no strain energy. The effects of using nondefault values are as follows:
  - a. IN = "THREE" or 3 produces an overly stiff element.
  - b. If IN = "TWO" or 2 and the element has midside nodes, modes of deformation may occur that lead to no strain energy.
  - c. Standard isoparametric integration (ISOP = "FULL" or 1 and IN = "TWO" or 2; or "THREE" or 3) produces an element overly stiff in shear. This type of integration is more suited to nonstructural problems.
  - d. In SOL105 the default reduced integration scheme often produces spurious modes in which case it is recommended that ISOP="FULL" and IN="THREE" be used.
7. IN = "BUBBLE" is not allowed for CTETRA elements or for CHEXA and CPENTA elements with midside nodes.
8. If you use IN = "BUBBLE" for CTETRA elements, NASTRAN internally switch to IN=2 if you have 4-noded CTETRA element and IN=3 greater than 4 nodes.
9. Stress output may be requested at the Gauss points (STRESS = "GAUSS" or 1) of linear CHEXA and CPENTA elements (i.e. elements with no midside nodes). Gauss point output is available for the linear and quadratic CTETRA and CPYRAM elements (i.e. elements with or without midside nodes).
10. The following tables indicate the allowed options and combination of options. If a combination not found in the table is used, then a warning message will be issued and default values will be assigned for all options.
11. The gauss point locations for the solid elements are documented in [Nonlinear Analysis, 535](#) in the *MSC Nastran Reference Guide*.

12. The entries with FCTN="PORO" must select MATPE1 identification number in MID field.

Table 9-35 CHEXA Entry Options

CHEXA	Integration	IN	STRESS (Default: GRID)	ISOP (Default: See Remarks 5 and 7.)	Nonlinear Capability				
					SOLs 106, 129, 400	SOL 600	SOL 700		
8 Node	2x2x2 Reduced Shear with BubbleFunction (default)	BUBBLE or Blank or 0 (Default)	Blank or GRID or GAUSS or 1	Blank or REDUCED (Default*)	Yes	Yes**	Yes		
	2x2x2 Reduced Shear Only	TWO or 2							
	2x2x2 Standard Isoparametric							FULL or 1	Yes
	3x3x3 Reduced Shear Only	THREE or 3	Blank or GRID	Blank or REDUCED	No	Yes	Yes		
	3x3x3 Standard Isoparametric								FULL or 1
9--20 Node	2x2x2 Reduced Shear Only	TWO or 2	Blank or GRID	Blank or REDUCED	No	Yes	No		
	2x2x2 Standard Isoparametric								FULL or 1
	3x3x3 Reduced Shear Only (default)	Blank or THREE or 3 (Default)		Blank or REDUCED (Default*)				No	No
	3 x3x3 Standard Isoparametric								
*REDUCED is the default only for structural elements (FCTN="SMECH").									
** Requires PARAM,MRALIAS									

Table 9-36 CPENTA Entry Options

CPENTA	Integration	IN	STRESS (Default: GRID)	ISOP (Default: See Remarks 5 and 7.)	Nonlinear Capability		
					SOLs 106, 129, 400	SOL 600	SOL 700
6 Node	2x3 Reduced Shear with Bubble Function (Default)	Blank or 0 or BUBBLE (Default)	GAUSS or 1 or Blank or GRID	Blank or REDUCED (Default*)	Yes	Yes**	Yes
	2x3 Reduced Shear Only	TWO or 2					
	2x3 Standard Isoparametric						
	3x7 Reduced Shear Only	THREE or 3	Blank or GRID	Blank or REDUCED	No	No	No
	3x7 Standard Isoparametric			FULL or 1		No	No
7-15 Node	2x3 Reduced Shear Only	TWO or 2	Blank or GRID	Blank or REDUCED	No	Yes**	No
	2x3 Standard Isoparametric			FULL or 1		Yes	No
	3x7 Reduced Shear Only (default)	Blank or THREE or 3 (Default)		Blank or REDUCED (Default*)		No	No
	3x7 Standard Isoparametric			FULL or 1		No	No
** Requires PARAM,MRALIAS							
*REDUCED is the default only for structural elements (FCTN="SMECH").							

Table 9-37 CTETRA Entry Options

CTETRA	Integration	IN	STRESS (Default: GRID)	ISOP	Nonlinear Capability		
					SOLs 106, 129, 400	SOL 600	SOL 700
4 Node	1-Point Standard Isoparametric (Default)	Blank or TWO or 2 (Default)	GAUSS or 1 or Blank or GRID	Blank or FULL	Yes	Yes**	Yes
	5-Point Standard Isoparametric	THREE or 3	Blank or GRID		No	Yes	No
5-10 Node	5-Point Standard Isoparametric	Blank or THREE or 3 (Default)	GAUSS or 1 or Blank or GRID	Blank or FULL	Yes	Yes	No
**Requires PARAM,MRALIAS							

Table 9-38 CPYRAM Entry Options

CPYRAM	Integration	IN	STRESS (Default: GRID)	ISOP	Nonlinear Capability		
					SOL 400	SOL 600	SOL 700
5 Node	5-Point Standard Isoparametric (Default)	Not applicable	GAUSS or 1 or Blank or GRID	Not applicable	Yes	No	No
	5-Point Standard Isoparametric	Not applicable	Blank or GRID		Yes	No	No
13 Node	8-Point Standard Isoparametric	Not applicable	GAUSS or 1 or Blank or GRID	Not applicable	Yes	No	No

- PSOLID entry with FCTN=PSLDSHL must select MAT1 identification number in MID field and should be used for trim component under 'BEGIN TRMC=trmid' only.

## PSPRMAT

## Spring and damper elements for translation and rotation - SOL 700

Defines linear and nonlinear spring element property for translation. Used in SOL 700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PSPRMAT	PID								
	K	FAILMTF	FAILMCF	LOAD	UNLOAD				

### Example:

PSPRMAT	1								
	20.0E3								

Descriptor	Meaning
PID	Property ID. PID is referenced on the CSPR entry. (Integer > 0; required.)
K	Elastic stiffness (force/displacement). (Real > 0; See Remarks 1. and 2.)
FAILMTF	Tensile failure force. See Remarks 1. and 2. (Real > 0; default=Not failure)
FAILMCF	Compressive failure force. See Remarks 1. and 2. (Real > 0; default=Not failure)
LOAD	Number of a TABLED1 entry defining the variation of force (y-value) with displacement (x-value) during loading. (Integer > 0; See Remarks 1., 3. and 4.)
UNLOAD	Number of a TABLExx entry defining the variation of force (y-value) with displacement (x-value) during unloading. (Integer > 0; See Remarks 3. and 4.)

### Remarks:

1. Only one set of K, FAILMTF and FAILMCF or LOAD and UNLOAD is allowed. If K is defined, LOAD and UNLOAD are not allowed. If LOAD is defined, K, FAILMTF and FAILMCF are not allowed.
2. For linear spring, K is required and FAILMTF and FAILMCF are optional.
3. For nonlinear spring, LOAD is required and UNLOAD is optional. If UNLOAD is not defined, unloading path is identical as LOAD.
4. Input for loading and unloading must be consistent. Both curves must be either completed defined or have only positive values (start from (0.,0.)). When only positive values are defined, the curves are automatically mirrored.

## PSSHL Properties for Solid Shell (CSSHL) Elements in SOL 600

Defines the properties for Solid Shell (CSSHL) elements in SOL 600.

### Format:

1	2	3	4	5	6	7	8	9	10
PSSHL	PID	MID	IT	SF	MCID				

### Example:

PSSHL	11	33		.8333					
-------	----	----	--	-------	--	--	--	--	--

Describer	Meaning
PID	Property identification number. (Integer > 0; Required)
MID	Identification of a MAT <sub>xxx</sub> entry. All MAT entries available in SOL 600 can be specified except for hyperelastic materials. (Integer > 0)
IT	Transition thickness - Enter only if a solid shell is attached to a standard shell (such as CQUAD4), in which case TT is the thickness of the standard shell. (Real; Default = 0.0)
SF	Transverse shear factor - Leave blank if transverse shear is not to be considered. (Real or blank, if entered SF must range between 0.0 and 1.0)
CORDM	Identification number of a material coordinate system. See Remark 3. (Integer; Default = 0)

### Remarks:

1. PSSHL entries should have unique identification numbers with respect to all other property entries.
2. MID may reference isotropic, orthotropic or anisotropic materials with or with plasticity, however hyperelastic and foam materials are not available.
3. See the CHEXA entry for the definition of the element coordinate system. The material coordinate system (CORDM) may be the basic system (0 or blank) or any defined system (Integer > 0), or the element coordinate system (-1). The default value for CORDM is zero.

**PTUBE**

## Tube Property

Defines the properties of a thin-walled cylindrical tube element (CTUBE entry).

**Format:**

1	2	3	4	5	6	7	8	9	10
PTUBE	PID	MID	OD	T	NSM	OD2			

**Example:**

PTUBE	2	6	6.29	0.25					
-------	---	---	------	------	--	--	--	--	--

**Describer****Meaning**

PID	Property identification number. (Integer > 0)
MID	Material identification number. See Remarks 3. and 4. (Integer > 0)
OD	Outside diameter of tube. (Real > 0.0)
T	Thickness of tube. (Real; $T \leq OD/2.0$ )
NSM	Nonstructural mass per unit length. (Real)
OD2	Diameter of tube at second grid point (G2) on CTUBE entry. (Real; Default = OD)

**Remarks:**

1. If T is zero, a solid circular rod is assumed.
2. PTUBE is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PTUBE property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PTUBE entries.
3. For structural problems, MID must reference a MAT1 material entry.
4. For heat transfer problems, MID must reference a MAT4 or MAT5 material entry.
5. Tapered OD tubes with constant wall thickness are available for heat transfer only. The effective diameter is given by:

$$D_{effective} = T + \frac{D_2 - D_1}{\log_e \left( \frac{D_2 - T}{D_1 - T} \right)}$$

where:

$$D_1 = \text{OD}$$

$$D_2 = \begin{cases} \text{OD2 if OD2} \neq 0 \\ \text{OD if OD2} = 0 \text{ or blank} \end{cases}$$

## **PVISC** Viscous Damping Element Property

Defines properties of a one-dimensional viscous damping element (CVISC entry).

### **Format:**

1	2	3	4	5	6	7	8	9	10
PVISC	PID1	CE1	CR1		PID2	CE2	CR2		

### **Example:**

PVISC	3	6.2	3.94						
-------	---	-----	------	--	--	--	--	--	--

<b>Describer</b>	<b>Meaning</b>
PID <sub>i</sub>	Property identification number. (Integer > 0)
CE1, CE2	Viscous damping values for extension in units of force per unit velocity. (Real)
CR1, CR2	Viscous damping values for rotation in units of moment per unit velocity. (Real)

### **Remarks:**

1. Viscous properties are material independent; in particular, they are temperature independent.
2. One or two viscous element properties may be defined on a single entry.
3. PVISC is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PVISC property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PVISC entries.

## PVISC1

## Nonlinear Damper Property- SOL 700

Defines the properties of a nonlinear damper where the damping constant varies with the velocity. Used in SOL700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
PVISC1	PID	TABLE							

### Example:

PVISC1	8	236							
--------	---	-----	--	--	--	--	--	--	--

Field	Content
PID	Unique property number. (Integer > 0; required)
TABLE	TABLED1 ID defining the variation of the force (y-value) with velocity (x-value). (Integer > 0; required)

### Remarks:

1. This entry defines the properties of a nonlinear damper. Use the PVISC entry to define linear dampers.
2. The values in the table are interpolated to get the force for a particular velocity.

## PWELD Connector Element Property

Defines the property of connector (CWELD) elements.

### Format:

1	2	3	4	5	6	7	8	9	10
PWELD	PID	MID	D			MSET		TYPE	
	LDMIN	LDMAX							

### Example:

PWELD	100	3	1.0						
-------	-----	---	-----	--	--	--	--	--	--

Describer	Meaning	Type	Default
PID	Property identification number.	Integer > 0	Required
MID	Material identification number. See Remark 1.	Integer > 0	Required
D	Diameter of the connector. See Remark 1.	Real > 0	Required
MSET	Active ONLY for "PARAM,OLDWELD,YES". Flag to eliminate m-set degrees-of-freedom (DOFs). The MSET parameter has no effect in a nonlinear SOL 400 analysis.  =OFF m-set DOFs are eliminated, constraints are incorporated in the stiffness, see Remark 2. =ON m-set DOFs are not eliminated, constraints are generated.	Character	OFF
TYPE	Character string indicating the type of connection, see Remarks 3. and 4.  =blank general connector ="SPOT" spot weld connector	Character	Blank
LDMIN	Active ONLY for "PARAM,OLDWELD,YES". Smallest ratio of length to diameter for stiffness calculation, see Remark 4.	Real or blank	0.2
LDMAX	Active ONLY for "PARAM,OLDWELD,YES". Largest ratio of length to diameter for stiffness calculation, see Remark 4.	Real or blank	5.0

**Remarks:**

1. The material MID, the diameter D, and the length are used to calculate the stiffness of the connector in 6 directions. MID can only refer to the MAT1 Bulk Data entry. The length is the distance of GA to GB (see [Figure 9-138](#)).

Figure 9-138 Length and Diameter of the CWELD Connector

2. This remark is now valid only if "PARAM,OLDWELD,YES" is present. The parameter MSET is active only for the formats ELEMID and GRIDID (see [CWELD, 1685](#) for the format descriptions). MSET = "OFF" incorporates constraints at the element stiffness matrix level avoiding explicit m-set constraint equations. For the formats PARTPAT and ELPAT, constraints are always eliminated on the element level. MSET = "ON" generates explicit m-set constraints. For example, if a patch-to-patch connection is specified with the formats "GRIDID" or "ELEMID" on the CWELD entry, and MSET=ON is specified, 2x6 explicit constraints are generated that connect the 6 degrees-of-freedom of GA to the translational degrees-of-freedom of grid points GA<sub>i</sub> and the 6 degrees-of-freedom of GB to GB<sub>i</sub>. The 2x6 degrees-of-freedom of GA and GB are put into the m-set. The constraints are labeled "RWELD". The identification numbers of the generated RWELD constraint elements start with an offset of 100,001,001 by default. The offset number can be changed with PARAM, OSWELM. For MSET = "OFF" or blank, the 2x6 constraint equations are built into the stiffness matrix of the CWELD element, thereby condensing the 2x6 degrees-of-freedom of GA and GB.
3. TYPE = "SPOT" is good for the formats PARTPAT, ELPAT, or ELEMID with patch to patch connections. For point to patch connections or another formats of patch to patch connections, TYPE is always set to blank.

If "PARAM,OLDWELD,YES" is present, the effective length for the stiffness of the CWELD element is set to  $L_e = 1/2 \cdot (t_A + t_B)$  regardless of the distance GA to GB.  $t_A$  and  $t_B$  are the shell thicknesses of shell A and B, respectively. The effective length is used to avoid excessively stiff or soft connections due to mesh irregularities.

For the new CWELD, the locations of GA/GB (if GA/GB is not specified by the user or the SWLDPRM parameter MOVGAB is equal to 1) will be adjusted so that the distance GA to GB is equal to  $L = 1/2 \cdot (t_A + t_B)$ .

4. If TYPE=blank and "PARAM,OLDWELD,YES" is present, the effective length  $L_e$  of the CWELD is equal to the true length L, the distance of GA to GB, as long as the ratio of the length L to diameter D is in the range  $L_{DMIN} \leq L/D \leq L_{DMAX}$ . If L is below the range, the effective length is set to  $L_e = L_{DMIN} \cdot D$  and if L is above the range, the effective length is set to  $L_e = L_{DMAX} \cdot D$ .

For the new CWELD with TYPE=blank, LDMIN and LDMAX are ignored. If the distance of GA to GB (patch to patch connections) or GS to GA (point to patch connections) is less than  $1.0e-4$ , the locations of GA/GB (if GA/GB is not specified by the user or the SWLDPRM parameter MOVGAB is equal to 1) will be adjusted so that the distance is equal to  $1.0e-4$ .

5. PWELD is a primary property entry. Primary property entries are grouping entities for many applications in MSC Nastran. Therefore it is highly recommended that the PWELD property entries have unique identification numbers with respect to all other property entries else unexpected grouping results may occur. There must be uniqueness between PWELD entries.
6. The new CWELD will not contribute to MASS by default even if it's associated MATi entry has a non-zero density. To react to a non-zero density "SWLDPARM,WMASS,1" is required. If mass is computed, the PARAM,COUPMASS effects the mass calculation.

## Entries Q-S

### QBDY1

### Boundary Heat Flux Load for CHBDYj Elements, Form 1

Defines a uniform heat flux into CHBDYj elements.

#### Format:

1	2	3	4	5	6	7	8	9	10
QBDY1	SID	Q0	EID1	EID2	EID3	EID4	EID5	EID6	
	EID7	EID8	-etc.-						

#### Example:

QBDY1	109	1.-5	721						
-------	-----	------	-----	--	--	--	--	--	--

#### Alternate Format and Example:

QBDY1	SID	Q0	EID1	“THRU”	EID2				
QBDY1	109	1.-5	725	THRU	735				

Describer	Meaning
SID	Load set identification number. (Integer > 0)
Q0	Heat flux into element. (Real)
EIDi	CHBDYj element identification numbers. (Integer ≠ 0 or “THRU”. For “THRU” option EID2 > EID1.)

#### Remarks:

1. QBDY1 entries must be selected with the Case Control command LOAD = SID in order to be used in static analysis. The total power into an element is given by the equation:

$$P_{in} = (\text{Effective area}) \cdot Q0$$

2. QBDY1 entries must be referenced on a TLOADi Bulk Data entry through the EXCITEID specification for use in transient analysis. The total power into an element is given by the equation:

$$P_{in}(t) = (\text{Effective area}) \cdot Q0 \cdot F(t - \tau)$$

where the function of time  $F(t - \tau)$  is specified on a TLOADi entry.

3. The sign convention for Q0 is positive for heat input.
4. RC network solver does not support QBDY1 for thermal analysis.

## QBDY2

## Boundary Heat Flux Load for CHBDYj Elements, Form 2

Defines grid point heat flux into CHBDYj elements.

### Format:

1	2	3	4	5	6	7	8	9	10
QBDY2	SID	EID	Q01	Q02	Q03	Q04	Q05	Q06	
	Q07	Q08							

### Example:

QBDY2	109	721	1.-5	1.-5	2.-5	2.-5			
-------	-----	-----	------	------	------	------	--	--	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
EID	Identification number of an CHBDYj element. (Integer > 0)
Q0i	Heat flux at the i-th grid point on the referenced CHBDYj element. (Real or blank)

### Remarks:

1. QBDY2 entries must be selected with the Case Control command LOAD=SID in order to be used in static analysis. The total power into each point  $i$  on an element is given by

$$P_i = AREA_i \cdot Q0i$$

2. QBDY2 entries must be referenced on a TLOADi Bulk Data entry through the EXCITEID specification for use in transient analysis. All connected grid points will have the same time function but may have individual delays. The total power into each point  $i$  on an element is given by

$$P_i(t) = AREA_i \cdot Q0i \cdot F(t - \tau_i)$$

where  $F(t - \tau_i)$  is a function of time specified on a TLOADi entry.

3. The sign convention for Q0i is positive for heat flux input to the element.
4. RC network solver does not support QBDY2 for thermal analysis.

## QBDY3 Boundary Heat Flux Load for a Surface

Defines a uniform heat flux load for a boundary surface.

### Format:

1	2	3	4	5	6	7	8	9	10
QBDY3	SID	Q0	CNTRLND	EID1	EID2	EID3	EID4	EID5	
	EID6	etc.							

### Example:

QBDY3	2	20.0	10	1	THRU	50	BY	2	
-------	---	------	----	---	------	----	----	---	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
Q0	Thermal heat flux load, or load multiplier. Q0 is positive for heat flow into a surface. (Real)
CNTRLND	Control point for thermal flux load. (Integer ≥ 0; Default = 0)
EIDi	CHBDYj element identification numbers. (Integer ≠ 0 or “THRU” or “BY”)

### Remarks:

1. QBDY3 entries must be selected in Case Control (LOAD = SID) to be used in steady state. The total power into a surface is given by the equation:
  - if  $CNTRLND \leq 0$  then  $P_{in} = (\text{Effective area}) \cdot Q0$
  - if  $CNTRLND > 0$  then  $P_{in} = (\text{Effective area}) \cdot Q0 \cdot u_{CNTRLND}$

where  $u_{CNTRLND}$  is the temperature of the control point and is used as a load multiplier.
2. In transient analysis, SID is referenced by a TLOADi Bulk Data entry through the EXCITEID specification. A function of time  $F(t - \tau)$  defined on the TLOADi multiplies the general load, with  $\tau$  specifying time delay. The load set identifier on the TLOADi entry must be selected in Case Control (DLOAD = SID) for use in transient analysis. If multiple types of transient loads exist, they must be combined by the DLOAD Bulk Data entry.
3. The CNTRLND multiplier cannot be used with any higher-order elements.
4. When using “THRU” or “BY”, all intermediate CHBDYE, CHBDYG, or CHBDYP elements must exist.
5. For RC network solver in thermal analysis, CNTRLND can only be used as the ID in CONTROLT as thermostats controller.

## QHBDY Boundary Heat Flux Load

Defines a uniform heat flux into a set of grid points.

### Format:

1	2	3	4	5	6	7	8	9	10
QHBDY	SID	FLAG	Q0	AF	G1	G2	G3	G4	
	G5	G6	G7	G8					

### Example:

QHBDY	2	AREA4	20.0		101	102	104	103	
-------	---	-------	------	--	-----	-----	-----	-----	--

Describer	Meaning
SID	Load set identification number. (Integer > 0)
FLAG	Type of face involved (must be one of the following: "POINT", "LINE", "REV", "AREA3", "AREA4", "AREA6", "AREA8")
Q0	Magnitude of thermal flux into face. Q0 is positive for heat into the surface. (Real)
AF	Area factor depends on type. (Real > 0.0 or blank)
Gi	Grid point identification of connected grid points. (Integer > 0 or blank)

### Remarks:

- The continuation entry is optional.
- For use in steady state analysis, the load set is selected in the Case Control Section (LOAD = SID).
- In transient analysis, SID is referenced by a TLOADi Bulk Data entry through the EXCITEID specification. A function of time  $F(t - \tau)$  defined on the TLOADi entry multiplies the general load.  $\tau$  specifies time delay. The load set identifier on the TLOADi entry must be selected in Case Control (DLOAD = SID) for use in transient analysis. If multiple types of transient loads exist, they must be combined by the DLOAD Bulk Data entry.
- The heat flux applied to the area is transformed to loads on the points. These points need not correspond to an HBDY surface element.
- The flux is applied to each point  $i$  by the equation
 
$$P_i = AREA_i \cdot Q0$$
- The number of connected points for the types are 1 (POINT), 2 (LINE, REV), 3 (AREA3), 4 (AREA4), 4-6 (AREA6), 5-8 (AREA8).

7. The area factor *AF* is used to determine the effective area for the POINT and LINE types. It equals the area and effective width, respectively. For axisymmetric elements, the magnitude of the area factors should account for an integration over the entire circumference (i.e.,  $2\pi$  radians). Note that the REV option can be used to apply the heat flux along the edges of axisymmetric elements. *AF* is not used for the other types, which have their area defined implicitly and must be left blank.
8. The type of face (FLAG) defines a surface in the same manner as the CHBDYi Bulk Data entry. For physical descriptions of the geometry involved, see the CHBDYG discussion.

## QSET Generalized Degree-of-Freedom

Defines generalized degrees-of-freedom (q-set) to be used for dynamic reduction or component mode synthesis.

### Format:

1	2	3	4	5	6	7	8	9	10
QSET	ID1	C1	ID2	C2	ID3	C3	ID4	C4	

### Example:

QSET	15	123456	1	3	9	2	105	6	
------	----	--------	---	---	---	---	-----	---	--

Describer	Meaning
ID <sub>i</sub>	Grid or scalar point identification number. (Integer > 0)
C <sub>i</sub>	Component number. (Integer zero or blank for scalar points or any unique combination of the Integers 1 through 6 for grid points with no embedded blanks.)

### Remarks:

- Degrees-of-freedom specified on this entry form members of the mutually exclusive q-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
- Degrees-of-freedom specified on QSET and QSET1 entries are automatically placed in the a-set.
- When ASET, ASET1, QSET, and/or QSET1 entries are present, all degrees-of-freedom not otherwise constrained (e.g., SPC<sub>i</sub> or MPC entries) will be placed in the omitted set (o-set).
- If Modules are present then this entry may only be specified in the main Bulk Data section.
- The SUPORT entry is not allowed in SOLs 106 and 129. SOL 400 does not support ASET<sub>i</sub>, OMIT<sub>i</sub>, BSET<sub>i</sub>, CSET<sub>i</sub>, SUPORT<sub>i</sub>, and QSET<sub>i</sub> except in the following situations:
  - Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
  - Linear perturbation with:
    - EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
    - ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
  - Superelements defined with BEGIN SUPER may contain ASET<sub>i</sub>, OMIT<sub>i</sub>, BSET<sub>i</sub>, CSET<sub>i</sub>, and QSET<sub>i</sub> entries.

## QSET1 Generalized Degree-of-Freedom (Alternate Form of QSET Entry)

Defines generalized degrees-of-freedom (q-set) to be used for generalized dynamic reduction or component mode synthesis.

### Format:

1	2	3	4	5	6	7	8	9	10
QSET1	C	ID1	ID2	ID3	ID4	ID5	ID6	ID7	
	ID8	ID9	-etc.-						

### Example:

QSET1	123456	1	7	9	22	105	6	22	
	52	53							

### Alternate Format and Example:

QSET1	C	ID1	“THRU”	ID2					
QSET1	0	101	THRU	110					

Describer	Meaning
C	Component number. (Integer zero or blank for scalar points or any unique combination of the Integers 1 through 6 for grid points with no embedded blanks.)
IDi	Grid or scalar point identification number. (Integer > 0; For THRU option, ID1 < ID2.)

### Remarks:

1. Degrees-of-freedom specified on this entry form members of the mutually exclusive q-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
2. Degrees-of-freedom specified on QSET and QSET1 entries are automatically placed in the a-set.
3. When ASET, ASET1, QSET, and/or QSET1 entries are present, all degrees-of-freedom not otherwise constrained (e.g., SPCi or MPC entries) will be placed in the omitted set (o-set).
4. If Modules are present then this entry may only be specified in the main Bulk Data section.
5. The SUPORT entry is not allowed in SOLs 106 and 129. SOL 400 does not support ASETi, OMITi, BSETi, CSETi, SUPORTi, and QSETi except in the following situations:
  - a. Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
  - b. Linear perturbation with:

- i. EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
- ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
- c. Superelements defined with BEGIN SUPER may contain ASETi, OMITi, BSETi, CSETi, and QSETi entries.

## QVECT

## Thermal Vector Flux Load

Defines thermal vector flux from a distant source into a face of one or more CHBDYi boundary condition surface elements.

### Format:

1	2	3	4	5	6	7	8	9	10
QVECT	SID	Q0	TSOUR	CE	E1 or TID1	E2 or TID2	E3 or TID3	CNTRLND	
	EID1	EID2	-etc.-						

### Example:

QVECT	10	20.0	1000.0		1.0	1.0	1.0	101	
	20	21	22	23					

Describer	Meaning
SID	Load set identification number. (Integer > 0)
Q0	Magnitude of thermal flux vector into face. (Real or blank)
TSOUR	Temperature of the radiant source. (Real or blank)
CE	Coordinate system identification number for thermal vector flux. See Remark 9. (Integer ≥ -1 or blank)
Ei	Vector components (direction cosines in coordinate system CE) of the thermal vector flux. (Real; Default = 0.0)
TIDi	TABLEDi entry identification numbers defining the components as a function of time. (Integer > 0)
CNTRLND	Control point. (Integer ≥ 0; Default = 0)
EIDi	Element identification number of a CHBDYE, CHBDYG, or CHBDYP entry. (Integer > 0) Key word "THRU" can be used to assist the listing with ascending order of EIDi

### Remarks:

1. The continuation entry is required.
2. If the coordinate system CE is not rectangular, then the thermal vector flux is in different directions for different CHBDYi elements. The direction of the thermal vector flux over an element is aligned to be in the direction of the flux vector at the geometric center of the element. The geometric center is measured using the grid points and includes any DISLIN specification on the VIEW entry for TYPE=LINE CHBDYi elements. The flux is presumed to be uniform over the face of each element; i.e., the source is relatively distant.

3. For use in steady-state analysis, the load set is selected in the Case Control Section (LOAD = SID). The total power into an element is given by:

- If CNTRLND = 0 then,  $P_{in} = -\alpha A(\vec{e} \cdot \vec{n}) \cdot Q0$ .
- If CNTRLND > 0 then,  $P_{in} = -\alpha A(\vec{e} \cdot \vec{n}) \cdot Q0 \cdot u_{CNTRLND}$ .

where

$\alpha$  = face absorptivity (supplied from a RADM statement).

A = face area as determined from a CHBDYi surface element.

$\vec{e}$  = vector of direction cosines E1, E2, E3.

$\vec{n}$  = face normal vector. See CHBDYi entries.

$\vec{e} \cdot \vec{n}$  = 0 if the vector product is positive, (i.e., the flux is coming from behind the face).

$u_{cntrlnd}$  = temperature value of the control point used as a load multiplier.

4. If the absorptivity is constant, its value is supplied by the ABSORP field on the RADM entry. If the absorptivity is not a constant, the thermal flux is assumed to have a wavelength distribution of a black body at the temperature TSOUR.

- For a temperature-dependent absorptivity, the element temperature is used to determine  $\alpha$ .
- For a wavelength-dependent absorptivity, the integration of the flux times  $\alpha$  is computed for each wavelength band. The sum of the integrated thermal fluxes over all the wavelength bands is Q0. The wave bands are specified with the RADBND entry.
- The user has the responsibility of enforcing Kirchhoff's laws.

5. In transient analysis, SID is referenced by a TLOADi Bulk Data entry through the EXCITEID specification. A function of time  $F(t - \tau)$  defined on the TLOADi entry multiplies the general load.  $\tau$  provides any required time delay.  $F(t - \tau)$  is a function of time specified on the TLOADi entry. The value of  $F(t - \tau)$  is calculated for each loaded grid point. The load set identifier on the TLOADi entry must be selected in Case Control (DLOAD = SID) for use in transient analysis. If multiple types of transient loads exist, they must be combined by the DLOAD Bulk Data entry.

The total power into an element is given by:

- If CNTRLND = 0 then,  $P_{in} = -\alpha A(\vec{e}(t) \cdot \vec{n}) \cdot Q0 \cdot F(t - \tau)$ .
- If CNTRLND > 0 then,

$$P_{in} = -\alpha A(\vec{e}(t) \cdot \vec{n}) \cdot F(t - \tau) \cdot Q0 \cdot u_{CNTRLND}$$

6. If the referenced face is of TYPE = ELCYL, the power input is an exact integration over the area exposed to the thermal flux vector.
7. If the referenced face is of TYPE = REV, the thermal flux vector must be parallel to the axis of symmetry if an axisymmetric boundary condition is to be maintained.

8. When applied to a surface element associated with a radiation enclosure cavity, any incident energy that is not absorbed ( $\alpha < 1.0$ ) is lost from the system and is not accounted for in a reflective sense ( $\alpha + \rho = 1.0$ ).
9. If a heat flux normal to the surface is desired, set CE to -1. This allows a nondirectional temperature dependent heat load on the CHBDYi. the RADMT scale factor times Q0 equals to the total power. Remember that the absorptivity must fall between 0.0 and 1.0, (see the RADMT Bulk Data entry).
10. For RC network solver in thermal analysis, CNTRLND can only be used as the ID in CONTROLT as thermostats controller.

## QVOL Volume Heat Addition

Defines a rate of volumetric heat addition in a conduction element.

### Format:

1	2	3	4	5	6	7	8	9	10
QVOL	SID	QVOL	CNTRLND	EID1	EID2	EID3	EID4	EID5	
	EID6	etc.							

### Example:

QVOL	5	10.0	101	10	12	11	9		
------	---	------	-----	----	----	----	---	--	--

Describer	Meaning
SID	Load set identification. (Integer > 0)
QVOL	Power input per unit volume produced by a heat conduction element. (Real)
CNTRLND	Control point used for controlling heat generation. (Integer ≥ 0; Default = 0)
EIDi	A list of heat conduction elements. (Integer > 0 or “THRU” or “BY”)

### Remarks:

- EIDi has material properties (MAT4) that include HGEN, the element material property for heat generation, which may be temperature dependent. This association is made through the element EID. If HGEN is temperature dependent, it is based on the average element temperature.
- QVOL provides either the constant volumetric heat generation rate or the load multiplier. QVOL is positive for heat generation. For steady-state analysis, the total power into an element is
  - If CNTRLND = 0, then  $P_{in} = \text{volume} \cdot \text{HGEN} \cdot \text{QVOL}$ .
  - If CNTRLND > 0, then  $P_{in} = \text{volume} \cdot \text{HGEN} \cdot \text{QVOL} \cdot u_{\text{CNTRLND}}$ .

where  $u_{\text{CNTRLND}}$  is the temperature multiplier.

- For use in steady-state analysis, the load set is selected in the Case Control Section (LOAD = SID).
- In transient analysis SID is referenced by a TLOADi Bulk Data entry. A function of time  $F[t - \tau]$  defined on the TLOADi entry multiplies the general load where  $\tau$  specifies time delay. The load set identifier on the TLOADi entry must be selected in Case Control (DLOAD = SID) for use in transient analysis. If multiple types of transient loads exist, they must be combined by the DLOAD Bulk Data entry.
- For “THRU” or “BY”, all intermediate referenced heat conduction elements must exist.
- The CNTRLND multiplier cannot be used with any higher-order elements.
- For RC network solver in thermal analysis, CNTRLND can only be used as the ID in CONTROLT as thermostats controller.

8. QVOL is not supported for CQUADX and CTRIAX axisymmetric elements. It is supported for the CTRIAX6 element.

## RADBC

## Space Radiation Specification

Specifies an CHBDYi element face for application of radiation boundary conditions.

### Format:

1	2	3	4	5	6	7	8	9	10
RADBC	NODAMB	FAMB	CNTRLND	EID1	EID2	EID3	EID4	EID5	
	EID6	EID7	-etc.-						

### Example:

RADBC	5	1.0	101	10					
-------	---	-----	-----	----	--	--	--	--	--

Describer	Meaning
NODAMB	Ambient point for radiation exchange. (Integer > 0)
FAMB	Radiation view factor between the face and the ambient point. (Real ≥ 0.0)
CNTRLND	Control point for radiation boundary condition. (Integer ≥ 0; Default = 0)
EIDi	CHBDYi element identification number. (Integer > 0) Key words "THRU" and "BY" can be used to assist the listing with ascending order of EIDi

### Remarks:

- The basic exchange relationship is:
  - if CNTRLND = 0, then  $q = \sigma \cdot \text{FAMB} \cdot \epsilon_e \cdot (T_e^A - T_{amb}^A)$
  - if CNTRLND > 0, then
 
$$q = \sigma \cdot \text{FAMB} \cdot u_{\text{CNTRLND}} \cdot \epsilon_e \cdot (T_e^A - T_{amb}^A)$$
- NODAMB is treated as a black body with its own ambient temperature for radiation exchange between the surface element and space. No surface element that is a member of a radiation enclosure cavity may also have a radiation boundary condition applied to it.
- Two PARAM entries are required when stipulating radiation heat transfer:
  - ABS defines the absolute temperature scale; this value is added internally to any specified temperature given in the problem. Upon solution completion, this value is subtracted internally from the solution vector.
  - SIGMA ( $\sigma$ ) is the Stefan-Boltzmann constant.
- RADBC allows for surface radiation to space in the absence of any cavity behavior. The emissivity is supplied from a RADM entry.
- When using "THRU" or "BY", all intermediate referenced CHBDYi surface elements must exist.

## RADBND

## Radiation Wavelength Band Definition

Specifies Planck's second radiation constant and the wavelength breakpoints used for radiation exchange problems.

### Format:

<b>1</b>	<b>2</b>	<b>3</b>	<b>4</b>	<b>5</b>	<b>6</b>	<b>7</b>	<b>8</b>	<b>9</b>	<b>10</b>
RADBND	NUMBER	PLANCK2	LAMBDA1	LAMBDA2	LAMBDA3	LAMBDA4	LAMBDA5	LAMBDA6	
	LAMBDA7	etc.							

### Example:

RADBND	6	14388.0	1.0	2.0	4.0	8.0	12.0		
--------	---	---------	-----	-----	-----	-----	------	--	--

Describer	Meaning
NUMBER	Number of radiation wave bands. See Remarks. (Integer > 1)
PLANCK2	Planck's second radiation constant. See Remarks. (Real > 0.0)
LAMBDAi	Highest wavelength of the i-th wave band. See Remarks. (Real ≥ 0.0)

### Remarks:

1. Only one RADBND entry may be specified in the Bulk Data Section and must always be used in conjunction with the RADM entry.
2. PLANCK2 has the units of wavelength times temperature. The same units of length must be used for LAMBDAi as for PLANCK2. The units of temperature must be the same as those used for the radiating surfaces. For example: 25898.μm °R or 14388.μm °K.
3. The first wavelength band extends from 0 to LAMBDA1 and the last band extends from LAMBDA<sub>n</sub> to infinity, where n = NUMBER – 1.
4. Discontinuous segments in the emissivity versus wavelength piecewise linear curve must be treated as a wavelength band of zero width.
5. LAMBDAi must be specified in ascending order, and all LAMBDAi fields where i is greater than or equal to NUMBER must be blank.
6. If Modules are present then this entry may only be specified in the main Bulk Data section.

**RADC** Thermal Radiative Coating Properties - SOL400 - RC Network solver

Defines the radiative properties of advanced materials such as coatings and multilayer insulation, commonly used in the aerospace market.

**Format: (COAT)**

1	2	3	4	5	6	7	8	9	10
RADC	RADMID	Emis	Absorptivity	IR Spec	UV Spec				
	"COAT"	IR Traspa	IR Transluc	UV Transpa	UV Transluc	IR Refrac Ind	UV Refrac Ind		

**Example:**

RADC	101	1.	1.	0.					
	COAT	0.	0.	0.	0.	1.	1.		

**Format: (MLI)**

1	2	3	4	5	6	7	8	9	10
RADC	RADMID	Emis	Absorptivity	IR Spec	UV Spec				
	"MLI"	Estar							

**Example:**

RADC	102	1.	1.	0.					
	MLI	0.02							

Describer	Meaning
RADMID	Radiation material identification number (Integer > 0; Required)
COAT	Identification that a coating type material has been started (Character)
Emis	Emissivity (Real $\geq$ 0.0; Default 1.0)
Absorptivity	Absorptivity (Real $\geq$ 0.0; Default 1.0)
IR Spec	IR Specularity (0.0 $\leq$ Real $\leq$ 1.0; Default 0.0)
UV Spec	UV Specularity (0.0 $\leq$ Real $\leq$ 1.0; Default 0.0)
IR Transpa	IR Transparency (0.0 $\leq$ Real $\leq$ 1.0; Default 0.0)
IR Transluc	IR Translucency (0.0 $\leq$ Real $\leq$ 1.0; Default 0.0)
UV Transpa	UV Transparency (0.0 $\leq$ Real $\leq$ 1.0; Default 0.0)
UV Transluc	UV Translucency (0.0 $\leq$ Real $\leq$ 1.0; Default 0.0)
IR Refrac Ind	IR Refraction Index (Real $\geq$ 1.0; Default 1.0)
UV Refrac Ind	UV Refraction Index (Real $\geq$ 1.0; Default 1.0)
MLI	Identification that an MLI type material has been started (Character)
Estar	MLI E-star parameter (Real; Default 0.0)

**Remarks:**

1. This entry is for RC Network solver only.
2. Estar is defined as the effective emissivity from the wall to MLI outer surface. The general value is around 0.01 to 0.03, the typical value is 0.02.
3. Emis is usually for the IR waveband, and Absorptivity is for the UV waveband.

## RADCAV

## Radiation Cavity Identification

Identifies the characteristics of each radiant enclosure.

### Format:

1	2	3	4	5	6	7	8	9	10
RADCAV	ICAVITY	ELEAMB	SHADOW	SCALE	PRTPCH	NFECI	RMAX	NCOMP	
	SET11	SET12	SET21	SET22	SET31	SET32	etc.		

### Example:

RADCAV	1	1					.99		
	3	5	4	5	7	5			

Describer	Meaning
ICAVITY	Unique cavity identification number associated with enclosure radiation. (Integer > 0)
ELEAMB	CHBDYi surface element identification number for radiation if the view factors add up to less than 1.0. (Unique Integer > 0 among all CHBDYi elements or blank.)
SHADOW	Flag to control third body shading calculation during view factor calculation for each identified cavity. (Character = "YES" or "NO"; Default = "YES")
SCALE	View factor that the enclosure sum will be set to if a view factor is greater than 1.0. (0.0 ≤ Real ≤ 1.0; Default = 0.0)
PRTPCH	Facilitates the blocking of view factor printing and punching onto RADLST and RADMTX entries. (Integer = 0, 1, 2, 3, 4, or 5; Default = blank):

Hemi-Cube & VIEW3D		
Value	Printout in .f06 file	Printout in .pch file
Blank	No	Yes
0	Full Print	Yes
1	No	Yes
2	Full Print	No
3	No	No
4	Summary Print	Yes
5	Summary Print	No

NFECI	Controls whether finite difference or contour integration methods are to be used in the calculation of view factors in the absence of a VIEW3D Bulk Data entry. (Character = "FD" or "CONT"; See Remark 4. for default.)
RMAX	Subelement area factor. See Remark 5. (Real $\geq 0.0$ ; Default = 0.1)
NCOMP	Total number of computational element for one-half ring. See Remark 8. (Default = 32)
SETij	Set identification pairs for the calculation of global view factors. Up to 30 pairs may be specified (i = 1 to 2 and j = 1 to 30). (Integer > 0)

**Remarks:**

1. For the surfaces of an incomplete enclosure (view factors add up to less than 1.0), a complete enclosure may be achieved (SUM = 1.0) by specifying an ambient element, ELEAMB. When multiple cavities are defined, each cavity must have a unique ambient element if ambient elements are desired. No elements can be shared between cavities.
2. Third-body shadowing is ignored in the cavity if SHADOW = "NO". In particular, if it is known a priori that there is no third-body shadowing, SHADOW = NO overrides KSHD and KBSHD fields on the VIEW Bulk Data entry as well as reduces the calculation time immensely.
3. The view factors for a complete enclosure may add up to slightly more than 1.0 due to calculation inaccuracies. SCALE can be used to adjust all the view factors proportionately to acquire a summation equal to the value specified for SCALE. If SCALE is left blank or set to 0.0, no scaling is performed.
4. If the VIEW3D Bulk Data entry is not specified, the view factors are calculated using finite difference and contour integration methods. If NFECI = "FD", then all view factors are calculated using the finite difference technique. NFECI = "CONT" invokes contour integration for all view factor calculations. If NFECI is blank, the program selects a method to use between any two particular elements based on RMAX.
5. The comparison value for RMAX is equal to  $A_s/d_{rs}^2$  where  $A_s$  is the area of a subelement and  $d_{rs}$  is the distance between two subelements r and s for which view factors are being computed. When NFECI is blank, the program selects the contour integral method only if  $A_s/d_{rs}^2 > RMAX$ .
6. When a number of elements are grouped together and considered as a conglomerate surface, view factors can be calculated between these groups. These are referred to as global view factors. The SET1 Bulk Data entry is used to define the conglomerate. When using this feature, negative EIDs are not allowed.
7. If a RADLST and RADMTX entry exists for this cavity ID, new view factors are not computed and the existing RADLST and RADMTX are used in the thermal analysis.
8. The VIEW3D Bulk Data entry must be specified for the calculation of axisymmetric view factors. The process relies on the internal construction of a semi-circle of computational elements. NCOMP specifies the number of such elements desired.
9. For SOL 600, fields 4-8 of the primary entry and all continuation lines are ignored.

10. For SOL 600 field 9 of the primary entry (NCOMP) is used to indicate if the cavity is open or closed according to the following designation:
  - 0 Cavity is closed
  - 1 Cavity is closed an view factors are scaled such that they sum to exactly 1.0
  - 2 Cavity is open
11. For RC network solver in thermal analysis, RADCAV is only used to specify radiation space node, the ELEAMB must be a POINT type CHBDYP element. The SHADOW, SCALE, PRTPCH, NFECI, RMAX, NCOMP, SET11, SET12, SET21, SET22, SET31 and SET32 are ignored.

**RADCOL****Radiation Collective Entity - SOL400 - RC Network solver**

Specifies a collection of boundary elements to be used as a single face in the radiation calculation. This will decrease computation time at the small cost of accuracy. Computational savings and accuracy are dependent on the coarseness of the collection versus the constituents. View factors of the collection are redistributed across the elements for calculation of the radiative energy transfer.

**Format:**

1	2	3	4	5	6	7	8	9	10
RADCOL	RADCOLID	IVIEWF	IVIEWB	RADMIDF	RADMIDB	SET3ID			

**Example:**

RADCOL	101	5	6	2	3	7			
--------	-----	---	---	---	---	---	--	--	--

Describer	Meaning
RADCOLID	Radiation Collection identification number. (Integer > 0; Required)
IVIEWF	A VIEW entry identification number for the front face. (Integer ≥ 0; Default 0)
IVIEWB	A VIEW entry identification number for the back face. (Integer ≥ 0; Default 0)
RADMIDF	RADM identification number for the front face. (Integer ≥ 0; Default 0)
RADMIDB	RADM identification number for the back face. (Integer ≥ 0; Default 0)
SET3 idn	ID of the element collection to be considered a super element. (Integer > 0)

**Remarks:**

1. This entry is for RC Network solver only.
2. IVIEWF/IVIEWB will default to 0 if left blank. This would indicate that the corresponding front and/or back do not participate in the radiation.
3. If an IVIEWF is specified, there must also be a RADMIDF for surface material properties. If a IVIEWB is specified, there must also be a RADMIDB for surface material properties.

**RADCT** Thermal Radiative Functionally-Dependent Properties - SOL400 - RC Network solver

Specifies table references for RADC properties that are functionally dependent.

**Format:**

1	2	3	4	5	6	7	8	9	10
RADCT	RADMID	Emis f(T)	Abs f(T)						

**Example:**

RADCT	11	101	102						
-------	----	-----	-----	--	--	--	--	--	--

Describer	Meaning
RADMID	Radiation material identification number (Integer > 0; Required)
Emis f(T)	Emissivity TABLEMj table ID (Integer ≥ 0; Default.0)
Absorptivity f(T)	Absorptivity TABLEDj table ID (Integer ≥ 0; Default 0)

**Remarks:**

1. This entry is for RC Network solver only.
2. RADCT always comes with the RADC entry. They have the same RADMID so that they can be referenced together.
3. Currently, RC Network solver does not support this entry for enclosure radiation.

**RADLST**

## Listing of Enclosure Radiation Faces

Identifies the individual CHBDYi surface elements that comprise the entire radiation enclosure.

**Format:**

1	2	3	4	5	6	7	8	9	10
RADLST	ICAVITY	MTXTYP	EID1	EID2	EID3	EID4	EID5	EID6	
	EID7	-etc.-							

**Example:**

RADLST	2	1	2	3	4	5	6	7	
--------	---	---	---	---	---	---	---	---	--

Describer	Meaning
ICAVITY	Unique cavity identification number that links a radiation exchange matrix with its listing of enclosure radiation faces. (Integer > 0)
MTXTYP	Type of radiation exchange matrix used for this cavity. (Integer $\leq 4$ and $\neq 0$ ; Default = 1 for an enclosure without an ambient element. Default = 4 for an enclosure with an ambient element as specified on the RADCAV entry.) <ul style="list-style-type: none"> <li>1 Symmetric view factor matrix [F] and nonconservative radiation matrix [R].</li> <li>2 Symmetric exchange factor matrix [<math>\mathfrak{F}</math>] and conservative radiation matrix [R].</li> <li>3 Unsymmetric exchange factor matrix [<math>\mathfrak{F}</math>] and conservative radiation matrix [R].</li> <li>4 Symmetric view factor matrix [F] and conservative radiation matrix [R].</li> <li>-n The first n CHBDYi elements may lose energy to space but the remainder may not. Symmetric exchange factor matrix [F] and nonconservative radiation matrix [R].</li> </ul>
EIDi	Identification numbers for the CHBDYi elements in this radiation cavity. (Integer $\neq 0$ or "THRU")

**Remarks:**

1. A radiation EIDi list isolates those CHBDYi surface element faces that are to communicate in a radiation enclosure. View-factor calculation and RADMTX formation for an enclosure is performed only for (or among) those faces identified within the same RADCAV.
2. A radiation exchange matrix (RADMTX) can only reference one radiative face list (RADLST). The companion RADCAV, RADLST, and RADMTX must share a unique ICAVITY.
3. For each EIDi, the appropriate CHBDYi element is located, and the proper RADM entry ID field found.
4. If the radiation exchange matrix or any radiation boundary conditions are available from an external source, the RADMTX must be user generated.

5. Multiple RADLST entries may be specified.
6. If any RADLST entry is changed or added on restart then a complete re-analysis may be performed. Therefore, RADLST entry changes or additions are not recommended on restart.
7. RC network solver does not support RADLST for thermal analysis.

## RADM

## Radiation Boundary Material Property

Defines the radiation properties of a boundary element for heat transfer analysis.

### Format:

1	2	3	4	5	6	7	8	9	10
RADM	RADMID	ABSORP	EMIS1	EMIS2	EMIS3	EMIS4	EMIS5	EMIS6	
	EMIS7	-etc.-							

### Example:

RADM	11		.45	.33	.29	.20	.17	.13	
------	----	--	-----	-----	-----	-----	-----	-----	--

Describer	Meaning
RADMID	Material identification number. (Integer > 0)
ABSORP	Surface absorptivity or the temperature function curve multiplier if ABSORP is variable. See Remark 2. ( $0.0 \leq \text{Real} \leq 1.0$ )
EMIS <sub>i</sub>	Surface emissivity at wavelength LAMBDA <sub>i</sub> or the temperature function curve multiplier if EMIS <sub>i</sub> is variable (See the RADBND entry.) ( $0.0 \leq \text{Real} \leq 1.0$ )

### Remarks:

1. The RADM entry is directly referenced only by one of the CHBDYE, CHBDYG, or CHBDYP type surface element entries.
2. For radiation enclosure problems, ABSORP is set equal to emissivity. For QVECT loads, absorptivity is specified by ABSORP.
3. If there is more than one EMIS<sub>i</sub>, then:
  - There must be a RADBND entry.
  - The number of EMIS<sub>i</sub> may not exceed the number of LAMBDA<sub>i</sub> on the RADBND entry.
  - The emissivity values are given for a wavelength specified by the corresponding LAMBDA<sub>i</sub> on the RADBND entry. Within each discrete wavelength band, the emissivity is assumed to be constant.
  - At any specific wavelength and surface temperature, the absorptivity is exactly equal to the emissivity.
4. To perform any radiation heat transfer exchange, the user must furnish PARAM entries for:
  - TABS to define the absolute temperature scale.
  - SIGMA ( $\sigma$ ) to define the Stefan-Boltzmann constant in appropriate units.
5. RC network solver only supports RADMID, ABSORP and EMIS1 for thermal analysis, other fields are ignored.

## RADMT

## Radiation Boundary Material Property Temperature Dependence

Specifies table references for temperature dependent RADM entry radiation boundary properties.

### Format:

1	2	3	4	5	6	7	8	9	10
RADMT	RADMID	T(A)	$T(\epsilon_1)$	$T(\epsilon_2)$	$T(\epsilon_3)$	$T(\epsilon_4)$	$T(\epsilon_5)$	$T(\epsilon_6)$	
	$T(\epsilon_7)$	-etc.-							

### Example:

RADMT	11		1	2	3	4	5	6	
-------	----	--	---	---	---	---	---	---	--

Describer	Meaning
RADMID	Material identification number. (Integer > 0)
T(A)	TABLEMj identifier for surface absorptivity. (Integer $\geq 0$ or blank)
$T(\epsilon_j)$	TABLEMj identifiers for surface emissivity. (Integer $\geq 0$ or blank)

### Remarks:

1. The basic quantities on the RADM entry of the same RADMID are always multiplied by the corresponding tabular function.
2. Tables T(A) and  $T(\epsilon_j)$  have an upper bound that is less than or equal to one and a lower bound that is greater than or equal to zero.
3. The TABLEMj enforces the element temperature as the independent variable. Blank or zero fields means there is no temperature dependence of the referenced property on the RADM entry.
4. RC network solver only supports RADMID, T(A) and  $T(\epsilon_1)$  for thermal analysis, other fields are ignored.

## RADMTX Radiation Exchange Matrix

Provides the  $F_{ji} = A_j f_{ji}$  exchange factors for all the faces of a radiation enclosure specified in the corresponding RADLST entry.

### Format:

1	2	3	4	5	6	7	8	9	10
RADMTX	ICAVITY	INDEX	$F_{i,j}$	$F_{i+1,j}$	$F_{i+2,j}$	$F_{i+3,j}$	$F_{i+4,j}$	$F_{i+5,j}$	
	$F_{i+6,j}$	-etc.-							

### Example:

RADMTX	2	1	0.0	0.1	0.2	0.2	0.3	0.2	
--------	---	---	-----	-----	-----	-----	-----	-----	--

Descriptor	Meaning
ICAVITY	Unique cavity identification number that links a radiation exchange matrix with its listing of enclosure radiation surface elements. (Integer > 0)
INDEX	Column number in the matrix. (Integer > 0)
$F_{k,j}$	If symmetric, the matrix values start on the diagonal ( $i = j$ ) and continue down the column ( $k = i + 1, i + 2, \text{etc.}$ ). If unsymmetric, the values start in row ( $i = 1$ ). $i$ refers to EID <sub>i</sub> on the RADLST entry. (Real $\geq 0$ )

### Remarks:

1. If the matrix is symmetric, only the lower triangle is input, and  $i = j = \text{INDEX}$ . If the matrix is unsymmetric,  $i = 1$ , and  $j = \text{INDEX}$ .
2. Only one ICAVITY may be referenced for those faces that are to be included in a unique radiation matrix.
3. Coefficients are listed by column with the number of columns equal to the number of entries in the RADLST.
4. All faces involved in any radiation enclosure must be defined with an CHBDY<sub>i</sub> element.
5. If any RADMTX entry is changed or added on restart then a complete re-analysis may be performed. Therefore, RADMTX entry changes or additions are not recommended on restart.
6. Set NASTRAN SYSTEM (87) = 3 is a new option in MSC Nastran 2005 that prevents radiation energy from being lost to space.
7. RC network solver does not support RADMTX for thermal analysis.

**RADSET** Identifies a Set of Radiation Cavities

Specifies which radiation cavities are to be included for radiation enclosure analysis.

**Format:**

1	2	3	4	5	6	7	8	9	10
RADSET	ICAVITY1	ICAVITY2	ICAVITY3	ICAVITY4	ICAVITY5	ICAVITY6	ICAVITY7	ICAVITY8	
	ICAVITY9	-etc.-							

**Example:**

RADSET	1	2	3	4					
--------	---	---	---	---	--	--	--	--	--

Describer	Meaning
ICAVITYi	Unique identification number for a cavity to be considered for enclosure radiation analysis. (Integer > 0)

**Remark:**

1. For multiple radiation cavities, RADSET specifies which cavities are to be included in the analysis.

## RANDPS Power Spectral Density Specification

Defines load set power spectral density factors for use in random analysis having the frequency dependent form

$$S_{jk}(F) = (X + iY)G(F)$$

### Format:

1	2	3	4	5	6	7	8	9	10
RANDPS	SID	J	K	X	Y	TID			

### Example:

RANDPS	5	3	7	2.0	2.5	4			
--------	---	---	---	-----	-----	---	--	--	--

Descriptor	Meaning
SID	Random analysis set identification number. See Remarks 1. and 9. (Integer > 0)
J	Subcase identification number of the excited load set. See Remarks 6. through 9. (Integer > 0)
K	Subcase identification number of the applied load set. See Remarks 6. through 9. (Integer ≥ 0; K ≥ J)
X, Y	Components of the complex number. See Remarks 2. and 7. (Real)
TID	Identification number of a TABRNDi entry that defines G(F). See Remarks 3. and 7. (Integer > 0 or Blank)

### Remarks:

1. Set identification numbers must be selected with the Case Control command (RANDOM = SID) or through use of FTGLOAD when doing random vibration fatigue analysis.
2. For auto spectral density, J = K, X must be greater than zero and Y must be equal to zero.
3. For TID = Blank, G(F) = 1.0.
4. RANDPS may only reference subcases included within a single loop (a change in direct matrix input is not allowed).
5. See the [MSC Nastran Dynamic Analysis User's Guide](#) for a discussion of random analysis.
6. In the case of cyclic symmetry Solution Sequence 118, J and K must refer to the coded subcase IDs.
7. In superelement analysis, J and K must refer to the superelement subcases. For example, if superelement 10 has SUBCASEs 1 and 2 and superelement 20 has SUBCASEs 3 and 4, then a separate RANDPS entry is required for each superelement, even though X, Y, and TID may be identical.
8. For uncoupled PSDF (no J < K entries) only one J = K entry is allowed for unique value of J. For coupled PSDF (some J < K entries) any number of entries are allowed.

9. J and K must reference valid subcase IDs. In superelement analysis, J and K must reference valid subcase IDs that pertain to the applicable superelement. If this requirement is not met, the program issues an appropriate user warning message and ignores the associated RANDOM=SID command.
10. If Modules are present then this entry may only be specified in the main Bulk Data section.

## RANDT1 Autocorrelation Function Time Lag

Defines time lag constants for use in random analysis autocorrelation function calculation.

### Format:

1	2	3	4	5	6	7	8	9	10
RANDT1	SID	N	T0	TMAX					

### Example:

RANDT1	5	10	3.2	9.6					
--------	---	----	-----	-----	--	--	--	--	--

Describer	Meaning
SID	Random analysis set identification number. (Integer > 0)
N	Number of time lag intervals. (Integer > 0)
T0	Starting time lag. (Real ≥ 0.0)
TMAX	Maximum time lag. (Real > T0)

### Remarks:

1. Time lag sets must be selected with the Case Control command RANDOM = SID.
2. At least one RANDPS entry must be present with the same set identification number.
3. The time lags defined on this entry are given by

$$T_i = T0 + \frac{TMAX - T0}{N}(i - 1), i = 1, N + 2$$

4. See the [MSC Nastran Dynamic Analysis User's Guide](#) for a discussion of random analysis.
5. If Modules are present then this entry may only be specified in the main Bulk Data section.

**RBAR**

## Rigid Bar

Defines a rigid bar with six degrees-of-freedom at each end.

**Format:**

1	2	3	4	5	6	7	8	9	10
RBAR	EID	GA	GB	CNA	CNB	CMA	CMB	ALPHA	
	TREF								

**Example:**

RBAR	5	1	2	123456				6.5-6	
------	---	---	---	--------	--	--	--	-------	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
GA, GB	Grid point identification number of connection points. (Integer > 0)
CNA, CNB	Component numbers of independent degrees-of-freedom in the global coordinate system for the element at grid points GA and GB. See Remark 3. (Integers 1 through 6 with no embedded blanks, or zero or blank.)
CMA, CMB	Component numbers of dependent degrees-of-freedom in the global coordinate system assigned by the element at grid points GA and GB. See Remarks 4. and 5. (Integers 1 through 6 with no embedded blanks, or zero or blank.)
ALPHA	Thermal expansion coefficient. See Remark 11. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

**Remarks:**

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, Nastran will create the Lagrange multiplier degrees-of-freedom internally in addition to the 12 displacement degrees-of-freedom given by grid points GA and GB. The number of Lagrange multiplier degrees-of-freedom is equal to the number of dependent degrees-of-freedom.
- For the linear method, the total number of components in CNA and CNB must equal six; for example, CNA = 1236, CNB = 34. Furthermore, they must jointly be capable of representing any general rigid body motion of the element. For the Lagrange method, the total number of components must also be six. However, only CNA = 123456 or CNB = 123456 is allowed. If both CNA and CNB are blank, then CNA = 123456. For this method, RBAR1 gives the simpler input format.

4. If both CMA and CMB are zero or blank, all of the degrees-of-freedom not in CNA and CNB will be made dependent. For the linear method, the dependent degrees-of-freedom will be made members of the m-set. For the Lagrange method, they may or may not be member of the m-set, depending on the method selected in the RIGID Case Control command. However, the rules regarding the m-set described below apply to both methods.
5. The m-set coordinates specified on this entry may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
6. Element identification numbers should be unique with respect to all other element identification numbers.
7. RBAR, among other eligible rigid element types, can be selected via MPC and SET3.
8. Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.
9. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
10. See [Rigid Elements and Multipoint Constraints \(R-type, MPC\)](#) in the *MSC Nastran Reference Guide* for a discussion of rigid elements.
11. For the Lagrange method, the thermal expansion effect will be computed for the rigid bar element if user supplies the thermal expansion coefficient ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The temperature of the element is taken as the average temperature of the two connected grid points GA and GB.
12. When there is large rotation, CMA and CMB must have all “456” if any rotational degrees of freedom is used.

**RBAR1**

## Rigid Bar

Alternative format for RBAR.

**Format:**

1	2	3	4	5	6	7	8	9	10
RBAR1	EID	GA	GB	CB	ALPHA	TREF			

**Example:**

RBAR1	5	1	2	123	6.5-6				
-------	---	---	---	-----	-------	--	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
GA, GB	Grid point identification numbers. (Integer > 0)
CB	Component numbers in the global coordinate system at GB, which are constrained to move as the rigid bar. See Remark 4. (Integers 1 through 6 with no embedded blanks or blank.)
ALPHA	Thermal expansion coefficient. See Remark 8. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

**Remarks:**

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, Nastran will create internally the Lagrange multiplier degrees-of-freedom in addition to the 12 displacement degrees-of-freedom given by grid points GA and GB. The number of Lagrange multiplier degrees-of-freedom is equal to the number of dependent degrees-of-freedom given by CB.
- RBAR1 is a preferred input format to define the Lagrange method for a rigid bar.
- When CB = "123456" or blank, the grid point GB is constrained to move with GA as a rigid bar. For default CB = "123456". Any number of degrees-of-freedom at grid point GB can be released not to move with the rigid body.
- For the Lagrange method, the theory is formulated such that a consistent rigid body motion for grid points GA and GB will be computed even if these two points have different global coordinate systems.
- For the Lagrange method, the thermal expansion effect will be computed for the rigid bar element if user supplies the thermal expansion coefficient ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The temperature of the element is taken as the average temperature of the two connected grid points GA and GB.

7. Element identification numbers should be unique with respect to all other element identification numbers.
8. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
9. Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.

## RBAX3D

## Axisymmetric Harmonic Element Rigid Connection

Defines a rigid connection between a point on an axisymmetric harmonic element (CQUADX or CTRIAX) and a point on the axis of symmetry of that element.

### Format:

1	2	3	4	5	6	7	8	9	10
RBAX3D	EID	G3D	GAX						

### Example:

RBAX3D	100	10	20						
--------	-----	----	----	--	--	--	--	--	--

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000). See Remark 1..
G3D	Identification number of a grid point on the axis of symmetry (Integer > 100,000,000). See Remarks 2. and 4. through 7.
GAX	Identification number of a grid point referenced on an axisymmetric harmonic element (CQUADX or CTRIAX). (0 < Integer < 100,000,000). See Remarks 3. through 7.

### Remarks:

1. The EID should be unique with respect to all other elements.
2. The G3D point may not be referenced on an axisymmetric harmonic element. If it is, the program terminates the execution with an appropriate user fatal message.
3. The GAX point must be referenced on an axisymmetric harmonic element. If it is not, the program terminates the execution with an appropriate user fatal message. Further, the axisymmetric harmonic element (or elements) that reference GAX must have harmonic index 1 specified on the associated PAXSYMH entry. If this condition is not satisfied, the program terminates the execution with an appropriate user fatal message.
4. The G3D point must be on the axis of symmetry. The GAX point need not be on the axis of symmetry.
5. The G3D and GAX points must both have the same axial coordinate along the axis of symmetry.
6. The G3D point is regarded as the independent point and the GAX point is regarded as the dependent point. The dependent degrees of freedom of GAX will be selected from the axisymmetric harmonic degrees of freedom.

7. If the GAX point is on the axis of symmetry, the connection is made only to the G3D displacement components perpendicular to the axis. However, if the GAX point is not on the axis of symmetry, then connection is made not only to the G3D displacement components perpendicular to the axis, but also to the slopes. The tolerance to determine if the GAX point is on the axis of symmetry is  $1.0E-6$ .

## RBE1 Rigid Body Element, Form 1

Defines a rigid body connected to an arbitrary number of grid points.

### Format:

1	2	3	4	5	6	7	8	9	10
RBE1	EID	GN1	CN1	GN2	CN2	GN3	CN3		
		GN4	CN4	GN5	CN5	GN6	CN6		
	“UM”	GM1	CM1	GM2	CM2	GM3	CM3		
		GM4	CM4	-etc.-	ALPHA	TREF			

### Example:

RBE1	59	59	123456						
	UM	61	246	6.5-6					

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
GNi	Grid points at which independent degrees-of-freedom for the element are assigned. (Integer > 0)
CNi	Independent degrees-of-freedom in the global coordinate system for the rigid element at grid point(s) GNi. See Remark 1. (Integers 1 through 6 with no embedded blanks.)
“UM”	Indicates the start of the dependent degrees-of-freedom. (Character)
GMj	Grid points at which dependent degrees-of-freedom are assigned. (Integer > 0)
CMj	Dependent degrees-of-freedom in the global coordinate system at grid point(s) GMj. (Integers 1 through 6 with no embedded blanks.)
ALPHA	Thermal expansion coefficient. See Remark 13. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

### Remarks:

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, Nastran will create internally the Lagrange multiplier degrees-of-freedom in addition to the displacement degrees-of-freedom given by connected grid points. The number of Lagrange multiplier degrees-of-freedom is equal to the number of dependent degrees-of-freedom given by CMj.

3. For the linear method, the total number of components in CN1 to CN6 must equal six; for example, CN1 = 123, CN2 = 3, CN3 = 2, CN4 = 3. Furthermore, they must jointly be capable of representing any general rigid body motion of the element. The first continuation entry is not required if there are fewer than four GN points. For the Lagrange method, the total number of components must also be six. In addition, CN1 must be 123456, and CN2 through CN6 must be blank.
4. For the linear method, the dependent degrees-of-freedom will be made members of the m-set. For the Lagrange method, they may or may not be member of the m-set, depending on the method selected on the RIGID Case Control command. However, the rules regarding to m-set described below apply to both types of methods.
5. Dependent degrees-of-freedom assigned by one rigid element may not also be assigned dependent by another rigid element or by a multipoint constraint.
6. A degree-of-freedom cannot be both independent and dependent for the same element. However, both independent and dependent components can exist at the same grid point.
7. Element identification numbers should be unique with respect to all other element identification numbers.
8. RBE1, among other eligible rigid element types, can be selected via MPC and SET3.
9. Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.
10. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
11. See [Rigid Elements and Multipoint Constraints \(R-type, MPC\)](#) in the *MSC Nastran Reference Guide* for a discussion of rigid elements.
12. The m-set coordinates specified on this entry may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
13. For the Lagrange method, the thermal expansion effect will be computed, if user supplies the thermal expansion coefficient ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The average temperature of the connected grid points is used as the temperature of the rigid body element. In this case, for the Lagrange method, PARAM, BAILOUT, -1 is activated within the solver.

## RBE2

## Rigid Body Element, Form 2

Defines a rigid body with independent degrees-of-freedom that are specified at a single grid point and with dependent degrees-of-freedom that are specified at an arbitrary number of grid points.

### Format:

1	2	3	4	5	6	7	8	9	10
RBE2	EID	GN	CM	GM1	GM2	GM3	GM4	GM5	
	GM6	GM7	GM8	-etc.-	ALPHA	TREF			

### Example:

RBE2	9	8	12	10	12	14	15	16	
	20	6.5-6							

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
GN	Identification number of grid point to which all six independent degrees-of-freedom for the element are assigned. (Integer > 0)
CM	Component numbers of the dependent degrees-of-freedom in the global coordinate system at grid points GMi. (Integers 1 through 6 with no embedded blanks.) See Remark 12.
GMi	Grid point identification numbers at which dependent degrees-of-freedom are assigned. (Integer > 0)
ALPHA	Thermal expansion coefficient. See Remark 11. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

### Remarks:

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, Nastran will create internally the Lagrange multiplier degrees-of-freedom in addition to the displacement degrees-of-freedom given by connected grid points. The number of Lagrange multiplier degrees-of-freedom is equal to the number of dependent degrees-of-freedom which is obtained by CM multiplied with the number of dependent grid points.
- For the linear method, the dependent degrees-of-freedom indicated by CM will be made members of the m-set at all grid points. For the Lagrange method, they may or may not be members of the m-set, depending on the method selected on the RIGID Case Control command. However, the rules regarding the m-set described below apply to both types of methods.
- Dependent degrees-of-freedom assigned by one rigid element may not also be assigned dependent by another rigid element or by a multipoint constraint.

5. Element identification numbers should be unique with respect to all other element identification numbers.
6. RBE2, among other eligible rigid element types, can be selected via MPC and SET3.
7. Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.
8. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
9. See [Rigid Elements and Multipoint Constraints \(R-type, MPC\)](#) in the *MSC Nastran Reference Guide* for a discussion of rigid elements.
10. The m-set coordinates specified on this entry may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
11. For the Lagrange method, the thermal expansion effect will be computed, if user supplies the thermal expansion coefficient ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The average temperature of the connected grid points is used as the temperature of the rigid body element. In this case, for the Lagrange method, PARAM, BAILOUT, -1 is activated within the solver.
12. It can be any combination in 1, 2, 3, but must have all "456" if any rotation DOF is used when there is large rotation.

## RBE2GS

## Internally Generate an RBE2 Element

Defines an RBE2 connecting the two closest grids to GS.

### Format:

1	2	3	4	5	6	7	8	9	10
RBE2GS	EID	GS	TYPE		TREF	R	CM	ALPHA	
	XS	YS	ZS	GNi	GMj				

### Example:

RBE2GS	3	17				1.3		6.5-6	
				end/	56	99			

### Alternate Formats and Examples:

RBE2GS	EID	GS	TYPE			R	CM	ALPHA	
	XS	YS	ZS	GNi	THRU	GNj	end/		
	GMk	THRU	GM/						

RBE2GS	15	35				-.66			
				88	THRU	107	end/	15	
	76	88							

RBE2GS	25					.66			
	5.173	0.0	19.3185	88	99	108	end/		
	15	THRU	88						

RBE2GS	35	28				-.66			
				56	THRU	102	end/	19	
	21	THRU	200						

RBE2GS	45	16				-.66			
				56	THRU	102	1129		
	1146	THRU	1200	end/					

Descriptor	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
GS	Search POINT or GRID point. (Integer ≥ 0 or blank)
TYPE	Connectivity: (Character)
	blank                      Search the complete model. (Default)

Describer	Meaning
	NMFLIP The independent and dependent DOF's are interchanged.
	IIRBE2 The grids chosen will be the independent GN's of the two closest existing RBE2 elements.
	NMIIRBE2 Same as 'IIRBE2' except the independent and dependent grids are interchanged.
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).
R	Radius. (Real > 0, or < 0)
CM	Component number of dependent degrees-of-freedom for grid GM. (Integers 1 through 6 with no embedded blanks. Blank defaults to 123456)
ALPHA	Thermal expansion coefficient. (Real or blank)
XS, YS, ZS	Location of search point if GS is blank. Used only if GS=0 or blank. (Real or blank)
GNi	List of grids to be excluded from candidate grids for GN. If a GNi list is given it must end with an <code>end/</code> . (Integer > 0 or blank or "THRU")
GMj	List of grids to be excluded from candidate grids for GM. If no GNi list is given and a GMj list is present, then GNi must have an <code>end/</code> entry. (Integer > 0 or blank or "THRU")

1. Element ID numbers must be unique with respect to all other element ID numbers.
2. This entry will internally define a RBE2 element with the same ID of the RBE2GS entry. The grid assigned to GN will always be the independent grid. GM will be the dependent grid. If GS is a 'POINT' entry (or GS is blank and XYZ is specified), the first two grids that fall within the search radius  $|R|$  about GS (or XYZ) will be chosen as GN and GM. The closest to the search location will be the independent grid GN the next closest will be the dependent grid GM. Any grids contained in a GNi list will be excluded from the GN search and any grids contained in a GMj list will be excluded from the GM search. After GN and GM have been determined (with or without use of the exclusion lists for GNi and GMj (and if TYPE = 'NMFLIP', then GN and GM will be reversed. If GS is 'GRID' entry, and is part of the physical model, i.e., it has physical structural elements attached to it, it will become GN the independent grid for the RBE2 to be generated. If it is in the GNi exclusion list, the next closest grid will be chosen. the closest grid within the search radius about  $|R|$  GN will be chosen as GM, the dependent grid. Any grids contained in a GNi list will be excluded from the GN search and any grids contained in a GMj list will be excluded from the GM search. After GN and GM have been determined (with our without use of the exclusion lists for GNi and GMj) and if TYPE = 'NMFLIP', then GN and GM will be reversed. If GS is a 'GRID' entry, and is determined not to be part of the physical model, the first two grids that fall within the search radius  $|R|$  about GS (or XYZ) will be chosen as GN and GM. The closest to the search location will be the independent grid, GN, the next closest will be the dependent grid, GM. Any grids contained in a GNi list will be excluded from the GN search and any grids contained in a GMj list will be excluded from the GM search. After GN and GM have been determined (with or without use of the exclusion lists for GNi and GMj) and if TYPE='NMFLIP', then GN and GM

will be reversed. The GS grid will remain on the GEOM1 table for post-processing viewing purposes, but will not be part of the Nastran solution g-set. If TYPE='IIRBE2', the two grids chosen for the RBE2 will be the independent GN's of existing RBE2 elements whose independent grids lie within the search radius. If TYPE='NMIIRB2', then GN and GM will be reversed. If no existing RBE2 elements have independent grids within the search radius or if only one existing RBE2 has an independent grid within the search radius, then a fatal message will be issued. POINT and GRID entries must be unique with respect to all other POINT and GRID entries. If TYPE='IIRB2', it is recommended that PARAM,AUTOMSET,YES be used in the analysis run.

3. If  $R < 0$ , the two located grids GN and GM will be made coincident to the GS (or XYZ) location.
4. If CM is 123456 and GM is touching only solid elements, CM will be internally changed to 123. For solid elements, the grids GN and GM should always be coincident.
5. When Module GP4 is run, checks are made to insure that the selected grids, GN and GM, do not violate existing constraint sets. If a violation occurs a fatal message will be issued for the offending grids. These grids can be excluded from further search inclusion by specifying them on the GNi or GMj list. PARAM,AUTOMSET,YES will often prevent any violation.
6. If GS=0 or blank and XS, YX, ZS is not specified or if both GS and XS, YS, ZS are specified a fatal error will occur.
7. The end of a grid exclusion lists is indicated by the existence of "end/" in the field following the last entry in the list. In the "thru" option, not all grids in the range need exist.
8. For superelement or part superelement connection the independent grid assigned to GN will be exterior to the superelement. The dependent grid GM will be an interior grid to the superelement. If the resulting RBE2 element, connects two different superelements, the element will be assigned to the superelement with the lower ID and the grid attached to the superelement with the higher ID will be moved to the superelement with the lower ID.
9. If the RBE2GS is listed on a SEELT entry, it will be placed as the SEELT directs. If say grid G1 lies in another superelement and G2 lies in the SEELT superelement, G1 will be moved to the SEELT defined superelement.
10. "THRU" should not be the first nonblank field of a continuation line. Blank fields are allowed in the exclusion lists for readability.
11. Use PARAM,SEP1XOVR,16 to print the grids found by each RBE2GS entry.
12. RBE2GS is not supported in the presence of part (BEGIN SUPER) superelements.
13. For the Lagrange method, the thermal expansion effect will be computed, if user supplies the thermal expansion coefficient ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The average temperature of the connected grid points is used as the temperature of the rigid body element. In this case, for the Lagrange method, PARAM, BAILOUT, -1 is activated within the solver.

## RBE3 Interpolation Constraint Element

Defines the motion at a reference grid point as the weighted average of the motions at a set of other grid points.

### Format:

1	2	3	4	5	6	7	8	9	10
RBE3	EID		REFGRID	REFC	WT1	C1	G1,1	G1,2	
	G1,3	WT2	C2	G2,1	G2,2	-etc.-	WT3	C3	
	G3,1	G3,2	-etc.-	WT4	C4	G4,1	G4,2	-etc.-	
	“UM”	GM1	CM1	GM2	CM2	GM3	CM3		
		GM4	CM4	GM5	CM5	-etc.-			
	“ALPHA”	ALPHA	TREF						

### Example:

RBE3	14		100	1234	1.0	123	1	3	
	5	4.7	1	2	4	6	5.2	2	
	7	8	9	5.1	1	15	16		
	UM	100	14	5	3	7	2		
	ALPHA	6.5-6							

Descriptor	Meaning
EID	Element identification number. Unique with respect to all elements. (0 < Integer < 100,000,000)
REFGRID	Reference grid point identification number. (Integer > 0)
REFC	Component numbers at the reference grid point. (Any of the integers 1 through 6 with no embedded blanks.)
WTi	Weighting factor for components of motion on the following entry at grid points Gi,j. (Real)
Ci	Component numbers with weighting factor WTi at grid points Gi,j. (Any of the integers 1 through 6 with no embedded blanks.)
Gi,j	Grid points with components Ci that have weighting factor WTi in the averaging equations. (Integer > 0)
“UM”	Indicates the start of the degrees-of-freedom belonging to the dependent degrees-of-freedom. The default action is to assign only the components in REFC to the dependent degrees-of-freedom. (Character)
GMi	Identification numbers of grid points with degrees-of-freedom in the m-set. (Integer > 0)

Describer	Meaning
CMi	Component numbers of GMi to be assigned to the m-set. (Any of the Integers 1 through 6 with no embedded blanks.)
“ALPHA”	Indicates that the next number is the coefficient of thermal expansion. (Character)
ALPHA	Thermal expansion coefficient. See Remark 14. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

### Remarks:

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, the REFC must be “123”, “456”, or “123456”. No other combination is allowed.
- For the Lagrange method, Nastran will create internally the Lagrange multiplier degrees-of-freedom in addition to the displacement degrees-of-freedom given by connected grid points. The number of Lagrange multiplier degrees-of-freedom is equal to the number of degrees-of-freedom given by REFC.
- For the linear method, the dependent degrees-of-freedom indicated by REFC will be made members of the m-set. For Lagrange rigid element, they may or may not be members of the m-set, depending on the method selected on the RIGID Case Control command. However, the rules regarding the m-set described below apply to both types of methods.
- We recommend that for most applications only the translation components 123 be used for Ci. An exception is the case where the Gi,j are colinear. A rotation component may then be added to one grid point to stabilize its associated rigid body mode for the element.
- Blank spaces may be left at the end of a Gi,j sequence.
- For the Lagrange method, the default for “UM” must be used. For the linear method, the default for “UM” should be used except in cases where the user wishes to include some or all REFC components in displacement sets exclusive from the m-set. If the default is not used for “UM”:
  - The total number of components in the m-set (i.e., the total number of dependent degrees-of-freedom defined by the element) must be equal to the number of components in REFC (four components in the example).
  - The components specified after “UM” must be a subset of the components specified under REFC and (Gi,j, Ci).
  - The m-rows by m-columns partition [Rm,m] of the global stiffness containing the dependent degrees-of-freedom of multipoint constraints and rigid elements must be nonsingular. PARAM,CHECKOUT in SOLs 101 through 200 may be used to check for this condition. For some complex constraints, forming a well-conditioned [Rm,m] is difficult for a user to perform manually and PARAM,AUTOMSET,YES will automatically determine a well-conditioned partition by employing a rectangular decomposition of the [Rm,g] matrix.
- Dependent degrees-of-freedom assigned by one rigid element may not also be assigned dependent by another rigid element or by a multipoint constraint.

9. RBE3, among other eligible rigid element types, can be selected via MPC and SET3.
10. Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.
11. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
12. The m-set coordinates specified on this entry may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets, 1103](#) for a list of these entries.
13. The formulation for the RBE3 element was changed in Version 70.7. This change allowed the element to give consistent answers that are not dependent upon the units of the model. Only models that connected rotation degrees-of-freedom for Ci were affected. Note that these models are ignoring the recommendation in Remark 5. The formulation prior to Version 70.7 may be obtained by setting SYSTEM(310)=1.
14. For the Lagrange method, the thermal expansion effect will be computed, if user supplies the thermal expansion coefficient ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The average temperature of the connected grid points is used as the temperature of the rigid body element. In this case, for the Lagrange method, PARAM, BAILOUT, -1 is activated within the solver.

**RBE3U** Defines Method to Distribute Applied Loads to a Surface in SOL 600

**Format:**

1	2	3	4	5	6	7	8	9	10
RBE3U	EID	IOPT	GREF	G1	G2	G3	G4	G5	
	G6	G7	G8	G9	etc.				

**Alternate Format:**

1	2	3	4	5	6	7	8	9	10
RBE3U	EID	IOPT	GREF	G1	THRU	G3	BY	G4	
	G5	THRU	G6	BY	G7				
	G8	THRU	G9	BY	G10	etc.			

**Examples:**

RBE3U	250	1	1000	100	THRU	120			
-------	-----	---	------	-----	------	-----	--	--	--

Describer	Meaning
EID	Identification number, unique among all elements. (Integer; no Default; Required)
IOPT	Option of how to distribute the load. (Integer; Default = 1) 1 Equal loads values will be applied to all grid points on the surface. 2 Loads will be distributed according to how close each grid point on the surface is to GREF.
Gi	List of grids to which forces at GREF will be distributed. (Integer; Default = 123)

**Remarks:**

1. The sum of the loads on all grid points is the same as the applied to GREF in each of the CREF directions. If IOPT=1 the force on each grid point will be the total loads divided by the number of applicable grid points. If IOPT=2 the load of each grid point will be weighted according to its distance from GREF, however the sum of all loads will be the same as that applied to GREF. The load is removed from GREF after distribution.
2. RBE3U is only used to distributed applied loads. No actual rigid elements are included in the analysis. If rigid elements are desired, use RBE2 or RBE3.
3. Only FORCE and MOMENT will be distributed using this entry. All other types of forces such as FORCE1, MOMENT1, TEMP, etc. applied to GREF will not be distributed.

## RBJOINT

### Defines a Joint Between Two Rigid Bodies

Defines a joint between two rigid bodies. Used in SOL 700 only.

#### Format:

1	2	3	4	5	6	7	8	9	10
RBJOINT	ID	TYPE	N1	N2	N3	N4	N5	N6	
		RPS							

#### Examples:

##### Example 1 - Cylindrical Joint

RBJOINT	1	CYLIND	101	201	103	204			
---------	---	--------	-----	-----	-----	-----	--	--	--

Describer	Meaning
ID	RBJOIN identification number. (Integer > 0; Required)
TYPE	Type of RBJOIN. (Character; Required) Types available are (node numbers in the images correspond to N1, N2, etc.): TYPE=SPHER(spherical), The relative motion of the rigid bodies are constrained so that nodes which are initially coincident remain coincident. In the below figure the socket's node is not interior to the socket-SOL700 does not require that a rigid body's nodes be interior to the body.

Spherical joint

Describer	Meaning
-----------	---------

TYPE=REVOLUTE, Both nodal pairs (1,2) and (3,4) are constrained to remain coincident. Consequently, the relative motion of these rigid bodies is restricted to rotations about the line segment formed by the two pairs of coincident nodes. This segment is labeled the "centerline".

Revolute joint

TYPE=CYLIND (cylindrical), This joint is derived from the rotational joint by relaxing the constraints along the centerline. This joint admits relative rotation and translation along the centerline.

Cylindrical joint

TYPE=PLANAR, This joint is derived from the rotational joint by relaxing the constraints normal to the centerline. Relatively displacements along the direction of the centerline are excluded.

Planar joint

Describer	Meaning
-----------	---------

TYPE=UNIVERS (universal joint), In contrast with the preceding joints, nodal pairs (1,2) and (3,4) are not initially coincident. Rather, the segments formed by (1,3) and (2,4) must be orthogonal; and they serve as axes about which the two bodies may undergo relative rotation. The universal joint excludes all other relative motion and the axes remain orthogonal at all time.

Universal joint

TYPE=TRANSL (translational), This is a cylindrical joint with a third pair of off-centerline nodes which restrict rotation. Aside from translation along the centerline the two rigid bodies are stuck together.

Translational joint

- N1 GRID id of Node 1, in rigid body A. Define for all joint types
- N2 GRID id of Node 2, in rigid body B. Define for all joint types
- N3 GRID id of Node 3, in rigid body A. Define for all joint types except SPHER.
- N4 GRID id of Node 4, in rigid body B. Define for all joint types except SPHER.
- N5 GRID id of Node 5, in rigid body A. Define only for joint types TRANSL.
- N6 GRID id of Node 6, in rigid body B. Define only for joint types TRANSL.
- RPS Relative penalty stiffness (Default = 1.0)

**RCONN**

## Rigid Connection

Defines a rigid connection between the different parts of Lagrangian meshes (tied surfaces). Used in SOL 700 only.

**Format:**

1	2	3	4	5	6	7	8	9	10
RCONN	CID	STYPE	MTYPE	SID	MID	OPTION			
	CLSGAP	GAPDIS	GAPDISV						

**Example:**

RCONN	7	GRID	SURF	3	7	NORMAL			
-------	---	------	------	---	---	--------	--	--	--

Field	Content
CID	Unique rigid-connection number (Integer; Required)
STYPE	Type of entity used to define the secondary surface (Character; Default = SURF)
	<p>SURF                    The faces of the elements are used for the secondary surface. SID refers to BSURF ID. See Remark 1.</p> <p>GRID                    Grid points will be tied to the primary surface. SID then refers to a SET or BCGRID ID containing the list of grid points to be used. See Remarks 2. and 3.</p>
MTYPE	Type of entity used to define the primary surface (Character; Default = SURF)
	<p>SURF                    The faces of the elements are used for the primary surface. MID refers to BSURF ID.</p>
SID	Secondary BSURF ID or SET1 ID containing the list of grid points (Integer; Required)
MID	Primary BSURF ID (Integer; Required)
OPTION	Only used if discrete grid points are tied to a surface (STYPE is equal to GRID). (Character; Default = NORMAL)
	<p>NORMAL                The grid points are tied to the primary surface. See Remark 2.</p> <p>SHELL                  The grid points are attached to the edge of shell or beam elements, which are tied to the shell surface. See Remark 3.</p>
CLSGAP	Switch to automatically close any gaps that are present between the primary-secondary surface (Character; Default = NO)
	<p>YES                      Gaps are automatically closed</p> <p>NO                        Gaps are not closed. See Remark 2.</p>

Field	Content
GAPDIS	Defines the tolerance used in the search for a primary face. If the distance between a secondary point and a primary face falls within this tolerance, the primary face is accepted. If not, the search for a correct primary face continues (Character; Default = DISTANCE)  DISTANCE      The tolerance has the length as specified at GAPDISV
GAPDISV	The value of the gap tolerance or a factor to calculate this tolerance depending on the value of GAPDIS (Real; Default = 1.0E20)

### Remarks

1. The RCONN entry can be used to define three types of connection:
  - a. Two Surfaces Tied Together.
  - b. Define secondary and primary segments representing the two surfaces to be tied together. There should not be a gap between the two sets of segments. The two surfaces are tied together during the analysis.
  - c. Grid Points Tied to a Surface.
  - d. If STYPE is set to GRID and OPTION is set to NORMAL, the secondary entities comprise discrete grid points that are tied to the primary surface during the analysis. The grid points must lie on the surface.
  - e. Shell Edge Tied to a Shell Surface.
  - f. If STYPE is set to GRID and OPTION is set to SHELL, the edges of shell or beams elements can be tied to the faces of other shells. The grid points attached to the edge of the shells/beams must be selected as the secondary grid points. The shell surface to which they are tied must be selected as the primary surface. The two sets will then be tied together throughout the analysis. All degrees of freedom will be coupled.
2. The CLSGAP entry enables you to define two different meshes that are not coincident over the primary/secondary interface. If the option is set to YES, the secondary surface becomes coincident (according to projections) with the primary surface.
3. The search method of the contact algorithm is used to find the closest primary face. The tolerance defined with the GAPDIS/GAPDISV fields is similar to the monitoring distance defined on the CONTACT entry with the MONDIS/ MONDISV fields.
4. The use of the gap closing CLSGAP can cause an element to collapse. This may happen if the GAPDISV tolerance is set to a value greater than the length of the side of an element.
5. When a solid and a shell mesh are tied together, the rotational degrees of freedom of the shell grid points are not coupled.
6. When OPTION=SHELL and CLSGAP=NO, the time step scale factor will be set to 0.4. This can be overwritten by:  
PARAM\*, STEPFCRCONN, xxx

## RCPARM

## Parameters for RC Heat Transfer Analysis Control

Defines a set of parameters for nonlinear resistance-capacitance based analysis.

### Format:

1	2	3	4	5	6	7	8	9	10
RCPARM	ID	SOLVER	DRLXCA	ARLXCA	BALENG	NLOOP	DAMPD	GRVCON	
	TIMEND	OUTPUT	CSGFAC	DTIMEI					

### Example:

RCPARM	1	SNDUFR	1.0-2	1.0-2	1.0-4	2000	0.7	9.81	
	1800.	60.	1.2	0.0					

Describer	Meaning
ID	Identification number. See Remark 2. (Integer > 0; Required)
Solver	Equivalent Sinda Solution name. See Remarks 3. and 7. (String; Required) Possible values: RCNS "SNSOR", "STDSTL" RCNT "SNFRDL", "FWDBKL", "SNADE", "SNDUFR", "ATSDUF", "ATSF BK", "SNTSM", "SNTSM3", "SNTSM1", "SNTSM4", Maintained for legacy, but not shown in GUI "SNSOR1", "SNSORA", "SNSOR1A", "SNHOSD", "SNSOSS", "SNHOSS", "SCROUT", "SNDSDNR", "TRSPMA"
DRLXCA	Diffusion node convergence criterion (Real $\geq$ 0.0; Default 1.0e-3 degrees) (SimX: Default 1.0e-4 for transient)
ARLXCA	Arithmetic node convergence criterion (Real $\geq$ 0.0; Default 1.0e-3 degrees) (SimX: Default 1.0e-4 for transient)
BALENG	Allowable system energy imbalance (Real $\geq$ 0.0; Default 0.0 energy/time)
NLOOP	Number of iterations allowable (Integer $\geq$ 0; Default 5000 loop) (SimX: Default 50 for transient)
DAMPD	Damping constant (Real $\geq$ 0.0; Default 0.0 non dimensional)
GRVCON	Gravitation constant (Real $\geq$ 0.0; Default 9.81 length/time <sup>2</sup> )
TIMEND	Problem end time (Real; Default 3600.0 time)
OUTPUT	Output interval (Real $\geq$ 0.0; Default 60.0 time)
CSGFAC	Time step control factor (Real $\geq$ 0.0; Default 1.0 non dimensional)
DTIMEI	Time step (Real $\geq$ 0.0; Default 0.0 time)

**Remarks:**

1. This entry is for RC Network solver only.
2. ID can be referenced by the case control command. Different cases may reference different RCPARM entries. It is possible to have multiple RCPARM entries inside one BDF file.
3. RCNS stands for RC Network Steady-state (static), RCNT stands for RC Network Transient
4. The default values are for Nastran only. The modeler (Patran or SimXpert) will have their default values. Some are related with the model units. The default values will not be all 0.0.
5. Default solvers and result checking SNSOR and SNDUFR are the default steady and transient solvers. They are good for most of the cases. Users are encouraged to check the results by the following methods.

Obtain nearly identical results with a different solver

Obtain nearly identical results with tighter convergence

Obtain nearly identical results with a smaller time step (transient)

Obtain nearly identical results with more rays or different random seeds (external radiation solvers)

6. About non-default solvers:

For non-spacecraft, non-radiation problems:

Solid type model – SNSOR, SNTSM1

For spacecraft/radiation models:

SNSOR (with user-specified DAMPD if necessary)

FWDBKL if thermo-stats are present

ATSDUF, SNTSM1 for most other cases

7. About the time step
  - a. The default computed time step (DTIMEU) = CSGMIN\* CSGFAC. CSGMIN can be checked in the .sot file. If CSGFAC is not specified, it is internally set to 1.0. The DTIMEU in the .sot file has been truncated by the OUTPUT point.
  - b. In a normal sized model, CSGMIN usually is small enough for the time step which will assure a convergent transient run.
  - c. CSGFAC is used to adjust the time step. It is recommended to determine the best CSGFAC to the model while maintaining acceptable temperature errors.
  - d. If  $OUTPUT < CSGFAC * CSGMIN$  or  $OUTPUT < DTIMEI$ , then OUTPUT becomes the time step. All the OUTPUT points are automatically required to be calculated.
  - e. DTIMEI is the forced time step which will ignore any other factors. Sometimes it may lead to inaccurate answer if it is too large. DTIMEI does not affect the automatic time step solvers.
  - f. If the model size is very small, CSGMIN may be too big for the time step. A small CSGFAC or DTIMEI should be used to adjust the time step.
  - g.  $CSGFAC * CSGMIN$  or DTIMEI should be small enough to “catch” any details in time fields, temperature fields or orbital flux arrays.

8. For more details about these parameters, please reference *MSC SINDA User's Guide and Library Reference*.

**RCROSS****Cross-Power Spectral Density and Cross-Correlation Functions Output**

Defines a pair of response quantities for computing the cross-power spectral density and cross-correlation functions in random analysis.

**Format:**

1	2	3	4	5	6	7	8	9	10
RCROSS	SID	RTYPE1	ID1	COMP1	RTYPE2	ID2	COMP2	CURID	

**Example:**

RCROSS	10	DISP	100	3	STRESS	200	10	2	
--------	----	------	-----	---	--------	-----	----	---	--

Describer	Meaning
SID	Case Control RCROSS identification number for cross-power spectral density function and cross-correlation function. (Integer > 0)
RTYPEi	Type of response quantity. At least one field must be selected. See Remark 2. (Character or blank)
IDI	Element, grid or scalar point identification number. (Integer > 0)
COMPi	Component code (item) identification number. See Remark 3. (Integer > 0)
CURID	Curve identification number. See Remark 4. (Integer ≥ 0 or blank)

**Remarks:**

1. This entry is required for computing the cross-power spectral density function and cross-correlation function. SID must be selected with the Case Control command (RCROSS = SID). Fields RTYPE1, ID1, and COMP1 represent the first response quantity, and fields RTYPE2, ID2, and COMP2 the second in the correlation.
2. The keywords for field RTYPEi are listed as follows:

Keyword	Meaning
DISP	Displacement Vector
VELO	Velocity Vector
ACCEL	Acceleration Vector
OLOAD	Applied Load Vector
SPCF	Single-point Constraint Force Vector

Keyword	Meaning
MPCF	Multi-point Constraint Force Vector
STRESS	Element Stress
STRAIN	Element Strain
FORCE	Element Force

If anyone of RTYPE1 or RTYPE2 is blank, then the default is the one same as the other field.

- For elements, the item code COMP<sub>i</sub> represents a component of the element stress, strain, and force and is described in Tables [Element Stress-Strain Item Codes](#) and [Element Force Item Codes Part 1](#). For an item having both a real and imaginary part, the code of the real part must be selected. This is required for computing both the cross-power spectral density function and cross-correlation function.

For grid point, the item code is one of 1, 2, 3, 4, 5, and 6, which represent the mnemonics T1, T2, T3, R1, R2, and R3, respectively. For scalar point, always use 1.

- Field CURID is optional. It is for the user's convenience to identify the output by using a single index.

Defines the reference rotor for non-reference rotors in residual (SE 0). Applicable only for Complex Eigenvalue analysis (SOL 107 / 110 / 200 / 400 (ANALYSIS=DCEIG or MCEIG))

## REFROT

Defines the reference rotor for non-reference rotors in residual (SE 0). Applicable only for Complex Eigenvalue analysis (SOL 107 / 110 / 200 / 400 (ANALYSIS=DCEIG or MCEIG))

Specifies the reference rotor for non-reference rotors.

### Format:

1	2	3	4	5	6	7	8	9	10
REFROT	RID	REFROTID	NFROTID1	NFROTID2	NFROTID3	NFROTID4	NFROTID5	NFROTID6	
	NFROTID7	NFROTID8	-etc.-						

or

1	2	3	4	5	6	7	8	9	10
REFROT	RID	REFROTID	NFROTID1	THRU	NFROTIDn	BY	INC		

### Example:

REFROT	100	10	20	35	1	2	60	88	
	99	4001	100						

or

REFROT	100	10	20	THRU	100	BY	10		
--------	-----	----	----	------	-----	----	----	--	--

Describer	Meaning
RID	Identification number of RGYRO entry. Selected by Case Control command, RGYRO. (Required; no Default). See Remark 1.
REFROTID	Specifies the reference rotor ID for all non-reference rotors entered in NFROTIDn field. (Integer > 0; Required; no Default)
NFROTIDi	Specifies the non-reference rotor ID. (Integer > 0; Required; no Default)
THRU	Specifies a range of identification numbers. (Optional)
BY	Specifies an increment for a THRU specification (Optional)
INC	ID number increment. (Integer)

### Remarks:

- Any REFROT bulk data entries with RID will be invoked for any subcase having a RGYRO=RID case control command. Multiple REFROT entries with same RID are allowed.
- REFROTID and NFROTID fields assume the rotor IDs are in the residual structure (SE 0).
- Any rotor whose id is used as REFROTID (in 3<sup>rd</sup> field) should have a valid RGYRO entry. REFROTID should match the RGYRO entry's REFROTR (4<sup>th</sup> field) entry. The 9<sup>th</sup> field in that RGYRO call should be 0 (meaning REFROTR rotor should be in the residual structure).

4. The same NFROTIDi (non-reference rotor id) should not be used on more than one REFROT entry. If a NFROTIDi is defined more than once, a User Fatal message will be issued. This is to make sure that each non-reference rotor can have only one reference rotor.
5. NFROTIDi (non-reference rotor ID) should not be used on any valid RGYRO definition.
6. All rotors in the residual structure (SE 0) should have either an individual RGYRO definition for it be reference rotor (or) use a REFROT entry to identify the reference rotor. If more than one RGYRO entry is used and a rotor does not have either one of these required valid definitions, a User Fatal Message will be issued. Alternately use only one RGYRO entry, which will be used as the reference rotor for all remaining rotors in the model.

Define the reference rotor for non-reference rotors in any superelement. Applicable only for Complex Eigenvalue analysis (SOL 107 / 110 / 200 / 400 (ANALYSIS=DCEIG or MCEIG))

**REFRTSE** Define the reference rotor for non-reference rotors in any superelement. Applicable only for Complex Eigenvalue analysis (SOL 107 / 110 / 200 / 400 (ANALYSIS=DCEIG or MCEIG))

Specifies the reference rotor for non-reference rotors in superelements.

**Format:**

1	2	3	4	5	6	7	8	9	10
REFRTSE	RID	REFROTID	REFROTSE	NFROTID1	NFROTSE1	NFROTID2	NFROTSE2	NFROTID3	
	NFROTSE2	NFROTID4	NFROTSE4						

**Example:**

REFRTSE	100	10	20	35	1	2	0	88	
	10	4001	100						

Describer	Meaning
RID	Identification number of RGYRO entry. Selected by Case Control command, RGYRO. (Required; no Default). See Remark 1.
REFROTID	Specifies the reference rotor ID for all non-reference rotors entered in NFROTIDn field. (Integer > 0; Required; no Default)
REFROTSE	Specifies the reference rotor REFROTID Superelement ID (Integer; Default=0)
NFROTIDi	Specifies the non-reference rotor ID. (Integer > 0; Required; no Default)
NFROTSEi	Specifies the non-reference rotor Superelement ID (Integer; Default=0)

**Remarks:**

- REFRTSE bulk data entries with RID will be invoked for any subcase having RGYRO=RID. Multiple REFRTSE entries with the same RID are allowed.
- The rotor ID used as REFROTID (in 3<sup>rd</sup> field) and its superelement ID used as REFROTSE (in 4<sup>th</sup> field) should have a valid RGYRO entry. Meaning, REFROTID field should match RGYRO's REFROTR (4<sup>th</sup> field) and REFROTSE entry should match with same RGYRO's ROTRSEID (9<sup>th</sup> field).
- The same NFROTIDi and NFROTSEi combination (non-reference rotor in any superelement) should not be used in more than one REFRTSE definition with the same RID. If defined, User Fatal message will be issued. This is to make sure that non-reference rotors can have only one reference rotor.
- NFROTIDi and NFROTSEi combination (non-reference rotor id) should not be used on a valid RGYRO definition.

5. All rotors defined in any superelement should have either individual RGYRO definition for it if it is a reference rotor (or) use REFRTSE definition to identify its reference rotor. If a rotor does not have either one of these required valid definitions and there is more than one RGYRO entry with the RID, a User Fatal Message will be issued. Alternately use only one RGYRO entry, which will be used as the reference rotor for all remaining rotors in the model.

## RELEASE Superelement Boundary Grid Point Release

Defines degrees-of-freedom for superelement exterior grid points that are not connected to the superelement.

### Format:

1	2	3	4	5	6	7	8	9	10
RELEASE	SEID	C	G1	G2	G3	G4	G5	G6	
	G7	G8	-etc.-						

### Example:

RELEASE	15	456	3	7	11	2	156	9	
	152	162							

### Alternate Formats and Examples:

RELEASE	SEID	C	G1	"THRU"	G2				
RELEASE	6	2	15	THRU	127				

(ALL must be in FIELD 4 and no continuation is allowed)

RELEASE	SEID	C	"ALL"						
RELEASE	127	156	ALL						

Describer	Meaning
SEID	Superelement identification number. (Integer > 0)
C	Component number. (Any unique combination of the Integers 1 through 6 with no embedded blanks.)
Gi	Grid point identification numbers. (Integer > 0; "THRU", or "ALL"; For THRU option, G1 < G2.)

### Remarks:

1. A grid point referenced on this entry must be an exterior grid point of the superelement referenced on the entry.
2. In the first alternate format, all grid points in the sequence G1 through G2 are not required to be exterior grid points. Such grid points will collectively produce a warning message but will otherwise be ignored.
3. If the "ALL" option is used, all exterior grid points are released for the referenced degrees-of-freedom.
4. The RELEASE entry is applicable to only the superelement solution sequences (SOLs 101 through 200). It may not reference the residual structure (SEID = 0).
5. This entry is not supported for partitioned superelements.

## RELEX

## External Definition of a Rigid Ellipsoid- SOL 700

Defines a rigid ellipsoid whose properties and motion are defined by either ATB. Used in SOL700 only.

### Format:

1	2	3	4	5	6	7	8	9	10
RELEX	NAME	PROG					etc		

### Example:

RELEX	HEAD	ATB							
-------	------	-----	--	--	--	--	--	--	--

Field	Content
NAME	<p>This name is used within the input file to define the interactions between the external ellipsoid and grid points and rigid bodies. This name is also used in the output requests.</p> <p>When coupled to ATB, the name must correspond to the name of the ATB segment. (Character; required)</p>
PROG	<p>Name of the external program. (Character; required)</p> <p>ATB SOL700 runs coupled with ATB</p>

**RESTART**

## Restart Data for Marc Executed from SOL 600

Specifies writing or reading of restart data for Nonlinear Analysis when Marc is executed from SOL 600. If this Bulk Data entry is found in the job stream, the type of “restart” specified by KIND and KTYPE will be performed. Only one RESTART entry is allowed.

**Format:**

1	2	3	4	5	6	7	8	9	10
RESTART	ID	KIND	NINC	NBEGIN					
	NAME		TSTEP	ENDTIME	NSTEPS	NDCYC	STEPMAX	PERCENT	

**Example(s):**

RESTART	101	1	1						
---------	-----	---	---	--	--	--	--	--	--

The above example writes a restart file. The original run named is abcde.dat.

RESTART	201	3	1	15					
	abcde								

The above example restarts the original abcde.dat run. The name of the restart run must not be abcde.dat in this case.

RESTART	151	2		11					
	my_first	_run							

The above example reads the restart file and prints out results not printed in the original run.

Descriptor	Meaning
ID	Identification number of the restart entry -- Not presently used (Integer)
KIND (2,1)	Type of restart (Integer > 0; required field; no Default) 1 = Write a restart file 2 = Restart a previous analysis (Read an existing restart file) 3 = Restart a previous analysis and write new data on restart file. 11 = Only write restart file for the last converged increment of the run. 12 = Read a restart file written with KIND=11 13 = Read a restart file written with KIND=11 and write the last increment or time step of the present run on that file as well.
NBEGIN (2,3)	The “time” increment at which the restart run begins (used only if KIND=2 or 3). (Integer > 0. See Remarks 3., 4.)
NINC (2,2)	Number of increments between writing of restart data. (Integer > 0; Default = 1)

Descriptor	Meaning
IPRINT (2,8)	Set this field to 1 if the restart data is to be printed (All data from increment INCBEG to LAST will be printed if IPRINT=1). Use this option if printing on a previous run was suppressed but now is desired. (Integer $\geq 0$ ; Default = 0)
LAST (2,9)	The last time increment is printed if IPRINT=1, otherwise this field is ignored. (Integer $> 0$ , Default = 0. See Remarks 3., 4.)
NAME	Name of input file for the original MSC Nastran run without extension. NAME is limited to 16 characters and may not contain imbedded blanks. If the small field format is used, NAME may span fields 2 and 3 of the continuation entry. If the large field is used, NAME should be coded in the 2nd field. NAME is required for a restart run, see Remarks 3., 7. If NAME exceeds 8 characters, the continuation line must be coded in small-field fixed format or in large field fixed or free-format.
TSTEP [2.1]	Time step size after restart -- For dynamic problems only. (Real $\geq 0.0$ or blank; if the value is $\leq 0.0$ the original step size is used)
ENDTIME [2,2]	Ending time for this restart run (Real $\geq 0.0$ or blank, if the value is $\leq 0.0$ the original end time is used)
NSTEPS [2,3]	Total number of time steps for the restart run plus the original run. (Integer $\geq 1$ ; Default = 1)
NDCYC [2,6]	Desired number of cycles if AUTO INCREMENT options were specified on the original run. (Integer $\geq 0$ ; if the value is $\leq 0$ the original is used)
STEPMAX [2,7]	Maximum step size if AUTO INCREMENT options were specified on the original run. (Real $\geq 0.0$ ; if the value is $\leq 0$ the original is used)
PERCENT [2,8]	Percentage of total load to be applied. (Real $\geq 0.0$ ; if the value is $\leq 0$ the original is used)

**Remarks:**

1. RESTART is available only when Marc is executed from within MSC Nastran Implicit Nonlinear (SOL 600).
2. There should only be one RESTART entry in the bulk data. If more than one exists, the first one will be used.
3. (i,j) Indicate the field in Marc's RESTART model definition options. [i,j] Indicate the field in Marc's REAUTO model definition options.
4. The jid.marc.t16 and jid.marc.t08 files must be saved from the first run when a restart run is executed. Both original and restart runs must be located in the same directory. File extensions are .t08 and t16.
5. A restart run may not have the same input file name (jid) as that of the original run. In other words, if the input file for the original run is named abcd.dat, the input file for a restart run may not be named abcd.dat.

6. For static analyses, normally each load case has a total time of 1.0. The first case goes from 0.0 to 1.0, the second from 1.0 to 2.0, etc. If the first run has two static load cases and terminates at 1.6, it is in the middle of the second load case. The original run should be examined to determine which increment (before 1.6) to begin the restart run.
7. In the second example above, the original run was named `my_first_run.dat` (or `first_run.bdf`, etc). This is a small field example. There are 8 characters in the 2nd field of the continuation line and 4 characters in the third field. The name can start anywhere within the two fields. There must not be any blank spaces in the name. If the name exceeds 8 characters, the continuation line must be coded in small-field fixed format or in large-field fixed or free format. NAME is limited to a maximum of 16 characters.
8. Both original and restart run names (jid's) should use only lower case letters except on computer systems that are not case sensitive. "NAME" (continue line, fields 2-3) will be converted automatically to lower case.
9. The restart run must use the same values of Marc's DIST LOAD parameter as the original run or it may fail. Be sure to use parameters MARCDIS2, MARCDIS3 and MARCDIS4 to set these values to be exactly the same as the original run (examine `jid.marc.dat` from the original run to determine these values before submitting the new run).
10. The RSF options creates a complete database which is necessary for restarts. When RSF=0 is specified, the same file is overwritten after each interval. When RSF=1 is specified, a new restart file is created after each interval, thus a "family" of files is created numbered sequentially `jid.dytr.d3dump10`, `jid.dytr.d3dump02`, etc. These files can take significant disk space but are important if a model might need to be modified prior to the end time.
11. It is not necessary to enter continuation lines if not needed for the particular job to be run.
12. Restarts are not available for models with bolt loading using entries MBOLT, MBOLTUS or BOLT.

**RFORCE**

## Rotational Force

Defines a static loading condition due to an angular velocity and/or acceleration.

**Format:**

1	2	3	4	5	6	7	8	9	10
RFORCE	SID	G	CID	A	R1	R2	R3	METHOD	
	RACC	MB	IDRF						

**Example:**

RFORCE	2	5		-6.4	0.0	0.0	1.0	2	
	1.0								

Describer	Meaning
SID	Load set identification number. (Integer > 0)
G	Grid point identification number through which the rotation vector acts. (Integer ≥ 0)
CID	Coordinate system defining the components of the rotation vector. See Remark 16. (Integer ≥ 0; Default = 0)
A	Scale factor of the angular velocity in revolutions per unit time. (Real)
R1, R2, R3	Rectangular components of rotation vector $\vec{R}$ . The vector defined will pass through point G. (Real; $R1^2 + R2^2 + R3^2 > 0.0$ unless A and RACC are both zero)
METHOD	Method used to compute centrifugal forces due to angular velocity, see Remark 20.. For angular acceleration, see Remark 13. (Integer = 1 or 2; Default = 1)
RACC	Scale factor of the angular acceleration in revolutions per unit time squared. (Real; Default = 0.0)
MB	Indicates whether the CID coordinate system is defined in the main Bulk Data Section (MB = -1) or the partitioned superelement Bulk Data Section (MB = 0). Coordinate systems referenced in the main Bulk Data Section are considered stationary with respect to the assembly basic coordinate system. See Remark 15. (Integer; Default = 0)
IDRF (SOL 600 only)	ID indicating to which portion of the structure this particular RFORCE entry applies. It is possible to have multiple RFORCE entries in the same subcase for SOL 600 to represent different portions of the structure with different rotational accelerations. IDRF corresponds to a SET3 entry specifying the elements with this acceleration. A BRKSQL entry may also be specified with a matching IDRF entry. (Integer; Default = 0)

**Remarks:**

1. The forces that are created with the RFORCE entry act on the structure as follows: the forces that are defined with the RFORCE entry for a constant angular velocity (A), act in the positive radial direction. These forces represent the inertia forces on the structure due to a constant angular velocity. The forces that are defined with the RFORCE entry for a constant angular acceleration (RACC), act in the same direction as the angular acceleration. These forces would be opposite to the inertia forces on the structure due to a constant angular acceleration. In Figure 9-139, the force vector at grid point Gi is given by

$$\{\vec{F}\}_i = [m]_i[\vec{\omega} \times (\vec{\omega} \times (\vec{r}_i - \vec{r}_a)) + \vec{\alpha} \times (\vec{r}_i - \vec{r}_a)] \quad (9-29)$$

where:

$$\begin{aligned} \text{angular velocity} &= \vec{\omega} = 2\pi A \cdot \vec{R} \text{ (radians/unit time)} \\ \text{angular acceleration} &= \vec{\alpha} = 2\pi RACC \cdot \vec{R} \text{ (radians/unit time}^2\text{)} \\ [m]_i &= 3 \times 3 \text{ translational mass matrix at grid point Gi} \end{aligned}$$

**Note:** The equation for  $\vec{F}_i$  will have additional terms if the mass is offset or  $I_{23}^i, I_{13}^i$  terms exist relative to the rotation axes and METHOD = 1 is selected.

Figure 9-139 RFORCE Vector at Grid Point Gi

2. In the static solution sequences, SID must be selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
3.  $G = 0$  signifies that the rotation vector acts through the origin of the basic coordinate system.
4.  $CID = 0$  (Default) signifies that the rotation vector is defined in the basic coordinate system.
5. The load vector generated by this entry can be printed with an OLOAD command in the Case Control Section.
6.  $METHOD = 1$  yields correct results only when there is no coupling in the mass matrix. This occurs when the lumped mass option is used with or without the ZOFFS option (see the CQUAD4 entry for a description of ZOFFS).  $METHOD = 2$  yields correct results for lumped or consistent mass matrix only if the ZOFFS option is not used. The acceleration terms due to the mass offset ( $X1$ ,  $X2$ ,  $X3$ ) on the CONM2 entry are not computed with  $METHOD = 2$ . All the possible combinations of mass matrices and offset and the correct method to be used are shown below.

	No Offset	Offset
Lumped	METHOD = 1 or METHOD = 2	METHOD = 1
Coupled	METHOD = 2	Neither

7. In cyclic symmetry analyses, the T3 axis of the basic coordinate system must be coincident with the axis of symmetry. In the DIH type of cyclic symmetry, the T1 axis also must be parallel to side 1 of segment 1R of the model.
8. For superelement analysis, G should reference a residual structure point that is exterior to all superelements when loading Superelement 0 and a separate G must be interior to each superelement when loading an upstream superelement else centrifugal loads will not be generated for that superelement. However, in cyclic analysis, User Fatal Message 4347 will be issued.
9. In a geometric nonlinear static analysis (SOL 106 and 400 when PARAM LDGISP is set to +1), this type of loading is a follower force type of loading. However, the orientation of coordinate system CID is not updated.
10. In nonlinear static solutions when there is more than one increment (INC) specified on the NLPARM entry for a given subcase, the load vector resulting from the RFORCE input (and not the angular velocity vector) is scaled linearly. This means that loading by increments in the angular velocity can only be achieved by having subcases where the RFORCE loading is applied in a single increment.
11. The continuation entry is optional.
12. Forces due to angular acceleration (RACC) are computed with  $METHOD = 2$  even if  $METHOD = 1$  is specified.
13. Loads derived from this entry do not include effects due to mass specified for scalar points.

14. The follower force effects due to loads from this entry are included in the stiffness in all linear solution sequences that calculate a differential stiffness. The solution sequences are SOLs 103, 105, 107 to 112, 115 and 116 (see also the parameter [FOLLOWK](#) (Ch. 6)). In addition, follower force effects are included in the force balance in the nonlinear solution sequences, SOLs 106, 129, 153, 159 and 400, if geometric nonlinear effects are turned on with `PARAM, LGDISP, 1`. The follower force stiffness is included in the nonlinear static solution sequences (SOLs 106, 153 and 400) and general nonlinear solution sequence (SOL 400) for both `ANALYSIS=NLSTAT` and `NLTRAN` but not in the nonlinear transient dynamic solution sequences (SOLs 129 and 159).
15. The coordinate systems in the main Bulk Data Section are defined relative to the assembly basic coordinate system which is fixed. This feature is useful when a superelement defined by a partitioned Bulk Data Section is rotated or mirrored and the gravity load is more conveniently defined in terms of coordinates which are fixed.
16. If `CID` is not a rectangular coordinate system, RFORCE will treat it as if it were and unexpected answers may result.
17. Follower force stiffness (`param,followk,yes`) is supported for method 2 only.
18. Multiple RFORCE entries with different `SID`'s may be used in SOL 600 in the same subcase or SOL 400 in the same loadcase (`STEP` and/or `SUBCASE`). They should be combined using the `LOAD` entry similar to the way `FORCE` or `PLOAD4` with different `ID`'s are combined.
19. Fields `CID`, `METHOD`, `RACC`, `MB` and `IDRF` will be ignored for SOL 700.
20. For Axisymmetric Harmonic elements, (elements selected with `PAXSYMH` entry), `METHOD=2` is required. A selection of `METHOD=1` will automatically be overridden and be replaced by `METHOD=2` for all elements of the model.
21. Note that the `LOAD` entry scaling for RFORCE uses the square root of the absolute  $S \times S_i$  in rotor dynamics. Thus it is recommended that the `LOAD` entry not be used with RFORCE in rotor dynamics with a value other than  $S=1.0$  and  $S_i=1.0$  value. See Remark 6. of the `LOAD` entry.
22. If Modules are present then this entry may only be specified in the main Bulk Data section.

## RGYRO

### Rotordynamic Analysis Parameters

Specifies synchronous or asynchronous analysis, reference rotor, and rotation speed of the reference rotor.

#### Format:

1	2	3	4	5	6	7	8	9	10
RGYRO	RID	SYNCFLG	REFROTR	SPDUNIT	SPDLOW	SPDHIGH	SPEED	ROTRSEID	
	WR3WRL	WR4WRL	WRHWRL						

#### Example:

1	2	3	4	5	6	7	8	9	10
RGYRO	100	SYNC	1	RPM	1000.0	5000.0		10	

Describer	Meaning
RID	Identification number of RGYRO entry. Selected by Case Control command, RGYRO. (Required; no Default). See Remarks 1. and 4.
SYNCFLG	Specifies whether the analysis is synchronous or asynchronous analysis. Required input for frequency response and complex modes analyses. Not required for static analyses. (Character: 'SYNC', 'ASYNC', or blank). See Remarks 4. through 4.
REFROTR	Specifies the reference rotor ID for the analysis. (Integer > 0; Required; no Default)
SPDUNIT	Specifies whether the entries SPDLOW, SPDHIGH, and SPEED are given in terms of RPM (revolutions/minute) or frequency (revolutions (cycles)/unit time). (Character: 'RPM' or 'FREQ'; no Default). See Remark 4.
SPDLOW	Specifies the low speed for synchronous analysis. See Remark 4. (Real; Default = 0.0)
SPDHIGH	Specifies the high speed for synchronous analysis. See Remark 4. (Real; Default = 99999.0)
SPEED	Specifies reference rotor speed for asynchronous analysis. Also required for static analyses. See Remark 4. (Default = 0)
ROTRSEID	Identification number of the superelement in which the rotor specified in the REFROTR field is defined. (Integer >= 0, Default = 0).
WR3WRL	Specifies whirl frequency for calculation of rotor damping and circulation terms for rotor structural damping specified through GR field for asynchronous complex eigenvalue analysis. (Real, Default = 0.)
WR4WRL	Specifies whirl frequency for calculation of rotor damping and circulation terms for rotor structural damping specified through material entries for asynchronous complex eigenvalue analysis. (Real, Default = 0.)
WRHWRL	Specifies whirl frequency for calculation of rotor damping and circulation terms for rotor structural hybrid damping specified through ROTHYBD card for asynchronous complex eigenvalue analysis. (Real, Default = 0.)

**Remarks:**

1. Multiple RGYRO entries with the same RID value are allowed. All RGYROs with same RID will be analyzed for either SYNC (or) ASYNC option only.
2. For multiple RGYRO with same RID entries, reference rotors ID specified in REFROTR (4<sup>th</sup>) field are treated as individual rotors. Non-reference rotors (rotor ID not defined in RGYRO) will need REFROT (or) REFRTSE bulk data card to identify its reference rotor.
3. If single RGYRO entry with RID is used, then all rotors in the models will reference the rotor id specified in REFROTR (4<sup>th</sup>) field.
4. The required information on the RGYRO entries varies for different analyses. Values for the RID and SPDUNIT fields are always required. Values for SPDLOW, SPDHIGH and SPEED are analysis dependent as shown in the table below:

Solution Sequence	Type of Analysis	PARAM, GYROAVG	Required Entry	COMMENT
Frequency	SYNC	0	None	--
Response	SYNC	-1	SPDLOW, SPDHIGH	a, b
	ASYNC	0	SPEED	--
	ASYNC	-1	SPEED	b
Complex Modes	SYNC	--	SPDLOW, SPDHIGH	a, b
	ASYNC	--	SPEED	b, Remark 4.
Static Analysis	--	--	SPEED	Remark 3.

- a. The relative rotor speeds will be treated as linearly dependent on the reference rotor speed ( $\Omega = A0 + A1\Omega_{\text{reference}}$ ). The scale factors A0 and A1 will be determined by a least-mean-square fit of the relative rotor speeds input on the RSPINR entries between SPDLOW and SPDHIGH of the reference rotor. If SPDLOW or SPDHIGH are outside the range specified on the RSPINR entry, the values will be extrapolated from the RSPINR entry values.
  - b. PARAM, WR3 and PARAM, WR4 are required for rotor damping.
5. For static analysis, the SYNCFLG field must be left blank or must have the ASYNC option specified in it. Otherwise, the program terminates the execution with an appropriate fatal message.
6. When there is a Case Control request for Campbell diagram, the selected RGYRO Bulk Data entry must have the ASYNC option specified in its SYNCFLG field. Otherwise, the program terminates the execution with an appropriate fatal message.
7. In the presence of GR field, the rotor damping matrix (BR) in complex eigenvalue analysis is given by:

$$BR = KR1.GR1/[\Omega1(\Omega_{\text{ref}}) - WR3WRL]$$

where,

KR is the rotor stiffness matrix.

GR is the structural damping parameters specified in the RSPINR entry

$\Omega_1$  ( $\Omega_{ref}$ ) is the specified rotor speed.

8. If non-zero WR3WRL is specified in RGYRO, then PARAM,WR3 and WR3R (in RSPINR) cannot be specified. Appropriate FATAL message will be issued, in case these entries are specified.
9. WR3WRL/ WR3WRL/ WRHWRL affect both the rotor damping terms and the circulation terms. For the fixed reference frame, the circulation terms are generated from the rotating structure. For the rotating reference frame, the circulation terms are generated from the stator.

## RINGAX Conical Shell Ring

Defines a ring for conical shell problems.

### Format:

1	2	3	4	5	6	7	8	9	10
RINGAX	ID		R	Z			PS		

### Example:

RINGAX	3		2.0	-10.0			162		
--------	---	--	-----	-------	--	--	-----	--	--

Describer	Meaning
ID	Ring identification number. See Remark 6. (Integer > 0)
R	Ring radius. (Real > 0.0)
Z	Ring axial location. (Real)
PS	Permanent single-point constraints. (Any unique combination of the Integers 1 through 6 with no embedded blanks.)

### Remarks:

1. RINGAX is allowed only if an AXIC entry is also present.
2. The number of degrees-of-freedom defined is  $(6 - \text{NPS}) \cdot H$  where  $H$  is the harmonic count and NPS is the number of digits in field 8. (See [AXIC](#)).
3. RINGAX identification numbers must be unique with respect to all other POINTAX, RINGAX, and SECTAX identification numbers.
4. For a discussion of the conical shell problem, see [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide*.
5. Constraints may be necessary to avoid matrix singularities. The CONEAX element has no stiffness for rotation about the normal. In addition, there is no stiffness for rotation about V (see [Figure 9-140](#)) when transverse shear flexibility is not included.

Figure 9-140 RINGAX Coordinate System

6. In order to reference this entry on a SET Case Control command, the ID must be modified by  $ID(n) = ID + 1000000 \cdot n$  where  $n$  is the harmonic number plus one and  $ID(n)$  is the value specified on the SET entry.

## RINGFL

## Axisymmetric Fluid Point

Defines a circle (fluid point) in an axisymmetric fluid model.

### Format:

1	2	3	4	5	6	7	8	9	10
RINGFL	IDFA	XA1	XA2	XA3	IDFB	XB1	XB2	XB3	

### Example:

RINGFL	3	1.0		30.0					
--------	---	-----	--	------	--	--	--	--	--

Describer	Meaning
IDFA, IDFB	Unique identification number of the fluid points. (0 < Integer < 500000)
XAi, XBi	Coordinates of the point defined in the coordinate system specified on the AXIF entry. (Real; XA1 and XB1 > 0.0)

### Remarks:

1. RINGFL is allowed only if an AXIF entry is also present.
2. All fluid point identification numbers must be unique with respect to other scalar, structural, and fluid points.
3. X1, X2, X3 are (r,  $\phi$ , z) for a cylindrical coordinate system and ( $\rho$ ,  $\theta$ ,  $\phi$ ) for a spherical coordinate system.  $\theta$  is in degrees. The value of  $\phi$  must be blank or zero.
4. One or two fluid points may be defined per entry.

**RJOINT**

## Rigid Joint

Defines a rigid joint element connecting two coinciding grid points.

**Format:**

1	2	3	4	5	6	7	8	9	10
RJOINT	EID	GA	GB	CB					

**Example:**

RJOINT	5	1	2	12345					
--------	---	---	---	-------	--	--	--	--	--

Describer	Meaning
EID	Element identification number. (Integer > 0)
GA, GB	Grid point identification numbers. (Integer > 0)
CB	Component numbers in the global coordinate system at GB. These degrees-of-freedom are constrained to move with the same degrees-of-freedom at GA. See Remarks 4. and 5. (Integers 1 through 6 with no embedded or blank.)

**Remarks:**

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, Nastran will create internally the Lagrange multiplier degrees-of-freedom in addition to the 12 displacement degrees-of-freedom given by grid points GA and GB. The number of Lagrange multiplier degrees-of-freedom is equal to the number of dependent degrees-of-freedom given by CB.
- The length between grid points GA and GB must be zero.
- When CB = "123456" or blank, the grid point GB is constrained to move with GA and the two grid points moves as a single point. For default CB = "123456".
- If any degree-of-freedom is released on CB, RJOINT becomes a mechanical joint element. For example, CB = "12345", then RJOINT becomes a hinge. CB = "1234", then RJOINT becomes a universal joint. And CB = "123", RJOINT becomes a spherical joint.
- For the Lagrange method, the theory for the RJOINT is formulated such that a consistent mechanical joint is created even if the user requests different global coordinate systems at grid points GA and GB.
- Thermal expansion effect is not applicable for the RJOINT element, since the distance between grid points GA and GB is zero.
- Element identification numbers should be unique with respect to all other element identification numbers.

## RLOAD1 Frequency Response Dynamic Excitation, Form 1

Defines a frequency-dependent dynamic load of the form

$$\{P(f)\} = \{A\}[C(f) + iD(f)]e^{i\{\theta - 2\pi f\tau\}}$$

for use in frequency response problems.

### Format:

1	2	3	4	5	6	7	8	9	10
RLOAD1	SID	EXCITEID	DELAYI/ DELAYR	DPHASEI/ DPHASER	TC/RC	TD/RD	TYPE		

### Example:

RLOAD1	5	3	2.0	10	1				
--------	---	---	-----	----	---	--	--	--	--

Describer	Meaning
SID	Set identification number. See Remarks 1. and 3. (Integer > 0)
EXCITEID	Identification number of a static or thermal load set or a DAREA or FBALOAD (in FRF Based Assembly or FBA process) or SPCD entry set that defines $\{A\}$ . See Remarks 4. and 5. (Integer > 0)
DELAYI	Identification number of DELAY or FBADLAY (in FRF Based Assembly or FBA process) Bulk Data entry that defines time delay $\tau$ . See Remark 2. (Integer > 0 or blank)
DELAYR	Value of time delay $\tau$ that will be used for all degrees-of-freedom that are excited by this dynamic load entry. See Remark 2. (Real or blank)
DPHASEI	Identification number DPHASE or FBAPHAS (in FRF Based Assembly or FBA process) Bulk Data entry that defines phase angle $\theta$ . (See Remark 2. (Integer > 0 or blank)
DPHASER	Value of phase angle $\theta$ (in degrees) that will be used for all degrees-of-freedom that are excited by this dynamic load entry. See Remark 2. (Real or blank)
TC	Set identification number of the TABLEDi entry that gives $C(f)$ . See Remark 2. (Integer > 0 or blank)
RC	Value of C to be used for all frequencies. See Remark 2.. (Real or blank)
TD	Set identification number of the TABLEDi entry that gives $D(f)$ . See Remark 2. (Integer > 0 or blank)
RD	Value of D to be used for all frequencies. See Remark 2.. (Real or blank)
TYPE	Defines the type of the dynamic excitation. See Remarks 4. and 5. (Integer, character or blank; Default = 0)

**Remarks:**

1. Dynamic excitation sets must be selected with the Case Control command DLOAD = SID.
2. If any of DELAYI/DELAYR, DPHASEI/DPHASER, TC/RC, or TD/RD fields are blank or zero, the corresponding  $\tau$ ,  $\theta$ ,  $C(f)$  or  $D(f)$  will be zero. Either TC/RC or TD/RD may be blank or zero, but not both.
3. SID need not be unique for all ACSRCE, RLOAD1, RLOAD2, TLOAD1 and TLOAD2 dynamic load entries. The DLOAD = SID Case Control command will select all dynamic load entries with the set identification of SID.
4. The type of the dynamic excitation is specified by TYPE (field 8) according to the following table:

TYPE	TYPE of Dynamic Excitation
0, L, LO, LOA or LOAD	Applied load (force or moment) (Default)
1, D, DI, DIS or DISP	Enforced displacement using SPC/SPCD data
2, V, VE, VEL or VELO	Enforced velocity using SPC/SPCD data
3, A, AC, ACC or ACCE	Enforced acceleration SPC/SPCD data

The enforced motion options (SPC/SPCD) defined by TYPE=1, 2, 3 are currently used for SOLs 108, 111, 146, 200, and 400. For other solution sequences such as SOL118 (Cyclic Frequency Response) the large mass method must still be used.

5. TYPE (field 8) also determines the manner in which EXCITEID (field 3) is used by the program as described below:

Excitation specified by TYPE is applied load

- There is no LOADSET request in Case Control  
EXCITEID may reference DAREA, FBALOAD (in FRF Based Assembly or FBA process), static and thermal load set entries.
- There is a LOADSET request in Case Control  
The program may reference DAREA entries as well as static and thermal load set entries specified by the LID and TID fields, respectively, in the selected LSEQ entry corresponding to EXCITEID.

Excitation specified by TYPE is enforced motion

- There is no LOADSET request in Case Control  
EXCITEID will reference SPCD entries.
- There is a LOADSET request in Case Control  
The program will reference SPCD entries specified by the LID field in the selected LSEQ entry corresponding to EXCITEID.

6. If Modules are present then this entry may only be specified in the main Bulk Data section.

**RLOAD2**

Frequency Response Dynamic Excitation, Form 2

Defines a frequency-dependent dynamic excitation of the form.

$$\{P(f)\} = \{A\} \cdot B(f)e^{i\{\phi(f) + \theta - 2\pi f\tau\}}$$

for use in frequency response problems.

**Format:**

1	2	3	4	5	6	7	8	9	10
RLOAD2	SID	EXCITEID	DELAYI/ DELAYR	DPHASEI/ DPHASER	TB/RB	TP/RP	TYPE		

**Example:**

RLOAD2	5	3	15	5.0	7				
--------	---	---	----	-----	---	--	--	--	--

Describer	Meaning
SID	Set identification number. See Remarks 1. and 3. (Integer > 0)
EXCITEID	Identification number of a static or thermal load set or a DAREA or FBALOAD (in FRF Based Assembly or FBA process) or SPCD entry set that defines {A}. See Remarks 4. and 5. (Integer > 0)
DELAYI	Identification number of DELAY or FBADLAY (in FRF Based Assembly or FBA process) Bulk Data entry that defines time delay τ. See Remark 2. (Integer > 0 or blank)
DELAYR	Value of time delay τ that will be used for all degrees-of-freedom that are excited by this dynamic load entry. See Remark 2. (Real or blank)
DPHASEI	Identification number DPHASE or FBAPHAS (in FRF Based Assembly or FBA process) Bulk Data entry that defines phase angle θ. (See Remark 2. (Integer > 0 or blank)
DPHASER	Value of phase angle θ (in degrees) that will be used for all degrees-of-freedom that are excited by this dynamic load entry. See Remark 2. (Real or blank)
TB	Set identification number of the TABLEDi entry that gives B(f). (Integer > 0)
RB	Value of B to be used for all frequencies. (Real, non-zero)
TP	Set identification number of the TABLEDi entry that gives φ(f) in degrees. (Integer ≥ 0)
RP	Value of φ to be used for all frequencies. See Remark 2. (Real or blank)
TYPE	Defines the type of the dynamic excitation. See Remarks 4. and 5. (Integer, character or blank; Defaults = 0)

**Remarks:**

- Dynamic excitation sets must be selected with the Case Control command DLOAD = SID.

2. If any of DELAYI/DELAYR, DPHASEI/DPHASER, or TP/RP fields are blank or zero, the corresponding  $\tau$ ,  $\theta$ , or  $\phi(f)$  will be zero.
3. SID need not be unique for all ACSRCE, RLOAD1, RLOAD2, TLOAD1 and TLOAD2 dynamic load entries. The DLOAD = SID Case Control command will select all dynamic load entries with the set identification of SID.
4. The type of the dynamic excitation is specified by TYPE (field 8) according to the following table:

TYPE	TYPE of Dynamic Excitation
0, L, LO, LOA or LOAD	Applied load (force or moment) (Default)
1, D, DI, DIS or DISP	Enforced displacement using SPC/SPCD data
2, V, VE, VEL or VELO	Enforced velocity using SPC/SPCD data
3, A, AC, ACC or ACCE	Enforced acceleration SPC/SPCD data

The enforced motion options (SPC/SPCD) defined by TYPE=1, 2, 3 are currently used for SOLs 108, 111, 146, 200, and 400. For other solution sequences such as SOL118 (Cyclic Frequency Response) the large mass method must still be used.

5. TYPE (field 8) also determines the manner in which EXCITEID (field 3) is used by the program as described below:

Excitation specified by TYPE is applied load

- There is no LOADSET request in Case Control  
EXCITEID may reference DAREA, FBALOAD (in FRF Based Assembly or FBA process), static and thermal load set entries.
- There is a LOADSET request in Case Control  
The program may reference DAREA entries as well as static and thermal load set entries specified by the LID and TID fields, respectively, in the selected LSEQ entry corresponding to EXCITEID.

Excitation specified by TYPE is enforced motion

- There is no LOADSET request in Case Control  
EXCITEID will reference SPCD entries.
- There is a LOADSET request in Case Control  
The program will reference SPCD entries specified by the LID field in the selected LSEQ entry corresponding to EXCITEID.

6. If Modules are present then this entry may only be specified in the main Bulk Data section.

Define kinks and offsets to be applied on a rotor, pull the rotor on to its bearing and then carry out rotordynamic analysis (SOL 400 only).

**ROT BENT** Define kinks and offsets to be applied on a rotor, pull the rotor on to its bearing and then carry out rotordynamic analysis (SOL 400 only).

Specifies rotor initial deformation due to kink and offset.

**Format:**

1	2	3	4	5	6	7	8	9	10
ROT BENT	Bent ID	Rotor ID	Load ID						
	Unbcord	x1	x2	x3					
	Kink	Station	Kink angle	Phase angle					
	Offset	Station	Offset value	Phase angle					
	Brgdpr	Rotor Grid ID	Stator Grid ID						

**Example:**

1	2	3	4	5	6	7	8	9	10
ROT BENT	101	10	99						
	Unbcord	1.0	0.0	0.0					
	Kink	30.0	0.06	135.0					
	Brgdpr	1	111						
		51	151						
		81	181						

ROT BENT	200	10	1						
	Offset	3.82	0.001	30.0					
		15.54	0.002	130.0					
		28.45	0.003	230.0					
		38.45	0.004	330.0					
	Kink	10.35	0.06	45.0					
		22.02	0.12	145.0					
		33.45	0.18	245.0					
		48.45	0.24	345.0					
	Brgdpr	11	111						
		17	117						
		35	135						
	Unbcord	0.0	-1.0	2.0					

Describer	Meaning
Bent ID	Identification number of ROTBENT. (Integer > 0, required, no default).
Rotor ID	Rotor identification number for which the kinks and offsets are defined. See Remark 2., 3. (Integer > 0, required, no default).
Load ID	Load identification number, to be selected by LOAD case control in the first STEP. See Remark 4. (Integer > 0, required, no default).
Unbcord	Components of the vector to determine the X-Y plane of the rotor system for Kinks and Offsets. See Remark 6. (Real, required, no default).
Kink	Flag indicating that the next 3 fields are for kink definition. See Remark 7. (Character, optional)
Station	Location on rotor from ROTOR ID 1 <sup>st</sup> grid along the rotor axis, from where the Kink starts. (Real, required if kink is specified, no default).
Kink angle	Kink angle based on Unbcord defined rotor Z-axis. See Remark 8. (Real, DEG, required if kink is specified, no default).
Phase angle	Phase angle about the rotor X-axis, based on Unbcord defined rotor X-Y plane. (Real, DEG, required if kink is specified, no default).
Offset	Flag indicating that the next 3 fields are for offset definition. See Remark 7. (Character, optional)
Station	Location on rotor from ROTOR ID 1st grid along the rotor axis, from where the Offset starts. (Real, required if offset is specified, no default).
Offset value	Offset value on the axis of the rotor. (Real, required if offset is specified, no default).
Phase angle	Phase angle based on Unbcord defined rotor X-Y plane. (Real, DEG, required if offset is specified, no default). A phase angle of 0.0 results in an offset in the positive Rotor Y-axis.
Brgdpr	Flag indicating that the next 2 fields are for paired grids. See Remark 12. (Character, required).
GRID IDi	Paired grids ID to indicate paired connection between rotor and support after initial deformation. (Integer > 0, required, no default). First grid should be part of ROTOR & second grid should be part of Stator.

**Remarks:**

1. ROTBENT is supported only in SOL 400 analysis.
2. One ROTBENT entry with unique BENT ID value is allowed. ROTBENT analysis is supported for only one SUBCASE definition, having 2 STEP analyses. STEP1 analysis should be NLSTATIC/NLSTAT. STEP 2 analysis runs rotordynamics analysis (complex eigenvalue, frequency response).
3. ROTBENT only support 1D element rotor defined by ROTOR entry.
4. ROTBENT uses Load ID to perform STEP 1 NLSTATIC analysis.

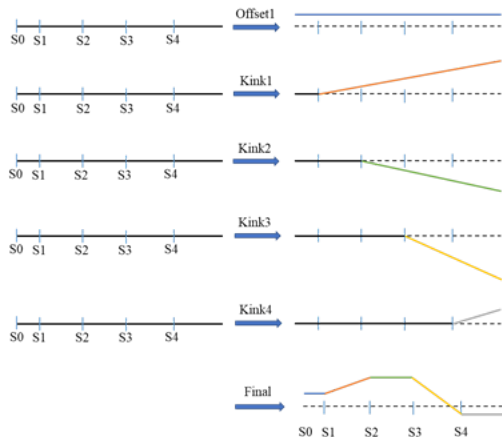

Define kinks and offsets to be applied on a rotor, pull the rotor on to its bearing and then carry out rotordynamic analysis (SOL 400 only).

5. In a ROTBENT bulk data card, the keywords (Kink, Offset, or Brgdpr) can only be defined once. Multiple rows for each keyword are allowed, except for Unbcord.
6. ROTBENT can take only one set of 'Unbcord' input, with three REAL values. The first 2 grids in AXIS option of ROTOR entry determine the X-axis of the Rotor system, with origin of this system to be at the first grid entry in AXIS option. Unbcord entries will form the vector used to determine the X-Y plane of Rotor system, defined using the CD of the first grid on AXIS option of ROTOR entry linked to the Rotor ID.
7. A rectangular coordinate (rotor system) formed in remark 6., is used to determine the phase angle, which starts from the X-Y plane based on UNBCORD, and the kink angle, which rotates about Z-axis. In the following figures in the Rotor system, the rotor axis is X, and X-Y plane is determined by the Unbcord vector.

8. Kink is calculated in the rotor system X-Y plane, where the phase is zero (See Remark 7.), by rotating the shaft at the station point about Z-axis to the defined kink angle, then the Kink shaft is rotated about the shaft axis (X) to the defined phase angle from the X-Y plane.
9. Offset is calculated in the rotor X-Y plane, where the phase is zero (See Remark 7.) then the Offset is rotated about the shaft axis (X) to the defined phase angle from the X-Y plane and applied to the rotor.
10. Offsets and Kinks are calculated separately at the shaft axis or the shaft center line. All the Kinks and Offsets are then accumulated to generate the initial unconstrained rotor geometry. Grid coordinate of unconstrained rotor will be printed out in f06 file.

11. Brgdpr entry needs at least one pair of existing GRID IDs. First id of the pair of entries of Brgdpr keyword should be part of referenced rotor and second id should be part of bearing (stator) connected to the rotor. All the first grid ids of each pair of entry should be added to AXIS option of reference ROTOR. It is recommended that both grid ids should not be part of any MPC, RBEs definition.
12. The initial step (NLSTATIC) updates the rotor geometry, writes the bulk data (program internally created MPC, SPOINTs, SPC1 and SPCD) entries to pull the rotor into the bearings and runs the static solution. This static solution step will result in the deformed shape of the model with the rotor pulled into the bearings. At this point, the rotor and bearing GRIDs of Brgdpr entry are coincident.
13. It is advised to have both grid entries of Brgdpr keyword to be at the same axial location. A small Kink angle is assumed ( $<1$  deg) and the deformation in axial direction (axial and angular displacement) of the rotor grids is ignored.
14. The following figures are the brief description of the Kinks and Offsets in a rotor, where B1 and B2 are support locations and are paired with rotor grids in Brgdpr keyword.

## ROTHYBD

## Hybrid damping for rotors

Specifies hybrid damping data for rotors.

### Format:

1	2	3	4	5	6	7	8	9	10
ROTHYBD	ROTORID1	HYBDAMP1	ROTORID2	HYBDAMP2	ROTORID3	HYBDAMP3	ROTORID4	HYBDAMP4	
	ROTORID5	HYBDAMP5	-etc.-						

### Examples:

ROTHYBD	1	15							
ROTHYBD	10	100	20	200	30	300			

Describer	Meaning
ROTORID <sub>i</sub>	Identification number of rotor. (Integer > 0). See Remarks 1 and 2.
HYBDAMP <sub>i</sub>	Identification number of a HYBDAMP entry defining hybrid modal damping data. (Integer > 0). See Remarks 1 and 2.

### Remarks:

1. ROTORID<sub>i</sub> - HYBDAMP<sub>i</sub> pair values referencing non-existent rotors are ignored.
2. If there is no HYBDAMP entry defined in the data for a HYBDAMP<sub>i</sub> specified for a valid ROTORID<sub>i</sub>, the program terminates the execution with an appropriate fatal error.
3. Hybrid damping can result in very densely populated damping matrix causing significant performance penalty.

## ROTOR

### Rotor Model Definition

Specifies list of grids, elements or properties that comprise the rotor 3D model.

#### Format:

1	2	3	4	5	6	7	8	9	10
ROTOR	ROTORID	FRAME							
	LTYPE	ID1	ID2	ID3	etc.				
	AXIS	GID1	GID2	etc.					

#### Example:

ROTOR	10	ROT							
	ELEM	10	THRU	12					
	PROP	1	THRU	5					
	AXIS	101	102						

Descriptor	Meaning
ROTORID	Identification number of rotor. (Integer > 0).
FRAME	Analysis frame (Char, ROT or FIX, Required, Default: FIX)
LTYPE	ELEM or PROP or both, indicating whether the specified list references element IDs or property IDs. (Character; Required; No default)
	Note that the order is important. In case both ELEM and PROP are specified, ELEM should be specified first.
Idi	IDs of elements or properties comprising the rotor. (Integer > 0; Required; No default)
AXIS	Defines grid points which define the axis of rotation.
GIDi	IDs of grids comprising the axis of the rotor (Integer > 0; Required; No default)

#### Remarks:

- Supported element types for analysis in rotating reference frame:
  - 0D elements : CONM1, CONM2
  - 1D elements : CBEAM, CBAR
  - 2D elements : CQUAD4, CTRIA3
  - 3D elements : CHEXA, CPENTA, CTETRA, CPYRAM
- Supported element types for analysis in fixed reference frame:
  - 0D elements : CONM1, CONM2
  - 1D elements : CBEAM, CBAR

2D elements : CQUAD4, CQUAD8, CTRIA3, CTRIA6

3D elements : CHEXA, CPENTA, CTETRA, CPYRAM

3. Current limitation for analysis in fixed reference frame:
  - a. If shell elements are defined perpendicular to the rotor axis for a 3D rotor defined using ROTOR entry, then gyroscopic matrix is not available for those elements. For example, a flat disk like CD spinning about the center. If the shell elements are replaced by SOLID elements, then correct gyroscopic effects can be obtained.
  - b. Bar elements (default version) do not have polar moment of inertia. Thus, if CBAR elements are defined along the axis of rotation (for both ROTOR and ROTORG entries), then they do not provide any contribution to gyroscopic matrix. The CABR elements can be replaced by CBEAM elements in case gyroscopic terms are needed for those elements.
4. THRU option is supported in ROTOR entry. Note that the order is important for LTYPE. In case both ELEM and PROP are specified, ELEM should be specified first.
5. Analysis can be performed using coupled mass or diagonal mass for all the elements.
6. ROTORAX, ROTORG and ROTORSE should not be used along with ROTOR in ROT frame. They can only be used with ROTOR in FIX frame. (since ROTORAX, ROTORG and ROTORSE assume fixed reference frame.)
7. At least 2 grid points need to be defined on AXIS to complete ROTOR definition, these points may not be part of rotor.
8. For unbalance loads the grid point, at which UNBALNC is defined, should be part of ROTOR AXIS list.
9. In order to include CONM1/2 elements as part of a rotor, its element ID should be listed using ELEM in ROTOR definition.
10. Stator portion of the model should only be defined in residual for external superelement runs in rotating system.
11. Only permanent glue option is supported for contact analysis for rotating portion of the model.

## ROTORAX Axisymmetric Model Rotor Definition

Specifies list of elements, properties or grid points that comprise an axisymmetric model rotor.

### Format:

1	2	3	4	5	6	7	8	9	10
ROTORAX	ROTORID	LTYPE	ID1	ID2	ID3	ID4	ID5	ID6	
	ID7	ID8	-etc.-						

or

ROTORAX	ROTORID	LTYPE	ID1	THRU	ID2	BY	INC		

### Example:

ROTORAX	100	ELEM	5	THRU	25				
ROTORAX	10	PROP	10						
ROTORAX	15	GRID	50	69	70				

Descriptor	Meaning
ROTORID	Identification number of rotor. (Integer > 0). See Remarks 1. and 2..
LTYPE	ELEM, PROP or GRID, indicating whether the specified list references element IDs, property IDs or grid point IDs, respectively. (Character; Required; No default). See Remarks 3. through 6..
IDI	IDs of elements, properties or grid points comprising the rotor. (Integer > 0; Required; No default)
THRU	Implies a range of identification numbers. (Optional).
BY	Implies that an increment is being specified for the THRU option (Optional)
INC	ID increment. (Integer > 0; Optional)

### Remarks:

1. ROTORIDs of ROTORAX entries may not be the same as the ROTORIDs of ROTORG entries or ROTORSE entries.
2. Multiple ROTORAX entries with the same ROTORID are supported.
3. When the GRID option is used for the LTYPE field, a minimum of two grid points must be specified in the list. If this condition is not satisfied, the program terminates the execution with an appropriate user fatal message.
4. For every rotor defined by a ROTORAX entry, there should be at least one entry using the GRID option for the LTYPE field to define the axis of symmetry.

5. Grid points specified on ROTORAX entries using the GRID option for the LTYPE field must be collinear. If this condition is not satisfied, the program terminates the execution with an appropriate user fatal message.
6. Only grid points specified on ROTORAX entries using the GRID option for the LTYPE field may be referenced by RSPINR, RSPINT and UNBALNC entries.

## ROTORG

### Rotor Line Model Grids

Specifies grids that compose the rotor line model.

#### Format:

1	2	3	4	5	6	7	8	9	10
ROTORG	ROTORID	GRID1	GRID2	GRID3	GRID4	GRID5	GRID6	GRID7	
	GRID8	GRID9	-etc.-						

or

ROTORG	ROTORID	GRID1	THRU	GRID2	BY	INC			
--------	---------	-------	------	-------	----	-----	--	--	--

#### Example:

ROTORG	100	101	1002	103	4001				
--------	-----	-----	------	-----	------	--	--	--	--

ROTORG	200	1001	THRU	1100	BY	2			
--------	-----	------	------	------	----	---	--	--	--

Describer	Meaning
ROTORID	Identification number of rotor. (Integer > 0; Required). See Remarks 1. and 2..
GRIDi	Grids comprising the rotor. (Integer > 0; Required; no Default). See Remarks 3. through 7.
THRU	Specifies a range of identification numbers. (Optional)
BY	Specifies an increment for a THRU specification (Optional)
INC	Grid point number increment. (Integer)

#### Remarks:

1. ROTORIDs of ROTORG entries may not be the same as the ROTORIDs of ROTORAX entries or ROTORSE entries.
2. Multiple ROTORG entries with the same ROTORID are supported.
3. Grid IDs must be unique. Duplicate grid IDs will produce a fatal error.
4. All grids specified on ROTORG entries for a specific ROTORID must be collinear. Collinearity will be checked.
5. If not using superelements, no element stiffness can be connected between any GRID listed on a ROTORG entry and any GRID not listed on the ROTORG. In this case, any connections to GRIDs listed on a ROTORG must be done using MPC equations or R-elements.
6. If superelements are used, no element stiffness in the residual structure may connect between a GRID listed on a ROTORG and any GRID not listed on the ROTORG. In this case, any connections in the residual structure to GRIDs listed on a ROTORG must be done using MPC equations or R-elements.

7. All mass for any rotor defined using a ROTORG entry should be defined on the GRIDs listed on the ROTORG entry. Any mass which should belong to the rotor, but is placed on GRIDs not listed on the ROTORG entry, will be ignored when calculating the gyroscopic terms for the rotor. Only the mass shown in the ROTOR DYNAMICS MASS SUMMARY in the .f06 file is included in the calculation of the gyroscopic terms for the rotor.
8. Bar elements (default version) do not have polar moment of inertia. Thus, if CBAR elements are defined along the axis of rotation (for both ROTOR and ROTORG entries), then they do not provide any contribution to gyroscopic matrix. The CABR elements can be replaced by CBEAM elements in case gyroscopic terms are needed for those elements.

## ROTORSE

### Rotor Superelement Identification

Specifies grids that compose the rotor line model. An alternate to the ROTORG entry when superelements are used.

#### Format:

1	2	3	4	5	6	7	8	9	10
ROTORSE	ROTORID	SEID	SEOPT						

#### Example:

ROTORSE	10	1							
---------	----	---	--	--	--	--	--	--	--

Describer	Meaning
ROTORID	Identification number of rotor line model. (Integer > 0; Required). See Remark 1.
SEID	Superelement identification number of rotor superelement. (Integer > 0; Required)
SEOPT	Form of superelement for calculation of gyroscopic terms. (Integer = 1 or 2; Default = 1) See Remark 3.

#### Remarks:

- ROTORIDs of ROTORSE entries may not be the same as the ROTORIDs of ROTORAX entries or ROTORG entries.
- A ROTORSE entry can be used when the rotor is placed in a superelement.
- The rotor line model may be the boundary of a 3D rotor superelement or the rotor line model may be a superelement itself. SEOPT is chosen to distinguish between these cases. The options are:
  - If the user has a 3D model of the rotor and places it in a superelement with SEID, the boundary (a-set) of this superelement must consist of no more and no less than the collinear rotor line model. This will be checked. Specify SEOPT as 1 to identify this configuration. When this option is used, the A-set matrices of the superelement are used to calculate the gyroscopic terms. This option should be used for external superelements.
  - If the user has a line model of the rotor and places it in a superelement with SEID, this superelement (g-set) may be partially or completely reduced in the SE reduction process. This superelement must consist of no more and no less than the rotor line model. Specify SEOPT as 2 to identify this configuration. When this option is used, the G-set matrices of the superelement are used to calculate the gyroscopic terms.
- Rotors specified using the ROTORSE entry can be connected directly to the support structure. In contrast, rotors specified using the ROTORG entry must employ rigid elements to keep the rotor disconnected from the support in the G-set of the residual structure.
- Static and component mode reduction of the rotor line model are supported when using ROTORSE entries.

## RROD Rigid Pin-Ended Element Connection

Defines a pin-ended element that is rigid in translation.

### Format:

1	2	3	4	5	6	7	8	9	10
RROD	EID	GA	GB	CMA	CMB	ALPHA	TREF		

### Example:

RROD	14	1	2	2		6.5-6			
------	----	---	---	---	--	-------	--	--	--

Describer	Meaning
EID	Element identification number. (0 < Integer < 100,000,000)
GA, GB	Grid point identification numbers of connection points. (Integer > 0)
CMA, CMB	Component number of one and only one dependent translational degree-of-freedom in the global coordinate system assigned by the user to either GA or GB. (Integer 1, 2, or 3. Either CMA or CMB must contain the integer, and the other must be blank for the linear RROD. For Lagrange RROD, both CMA and CMB can be blank.) See Remark 3.
ALPHA	Thermal expansion coefficient. See Remark 11. (Real or blank)
TREF	Reference temperature for the calculation of thermal loads. (Real; Default=0.0).

### Remarks:

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, Nastran will create internally one Lagrange multiplier degree-of-freedom in addition to the displacement degrees-of-freedom given by connected grid points.
- For the Lagrange method, if both CMA and CMB are blanks, Nastran will compute the best degree-of-freedom for the dependent degree-of-freedom.
- The m-set coordinates specified on this entry may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
- Element identification numbers should be unique with respect to all other element identification numbers.
- RROD, among other eligible rigid element types, can be selected via MPC and SET3.
- Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.

8. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
9. The degree-of-freedom selected to be dependent must have a nonzero component along the axis of the element. This implies that the element must have finite length.
10. See [Rigid Elements and Multipoint Constraints \(R-type, MPC\)](#) in the *MSC Nastran Reference Guide* for a discussion of rigid elements.
11. For the Lagrange method, the thermal expansion effect will be computed, if user supplies the thermal expansion coefficient, ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The temperature of the element is taken as the average temperature of the two connected grid points GA and GB.

**RSPINR****Relative Spin Rates Between Rotors**

Specifies the relative spin rates between rotors for complex eigenvalue, frequency response, and static analysis and rotor damping parameters.

**Format:**

1	2	3	4	5	6	7	8	9	10
RSPINR	ROTORID	GRIDA	GRIDB	SPDUNT	SPTID	ROTRSEID			
	GR	ALPHAR1	ALPHAR2	WR3R	WR4R	WRHR			

**Example:**

1	2	3	4	5	6	7	8	9	10
RSPINR	100	1001	1002	RPM	100	5			
	0.02	1	3	1000.	1500.	1200.			

Describer	Meaning
ROTORID	Identification number of rotor. (Integer > 0; Required). See Remark 1.
GRIDA/GRIDB	Positive rotor spin direction is defined from GRIDA to GRIDB. See Remark 4. (Integer > 0; Required)
SPDUNIT	Specifies whether the listing of relative spin rates is given in terms of RPM (revolutions/minute) or frequency (revolutions (cycles)/sec). (Character; 'RPM' or 'FREQ'; Required)
SPTID	Table for relative rotor spin rates. See Remark 5. (Real or Integer, if integer, must be > 0; Required)
GR	Rotor structural damping factor. See Remarks 8. and 10. (Real; Default = 0.0)
ALPHAR1	Scale factor applied to the rotor mass matrix for Rayleigh damping. See Remarks 9. and 10. (Real; Default = 0.0)
ALPHAR2	Scale factor applied to the rotor stiffness matrix for Rayleigh damping. See Remarks 9. and 10. (Real; Default = 0.0)
ROTRSEID	Identification number of the superelement in which the rotor specified in the ROTORID field is defined. (Integer >= 0, Default = 0). See Remark 1.
WR3R	Specifies "average" excitation frequency for calculation of rotor damping and circulation terms for rotor structural damping specified through GR field. (Real, Default = 0.)

Describer	Meaning
WR4R	Specifies “average” excitation frequency for calculation of rotor damping and circulation terms for rotor structural damping specified through material entries. (Real, Default = 0.)
WRHR	Specifies “average” excitation frequency for calculation of rotor damping and circulation terms for rotor structural hybrid damping specified through ROTHYBD card. (Real, Default = 0.)

**Remarks:**

1. The ROTORID-ROTRSEID pair must be unique across all RSPINR entries, but the ROTORID and ROTRSEID fields individually need not be unique.
2. Depending upon the type of analysis being performed, a RSPINR/RSPINT entry should be present for each rotor defined by a ROTORG or ROTORAX entry whose gyroscopic effects are to be included in the analysis. If missing for a rotor, then that rotor is assumed to be stationary and the analysis proceeds accordingly. The absence of a RSPINR/RSPINT entry for a rotor is noted in the .f06 file via an appropriate user information message.
3. RSPINR/RSPINT entries are honored and processed only in residual or assembly jobs and are ignored in external superelement creation jobs. For rotor defined in external SE, the GRIDA and GRIDB specified in RSPINR must be part of the SEs ASET during creation run. This requirement is relaxed for rotors defined in PART SE.
4. The rotor spin axis is determined from the ROTORG or ROTORAX entries. The positive rotation vector is from GRIDA to GRIDB. GRIDA and GRIDB must be specified on the ROTORG or ROTORAX entry.

If ROTRSEID refers to a secondary external superelement, then GRIDA and GRIDB must be points associated with the ROTORID of the primary external superelement since the secondary external superelement derives all of its properties from the primary external superelement.

5. If SPTID is a real number, the value is considered constant. For a reference rotor identified using a RGYRO entry, the speed of the rotor is equal to that defined in RGYRO entry itself.
6. For a rotor which is not a reference rotor, the speed is calculated based on the ratio of SPDIT entry of its RSPINR entry to SPDIT field of its reference rotor RSPINR entry, times reference rotor speed from the RGYRO entry.

**Example 1:**

```

$-----2-----3-----4-----5-----6-----7-----8-----9-----
$RSPINR ROTORID GRIDA  GRIDB  SPDUNT  SPDIT  ROTRSEID
$      GR      ALPHAR1 ALPHAR2 WR3R   WR4R   WRHR
RSPINR 40      2        1      RPM    2.0
      0.1
RSPINR 50      4        5      RPM    3.0
      0.1

```

7. If SPTID is an integer number, the value references a DDVAL entry that specifies the relative rotor spin rates. The number of spin rates for each rotor must be the same. Relative spin rates are determined by correlation of table entries. The  $i^{\text{th}}$  entry for each rotor specifies the relative spin rates between rotors at  $\text{RPM}_i/\text{FREQ}_i$ . Spin rates for the reference rotor must be in ascending or descending order.
8. Rotor structural damping specified by the GR entry will be added as equivalent viscous damping or structural damping depending on the solution. That is,

$$[B_{rotor}]_{structural} = \left( \frac{GR}{WR3} \right) [K_{rotor}]$$

where  $WR3$  is a user parameter, or

$$[K_{rotor}] = (1 + iGR)[K_{rotor}]$$

depending on the solution sequence, SYNC/ASYNC and value of PARAM, GYROAVG. See Remark 10. for all the damping and circulation terms added to the equation in the different cases.

In case WR3R is specified in RSPINR, then WR3R is used for determining equivalent viscous damping for this particular rotor instead of WR3.

9. Rayleigh damping for the rotor will be calculated as

$$[B_{rotor}]_{Rayleigh} = \alpha_{R1}(M_{rotor}) + \alpha_{R2}[K_{rotor}]$$

10. The various rotor damping and circulation matrices applicable to frequency response and complex eigenvalue solutions are shown in the following table. For the fixed reference frame, the circulation terms are generated from the rotating structure. For the rotating reference frame, the circulation terms are generated from the stator.

| Solution                                               |                    |                                                                                                                                                                                                                                                            |

| $[K4_R^C]$               | = | the circulation due to rotor material damping                                                                                                                                                     |
| $[BH_R^C]$               | = | the circulation due to rotor viscous hybrid damping                                                                                                                                               |
| $[KH_R^C]$               | = | the circulation due to rotor structural hybrid damping                                                                                                                                            |
| $\alpha 1_R, \alpha 2_R$ | = | used to specify Rayleigh viscous damping<br>( $[B_R]_{Rayleigh} = \alpha 1_R[M_R] + \alpha 2_R[K_R]$ )                                                                                            |
| $\alpha_R, \beta_R$      | = | scale factors of linear fit of rotor speed to reference rotor speed. The linear fit is calculated between the SPDLOW and SPDHIGH speeds (values specified on RGYRO entry) of the reference rotor. |
| $WR3, WR4, WRH$          | = | User parameters specified by PARAM statement. If the parameter values are zero (Default), the corresponding damping and circulation terms are not added.                                          |

- Parameter and hybrid damping applied to the rotor does not apply to the support and vice versa.
- For hybrid damping of the rotors, only the rotor mass and stiffness are used for the modes calculation.
- All rotor damping terms are cumulative. Multiple damping options should be selected with caution.
- If RDBOTH=16, the following damping and stiffness term will be used for Complex Modes (either ASYNC or SYNC option).

$$\text{The damping } i\omega \left( \begin{array}{l} [B_R] + \alpha 1_R[M_R] + \alpha 2_R[K_R] + [BH_R] \\ + \left(\frac{GR}{WR3}\right)[K_R] + \left(\frac{1}{WR4}\right)[K4_R] \\ + \left(\frac{1}{WRH}\right)[KH_R] \end{array} \right) \text{ changes to}$$

$i\omega \{ [B_R] + \alpha 1_R[M_R] + \alpha 2_R[K_R] + [BH_R] \}$  and the  $[K_R]/[K4_R]/[KH_R]$  will be added into the stiffness term with the imaginary formation of  $i \{ GR[K_R] + [K4_R] + [KH_R] \}$ .

## RSPINT Rotor Spin Rates

Specifies rotor spin rates for transient analysis.

### Format:

| 1      | 2       | 3       | 4       | 5       | 6     | 7      | 8       | 9 | 10 |
|--------|---------|---------|---------|---------|-------|--------|---------|---|----|
| RSPINT | ROTORID | GRIDA   | GRIDB   | SPDUNIT | SPTID | SPDOUT | ROTSEID |   |    |
|        | GR      | ALPHAR1 | ALPHAR2 | WR3R    | WR4R  | WRHR   |         |   |    |

### Example:

| 1      | 2    | 3    | 4     | 5     | 6     | 7     | 8 | 9 | 10 |
|--------|------|------|-------|-------|-------|-------|---|---|----|
| RSPINT | 100  | 1001 | 1002  | RPM   | 1001  |       |   |   |    |
|        | 0.01 | 0.01 | 0.002 | 1000. | 1500. | 1200. |   |   |    |

| Descriptor  | Meaning                                                                                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ROTORID     | Identification number of rotor. (Integer > 0; Required). See Remark 1.                                                                                                        |
| GRIDA/GRIDB | Positive rotor spin direction is defined from GRIDA to GRIDB. See Remark 4. (Integer > 0; Required)                                                                           |
| SPDUNIT     | Specifies whether the spin rates are given in terms of RPM (revolutions/minute) or frequency (revolutions(cycles)/sec). (Character; 'RPM' or 'FREQ'; Required)                |
| SPTID       | Rotor spin rate. See Remark 5. (Integer > 0; Required)                                                                                                                        |
| SPDOUT      | EPOINT to output the rotor speed vs. time. Output will be in SPDUNITs (Integer > 0 or blank)                                                                                  |
| GR          | Rotor structural damping factor. See Remark 6. and 8. (Real; Default = 0.0)                                                                                                   |
| ALPHAR1     | Scale factor applied to the rotor mass matrix for Rayleigh damping. See Remark 7. and 8. (Real; Default = 0.0)                                                                |
| ALPHAR2     | Scale factor applied to the rotor stiffness matrix for Rayleigh damping. See Remark 7. and 8. (Real; Default = 0.0)                                                           |
| ROTRSEID    | Identification number of the superelement in which the rotor specified in the ROTORID field is defined. (Integer >= 0, Default = 0). See Remark 1.                            |
| WR3R        | Specifies "average" excitation frequency for calculation of rotor damping and circulation terms for rotor structural damping specified through GR field. (Real, Default = 0.) |

| Describer | Meaning                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WR4R      | Specifies “average” excitation frequency for calculation of rotor damping and circulation terms for rotor structural damping specified through material entries. (Real, Default = 0.)    |
| WRHR      | Specifies “average” excitation frequency for calculation of rotor damping and circulation terms for rotor structural hybrid damping specified through ROTHYBD card. (Real, Default = 0.) |

**Remarks:**

1. The ROTORID-ROTRSEID pair must be unique across all RSPINT entries, but the ROTORID and ROTRSEID fields individually need not be unique.
2. Depending upon the type of analysis being performed, a RSPINR/RSPINT entry should be present for each rotor defined by a ROTORG or ROTORAX entry whose gyroscopic effects are to be included in the analysis. If missing for a rotor, then that rotor is assumed to be stationary and the analysis proceeds accordingly. The absence of a RSPINR/RSPINT entry for a rotor is noted in the .f06 file via an appropriate user information message.
3. RSPINR/RSPINT entries are honored and processed only in residual or assembly jobs and are ignored in external superelement creation jobs. For rotor defined in external SE, the GRIDA and GRIDB specified in RSPINT must be part of the SEs ASET during creation. This requirement is relaxed for rotors defined in PART SE.
4. The rotor spin axis is determined from the ROTORG or ROTORAX entries. The positive rotation vector is from GRIDA to GRIDB. GRIDA and GRIDB must be specified on the ROTORG or ROTORAX entry.

If ROTRSEID refers to a secondary external superelement, then GRIDA and GRIDB must be points associated with the ROTORID of the primary external superelement since the secondary external superelement derives all of its properties from the primary external superelement.

5. SPTID references a TABLED1 entry that specifies the rotor spin rate history.
6. Rotor structural damping specified by the GR entry will be added as equivalent viscous damping. The equivalent damping will be calculated using:

$$[B_{rotor}]_{structural} = \left( \frac{GR}{WR3} \right) [K_{rotor}]$$

where WR3 is a user parameter.

In case WR3R is specified in RSPINT, then WR3R is used for determining equivalent viscous damping for this particular rotor instead of WR3.

7. Rayleigh damping for the rotor will be calculated as

$$[B_{rotor}]_{Rayleigh} = \alpha_{R1}(M_{rotor}) + \alpha_{R2}[K_{rotor}]$$

8. The various rotor damping and circulation matrices used in transient analysis are shown in the following table. For the fixed reference frame, the circulation terms are generated from the rotating structure. For the rotating reference frame, the circulation terms are generated from the stator.

| Damping                                                                                                                                                             | Circulation (added to stiffness)                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| $[B_R] + [BH_R] + \alpha_{1R}[M_R] + \alpha_{2R}[K_R]$ $+ \left(\frac{GR}{WR3}\right)[K_R] + \left(\frac{1}{WR4}\right)[K4_R]$ $+ \left(\frac{1}{WRH}\right)[KH_R]$ | $\Omega_R(t) \left( \begin{array}{l} [B_R^C] + [BH_R^C] + \alpha_{1R}[M_R^C] + \alpha_{2R}[K_R^C] \\ + \left(\frac{GR}{WR3}\right)[K_R^C] + \left(\frac{1}{WR4}\right)[K4_R^C] \\ + \left(\frac{1}{WRH}\right)[KH_R^C] \end{array} \right)$ |

where:

- $[B_R]$  = the rotor viscous damping
- $[M_R]$  = the rotor mass
- $[K_R]$  = the rotor stiffness
- $[K4_R]$  = the rotor material damping
- $[BH_R]$  = the rotor viscous hybrid damping
- $[KH_R]$  = the rotor structural hybrid damping
- $[B_R^C]$  = the circulation due to rotor viscous damping
- $M_R^C$  = the circulation due to rotor 'mass'
- $K_R^C$  = the circulation due to rotor structural 'stiffness'
- $[K4_R^C]$  = the circulation due to rotor material damping
- $[BH_R^C]$  = the circulation due to rotor viscous hybrid damping
- $[KH_R^C]$  = the circulation due to rotor structural hybrid damping
- $\alpha_{1R}, \alpha_{2R}$  = used to specify Rayleigh viscous damping  
 $([B_R]_{Rayleigh} = \alpha_{1R}[M_R] + \alpha_{2R}[K_R])$
- $\alpha_R, \beta_R$  = scale factors of linear fit of rotor speed to reference rotor speed.  
 The linear fit is calculated between the SPDLOW and SPDHIGH speeds (values specified on RGYRO entry) of the reference rotor.
- $WR3, WR4, WRH$  = User parameters specified by PARAM statement. If the parameter values are zero (Default), the corresponding damping and circulation terms are not added.

- a. Parameter and hybrid damping applied to the rotor does not apply to the support and vice versa.
- b. For hybrid damping of the rotors, only the rotor mass and stiffness are used for the modes calculation.
- c. All rotor damping terms are cumulative. Multiple damping options should be selected with caution.

**RSPLINE**

## Interpolation Constraint Element

Defines multipoint constraints for the interpolation of displacements at grid points.

**Format:**

| 1       | 2   | 3   | 4  | 5  | 6      | 7  | 8  | 9  | 10 |
|---------|-----|-----|----|----|--------|----|----|----|----|
| RSPLINE | EID | D/L | G1 | G2 | C2     | G3 | C3 | G4 |    |
|         | C4  | G5  | C5 | G6 | -etc.- |    |    |    |    |

**Example:**

|         |     |     |     |    |        |    |  |    |  |
|---------|-----|-----|-----|----|--------|----|--|----|--|
| RSPLINE | 73  | .05 | 27  | 28 | 123456 | 29 |  | 30 |  |
|         | 123 | 75  | 123 | 71 |        |    |  |    |  |

| Describer | Meaning                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------|
| EID       | Element identification number. (0 < Integer < 100,000,000)                                                       |
| D/L       | Ratio of the diameter of the elastic tube to the sum of the lengths of all segments. (Real > 0.0; Default = 0.1) |
| Gi        | Grid point identification number. (Integer > 0)                                                                  |
| Ci        | Components to be constrained. See Remark 2. (Blank or any combination of the Integers 1 through 6.)              |

**Remarks:**

1. Displacements are interpolated from the equations of an elastic beam passing through the grid points. This is a linear method only element, and not controlled with the Case Control command RIGID.
2. A blank field for Ci indicates that all six degrees-of-freedom at Gi are independent. Since G1 must be independent, no field is provided for C1. Since the last grid point must also be independent, the last field must be a Gi, not a Ci. For the example shown G1, G3, and G6 are independent. G2 has six constrained degrees-of-freedom while G4 and G5 each have three.
3. Dependent (i.e., constrained) degrees-of-freedom assigned by one rigid element may not also be assigned dependent by another rigid element or by a multipoint constraint.
4. Degrees-of-freedom declared to be independent by one rigid body element can be made dependent by another rigid body element or by a multipoint constraint.
5. EIDs must be unique.
6. RSPLINE, among other eligible rigid element types, can be selected via MPC and SET3.
7. Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.

8. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
9. See [Rigid Elements and Multipoint Constraints \(R-type, MPC\)](#) in the *MSC Nastran Reference Guide* for a discussion of rigid elements.
10. The m-set coordinates specified on this entry may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
11. The constraint coefficient matrix is affected by the order of the Gi Ci pairs on the RSPLINE entry. The order of the pairs should be specified in the same order that they appear along the line that joins the two regions. If this order is not followed then the RSPLINE will have folds in it that may yield some unexpected interpolation results.
12. The independent degrees-of-freedom that are the rotation components most nearly parallel to the line joining the regions should not normally be constrained.
13. The RSPLINE has a limit of 100 grid points.

**RSSCON**

## Shell-to-Solid Element Connector

Defines multipoint constraints to model clamped connections of shell-to-solid elements.

**Format:**

| 1      | 2    | 3    | 4   | 5   | 6   | 7   | 8   | 9   | 10 |
|--------|------|------|-----|-----|-----|-----|-----|-----|----|
| RSSCON | RBID | TYPE | ES1 | EA1 | EB1 | ES2 | EA2 | EB2 |    |

**Examples:**

|        |     |      |    |    |    |    |    |    |  |
|--------|-----|------|----|----|----|----|----|----|--|
| RSSCON | 110 | GRID | 11 | 12 | 13 | 14 | 15 | 16 |  |
|--------|-----|------|----|----|----|----|----|----|--|

|        |     |      |    |    |    |  |  |  |  |
|--------|-----|------|----|----|----|--|--|--|--|
| RSSCON | 111 | GRID | 31 | 74 | 75 |  |  |  |  |
|--------|-----|------|----|----|----|--|--|--|--|

|        |     |      |     |     |  |  |  |  |  |
|--------|-----|------|-----|-----|--|--|--|--|--|
| RSSCON | 115 | ELEM | 311 | 741 |  |  |  |  |  |
|--------|-----|------|-----|-----|--|--|--|--|--|

| Descriptor | Meaning                                                                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RBID       | Element identification number. (0 < Integer < 100,000,000)                                                                                                                                                                      |
| TYPE       | Type of connectivity:<br>ELEM      Connection is described with element identification numbers.<br>GRID      Connection is described with grid point identification numbers.<br>(Character: "GRID" or "ELEM"; Default = "ELEM") |
| ES1        | Shell element identification number if TYPE = "ELEM". Shell grid point identification number if TYPE = "GRID". See <a href="#">Figure 9-141</a> . (Integer > 0)                                                                 |
| EA1        | Solid element identification number if TYPE = "ELEM". Solid grid point identification number if TYPE = "GRID". (Integer > 0)                                                                                                    |
| EB1        | Solid grid-point identification number for TYPE = "GRID" only. (Integer > 0 or blank)                                                                                                                                           |
| ES2        | Shell grid-point identification number for TYPE = "GRID" only. (Integer > 0 or blank)                                                                                                                                           |
| EA2        | Solid grid-point identification number for TYPE = "GRID" only. (Integer > 0 or blank)                                                                                                                                           |
| EB2        | Solid grid-point identification number for TYPE = "GRID" only. (Integer > 0 or blank)                                                                                                                                           |

**Remarks:**

1. RSSCON generates a multipoint constraint that models a clamped connection between a shell and a solid element. The shell degrees-of-freedom are put in the dependent set (m-set). The translational degrees-of-freedom of the shell edge are connected to the translational degrees-of-freedom of the upper and lower solid edge. The two rotational degrees-of-freedom of the shell are connected to the translational degrees-of-freedom of the lower and upper edges of the solid element face. Poisson's ratio effects are considered in the translational degrees-of-freedom.

2. The shell grid point must lie on the line connecting the two solid grid points. It can have an offset from this line, which can not be more than 5% of the distance between the two solid grid points. The shell grid points that are out of the tolerance will not be constrained, and a fatal message will be issued. This tolerance is adjustable. Please see `PARAM,TOLRSC` and `PARAM,SEPIXOVR`.
3. When using the `TYPE = "ELEM"` option
  - The solid elements are `CHEXA`, `CPENTA`, and `CTETRA` with and without midside nodes. The shell elements are `CQUAD4`, `CTRIA3`, `CQUADR`, `CTRIAR`, `CQUAD8`, or `CTRIA6`. If the solid element has mid-side nodes, then the shell element needs mid-side nodes on the common edge.
  - Both the shell and solid elements have to belong to the same superelement. This restriction can be bypassed using `SEELT` entry to reassign the downstream boundary element to an upstream superelement.
  - It is not recommended to connect more than one shell element to the same solid using the `ELEM` option. If attempted, conflicts in the multipoint constraint relations may lead to `UFM 6692`.
4. When using `TYPE = "GRID"` option
  - The `GRID` option does not verify that the grids used are valid shell and/or solid grids.
  - The grids in the `GRID` option can be in different superelements. The shell grid must be in the upstream superelement.
5. It is recommended that the height of the solid element's face is approximately equal to the shell element's thickness of the shell. The shell edge should then be placed in the middle of the solid face.
6. The shell edge may coincide with the upper or lower edge of the solid face.
7. `RSSCON`, among other eligible rigid element types, can be selected via `MPC` and `SET3`.
8. Forces of multipoint constraints may be recovered with the `MPCFORCE` Case Control command.
9. The `RSSCON` is ignored in heat-transfer problems. If used in a multi-physics coupled problem using `SUBSTEP`, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the `DEACTEL` keyword under the `NLMOPTS` Bulk Data entry and the associated Remark 10. for that entry.
10. The m-set coordinates (shell degrees-of-freedom) may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.

Figure 9-141 Shell Elements Connected to the Faces of Solid Elements

## RTRPLT

## Rigid Triangular Plate

Defines a rigid triangular plate.

### Format:

| 1      | 2   | 3   | 4   | 5     | 6    | 7   | 8   | 9 | 10 |
|--------|-----|-----|-----|-------|------|-----|-----|---|----|
| RTRPLT | EID | GA  | GB  | GC    | CNA  | CNB | CNC |   |    |
|        | CMA | CMB | CMC | ALPHA | TREF |     |     |   |    |

### Example:

|        |   |   |   |   |      |   |   |  |  |
|--------|---|---|---|---|------|---|---|--|--|
| RTRPLT | 7 | 1 | 2 | 3 | 1236 | 3 | 3 |  |  |
|--------|---|---|---|---|------|---|---|--|--|

| Describer     | Meaning                                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EID           | Element identification number. (0 < Integer < 100,000,000)                                                                                                                                                               |
| GA, GB, GC    | Grid point identification number of connection points.                                                                                                                                                                   |
| CNA, CNB, CNC | Independent degrees-of-freedom in the global coordinate system for the element at grid points GA, GB, and GC, indicated by any of the Integers 1 through 6 with no embedded blanks. See Remark 3. (Integer ≥ 0 or blank) |
| CMA, CMB, CMC | Component numbers of dependent degrees-of-freedom in the global coordinate system. (Any of the Integers 1 through 6 with no embedded blanks, or 0 or blank; Default = 0.)                                                |
| ALPHA         | Thermal expansion coefficient. See Remark 12. (Real or blank)                                                                                                                                                            |
| TREF          | Reference temperature for the calculation of thermal loads. (Real; Default=0.0).                                                                                                                                         |

### Remarks:

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, Nastran will create internally the Lagrange multiplier degrees-of-freedom in addition to the 18 displacement degrees-of-freedom given by grid points GA, GB, and GC. The number of Lagrange multiplier degrees-of-freedom is equal to the number of dependent degrees-of-freedom.
- For the linear method, the total number of components in CNA, CNB, and CNC must equal six; for example, CNA = 1236, CNB = 3, CNC = 3. Furthermore, they must jointly be capable of representing any general rigid body motion of the element. For the Lagrange method, the total number of components must also be six. However, only CNA= 123456 (Default) or CNB = 123456 or CNC = 123456 is allowed. For this type of element, RTRPLT1 gives a simpler input format.

4. For the linear method, the dependent degrees-of-freedom will be made members of the m-set. For the Lagrange method, they may or may not be members of the m-set, depending on the method selected on the RIGID Case Control command. However, the rules regarding the m-set described below apply to both types of methods.
5. Dependent degrees-of-freedom assigned by one rigid element may not also be assigned dependent by another rigid element or by a multipoint constraint.
6. Element identification numbers should be unique with respect to all other element identification numbers.
7. RTRPLT, among other eligible rigid element types, can be selected via MPC and SET3.
8. Forces of multipoint constraint may be recovered in all solution sequences, except SOL 129, with the MPCFORCE Case Control command.
9. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.
10. See [Rigid Elements and Multipoint Constraints \(R-type, MPC\)](#) in the *MSC Nastran Reference Guide* for a discussion of rigid elements.
11. The m-set coordinates specified on this entry may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
12. For the Lagrange method, the thermal expansion effect will be computed, if user supplies the thermal expansion coefficient, ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The temperature of the element is defined as the following. the bar GA-GB will have the average temperature of grid points GA and GB. The bar GA-GC will have the average temperature of the grid points GA and GC.

## RTRPLT1

### Rigid Triangular Plate (Alternative Format)

Alternative format to define a rigid triangular plate element connecting three grid points.

#### Format:

| 1       | 2   | 3  | 4  | 5  | 6   | 7   | 8     | 9    | 10 |
|---------|-----|----|----|----|-----|-----|-------|------|----|
| RTRPLT1 | EID | GA | GB | GC | CMB | CMC | ALPHA | TREF |    |

#### Example:

|         |   |   |   |   |      |   |       |  |  |
|---------|---|---|---|---|------|---|-------|--|--|
| RTRPLT1 | 7 | 1 | 2 | 3 | 1236 | 3 | 6.0-6 |  |  |
|---------|---|---|---|---|------|---|-------|--|--|

| Describer  | Meaning                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EID        | Element identification number. (0 < Integer < 100,000,000)                                                                                                                                 |
| GA, GB, GC | Grid point identification number of connection points. (Integer > 0)                                                                                                                       |
| CMB, CMC   | Component numbers at GB and GC in the global coordinate systems, which are constrained to move with the rigid body. See Remark 4. (Integers 1 through 6 with no embedded blanks or blank.) |
| ALPHA      | Thermal expansion coefficient. See Remark 9. (Real or blank)                                                                                                                               |
| TREF       | Reference temperature for the calculation of thermal loads. (Real; Default=0.0).                                                                                                           |

#### Remarks:

- Two methods are available to process rigid elements: equation elimination or Lagrange multipliers. The Case Control command, RIGID, selects the method.
- For the Lagrange method, Nastran will create internally the Lagrange multiplier degrees-of-freedom in addition to the 18 displacement degrees-of-freedom given by grid points GA, GB, and GC. The number of Lagrange multiplier degrees-of-freedom is equal to the number of dependent degrees-of-freedom.
- RTRPLT1 is a preferred input format for the Lagrange method.
- When CMB = "123456" or blank, CMC = "123456" or blank, the grid points GB and BC are constrained to move with GA as a rigid triangular plate. For default, CMB = "123456" and CMC = "123456". Any number of degrees-of-freedom at grid points GB and GC can be released not to move with the rigid body.
- The length of any two connected grid points must be greater than zero.
- For the Lagrange method, the theory is formulated such that a consistent rigid body motion for grid points GA, GB, and GC will be computed even if these three points have different global coordinate systems.

7. For the Lagrange method, the thermal expansion effect will be computed, if user supplies the thermal expansion coefficient, ALPHA, and the thermal load is requested by the TEMPERATURE(INITIAL) and TEMPERATURE(LOAD) Case Control commands. The bar GA-GB will have the average temperature of grid points GA and GB. The bar GA-GC will have the average temperature of the grid points GA and GC.
8. Element identification numbers should be unique with respect to all other element identification numbers.
9. Rigid elements are ignored in heat transfer problems. If used in a multi-physics coupled problem using SUBSTEP, they participate in the mechanical substep but are ignored in the heat transfer substep through automatic deactivation. For more information on deactivation, see the DEACTEL keyword under the NLMOPTS Bulk Data entry and the associated Remark 10. for that entry.

## **RVDOF**      Degrees-of-Freedom Specification for Residual Vector Computations

Specifies the degrees-of-freedom where unit loads are to be applied to obtain static solutions for use in residual vector computations.

**Format:**

|       |     |    |     |    |     |    |     |    |    |
|-------|-----|----|-----|----|-----|----|-----|----|----|
| 1     | 2   | 3  | 4   | 5  | 6   | 7  | 8   | 9  | 10 |
| RVDOF | ID1 | C1 | ID2 | C2 | ID3 | C3 | ID4 | C4 |    |

**Example:**

|       |     |   |     |   |  |  |  |  |  |
|-------|-----|---|-----|---|--|--|--|--|--|
| RVDOF | 800 | 1 | 850 | 2 |  |  |  |  |  |
|-------|-----|---|-----|---|--|--|--|--|--|

| Describer | Meaning                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------|
| IDI       | Grid or scalar identification number. (Integer > 0)                                                                  |
| CI        | Component numbers. (Any one of the integers 1 through 6 for grid points and integer zero or blank for scalar points) |

**Remarks:**

1. In multiple superelement analysis, the IDi points may be interior to any superelement. The program automatically partitions the data for allocation to the appropriate superelements. Separate entries for separate superelements are not required as in the case of USETi,U6 and SEUSETi,U6 entries.
2. The unit loads applied to the interior points of a superelement due to the RVDOF/RVDOF1 entries are passed downstream all the way down to the residual for the purpose of residual vector processing by all superelements in its downstream path, resulting in more accurate results. This is in contrast to the way residual vector processing is performed when USETi,U6 or SEUSETi,U6 entries are employed. In the latter case, unit loads on a superelement are not passed downstream for residual vector processing by the downstream superelements.

## RVDOF1 Degrees-of-Freedom Specification for Residual Vector Computations

Specifies the degrees-of-freedom where unit loads are to be applied to obtain static solutions for use in residual vector computations.

### Format:

| 1      | 2   | 3   | 4      | 5   | 6   | 7   | 8   | 9   | 10 |
|--------|-----|-----|--------|-----|-----|-----|-----|-----|----|
| RVDOF1 | C   | ID1 | ID2    | ID3 | ID4 | ID5 | ID6 | ID7 |    |
|        | ID8 | ID9 | -etc.- |     |     |     |     |     |    |

### Example:

|        |   |     |     |     |  |  |  |  |  |
|--------|---|-----|-----|-----|--|--|--|--|--|
| RVDOF1 | 3 | 100 | 210 | 450 |  |  |  |  |  |
|--------|---|-----|-----|-----|--|--|--|--|--|

### Alternate Format and Example:

|        |    |     |        |     |  |  |  |  |  |
|--------|----|-----|--------|-----|--|--|--|--|--|
| RVDOF1 | C  | ID1 | “THRU” | ID2 |  |  |  |  |  |
| RVDOF1 | 12 | 6   | THRU   | 21  |  |  |  |  |  |

| Describer | Meaning                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C         | Component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points. This number must be Integer 0 or blank for scalar points.) |
| IDi       | Grid or scalar identification numbers. (Integer > 0 or “THRU”; for “THRU” option, ID1 < ID2)                                                                               |

### Remarks:

1. In multiple superelement analysis, the IDi points may be interior to any superelement. The program automatically partitions the data for allocation to the appropriate superelements. Separate entries for separate superelements are not required as in the case of USETi,U6 and SEUSETi,U6 entries.
2. The unit loads applied to the interior points of a superelement due to the RVDOF/RVDOF1 entries are passed downstream all the way down to the residual for the purpose of residual vector processing by all superelements in its downstream path, resulting in more accurate results. This is in contrast to the way residual vector processing is performed when USETi,U6 or SEUSETi,U6 entries are employed. In the latter case, unit loads on a superelement are not passed downstream for residual vector processing by the downstream superelements.
3. If the alternate format is used, points in the sequence ID1 through ID2 are not required to exist. Points that do not exist will collectively produce a warning message but will otherwise be ignored.
4. When alternative format is used, single point IDs cannot be specified.

## SANGLE Analytical contact threshold angle in SOL 600

Defines automatic analytical contact threshold angle for multiple subcases in SOL 600 only.

### Format:

| 1      | 2   | 3   | 4     | 5   | 6   | 7     | 8 | 9 | 10 |
|--------|-----|-----|-------|-----|-----|-------|---|---|----|
| SANGLE | IDC | IDB | Angle | IDC | IDB | Angle |   |   |    |

### Example:

|        |   |   |      |   |   |      |  |  |  |
|--------|---|---|------|---|---|------|--|--|--|
| SANGLE | 1 | 4 | 50.0 | 1 | 6 |      |  |  |  |
|        | 2 | 4 | -1.0 | 2 | 6 | 55.0 |  |  |  |

| Describer | Meaning                                                                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| IDC       | Identification number of a SUBCASE Case Control command. (Integer; no Default) To enter a value corresponding to Marc's increment zero, set IDC=0. |
| IDB       | Identification of a contact body (must be the same as a BCBODY ID) (Integer; no Default)                                                           |
| Angle     | Threshold automatic analytical contact angle (SANGLE). (Real; Default = 60.0)<br>A value of -1.0 turns off analytical.                             |

### Remarks:

1. This entry should only be made if IDSPL=1 and if SANGLE is a non-zero integer value on one or more BCBODY entry.
2. This entry is available in SOL 600 only.
3. For the example, BCBODY with id=4 has a threshold angle of 50.0 degrees in subcase 1 and analytical contact is turned off in subcase 2. For bcbody=6, the analytical contact is on for subcases 1 and 2 and the threshold angle is 60.0 degrees (the default) and 55.0 degrees for subcases 1 and 2 respectively.
4. Only those contact bodies whose SANGLE changes from subcase to subcase or is turned on/off need be described here. Those with constant SANGLE may be described on the BCBODY entry.

## SEBNDRY Superelement Boundary-Point Definition

Defines a list of grid points in a partitioned superelement for the automatic boundary search between a specified superelement or between all other superelements in the model.

### Format:

| 1       | 2     | 3     | 4      | 5     | 6     | 7     | 8     | 9     | 10 |
|---------|-------|-------|--------|-------|-------|-------|-------|-------|----|
| SEBNDRY | SEIDA | SEIDB | GIDA1  | GIDA2 | GIDA3 | GIDA4 | GIDA5 | GIDA6 |    |
|         | GIDA7 | GIDA8 | -etc.- |       |       |       |       |       |    |

### Example 1:

|         |     |   |    |    |    |    |  |  |  |
|---------|-----|---|----|----|----|----|--|--|--|
| SEBNDRY | 400 | 4 | 10 | 20 | 30 | 40 |  |  |  |
|---------|-----|---|----|----|----|----|--|--|--|

### Example 2:

|         |     |     |    |    |    |      |    |  |  |
|---------|-----|-----|----|----|----|------|----|--|--|
| SEBNDRY | 400 | ALL | 10 | 20 | 30 | THRU | 40 |  |  |
|---------|-----|-----|----|----|----|------|----|--|--|

| Describer | Meaning                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------|
| SEIDA     | Partitioned superelement identification number. (Integer > 0)                                                              |
| SEIDB     | Superelement identification. See Remark 2. (Integer > 0 or Character "ALL"; Default = "ALL")                               |
| GIDAi     | Identification number of a boundary grid point in superelement SEIDA. (Integer > 0 or "THRU"; For "THRU" option, G1 < G2.) |

### Remarks:

1. SEBNDRY may only be specified in the main Bulk Data Section and is not recognized after the BEGIN SUPER=n.
2. SEIDB may reference partitioned superelements or superelements in the main Bulk Data Section.

## SEBSET Fixed Boundary Degree-of-Freedom

Defines boundary degrees-of-freedom to be fixed (b-set) during generalized dynamic reduction or component mode synthesis calculations.

### Format:

| 1      | 2    | 3   | 4  | 5   | 6  | 7   | 8  | 9 | 10 |
|--------|------|-----|----|-----|----|-----|----|---|----|
| SEBSET | SEID | ID1 | C1 | ID2 | C2 | ID3 | C3 |   |    |

### Example:

|        |   |   |     |    |   |  |  |  |  |
|--------|---|---|-----|----|---|--|--|--|--|
| SEBSET | 5 | 2 | 135 | 14 | 6 |  |  |  |  |
|--------|---|---|-----|----|---|--|--|--|--|

| Describer | Meaning                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. (Integer > 0)                                                                                                       |
| Ci        | Component number. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; Integer zero or blank for scalar points) |
| Idi       | Grid or scalar point identification numbers. (Integer > 0)                                                                                              |

### Remarks:

1. If there are no SECSETi or SEBSETi entries present, all boundary points are, by default, fixed during component mode analysis. If only SEBSETi are entries present, any boundary degrees-of-freedom not listed are placed in the free boundary set (c-set). If both SEBSETi and SECSETi entries are present, the c-set degrees-of-freedom are defined by the SECSETi entries and any remaining boundary points are placed in the b-set.
2. Degrees-of-freedom listed on SEBSETi entries must be exterior degrees-of-freedom of the superelement and may not be specified on SECSETi entries.
3. Degrees-of-freedom specified on this entry form members of the mutually exclusive b-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.

**SEBSET1**

## Fixed Boundary Degree-of-Freedom, Alternate Form of SEBSET

Defines boundary degrees-of-freedom to be fixed (b-set) during generalized dynamic reduction or component mode calculations.

**Format:**

| 1       | 2    | 3  | 4  | 5      | 6  | 7  | 8  | 9  | 10 |
|---------|------|----|----|--------|----|----|----|----|----|
| SEBSET1 | SEID | C  | G1 | G2     | G3 | G4 | G5 | G6 |    |
|         | G7   | G8 | G9 | -etc.- |    |    |    |    |    |

**Example:**

|         |     |     |     |    |   |    |    |    |  |
|---------|-----|-----|-----|----|---|----|----|----|--|
| SEBSET1 | 5   | 2   | 135 | 14 | 6 | 23 | 24 | 25 |  |
|         | 122 | 127 |     |    |   |    |    |    |  |

**Alternate Format and Example:**

|         |      |   |    |        |    |  |  |  |  |
|---------|------|---|----|--------|----|--|--|--|--|
| SEBSET1 | SEID | C | G1 | "THRU" | G2 |  |  |  |  |
| SEBSET1 | 5    | 3 | 6  | THRU   | 32 |  |  |  |  |

| Describer | Meaning                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. (Integer > 0)                                                                                             |
| C         | Component number. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points, 0 or blank for scalar points.) |
| Gi        | Grid or scalar point identification numbers. (Integer > 0 or "THRU"; for THRU option G1 < G2.)                                                |

**Remarks:**

1. If there are no SECSET<sub>i</sub> or SEBSET<sub>i</sub> entries present, all boundary points are, by default, fixed during component mode analysis. If there are only SEBSET<sub>i</sub> entries present, any boundary degrees-of-freedom not listed are placed in the free boundary set (c-set). If there are both SEBSET<sub>i</sub> and SECSET<sub>i</sub> entries present, the c-set degrees-of-freedom are defined by the SECSET<sub>i</sub> entries, and any remaining boundary points are placed in the b-set.
2. Degrees-of-freedom listed on SEBSET<sub>i</sub> entries must be exterior degrees-of-freedom of the superelement and may not be specified on SECSET<sub>i</sub> entries.
3. Degrees-of-freedom specified on this entry form members of the mutually exclusive b-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.

4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.

**SEBULK****Partition Superelement Connection**

Defines superelement boundary search options and a repeated, mirrored, or collector superelement.

**Format:**

| 1      | 2    | 3    | 4     | 5      | 6   | 7   | 8      | 9 | 10 |
|--------|------|------|-------|--------|-----|-----|--------|---|----|
| SEBULK | SEID | TYPE | RSEID | METHOD | TOL | LOC | UNITNO |   |    |

**Example:**

|        |    |        |   |      |        |  |  |  |  |
|--------|----|--------|---|------|--------|--|--|--|--|
| SEBULK | 14 | REPEAT | 4 | AUTO | 1.0E-3 |  |  |  |  |
|--------|----|--------|---|------|--------|--|--|--|--|

| Describer | Meaning                                                                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Partitioned superelement identification number. (Integer > 0). See Remark 11.                                                                 |
| TYPE      | Superelement type. (Character; no Default)                                                                                                    |
|           | PRIMARY Primary. See Remarks 2. and 5.                                                                                                        |
|           | COLLECTR Collector. See Remark 3.                                                                                                             |
|           | EXTERNAL External. See Remarks 4. and 5.                                                                                                      |
|           | EXTOP2 External using an OUTPUT2 file created in an earlier run. See Remarks 4. and 5.                                                        |
|           | EXTOP4 External using an OUTPUT4 file created in an earlier run. See Remarks 4. and 5.                                                        |
|           | REPEAT Identical. See Remark 6.                                                                                                               |
|           | MIRROR Mirror. See Remark 6.                                                                                                                  |
| RSEID     | Identification number of the reference superelement, used only if TYPE = "REPEAT" or "MIRROR". (Integer ≥ 0; Default = 0). See Remark 6.      |
| METHOD    | Method to be used when searching for boundary grid points. (Character: "AUTO" or "MANUAL"; Default = "AUTO"). See Remarks 7. and 8.           |
| TOL       | Location tolerance to be used when searching for boundary grid points. (Real; Default = 10E-5). See Remarks 10. and 11.                       |
| LOC       | Coincident location check option for manual connection option. (Character: "YES" or "NO"; Default = "YES"). See Remark 10.                    |
| UNITNO    | FORTTRAN unit number for the OUTPUT2 or OUTPUT4 file (applicable and meaningful only when TYPE = "EXTOP2" or "EXTOP4"). See Remarks 4. and 5. |

**Remarks:**

1. This specification must be specified in the MAIN Bulk Data and is meaningful only if part superelements (using BEGIN SUPER) or external superelements created by employing the EXTSEOUT Case Control command exist in the data.

2. TYPE = PRIMARY indicates that the superelement is a part superelement (using BEGIN SUPER).
3. TYPE = "COLLCTR" indicates a collector superelement which does not contain any grids or scalar points.
4. TYPE = "EXTERNAL", "EXTOP2" or "EXTOP4" indicates an external superelement created by employing the EXTSEOUT Case Control command in an earlier job. See discussion under the description of the EXTSEOUT Case Control command. (For employing external superelements using the old three-step procedure, see discussion under the description of parameter EXTDROUT in Chapter 5.)
5. A superelement whose TYPE is "PRIMARY", "EXTERNAL" or "EXTOP2" may itself be re-positioned by the use of an SELOC or an SEMPLN entry or both.

If it references an SELOC entry, then the primary superelement will be positioned at the location implied by the SELOC entry.

If it references an SEMPLN entry, then a mirror image of the primary superelement will be positioned using the plane defined by the SEMPLN entry.

If it references both an SELOC entry and an SEMPLN entry, then a mirror image of the primary superelement will first be created using the plane defined by the SEMPLN entry and then it will be positioned at the location implied by the SELOC entry.

6. TYPE = "REPEAT" and TYPE = "MIRROR" have many common features, but they also have some important differences. These are described below.

The following comments apply to both TYPE= "REPEAT" and TYPE = "MIRROR":

- a. An SEID whose TYPE is "REPEAT" or "MIRROR" is referred to as a secondary superelement. The RSEID specified in this case is regarded as the primary superelement.
- b. The primary superelement must be either a part superelement or an external superelement created by employing the EXTSEOUT Case Control command in an earlier job. It must be defined via its own SEBULK entry wherein TYPE must be either "PRIMARY", "EXTERNAL" or "EXTOP2".
- c. The primary superelement does not include superelements upstream of the primary superelement.
- d. The primary superelement may be re-positioned as indicated in Remark 5.
- e. If the primary superelement specified by RSEID is a part superelement, then the secondary superelement is a "G-set" copy of the primary superelement. In this case, the boundary, loads, constraints and reduction procedure of the secondary superelement can be different from those of its primary superelement.
- f. If the primary superelement specified by RSEID is an external superelement resulting from the use of the EXTSEOUT Case Control command in an earlier job, then the secondary superelement is an "A-set" copy of the primary superelement. In this case, the boundary, loads, constraints and reduction procedure of the secondary superelement are set and are the same as those of its primary superelement.

The following comments apply only to TYPE= "REPEAT":

- g. The secondary superelement in this case may reference an SELOC entry, an SEMPLN entry or both or none.

If it references an SELOC entry, then an identical copy of its primary superelement will be positioned at the location implied by the SELOC entry.

If it references an SEMPLN entry, then a mirror image copy of the primary superelement will be positioned using the plane defined by the SEMPLN entry.

If it references both an SELOC entry and an SEMPLN entry, then a mirror image copy of the primary superelement will first be created using the plane defined by the SEMPLN entry and then it will be positioned at the location implied by the SELOC entry.

If it references neither an SELOC entry nor an SEMPLN entry, then the secondary superelement will merely be a duplicate of the primary superelement positioned at the same location as the primary superelement. This usage is extremely uncommon. Hence the program cautions the user about this usage by issuing a user warning message.

The following comments apply only to TYPE= "MIRROR":

- h. The secondary superelement in this case must reference an SEMPLN entry. (Otherwise, the program will terminate the execution with an appropriate user fatal message.) In addition, the secondary superelement may also reference an SELOC entry.
 

If the secondary superelement references only an SEMPLN entry, then a mirror image copy of the primary superelement will be positioned using the plane defined by the SEMPLN entry.

If it references both an SELOC entry and an SEMPLN entry, then a mirror image copy of the primary superelement will first be created using the plane defined by the SEMPLN entry and then it will be positioned at the location implied by the SELOC entry.
7. METHOD = "MANUAL" requires SECONCT entries. SEBNDRY and SEEXCLD, which reference SEID, will produce a fatal message.
8. SECONCT, SEBNDRY, and SEEXCLD entries can be used to augment the search procedure and/or override the global tolerance.
9. For combined automatic and manual boundary search, the METHOD = "AUTO" should be specified and connections should be specified on a SECONCT entry.
10. TOL and LOC are the default values that can be modified between two superelements by providing the required tolerance on the SECONCT entry.
11. A SEID=0 is valid for the residual part only if it is desired to set a TOL value for the residual.

## SECONCT Partitioned Superelement Boundary-Point Connection

Explicitly defines grid and scalar point connection procedures for a partitioned superelement.

### Format:

| 1       | 2     | 3     | 4     | 5     | 6     | 7     | 8      | 9 | 10 |
|---------|-------|-------|-------|-------|-------|-------|--------|---|----|
| SECONCT | SEIDA | SEIDB | TOL   | LOC   |       |       |        |   |    |
|         | GIDA1 | GIDB1 | GIDA2 | GIDB2 | GIDA3 | GIDB3 | -etc.- |   |    |

### Example:

|         |      |      |        |     |      |      |  |  |  |
|---------|------|------|--------|-----|------|------|--|--|--|
| SECONCT | 10   | 20   | 1.0E-4 | YES |      |      |  |  |  |
|         | 1001 | 4001 |        |     | 2222 | 4444 |  |  |  |

### Alternate Format and Example:

|         |       |        |       |       |        |       |  |  |  |
|---------|-------|--------|-------|-------|--------|-------|--|--|--|
| SECONCT | SEIDA | SEIDB  | TOL   | LOC   |        |       |  |  |  |
|         | GIDA1 | 'THRU' | GIDA2 | GIDB1 | 'THRU' | GIDB2 |  |  |  |

|         |     |        |     |     |        |     |  |  |  |
|---------|-----|--------|-----|-----|--------|-----|--|--|--|
| SECONCT | 10  | 20     |     |     |        |     |  |  |  |
|         | 101 | 'THRU' | 110 | 201 | 'THRU' | 210 |  |  |  |

| Descriptor | Meaning                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------|
| SEIDA      | Identification number of superelement for connection to SEIDB. (Integer $\geq 0$ )                         |
| SEIDB      | Identification number of superelement for connection to SEIDA. (Integer $\geq 0$ )                         |
| TOL        | Location tolerance to be used when searching for or checking boundary grid points. (Real; Default = 10E-5) |
| LOC        | Coincident location check option for manual connection. (Character; "YES" or "NO"; Default = "YES")        |
| GIDAi      | Identification number of a grid or scalar point in superelement SEIDA, which will be connected to GIDBi.   |
| GIDBi      | Identification number of a grid or scalar point in superelement SEIDB, which will be connected to GIDAi.   |

### Remarks:

1. SECONCT can only be specified in the main Bulk Data Section and will cause a fatal error message if it appears after the BEGIN SUPER = n command.
2. TOL and LOC can be used to override the default values specified on the SEBULK entries.
3. The continuation entry is optional.
4. The (GIAi, GIBi) pair must both be grids or scalar points.

5. All six degrees-of-freedom of grid points will be defined as boundary degrees-of-freedom.
6. This entry will only work if PART superelements (BEGIN SUPER) exist.
7. Blank fields are allowed after the first GIDA1-GIDB1 pair. Blank fields must also occur in pairs. This remark does not apply to the alternate format.
8. For Alternate Format 1, the thru ranges must be closed sets. That is, all IDs listed between 101 and 110 in the example must exist in the model.

**SECSET**

Free Boundary Degree-of-Freedom

Defines boundary degrees-of-freedom to be free (c-set) during generalized dynamic reduction or component mode synthesis calculations.

**Format:**

|        |      |     |    |     |    |     |    |   |    |
|--------|------|-----|----|-----|----|-----|----|---|----|
| 1      | 2    | 3   | 4  | 5   | 6  | 7   | 8  | 9 | 10 |
| SECSET | SEID | ID1 | C1 | ID2 | C2 | ID3 | C3 |   |    |

**Example:**

|        |   |     |   |   |    |   |    |  |  |
|--------|---|-----|---|---|----|---|----|--|--|
| SECSET | 3 | 124 | 1 | 5 | 23 | 6 | 15 |  |  |
|--------|---|-----|---|---|----|---|----|--|--|

| Describer | Meaning                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. (Integer > 0)                                                                                                      |
| Ci        | Component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; Integer 0 or blank for scalar points.) |
| IDI       | Grid or scalar point identification number. (Integer > 0)                                                                                              |

**Remarks:**

1. Exterior grid and scalar points are, by default, fixed during component mode analysis and placed in the b-set unless listed on SECSETi or SESUP entries. Coordinates listed on this entry are considered free (c-set) during component mode calculations. Exterior grid and scalar points are determined by the program and listed in the SEMAP table output.
2. Degrees-of-freedom specified on this entry are assigned to the mutually exclusive c-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
3. There must be a sufficient number of degrees-of-freedom specified on SESUP entries to discard any free body modes of the superelement.
4. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.

**SECSET1**

## Free Boundary Degree-of-Freedom, Alternate Form of SECSET

Defines boundary degrees-of-freedom to be free (c-set) during generalized dynamic reduction or component mode synthesis calculations.

**Format:**

| 1       | 2    | 3  | 4  | 5      | 6  | 7  | 8  | 9  | 10 |
|---------|------|----|----|--------|----|----|----|----|----|
| SECSET1 | SEID | C  | G1 | G2     | G3 | G4 | G5 | G6 |    |
|         | G7   | G8 | G9 | -etc.- |    |    |    |    |    |

**Example:**

|         |     |     |     |    |   |    |    |    |  |
|---------|-----|-----|-----|----|---|----|----|----|--|
| SECSET1 | 5   | 2   | 135 | 14 | 6 | 23 | 24 | 25 |  |
|         | 122 | 127 |     |    |   |    |    |    |  |

**Alternate Formats and Example:**

|         |      |   |    |        |    |  |  |  |  |
|---------|------|---|----|--------|----|--|--|--|--|
| SECSET1 | SEID | C | G1 | "THRU" | G2 |  |  |  |  |
| SECSET1 | 5    | 3 | 6  | THRU   | 32 |  |  |  |  |

|         |      |  |       |  |  |  |  |  |  |
|---------|------|--|-------|--|--|--|--|--|--|
| SECSET1 | SEID |  | "ALL" |  |  |  |  |  |  |
| SECSET1 | SEID |  | ALL   |  |  |  |  |  |  |

**Describer****Meaning**

|      |                                                                                                                                                                             |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEID | Superelement identification number. (Integer > 0)                                                                                                                           |
| C    | Component numbers of degree-of-freedom. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; Integer 0 or blank for scalar points.) |
| Gi   | Grid or scalar point identification number. (Integer > 0)                                                                                                                   |

**Remarks:**

1. Exterior grid and scalar points are, by default, fixed during component mode analysis and placed in the b-set unless listed on SECSETi or SESUP entries. Degrees-of-freedom listed on this entry are considered free (c-set) during component mode calculations. Exterior grid and scalar points are determined automatically and listed in the SEMAP table output.
2. If the alternate formats are used, the grid points Gi are not required to exist or to be exterior degrees-of-freedom and may be listed on SECSET1 entries. Points of this type will cause one warning message but will otherwise be ignored.
3. Degrees-of-freedom specified on this entry are assigned to the mutually exclusive c-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.

4. There must be a sufficient number of degrees-of-freedom specified on SESUP entries to discard any free body modes of the superelement.
5. If PARAM,AUTOSPC is YES, then singular b-set and c-set degrees-of-freedom will be reassigned as follows:
  - If there are no o-set (omitted) degrees-of-freedom, then singular b-set and c-set degrees-of-freedom are reassigned to the s-set.
  - If there are o-set (omitted) degrees-of-freedom, then singular c-set degrees-of-freedom are reassigned to the b-set. Singular b-set degrees-of-freedom are not reassigned.

## SECTAX Conical Shell Sector

Defines a sector of a conical shell.

### Format:

| 1      | 2  | 3   | 4 | 5    | 6    | 7 | 8 | 9 | 10 |
|--------|----|-----|---|------|------|---|---|---|----|
| SECTAX | ID | RID | R | PHI1 | PHI2 |   |   |   |    |

### Example:

|        |   |   |     |      |      |  |  |  |  |
|--------|---|---|-----|------|------|--|--|--|--|
| SECTAX | 1 | 2 | 3.0 | 30.0 | 40.0 |  |  |  |  |
|--------|---|---|-----|------|------|--|--|--|--|

| Describer  | Meaning                                                     |
|------------|-------------------------------------------------------------|
| ID         | Sector identification number. (Unique Integer > 0)          |
| RID        | Ring identification number. See RINGAX entry. (Integer > 0) |
| R          | Effective radius. (Real)                                    |
| PHI1, PHI2 | Azimuthal limits of sector in degrees. (Real)               |

### Remarks:

1. SECTAX is allowed only if an AXIC entry is also present.
2. SECTAX identification numbers must be unique with respect to all other POINTAX, RINGAX and SECTAX identification numbers.
3. For a discussion of the conical shell problem, see [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide*.

## SEDLINK

## Multiple Design Variable Linking Across PART SE Boundary

Relates one design variable of a PART SE to one or more other design variables from other PART SEs.

### Format:

| 1       | 2      | 3     | 4     | 5      | 6     | 7      | 8    | 9  | 10 |
|---------|--------|-------|-------|--------|-------|--------|------|----|----|
| SEDLINK | ID     | DSEID | DDVID | C0     | CMULT | ISEID1 | IDV1 | C1 |    |
|         | ISEID2 | IDV2  | C2    | ISEID3 | IDV3  | C3     |      |    |    |
|         | ISEID4 | IDV4  | C4    | -etc.- |       |        |      |    |    |

### Example:

|         |    |    |      |     |      |     |   |      |  |
|---------|----|----|------|-----|------|-----|---|------|--|
| SEDLINK | 10 | 10 | 2    | 0.1 | 0.33 | 8   | 8 | -1.0 |  |
|         | 11 | 6  | -1.0 | 20  | 8    | 7.0 |   |      |  |
|         | 11 | 2  | 2.0  |     |      |     |   |      |  |

| Descriptor         | Meaning                                                          |
|--------------------|------------------------------------------------------------------|
| ID                 | Unique identification number. (Integer > 0)                      |
| DSEID              | PART SE identification number for DDVID (Integer ≥ 0)            |
| DDVID              | Dependent design variable identification number. (Integer > 0)   |
| C0                 | Constant term. (Real; Default = 0.0)                             |
| CMULT              | Constant multiplier. (Real; Default = 1.0)                       |
| ISEID <sub>i</sub> | PART SE identification number for IDV <sub>i</sub> (Integer ≥ 0) |
| IDV <sub>i</sub>   | Independent design variable identification number. (Integer > 0) |
| C <sub>i</sub>     | Coefficient <i>i</i> corresponding to IDV <sub>i</sub> . (Real)  |

### Remarks:

1. SEDLINK is provided for inter-PART SE design variables linking and must be placed in main Bulk Data Section for consideration. SEDLINK will be ignored if it shows up under 'BEGIN SUPER=seid' where seid>0.
2. SEDLINK defines the relationship

$$DDVID = C0 + CMULT \sum_i C_{i_{ISEIDi}} \cdot IDV_{i_{ISEIDi}}$$

3. This capability provides a means of linking physical design variables such as element thicknesses to nonphysical design variables such as the coefficients of interpolating functions.

4. *CMULT* provides a simple means of scaling the  $C_i$ . For example if  $C_i = 1/7, 2/7, 4/7$ , etc. is desired, then  $CMULT = 1/7$  and  $C_i = 1, 2, 4$ , etc., may be input.
5. An independent  $IDV_i_{ISEID_i}$  must not occur on the same SEDLINK entry more than once.
6. ID is for user reference only.
7. If a design variable of a PART SE is specified as dependent on a SEDLINK entry, then it cannot be specified as independent on another SEDLINK or DLINK entry.

## SEDRSP2

## Design Sensitivity Equation Response Quantities for PART SE

Defines equation responses that are used in the design, either as constraints or as an objective with quantities from multiple PART SEs.

### Format:

| 1       | 2         | 3       | 4            | 5       | 6       | 7       | 8      | 9  | 10 |
|---------|-----------|---------|--------------|---------|---------|---------|--------|----|----|

|  | DVMREL2 | 0  | 601 | 1  | 602 | 10 | 603 |  |

| Descriptor | Meaning                                                                                                                                                                                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID         | Unique identification number. (Integer > 0)                                                                                                                                                                                                                                              |
| LABEL      | User-defined label. (Character)                                                                                                                                                                                                                                                          |
| EQID       | DEQATN entry identification number. (Integer > 0)                                                                                                                                                                                                                                        |
| FUNC       | Function to be applied to the arguments. See Remark 8. of the DRESP2 entry. (Character)                                                                                                                                                                                                  |
| REGION     | Region identifier for constraint screening. See Remark 5. of the DRESP2 entry. (Integer > 0)                                                                                                                                                                                             |
| METHOD     | When used with FUNC = BETA, METHOD = MIN indicates a minimization task while MAX indicates a maximization task. (Default = MIN) When used with FUNCT = MATCH, METHOD = LS indicated a least squares while METHOD = BETA indicated minimization of the maximum difference. (Default = LS) |
| Ci         | Constants used when FUNC = BETA or FUNC = MATCH in combination with METHOD = BETA. See Remark 8. of the DRESP2 entry. (Real; Defaults: C1 = 100., C2 = .005)                                                                                                                             |
| “DESVAR”   | Flag indicating DESVAR entry identification numbers. (Character)                                                                                                                                                                                                                         |
| DVSEIDi    | PART SE identification number for DVIDi (Integer ≥ 0)                                                                                                                                                                                                                                    |
| DVIDi      | DESVAR entry identification number. (Integer > 0)                                                                                                                                                                                                                                        |
| “DTABLE”   | DTABLE flag. Indicates that the LABLs for the constants in a DTABLE or DTABLE2 entry follow. This field may be omitted if there are no constants involved in this relation. (Character)                                                                                                  |
| LBSEIDj    | PART SE identification number for LABLj. (Integer ≥ 0)                                                                                                                                                                                                                                   |
| LABLi      | Label for a constant on the DTABLE or DTABLE2 entry. (Character)                                                                                                                                                                                                                         |
| “DRESP1”   | Flag indicating DRESP1 entry identification numbers. (Character)                                                                                                                                                                                                                         |
| R1SEIDk    | PART SE identification number for NRk. (Integer ≥ 0)                                                                                                                                                                                                                                     |
| NRk        | DRESP1 entry identification number. (Integer > 0)                                                                                                                                                                                                                                        |
| “DNODE”    | Flag indicating grid point and component identification numbers. (Character)                                                                                                                                                                                                             |
| NDSEIDm    | PART SE identification number for (Gm,Cm). (Integer ≥ 0)                                                                                                                                                                                                                                 |
| Gm         | Identification number for any grid point in the model. (Integer > 0)                                                                                                                                                                                                                     |
| Cm         | Component number of grid point Gm. (1 < Integer < 3)                                                                                                                                                                                                                                     |
| “DVPREL1”  | Flag indicating DVPREL1 entry identification number. (Character)                                                                                                                                                                                                                         |

| Describer | Meaning                                                          |
|-----------|------------------------------------------------------------------|
| P1SEIDi   | PART SE identification number for DPIPi. (Integer $\geq 0$ )     |
| DPIPi     | DVPREL1 entry identification number. (Integer $> 0$ )            |
| “DVCREL1” | Flag indicating DVCREL1 entry identification number. (Character) |
| C1SEIDi   | PART SE identification number for DCiCi. (Integer $\geq 0$ )     |
| DCiCi     | DVCREL1 entry identification number. (Integer $> 0$ )            |
| “DVMREL1” | Flag indicating DVPREL2 entry identification number. (Character) |
| M1SEIDi   | PART SE identification number for DMiMi. (Integer $\geq 0$ )     |
| DMiMi     | DVMREL1 entry identification number. (Integer $> 0$ )            |
| “DVPREL2” | Flag indicating DVPREL2 entry identification number. (Character) |
| P2SEIDi   | PART SE identification number for DPI2Pi. (Integer $\geq 0$ )    |
| DPI2Pi    | DVPREL2 entry identification number. (Integer $> 0$ )            |
| “DVCREL2” | Flag indicating DVCREL2 entry identification number. (Character) |
| C2SEIDi   | PART SE identification number for DCi2Ci. (Integer $\geq 0$ )    |
| DCi2Ci    | DVCREL2 entry identification number. (Integer $> 0$ )            |
| “DVMREL2” | Flag indicating DVMREL2 entry identification number. (Character) |
| M2SEIDi   | PART SE identification number for DMi2Mi. (Integer $\geq 0$ )    |
| DMi2Mi    | DVMREL2 entry identification number. (Integer $> 0$ )            |

**Remarks:**

1. SEDRSP2 is provided specifically for creating synthetic response with quantities from multiple PART SEs and must be placed in main bulk data section for consideration. SEDRSP2 will be ignored if it shows up under ‘BEGIN SUPER=seid’ where  $seid > 0$ .
2. Items under DTABLE and DNODE flag requires companion items in the same SEID under flags of DESVAR. DVxRELy or DRESP1.
3. Other than the leading PART SE ID for each quantity, SEDRSP2 follows rules and shares limitations of DRESP2. Rules and limitations of DRESP2 will not be repeated here.
4. SEDRSP2 does not support DRESP2 flag.

**SEDRSP3****Defines External Response with User-Supplied Routines**

Defines constituents from multiple PART SE for an external response using user-supplied routine(s).

**Format:**

| 1       | 2         | 3       | 4      | 5       | 6       | 7       | 8      | 9 | 10 |
|---------|-----------|---------|--------|---------|---------|---------|--------|---|----|
| SEDRSP3 | ID        | LABEL   | GROUP  | TYPE    | REGION  |         |        |   |    |
|         | “DESVAR”  | DVSEID1 | DVID1  | DVSEID2 | DVID2   | DVSEID3 | DVID3  |   |    |
|         |           | DVSEID4 | DVID4  | -etc.-  |         |         |        |   |    |

|  | USRDATA | Constants: 12345.6789.0 99. |     |    |     |    |     |  |  |

| Descriptor | Meaning                                                                                                                                                                                  |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID         | Unique identification number. (Integer > 0)                                                                                                                                              |
| LABEL      | User-defined label. (Character)                                                                                                                                                          |
| GROUP      | Group name the external response type belongs to (Character). See Remark 2. of DRESP3.                                                                                                   |
| TYPE       | External response type (Character). See Remark 3. of the DRESP3.                                                                                                                         |
| “DESVAR”   | Flag indicating DESVAR entry identification numbers. (Character)                                                                                                                         |
| DVSEIDi    | PART SE identification number for DVIDi. (Integer ≥ 0)                                                                                                                                   |
| DVIDi      | DESVAR entry identification number. (Integer > 0)                                                                                                                                        |
| “DTABLE”   | DTABLE flag. Indicates that the LABELs for the constants in a DTABLE or DTABLE2 entry follow. This field may be omitted if there are no constants involved in this relation. (Character) |
| LBSEIDj    | PART SE identification number for LABELj. (Integer ≥ 0)                                                                                                                                  |
| LABELi     | Label for a constant on the DTABLE or DTABLE2 entry. (Character)                                                                                                                         |
| “DRESP1”   | Flag indicating DRESP1 entry identification numbers. (Character)                                                                                                                         |
| R1SEIDk    | PART SE identification number for NRk. (Integer ≥ 0)                                                                                                                                     |
| NRk        | DRESP1 entry identification number. (Integer > 0)                                                                                                                                        |
| “DNODE”    | Flag indicating grid point and component identification numbers. (Character)                                                                                                             |
| NDSEIDm    | PART SE identification number for (Gm,Cm). (Integer ≥ 0)                                                                                                                                 |
| Gm         | Identification number for any grid point in the model. (Integer > 0)                                                                                                                     |
| Cm         | Component number of grid point Gm. (1 < Integer < 3)                                                                                                                                     |
| “DVPREL1”  | Flag indicating DVPREL1 entry identification number. (Character)                                                                                                                         |
| P1SEIDi    | PART SE identification number for DPIPi. (Integer ≥ 0)                                                                                                                                   |
| DPIPi      | DVPREL1 entry identification number. (Integer > 0)                                                                                                                                       |
| “DVCREL1”  | Flag indicating DVCREL1 entry identification number. (Character)                                                                                                                         |
| C1SEIDi    | PART SE identification number for DCiCi. (Integer ≥ 0)                                                                                                                                   |
| DCiCi      | DVCREL1 entry identification number. (Integer > 0)                                                                                                                                       |
| “DVMREL1”  | Flag indicating DVPREL2 entry identification number. (Character)                                                                                                                         |
| M1SEIDi    | PART SE identification number for DMiMi. (Integer ≥ 0)                                                                                                                                   |

| Describer | Meaning                                                          |
|-----------|------------------------------------------------------------------|
| DMIMi     | DVMREL1 entry identification number. (Integer > 0)               |
| “DVPREL2” | Flag indicating DVPREL2 entry identification number. (Character) |
| P2SEIDi   | PART SE identification number for DPI2Pi. (Integer $\geq$ 0)     |
| DPI2Pi    | DVPREL2 entry identification number. (Integer > 0)               |
| “DVCREL2” | Flag indicating DVCREL2 entry identification number. (Character) |
| C2SEIDi   | PART SE identification number for DCI2Ci. (Integer $\geq$ 0)     |
| DCI2Ci    | DVCREL2 entry identification number. (Integer > 0)               |
| “DVMREL2” | Flag indicating DVMREL2 entry identification number. (Character) |
| M2SEIDi   | PART SE identification number for DMI2Mi. (Integer $\geq$ 0)     |
| DMI2Mi    | DVMREL2 entry identification number. (Integer > 0)               |
| “USRDATA” | Flag indicating user input data. (Character).                    |

#### Remarks:

1. SEDRSP3 is provided specifically for creating external response with quantities from multiple PART SEs and must be placed in main Bulk Data Section for consideration. SEDRSP3 will be ignored if it shows up under ‘BEGIN SUPER=seid’ where seid>0.
2. Items under DTABLE and DNODE flag requires companion items in the same SEID under flags of DESVAR. DVxRELy or DRESP1.
3. Other than the leading PART SE ID for each quantity, SEDRSP3 follows rules and shares limitations of DRESP3. Rules and limitations of DRESP3 will not be repeated here.
4. SEDRSP3 does not support DRESP2 flag.

## SEELT Superelement Boundary Element Reassignment

Reassigns superelement boundary elements to an upstream superelement.

### Format:

|       |      |      |        |      |      |      |      |      |    |
|-------|------|------|--------|------|------|------|------|------|----|
| 1     | 2    | 3    | 4      | 5    | 6    | 7    | 8    | 9    | 10 |
| SEELT | SEID | EID1 | EID2   | EID3 | EID4 | EID5 | EID6 | EID7 |    |
|       | EID8 | EID9 | -etc.- |      |      |      |      |      |    |

### Example:

|       |   |     |     |     |  |  |  |  |  |
|-------|---|-----|-----|-----|--|--|--|--|--|
| SEELT | 2 | 147 | 562 | 937 |  |  |  |  |  |
|-------|---|-----|-----|-----|--|--|--|--|--|

### Alternate Format and Example:

|       |      |       |        |       |  |  |  |  |  |
|-------|------|-------|--------|-------|--|--|--|--|--|
| SEELT | SEID | EID1  | “THRU” | EID2  |  |  |  |  |  |
| SEELT | 5    | 12006 | THRU   | 12050 |  |  |  |  |  |

| Describer | Meaning                                                                                 |
|-----------|-----------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. See Remark 7. (Integer > 0)                         |
| EIDi      | Element identification numbers. (Integer > 0 or “THRU”; for “THRU” option EID1 < EID2.) |

### Remarks:

1. Elements connected entirely to the exterior points of an upstream superelement are called boundary elements and are assigned to the downstream superelement. The SEELT entry provides the means of reassigning the element to the upstream superelement. This entry may be applied to boundary elements only.
2. Open sets are allowed with the “THRU” option.
3. Elements processed with primary superelements will also be contained in any referencing secondary superelement.
4. EIDi may refer to plot elements, general elements, and structural elements.
5. This entry does not change the exterior grid point set of the superelement.
6. SEELT can only be specified in the main Bulk Data Section and is ignored after the BEGIN SUPER=n command.
7. If the model contains a BEGIN SUPER, the SEELT entry will assign the specified elements to the SEID (not just the boundary elements). This is an alternative to using SESET. In this case, SEID = 0 is a valid entry. For further information, refer to the [MSC Nastran Reference Guide](#).

**SEEXCLD**

## Partitioned Superelement Exclusion

Defines grids that will be excluded during the attachment of a partitioned superelement.

**Format:**

| 1       | 2     | 3     | 4      | 5     | 6     | 7     | 8     | 9     | 10 |
|---------|-------|-------|--------|-------|-------|-------|-------|-------|----|
| SEEXCLD | SEIDA | SEIDB | GIDA1  | GIDA2 | GIDA3 | GIDA4 | GIDA5 | GIDA6 |    |
|         | GIDA7 | GIDA8 | -etc.- |       |       |       |       |       |    |

**Example1:**

|         |     |    |    |     |     |  |  |  |  |
|---------|-----|----|----|-----|-----|--|--|--|--|
| SEEXCLD | 110 | 10 | 45 | 678 | 396 |  |  |  |  |
|---------|-----|----|----|-----|-----|--|--|--|--|

**Example 2:**

|         |     |     |    |    |    |      |    |  |  |
|---------|-----|-----|----|----|----|------|----|--|--|
| SEEXCLD | 400 | ALL | 10 | 20 | 30 | THRU | 40 |  |  |
|---------|-----|-----|----|----|----|------|----|--|--|

| Describer | Meaning                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEIDA     | Partitioned superelement identification number. (Integer $\geq 0$ )                                                                                                       |
| SEIDB     | Superelement identification. (Integer $\geq 0$ or Character = "ALL"; Default = "ALL")                                                                                     |
| GIDAi     | Identification number of a grid in superelement SEIDA to be excluded from connection to superelement SEIDB. (Integer $> 0$ or "THRU"; for "THRU" option GIDA1 $<$ GIDA2.) |

**Remarks:**

1. SEEXCLD can only be specified in the main Bulk Data Section and will cause a fatal error message if it appears after the BEGIN SUPER=n command.
2. SEIDA and SEIDB may reference only substructures or the residual structure, that is, parts defined after a BEGIN SUPER = entry.
3. This entry will only work if PART superelements (BEGIN SUPER) exist.

## SELABEL Superelement Output Label

Defines a label or name to be printed in the superelement output headings.

### Format:

|         |      |       |   |   |   |   |   |   |    |  |
|---------|------|-------|---|---|---|---|---|---|----|--|
| 1       | 2    | 3     | 4 | 5 | 6 | 7 | 8 | 9 | 10 |  |
| SELABEL | SEID | LABEL |   |   |   |   |   |   |    |  |

### Example:

|         |    |                                 |  |  |  |  |  |  |  |  |
|---------|----|---------------------------------|--|--|--|--|--|--|--|--|
| SELABEL | 10 | LEFT REAR FENDER, MODEL XYZ2000 |  |  |  |  |  |  |  |  |
|---------|----|---------------------------------|--|--|--|--|--|--|--|--|

| Describer | Meaning                                                                  |
|-----------|--------------------------------------------------------------------------|
| SEID      | Partitioned superelement identification number. (Integer > 0)            |
| LABEL     | Label associated with superelement SEID for output headings. (Character) |

### Remarks:

1. SELABEL can only be specified in the main Bulk Data Section and is ignored after the BEGIN SUPER=n command.
2. Only one SELABEL per superelement may be specified.
3. The label will appear in all superelement output headings. However, in some headings the label may be truncated.
4. This entry will only work if PART superelements (BEGIN SUPER) exist.

**SELOAD****Selects and/or Scales External Superelement Loads**

Selects and/or scales external superelement loads identified by a label, subcase identification number, load case identification number or column number.

**Format:**

| 1      | 2                                            | 3              | 4                   | 5 | 6 | 7 | 8 | 9 | 10 |
|--------|----------------------------------------------|----------------|---------------------|---|---|---|---|---|----|
| SELOAD | SID                                          | S              |                     |   |   |   |   |   |    |
|        | SEID <sub>i</sub>                            | S <sub>i</sub> | LBLTYP <sub>i</sub> |   |   |   |   |   |    |
|        | Label, Subcase ID, Load ID, or Column Number |                |                     |   |   |   |   |   |    |
|        | -etc.-                                       |                |                     |   |   |   |   |   |    |
|        | -etc.-                                       |                |                     |   |   |   |   |   |    |

**Example:**

|        |           |     |       |  |  |  |  |  |  |
|--------|-----------|-----|-------|--|--|--|--|--|--|
| SELOAD | 11        | 1.0 |       |  |  |  |  |  |  |
|        | 100       | 0.5 |       |  |  |  |  |  |  |
|        | edge load |     |       |  |  |  |  |  |  |
|        | 200       | 1.2 | SUBID |  |  |  |  |  |  |
|        | 10        |     |       |  |  |  |  |  |  |

| Describer           | Meaning                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID                 | LOAD Case Control command identification number if static analysis or EXCITEID on TLOAD <sub>i</sub> and RLOAD <sub>i</sub> entries if dynamic analysis.                                                                              |
| S                   | Overall scale factor.                                                                                                                                                                                                                 |
| S <sub>i</sub>      | Scale factor for this superelement's load vector                                                                                                                                                                                      |
| LBLTYP <sub>i</sub> | Label type in the in the next entry: "LABEL" (default), "SUBID", "LOADID", or "COLNUM".                                                                                                                                               |
| Label               | If LBLTYP <sub>i</sub> ="LABEL" or "SUBCASE": String assigned to a column in the external superelement load matrix in the creation run by the LDLABEL Case Control command.                                                           |
| Subcase ID          | If LBLTYP <sub>i</sub> ="SUBID": Subcase identification number associated with a column in the external superelement load matrix.                                                                                                     |
| Load ID             | If LBLTYP <sub>i</sub> ="LOADID": Load identification number associated with a column in the external superelement load matrix.                                                                                                       |
| Column number       | If LBLTYP <sub>i</sub> ="COLNUM" or "COLUMN": Column number in the external superelement load matrix. Column number allows for load selection in pre-V2021.4 external superelement export files (.op2, .op4, .MASTER/.DBALL, or pch). |

**Remarks:**

1. In the static solution sequences, SID is selected by the LOAD Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an ACSRCE, RLOADi or TLOADi entry.
2. Multiple SELOAD entries may be specified but SID must be unique.
3. SEIDi may be duplicated on an SELOAD entry but may not select the same external superelement load case.
4. If SEIDi refers to a primary (internal) superelement or an undefined superelement then a User Fatal Message is issued.
5. If the LDLABEL Case Control command was not specified in the external superelement's creation run and SELOAD references this superelement in the assembly run then LBLTYPi must be "COLNUM" and the next continuation entry must contain a column number.
6. If in the assembly run there is no SELOAD specified for a given load case then a User Warning Message will be issued.
7. The LOAD Bulk Data entry will not combine SELOAD entries.

## SELOC Partitioned Superelement Location

Defines a partitioned superelement relocation by listing three noncolinear points in the superelement and three corresponding points not belonging to the superelement.

### Format:

| 1     | 2    | 3   | 4   | 5   | 6   | 7   | 8   | 9 | 10 |
|-------|------|-----|-----|-----|-----|-----|-----|---|----|
| SELOC | SEID | PA1 | PA2 | PA3 | PB1 | PB2 | PB3 |   |    |

### Example:

|       |     |    |     |     |      |     |    |  |  |
|-------|-----|----|-----|-----|------|-----|----|--|--|
| SELOC | 110 | 10 | 100 | 111 | 1010 | 112 | 30 |  |  |
|-------|-----|----|-----|-----|------|-----|----|--|--|

| Describer | Meaning                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Partitioned identification number of the partitioned superelement. (Integer > 0)                                                                             |
| PAi       | Identification numbers of three noncolinear grids (GRID entry) or points (POINT entry) which are in the partitioned superelement. (Integer > 0)              |
| PBi       | Identification numbers of three grids (GRID entry) or points (POINT entry) defined in the main Bulk Data Section to which PAi will be aligned. (Integer > 0) |

### Remarks:

- SELOC can only be specified in the main Bulk Data Section and will cause a fatal error message if it appears after the BEGIN SUPER=n command.
- The superelement will be rotated and translated for alignment of the G<sub>Ai</sub> and G<sub>Bi</sub> locations.
- The PA<sub>i</sub> and PB<sub>i</sub> can be either GRIDs or POINTs.
- PA<sub>1</sub>, PA<sub>2</sub>, and PA<sub>3</sub> must be contained in superelement SEID.
- PB<sub>1</sub>, PB<sub>2</sub>, and PB<sub>3</sub> must be specified in the main Bulk Data Section. If they belong to a superelement that is also relocated, then the original (unmoved) positions of PB<sub>1</sub>, PB<sub>2</sub>, and PB<sub>3</sub> are used.
- PB<sub>1</sub>, PB<sub>2</sub>, and PB<sub>3</sub> must have the same relative locations as PA<sub>1</sub>, PA<sub>2</sub>, and PA<sub>3</sub>.
- Three grids or points are required even if the superelement connects to only one or two exterior grids.
- Coordinate systems, global displacement directions, and element coordinate systems for the superelement will rotated and translated.
- The global coordinate directions of the boundary grid points of the upstream superelement will be transformed internally to the global coordinate directions of the attachment grid points in the downstream superelement. For displacement data recovery, the output will be in the original global coordinate system.
- The translation and rotation of the superelement to the new position is accomplished by defining local rectangular coordinate systems based on the specified grid locations:

- The local systems have their origin at PX1 and the x-axis points from PX1 to PX2.
  - The y-axis lies in the plane containing PX1, PX2, and PX3, is perpendicular to the x-axis, and points toward PX3.
  - The z-axis is defined by the cross product of the x-axis into the y-axis.
  - The rotation and translation transformation aligns the local system defined by the superelement grids with the local system defined by the main Bulk Data Section grids.
11. This entry will only work if PART superelements (BEGIN SUPER) exist.

## SEMPLN Superelement Mirror Plane

Defines a mirror plane for mirroring a partitioned superelement.

### Format:

| 1      | 2    | 3       | 4  | 5  | 6  | 7 | 8 | 9 | 10 |
|--------|------|---------|----|----|----|---|---|---|----|
| SEMPLN | SEID | "PLANE" | P1 | P2 | P3 |   |   |   |    |

### Example:

|        |     |       |    |    |      |  |  |  |  |
|--------|-----|-------|----|----|------|--|--|--|--|
| SEMPLN | 110 | PLANE | 12 | 45 | 1125 |  |  |  |  |
|--------|-----|-------|----|----|------|--|--|--|--|

| Describer | Meaning                                                                                |
|-----------|----------------------------------------------------------------------------------------|
| SEID      | Partitioned superelement identification number. (Integer > 0).                         |
| "PLANE"   | Flag indicating that the plane is defined by three noncolinear points.                 |
| Pi        | GRID or POINT entry identification numbers of three noncolinear points. (Integer > 0). |

### Remarks:

1. SEMPLN can only be specified in the main Bulk Data Section and will cause a fatal error message if it appears after the BEGIN SUPER=n command.
2. Grids or points referenced on this entry must be defined in the main Bulk Data Section.

**SENQSET** Superelement Internal Generalized Degree-of-Freedom

Defines number of internally generated scalar points for superelement dynamic reduction.

**Format:**

|         |      |   |   |   |   |   |   |   |    |
|---------|------|---|---|---|---|---|---|---|----|
| 1       | 2    | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
| SENQSET | SEID | N |   |   |   |   |   |   |    |

**Example:**

|         |     |    |  |  |  |  |  |  |  |
|---------|-----|----|--|--|--|--|--|--|--|
| SENQSET | 110 | 45 |  |  |  |  |  |  |  |
|---------|-----|----|--|--|--|--|--|--|--|

| Descriptor | Meaning                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------|
| SEID       | Partitioned superelement identification number. See Remark 3. (Integer > 0 or Character = "ALL")                       |
| N          | Number of internally generated scalar points for dynamic reduction generalized coordinates. (Integer > 0; Default = 0) |

**Remarks:**

1. SENQSET can only be specified in the main Bulk Data Section and is ignored after the BEGIN SUPER = n command.
2. SENQSET is only required if the user wants to internally generated scalar points used for dynamic reduction.
3. SEID = "ALL" will automatically generate N q-set degrees-of-freedom for all superelements, except the residual structure (SEID = 0). Specifying additional SENQSET entries for specific superelements will override the value of N specified on this entry.
4. If the user manually specifies q-set degrees-of-freedom using a SEQSETi or QSETi entries, then the internally generated scalar points will not be generated.
5. See PARAM,NQSET for an alternate method of specifying QSET degree-of-freedoms.
6. This entry will only work if PART superelements (BEGIN SUPER) exist.

**SEQGP****Grid and Scalar Point Resequencing**

Used to manually order the grid points and scalar points of the problem. This entry is used to redefine the sequence of grid and scalar points to optimize bandwidth.

**Format:**

| 1     | 2   | 3      | 4   | 5      | 6   | 7      | 8   | 9      | 10 |
|-------|-----|--------|-----|--------|-----|--------|-----|--------|----|
| SEQGP | ID1 | SEQID1 | ID2 | SEQID2 | ID3 | SEQID3 | ID4 | SEQID4 |    |

**Example:**

|       |      |      |     |     |   |     |   |   |  |
|-------|------|------|-----|-----|---|-----|---|---|--|
| SEQGP | 5392 | 15.6 | 596 | 0.2 | 2 | 1.9 | 3 | 2 |  |
|-------|------|------|-----|-----|---|-----|---|---|--|

| Describer | Meaning                                                      |
|-----------|--------------------------------------------------------------|
| IDI       | Grid or scalar point identification number. (Integer > 0)    |
| SEQIDI    | Sequenced identification number. (Real > 0.0 or Integer > 0) |

**Remarks:**

1. The real format is used to insert a point ID between two consecutively numbered and existing point IDs. In the example above, point ID 5392 is inserted between IDs 15 and 16 by specifying 15.6 for SEQID. If the SEQID is real and < 1.0 the value must be entered as 0.2 not .2 (see field 5 of example).
2. The SEQIDI numbers must be unique and may not be the same as a point IDi which is not being changed. No grid point IDi may be referenced more than once.
3. From one to four grid or scalar points may be resequenced on a single entry.
4. If a point IDi is referenced more than once, the last reference will determine its sequence.
5. Automatic resequencing is also available. See [OLDSEQ](#).

## SEQSEP Superelement Sequences

Used with the CSUPER entry to define the correspondence of the exterior grid points between an identical or mirror-image superelement and its primary superelement.

**Format:**

|        |      |      |        |     |     |     |     |     |    |
|--------|------|------|--------|-----|-----|-----|-----|-----|----|
| 1      | 2    | 3    | 4      | 5   | 6   | 7   | 8   | 9   | 10 |
| SEQSEP | SSID | PSID | GP1    | GP2 | GP3 | GP4 | GP5 | GP6 |    |
|        | GP7  | GP8  | -etc.- |     |     |     |     |     |    |

**Example:**

|        |     |    |     |     |     |     |  |  |  |
|--------|-----|----|-----|-----|-----|-----|--|--|--|
| SEQSEP | 121 | 21 | 109 | 114 | 124 | 131 |  |  |  |
|--------|-----|----|-----|-----|-----|-----|--|--|--|

| Describer | Meaning |
|-----------|---------|
|-----------|---------|

- SSID Identification number for secondary superelement. (Integer > 0).
- PSID Identification number for the primary superelement. (Integer ≥ 0).
- GPI Exterior grid point identification numbers for the primary superelement. (Integer > 0).

**Remarks:**

- This entry is not needed if the grid points listed on the CSUPER entry with the same SSID are in the order of the corresponding exterior grid points of the primary superelement.
- In [Figure 9-142](#), the exterior grid points of 10, 20, and 30 of SEID = 1 correspond to the points 13, 12, and 11, respectively, of image SEID = 2. The CSUPER entry may be defined alone or with a SEQSEP entry as shown in [Figure 9-142](#).

Figure 9-142 Grid Point Correspondence Between Primary and Secondary Superelements

**CSUPER Entry Only:**

|        |   |   |    |    |    |   |   |   |    |
|--------|---|---|----|----|----|---|---|---|----|
| 1      | 2 | 3 | 4  | 5  | 6  | 7 | 8 | 9 | 10 |
| CSUPER | 2 | 1 | 13 | 12 | 11 |   |   |   |    |

**CSUPER and SEQSEP Entries:**

|        |   |   |    |    |    |  |  |  |  |
|--------|---|---|----|----|----|--|--|--|--|
| CSUPER | 2 | 1 | 11 | 12 | 13 |  |  |  |  |
| SEQSEP | 2 | 1 | 30 | 20 | 10 |  |  |  |  |

## SEQSET

## Superelement Generalized Degree-of-Freedom

Defines the generalized degrees-of-freedom of the superelement to be used in generalized dynamic reduction or component mode synthesis.

### Format:

| 1      | 2    | 3   | 4  | 5   | 6  | 7   | 8  | 9 | 10 |
|--------|------|-----|----|-----|----|-----|----|---|----|
| SEQSET | SEID | ID1 | C1 | ID2 | C2 | ID3 | C3 |   |    |

### Example:

|        |    |   |        |   |   |    |   |  |  |
|--------|----|---|--------|---|---|----|---|--|--|
| SEQSET | 15 | 1 | 123456 | 7 | 5 | 22 | 3 |  |  |
|--------|----|---|--------|---|---|----|---|--|--|

| Describer | Meaning                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. Must be a primary superelement. (Integer > 0)                                                                        |
| Ci        | Component number. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; Integer zero or blank for scalar points.) |
| Idi       | Grid or scalar point identification numbers. Must be an exterior point. (Integer > 0)                                                                    |

### Remarks:

- Degrees-of-freedom specified on this entry may not be specified for another superelement.
- Generalized degrees-of-freedom are interior to the residual structure.
- Connectivity to the superelement is provided by this entry. There is no need to use a CSUPEXT entry for this purpose.
- Degrees-of-freedom specified on this entry form members of the mutually exclusive q-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
- This entry describes the set used for generalized degrees-of-freedom only for the SEID listed. Degrees-of-freedom listed on this entry must also be members of a downstream superelement. The set used for these variables in downstream superelements must be prescribed by user action using other entries. If they are scalar points, they are automatically in the residual structure, which is the recommended procedure. If they are grid points, it is the user's responsibility to place them in a downstream superelement.

Generalized degrees-of-freedom of superelements that are also members of the residual structure are included as dynamic variables by placing them in the a-set. It is also necessary to place some or all residual structure physical degrees-of-freedom in the a-set to allow the boundary points to participate in the system mode shapes.

Grid points of downstream superelements used as generalized degrees-of-freedom may be used for advanced applications, such as omitting upstream generalized degrees-of-freedom from assembly into downstream superelements. Again, it is the user's responsibility to place these variables in the proper set in all downstream superelements of which they are members.

6. This entry may be applied only to primary superelements. The CSUPER entry automatically defines these degrees-of-freedom for secondary superelements.

## SEQSET1

## Superelement Generalized Degree-of-Freedom, Alternate Form

Defines the generalized degrees-of-freedom of the superelement to be used in generalized dynamic reduction or component mode synthesis.

### Format:

|         |      |    |        |    |    |    |    |    |    |
|---------|------|----|--------|----|----|----|----|----|----|
| 1       | 2    | 3  | 4      | 5  | 6  | 7  | 8  | 9  | 10 |
| SEQSET1 | SEID | C  | G1     | G2 | G3 | G4 | GS | G6 |    |
|         | G7   | G8 | -etc.- |    |    |    |    |    |    |

### Example:

|         |    |        |   |   |   |    |     |   |  |
|---------|----|--------|---|---|---|----|-----|---|--|
| SEQSET1 | 15 | 123456 | 1 | 7 | 9 | 22 | 105 | 6 |  |
|         | 52 | 53     |   |   |   |    |     |   |  |

### Alternate Format and Example:

|         |      |   |     |        |     |  |  |  |  |
|---------|------|---|-----|--------|-----|--|--|--|--|
| SEQSET1 | SEID | C | G1  | “THRU” | G2  |  |  |  |  |
| SEQSET1 | 16   | 0 | 101 | THRU   | 110 |  |  |  |  |

| Describer | Meaning                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. Must be a primary superelement. (Integer > 0)                                                                      |
| C         | Component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; Integer 0 or blank for scalar points.) |
| Gi        | Grid or scalar point identification numbers. Must be exterior points. (Integer > 0 or “THRU”; for THRU option G1 < G2.)                                |

### Remarks:

- Degrees-of-freedom specified on this entry may not be specified for another superelement.
- Generalized degrees-of-freedom are interior to the residual structure.
- Connectivity to the superelement is provided by this entry. There is no need to use a CSUPEXT entry for this purpose.
- Degrees-of-freedom specified on this entry form members of a mutually exclusive set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
- This entry describes the set used for generalized degrees-of-freedom only for the SEID listed. Degrees-of-freedom listed on this entry must also be members of a downstream superelement. The set used for these variables in downstream superelements must be prescribed by user action using other entries. If they are scalar points, they are automatically in the residual structure, which is the recommended procedure. If they are grid points, it is the user’s responsibility to place them in a downstream superelement.

Generalized degrees-of-freedom of superelements that are also members of the residual structure are included as dynamic variables by placing them in the a-set. It is also necessary to place some or all residual structure physical degrees-of-freedom in the a-set, to allow the boundary points to participate in the system mode shapes.

Grid points of downstream superelements used as generalized degrees-of-freedom may be used for advanced applications, such as omitting upstream generalized degrees-of-freedom from assembly into downstream superelements. Again, it is the user's responsibility to place these variables in the proper set in all downstream superelements of which they are members.

6. This entry may be applied only to primary superelements. The CSUPER entry automatically defines these entries for secondary superelements.

## SESET Superlement Interior Point Definition

Defines interior grid points for a superlement.

### Format:

| 1     | 2    | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 |
|-------|------|----|----|----|----|----|----|----|----|
| SESET | SEID | G1 | G2 | G3 | G4 | G5 | G6 | G7 |    |

### Example:

|       |   |   |    |    |    |     |  |  |  |
|-------|---|---|----|----|----|-----|--|--|--|
| SESET | 5 | 2 | 17 | 24 | 25 | 165 |  |  |  |
|-------|---|---|----|----|----|-----|--|--|--|

### Alternate Format and Example:

|       |      |    |        |     |  |  |  |  |  |
|-------|------|----|--------|-----|--|--|--|--|--|
| SESET | SEID | G1 | “THRU” | G2  |  |  |  |  |  |
| SESET | 2    | 17 | THRU   | 165 |  |  |  |  |  |

| Describer | Meaning                                                                                      |
|-----------|----------------------------------------------------------------------------------------------|
| SEID      | Superlement identification number. Must be a primary superlement. (Integer $\geq 0$ )        |
| Gi        | Grid or scalar point identification number. ( $0 < \text{Integer} < 100000000$ ; $G1 < G2$ ) |

### Remarks:

1. Interior grid points may also be defined via field 9 of the GRID and GRIDG Bulk Data entries. The SESET entry takes precedence over the SEID field on the GRID on GRIDG entries. SESET defines grid and scalar points to be included as interior to a superlement. SESET may be used as the primary means of defining superlements or it may be used in combination with SEELT entries which define elements interior to a superlement.
2. Gi may appear on an SESET entry only once.
3. Scalar points are ignored unless a BEGIN SUPER is in the file.
4. Open sets are allowed with the “THRU” option. Missing grid points (whether in “THRU” range or mentioned explicitly) are not identified.
5. All degrees-of-freedom for Gi are placed in the o-set of the superlement. See [Degree-of-Freedom Sets](#).
6. SESET can only be specified in the main Bulk Data Section and is ignored after the BEGIN SUPER = n command.

## SESUP Fictitious Support

Defines determinate reaction superelement degrees-of-freedom in a free-body analysis.

### Format:

| 1     | 2    | 3   | 4  | 5   | 6  | 7   | 8  | 9 | 10 |
|-------|------|-----|----|-----|----|-----|----|---|----|
| SESUP | SEID | ID1 | C1 | ID2 | C2 | ID3 | C3 |   |    |

### Example:

|       |   |    |     |  |  |  |  |  |  |
|-------|---|----|-----|--|--|--|--|--|--|
| SESUP | 5 | 16 | 215 |  |  |  |  |  |  |
|-------|---|----|-----|--|--|--|--|--|--|

| Describer | Meaning                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. Must a primary superelement. (Integer > 0)                                                    |
| IDI       | Grid or scalar point identification number. Must be exterior points. (Integer > 0)                                                |
| Ci        | Component numbers. (Integer zero or blank for scalar points; Any unique combination of the Integers 1 through 6 for grid points.) |

### Remarks:

1. The degrees-of-freedom specified on this entry form members of the mutually exclusive r-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
2. The Ci degrees-of-freedom must be exterior degrees-of-freedom of the SEID superelement.
3. See [Rigid Body Supports](#) in the *MSC Nastran Reference Guide* for a discussion of supported degrees-of-freedom (members of the r-set).
4. There must be a sufficient number of degrees-of-freedom on SESUP entries to discard any free body modes of the superelement.
5. SESUP Bulk Data entries are not allowed for part (partitioned bulk data) superelements. Use the SUPPORT Bulk Data records to identify component rigid body modes.

**SET1****Set Definition**

Defines a list of structural grid points or element identification numbers.

**Format:**

| 1    | 2   | 3      | 4   | 5   | 6   | 7   | 8   | 9   | 10 |
|------|-----|--------|-----|-----|-----|-----|-----|-----|----|
| SET1 | SID | ID1    | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 |    |
|      | ID8 | -etc.- |     |     |     |     |     |     |    |

**Example 1:**

|      |    |    |    |    |     |    |    |    |  |
|------|----|----|----|----|-----|----|----|----|--|
| SET1 | 3  | 31 | 62 | 93 | 124 | 16 | 17 | 18 |  |
|      | 19 |    |    |    |     |    |    |    |  |

**Example 2:**

|      |    |    |    |      |    |    |      |    |  |
|------|----|----|----|------|----|----|------|----|--|
| SET1 | 6  | 29 | 32 | THRU | 50 | 61 | THRU | 70 |  |
|      | 17 | 57 |    |      |    |    |      |    |  |

**Example 3:**

|      |   |      |  |  |  |  |  |  |  |
|------|---|------|--|--|--|--|--|--|--|
| SET1 | 7 | SKIN |  |  |  |  |  |  |  |
|------|---|------|--|--|--|--|--|--|--|

| Describer | Meaning                                                                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Unique identification number. (Integer > 0)                                                                                                      |
| IDI       | List of structural grid point or element identification numbers. (Integer > 0 or "THRU"; for the "THRU" option, ID1 < ID2 or "SKIN"; in field 3) |

**Remarks:**

1. When using the "THRU" option for SPLINEi or PANEL data entries, all intermediate grid points must exist.
2. When using the "THRU" option for XYOUTPUT or AECOMP requests, missing grid points are ignored. The first and last points must exist.
3. When using the "SKIN" option, a panel will be generated consisting of the structural portion of the fluid-structural boundary. This option works ONLY with all fields of ACMODL having default value.
4. THRU may not appear in field 3 or 9 (2 or 9 for continuations).
5. RC network solver does not support SET1 for thermal analysis.

## SET2 Grid Point List

Defines a list of structural grid points in terms of aerodynamic macro elements.

### Format:

| 1    | 2   | 3     | 4   | 5   | 6   | 7   | 8    | 9    | 10 |
|------|-----|-------|-----|-----|-----|-----|------|------|----|
| SET2 | SID | MACRO | SP1 | SP2 | CH1 | CH2 | ZMAX | ZMIN |    |

### Example:

|      |   |     |     |      |     |       |      |  |  |
|------|---|-----|-----|------|-----|-------|------|--|--|
| SET2 | 3 | 111 | 0.0 | 0.75 | 0.0 | 0.667 | 3.51 |  |  |
|------|---|-----|-----|------|-----|-------|------|--|--|

| Describer     | Meaning                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID           | Unique identification number. (Integer > 0)                                                                                                           |
| MACRO         | Element identification number of an aerodynamic macro element. (Integer > 0)                                                                          |
| SP1, SP2      | Lower and higher span division points defining the prism containing the set. (Real)                                                                   |
| CH1, CH2      | Lower and higher chord division points defining the prism containing the set. (Real)                                                                  |
| ZMAX,<br>ZMIN | Z-coordinates of top and bottom (using right-hand rule with the order of the corners as listed on a CAEROi entry) of the prism containing set. (Real) |

### Remarks:

1. The SET2 entry is referenced by the SPLINEi entry.
2. Every grid point within the defined prism and within the height range will be in the list. For example:

Figure 9-143 SET2 Entry Example.

The shaded area in [Figure 9-143](#) defines the cross section of the prism for the sample data given above. Points exactly on the boundary may be missed; therefore, to get all the grid points within the area of the macro element, SP1=-.01, SP2=1.01, etc. should be used.

3. A zero value for ZMAX or ZMIN implies a value of infinity. Usually,  $ZMAX \geq 0.0$  and  $ZMIN \leq 0.0$ .
4. To print the (internal) grid IDs found, use DIAG 18.

**SET3** Defines a List of Grids, Elements, Points or Modules

Defines a list of grids, elements, points or modules.

**Format:**

|      |     |     |     |     |     |     |   |   |    |
|------|-----|-----|-----|-----|-----|-----|---|---|----|
| 1    | 2   | 3   | 4   | 5   | 6   | 7   | 8 | 9 | 10 |
| SET3 | SID | DES | ID1 | ID2 | ... | Idi |   |   |    |

**Example:**

|      |   |       |    |    |    |    |    |    |  |
|------|---|-------|----|----|----|----|----|----|--|
| SET3 | 1 | POINT | 11 | 12 | 13 | 15 | 18 | 21 |  |
|------|---|-------|----|----|----|----|----|----|--|

**Alternate Format and Example:**

|      |     |       |     |        |     |  |  |  |  |
|------|-----|-------|-----|--------|-----|--|--|--|--|
| SET3 | SID | DES   | ID1 | "THRU" | ID2 |  |  |  |  |
| SET3 | 33  | POINT | 20  | THRU   | 60  |  |  |  |  |

| Describer | Meaning                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------|
| SID       | Unique identification number. (Integer > 0)                                                                        |
| DES       | Set description (Character). Valid options are "GRID", "ELEM", "POINT", "PROP", "RBEin", and "RBEex" and "MODULE". |
| Idi       | Identifiers of grids points, elements, points or properties. (Integer ≥ 0)                                         |

**Remarks:**

1. If a SET3 entry is referenced on a PBMSECT or PBRSECT entry, the POINTs must lie in the (xy) plane of the basic coordinate system, and be in the order when traversing the boundary or the profile.
2. When the SET3 entry is referenced by a panel, describers can be "GRID", "ELEM" or "PROP".
3. THRU may not appear in field 4 or 9 (2 or 9 for continuations).
4. When SET3 is referenced by SOLs 400 entry only GRID or ELEM may be used.
5. When SET3 is referenced by RFORCE (IDRF field) for SOL 600, only ELEM may be used.
6. When SET3 is referenced by SOL 400 DEACTEL entries, only ELEM may be used.
7. When a SET3 is referenced by a ELSIDi or XELSIDi field on an FTGDEF entry, only ELEM may be used. When SET3 is referenced by a NDSIDi field on a FTGDEF entry, only GRID may be used.
8. When DES="RBEin", the SET selects rigid elements to be included for MPC=sid and is applicable to Rigid Element types of RBAR, RBAR1, RBE1, RBE2, RBE2GS, RBE3, RROD, RSPLINE, RSSCON, RTRPLT and RTRPLT1. Note that Rigid Elements with duplicate ID across Rigid Element types will all be utilized.
9. For DES="RBEex", the SET selects rigid elements to be excluded for MPC=sid and is applicable to Rigid Elements types of RBAR, RBAR1, RBE1, RBE2, RBE2GS, RBE3, RROD, RSPLINE, RSSCON, RTRPLT and RTRPLT1.

10. Note that "RBEin" and "RBEex" are mutually exclusive and should not appear together for a single SET.
11. By default, without SET3,SID,RBExx, all Rigid Elements in the input deck will be used.
12. SET selection for rigid elements does not cover additional IDs on MPCADD bulk data entry. This kind of selection is not supported in SOL 106 either.
13. Rigid element set selection is supported in SOL 400 if 'RIGID=LINEAR' is present in case control deck.
14. IDi can be 0 when DES is "MODULE", otherwise it must be greater than 0.

## SET4

### Property Set Definition

Defines a list of property IDs

#### Format:

| 1    | 2   | 3     | 4    | 5     | 6   | 7   | 8   | 9   | 10 |
|------|-----|-------|------|-------|-----|-----|-----|-----|----|
| SET4 | ID  | CLASS | TYPE | ID1   | ID2 | ID3 | ID4 | ID5 |    |
|      | ID6 | ID7   | ID8  | -etc- |     |     |     |     |    |

#### Example:

|      |    |      |        |   |      |    |  |  |  |
|------|----|------|--------|---|------|----|--|--|--|
| SET4 | 22 | PROP | PSOLID | 1 | THRU | 20 |  |  |  |
|------|----|------|--------|---|------|----|--|--|--|

| Describer | Meaning                                                                          |
|-----------|----------------------------------------------------------------------------------|
| ID        | Unique identification number. (Integer>0).                                       |
| CLASS     | Set to "PROP". (Character = PROP; no default)                                    |
| TYPE      | Property type. Valid options are PSOLID, PSHELL, PSHEAR, PBAR, PBEAM, and PWELD. |
| IDI       | Property IDs of the specified TYPE flag.                                         |

#### Remarks:

1. THRU option may not appear in field 5 or 9 on first line or field 2 or 9 for continuation lines.
2. Currently referenced from the FTGDEF entry.

## SETREE

### Superelement Tree Definition (Alternate Form of DTI,SETREE)

Specifies superelement reduction order.

#### Format:

|        |       |       |        |       |       |       |       |       |    |
|--------|-------|-------|--------|-------|-------|-------|-------|-------|----|
| 1      | 2     | 3     | 4      | 5     | 6     | 7     | 8     | 9     | 10 |
| SETREE | SEID  | SEUP1 | SEUP2  | SEUP3 | SEUP4 | SEUP5 | SEUP6 | SEUP7 |    |
|        | SEUP8 | SEUP9 | -etc.- |       |       |       |       |       |    |

#### Example:

|        |     |    |    |    |    |  |  |  |  |
|--------|-----|----|----|----|----|--|--|--|--|
| SETREE | 400 | 10 | 20 | 30 | 40 |  |  |  |  |
|--------|-----|----|----|----|----|--|--|--|--|

| Describer         | Meaning                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------|
| SEID              | Partitioned superelement identification number of a downstream superelement. (Integer $\geq 0$ ) |
| SEUP <sub>i</sub> | Identification number of superelements that are upstream of SEID. (Integer $> 0$ )               |

#### Remarks:

1. SETREE entries or DTI,SETREE entry are required for multilevel superelement configurations.
2. At least one SETREE entry is required for each nontip superelement, including the residual structure (SEID = 0). Multiple SETREE entries with the same SEID are allowed.
3. A superelement may appear only once in an SEUP<sub>i</sub> field on all SETREE entries.
4. If an DTI,SETREE entry is provided, then SETREE entries are not required.
5. If both SETREE entries and a DTI,SETREE entry exist, then the DTI,SETREE entry will be ignored.

6. If a superelement is not referenced on the DTI,SETREE or SETREE entry, then the manner in which it is handled depends on the type of that superelement. If it is a PART superelement, then the residual will be regarded as its downstream superelement and the undefined superelement will therefore be placed immediately above the residual in the tree. If it is a Main Bulk Data superelement, then it will also be handled like an undefined PART superelement as above *if all of its exterior points belong to the residual*. However, if one or more of its exterior points do not belong to the residual, then the program will terminate with a user fatal error complaining that one or more of the superelements are not in the same path.
7. The SETREE entry will only work if PART (BEGIN SUPER) superelements exist in the model. If there are no PARTs in the model, the SETREE entries will be ignored.

## SEUSET Superelement Degree-of-Freedom Set Definition

Defines a degree-of-freedom set for a superelement.

### Format:

| 1      | 2    | 3     | 4   | 5  | 6   | 7  | 8   | 9  | 10 |
|--------|------|-------|-----|----|-----|----|-----|----|----|
| SEUSET | SEID | SNAME | ID1 | C1 | ID2 | C2 | ID3 | C3 |    |

### Example:

|        |    |    |   |        |   |   |    |   |  |
|--------|----|----|---|--------|---|---|----|---|--|
| SEUSET | 15 | U4 | 1 | 123456 | 7 | 5 | 22 | 3 |  |
|--------|----|----|---|--------|---|---|----|---|--|

| Describer | Meaning                                                                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. (Integer > 0)                                                                                                    |
| SNAME     | Set name. (One to four characters or string "ZERO", followed by the set name.)                                                                       |
| IDI       | Grid or scalar point identification numbers. (Integer > 0)                                                                                           |
| CI        | Component number. (Any unique combination of the Integers 1 through 6 with no embedded blank for grid points; Integer 0 or blank for scalar points.) |

### Remarks:

1. SNAME may refer to any of the set names given in [Degree-of-Freedom Sets](#) or their new names on the DEFUSET entry. However, in the Solution Sequences 0 through 200, it is recommended that SNAME refer only to the set names "U1" through "U6" or their new names on the DEFUSET entry.
2. If SNAME = "ZEROi", where i is a set name, then the degrees-of-freedom are omitted from set i.

## SEUSET1 Superelement Degree-of-Freedom Set Definition, Alternate Form

Defines a degree-of-freedom set for a superelement.

### Format:

| 1       | 2    | 3     | 4      | 5  | 6  | 7  | 8  | 9  | 10 |
|---------|------|-------|--------|----|----|----|----|----|----|
| SEUSET1 | SEID | SNAME | C      | G1 | G2 | G3 | G4 | G5 |    |
|         | G6   | G7    | -etc.- |    |    |    |    |    |    |

### Example:

|         |    |    |   |    |    |    |    |    |  |
|---------|----|----|---|----|----|----|----|----|--|
| SEUSET1 | 15 | U4 | 1 | 12 | 15 | 17 | 22 | 25 |  |
|         | 52 | 53 |   |    |    |    |    |    |  |

### Alternate Format and Example:

|         |      |       |   |    |        |    |  |  |  |
|---------|------|-------|---|----|--------|----|--|--|--|
| SEUSET1 | SEID | SNAME | C | G1 | "THRU" | G2 |  |  |  |
| SEUSET1 | 15   | U4    | 1 | 12 | THRU   | 27 |  |  |  |

| Describer | Meaning                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| SEID      | Superelement identification number. (Integer > 0)                                                                                                      |
| SNAME     | Set name. (One to four characters or string "ZERO", followed by the set name.)                                                                         |
| C         | Component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; Integer 0 or blank for scalar points.) |
| Gi        | Grid or scalar point identification number. (Integer > 0)                                                                                              |

### Remarks:

1. SNAME may refer to any of the set names given in [Degree-of-Freedom Sets](#) or their new names on the DEFUSET entry. However, in the Solution Sequences 0 through 200, it is recommended that SNAME refer only to the set names "U1" through "U6" or their new names on the DEFUSET entry.
2. If SNAME= "ZEROi", where i is a set name, then the degrees-of-freedom are omitted from set i.
3. If the alternate format is used, all of the points G1 through G2 are assigned to the set.

**SHREL**

## Elastic Shear Model

Defines an elastic shear model with a constant shear modulus. Used in SOL 700 only.

**Format:**

| 1     | 2   | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-------|-----|---|---|---|---|---|---|---|----|
| SHREL | SID | G |   |   |   |   |   |   |    |

**Example:**

|       |     |       |  |  |  |  |  |  |  |
|-------|-----|-------|--|--|--|--|--|--|--|
| SHREL | 250 | 80.E6 |  |  |  |  |  |  |  |
|-------|-----|-------|--|--|--|--|--|--|--|

| Describer | Meaning                                                                            |
|-----------|------------------------------------------------------------------------------------|
| SID       | Unique shear model number referenced from a MATDEUL entry. (Integer > 0; Required) |
| G         | Shear-modulus value. (Real; Default = 0.0)                                         |

**Remark:**

1. SID must unique among all SHRxx entries in one model.

**SHRPOL****Polynomial Shear Model**

Defines an elastic shear model with a polynomial shear modulus. Used in SOL 700 only.

**Format:**

| 1      | 2   | 3     | 4     | 5     | 6     | 7 | 8 | 9 | 10 |
|--------|-----|-------|-------|-------|-------|---|---|---|----|
| SHRPOL | SID | $G_0$ | $G_1$ | $G_2$ | $G_3$ |   |   |   |    |

**Example:**

|        |     |       |  |  |  |  |  |  |  |
|--------|-----|-------|--|--|--|--|--|--|--|
| SHRPOL | 250 | 80.E6 |  |  |  |  |  |  |  |
|--------|-----|-------|--|--|--|--|--|--|--|

| Describer | Meaning                                                                            |
|-----------|------------------------------------------------------------------------------------|
| SID       | Unique shear model number referenced from a MATDEUL entry. (Integer > 0; Required) |
| $G_0$     | Coefficient $G_0$ . (Real; Default = 0.0)                                          |
| $G_1$     | Coefficient $G_1$ . (Real; Default = 0.0)                                          |
| $G_2$     | Coefficient $G_2$ . (Real; Default = 0.0)                                          |
| $G_3$     | Coefficient $G_3$ . (Real; Default = 0.0)                                          |

**Remark:**

1. SID must unique among all SHRxx entries in one model.
2. The shear modulus is computed from

$$G = G_0 + G_1\gamma + G_2\gamma^2 + G_3\gamma^3$$

where  $\gamma$  = effective plastic shear strain

and  $G_0$ ,  $G_1$ ,  $G_2$  and  $G_3$  are constants

## SHRUDS

## User-defined Shear Model for Elements.

Specifies that a user subroutine is being used to define the shear modulus. Use in SOL700 only.

### Format:

| 1      | 2   | 3     | 4     | 5 | 6 | 7 | 8 | 9 | 10 |
|--------|-----|-------|-------|---|---|---|---|---|----|
| SHRUDS | SID | GROUP | UNAME |   |   |   |   |   |    |

### Example:

In FMS Section of the MSC Nastran input stream:

```
CONNECT SERVICE mymat 'SCA.MDSolver.Obj.Uds.Dytran.Materials'
```

In Bulk Data:

| 1      | 2  | 3     | 4     | 5 | 6 | 7 | 8 | 9 | 10 |
|--------|----|-------|-------|---|---|---|---|---|----|
| SHRUDS | 12 | mymat | EXSHR |   |   |   |   |   |    |

| Describer | Meaning                                                                                    |
|-----------|--------------------------------------------------------------------------------------------|
| SID       | Unique porosity model ID. (Integer > 0; Required)                                          |
| GROUP     | The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default) |
| UNAME     | User subroutine name associated with the entry. (Character; default=EXSHR)                 |

### Remarks:

1. Only can be used for SOL 700.
2. The SID must be referenced by a MATDEUL or MAT1 entry.
3. UNAME=EXSHR can only be used.

## SLBDY

## Slot Boundary List

### Format:

| 1     | 2   | 3      | 4   | 5   | 6   | 7   | 8   | 9   | 10 |
|-------|-----|--------|-----|-----|-----|-----|-----|-----|----|
| SLBDY | RHO | M      | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 |    |
|       | ID7 | -etc.- |     |     |     |     |     |     |    |

### Example:

|       |       |   |    |    |    |    |    |    |  |
|-------|-------|---|----|----|----|----|----|----|--|
| SLBDY | 0.002 | 6 | 16 | 17 | 18 | 25 | 20 | 21 |  |
|       | 22    |   |    |    |    |    |    |    |  |

| Describer       | Meaning                                                                                                                      |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| RHO             | Density of fluid at boundary. (Real > 0.0 or blank)                                                                          |
| M               | Number of slots. (Integer $\geq$ 0 or blank)                                                                                 |
| ID <sub>j</sub> | Identification numbers of GRIDS slot points at boundary with axisymmetric fluid cavity, $j = 1, 2, \dots, J$ . (Integer > 0) |

### Remarks:

1. SLBDY is allowed only if an AXSLOT entry is also present.
2. If RHO or M is blank, the default value on the AXSLOT entry is used. The effective value must not be zero for RHO. If the effective value of M is zero, no matrices at the boundary will be generated.
3. The order of the list of points determines the topology of the boundary. The points are listed sequentially as one travels along the boundary in either direction. At least two points must be defined.

## SLOAD Static Scalar Load

Defines concentrated static loads on scalar or grid points.

### Format:

| 1     | 2   | 3  | 4  | 5  | 6  | 7  | 8  | 9 | 10 |
|-------|-----|----|----|----|----|----|----|---|----|
| SLOAD | SID | S1 | F1 | S2 | F2 | S3 | F3 |   |    |

### Example:

|       |    |   |     |    |      |    |       |  |  |
|-------|----|---|-----|----|------|----|-------|--|--|
| SLOAD | 16 | 2 | 5.9 | 17 | -6.3 | 14 | -2.93 |  |  |
|-------|----|---|-----|----|------|----|-------|--|--|

| Describer | Meaning                                                   |
|-----------|-----------------------------------------------------------|
| SID       | Load set identification number. (Integer > 0)             |
| Si        | Scalar or grid point identification number. (Integer > 0) |
| Fi        | Load magnitude. (Real)                                    |

### Remarks:

1. In the static solution sequences, SID is selected by the LOAD Case Control command.
2. In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an ACSRCE, RLOADi or TLOADi entry.
3. Up to three loads may be defined on a single entry.
4. If Si refers to a grid point, the load is applied to component T1 of the displacement coordinate system (see the CD field on the GRID entry).

## SLOADN1

Describes TOP/BOT/MID Scalar Load for Heat Shell Element in SOL 400

Defines concentrated static loads on grid points of heat shell elements with linear or quadratic temperature distribution through the thickness direction.

### Format:

| 1       | 2   | 3  | 4  | 5  | 6  | 7  | 8  | 9 | 10 |
|---------|-----|----|----|----|----|----|----|---|----|
| SLOADN1 | SID | G1 | C1 | Q1 | G2 | C2 | Q2 |   |    |

### Example:

|         |    |    |    |       |    |   |       |  |  |
|---------|----|----|----|-------|----|---|-------|--|--|
| SLOADN1 | 10 | 10 | 12 | 1300. | 20 | 2 | 1300. |  |  |
|---------|----|----|----|-------|----|---|-------|--|--|

| Describer | Meaning                                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Load set identification number. (Integer > 0)                                                                                                                                       |
| Gi        | Grid point identification number. (Integer > 0)                                                                                                                                     |
| Ci        | Component numbers. ( $0 \leq \text{Integer} \leq 3$ ; up to 3 unique Integers may be placed in the field with no embedded blanks.) 1=TOP, 2=BOT, 3=MID. (Integer > -1; Default = 1) |
| Qi        | Power. (Real)                                                                                                                                                                       |

### Remarks:

1. This entry is for shell elements defined on a PSHLN1 heat transfer to specify power input.
2. In the steady-state heat transfer analysis, SID is selected by the LOAD Case Control command.
3. In the transient heat transfer analysis, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an ACSRCE, RLOADi or TLOADi entry.

## SNORM Surface Normal Vector at Grid Point

Defines a surface normal vector at a grid point for CQUAD4, CQUADR, CTRIA3, and CTRIAR shell elements.

### Format:

|       |     |     |    |    |    |   |   |   |    |
|-------|-----|-----|----|----|----|---|---|---|----|
| 1     | 2   | 3   | 4  | 5  | 6  | 7 | 8 | 9 | 10 |
| SNORM | GID | CID | N1 | N2 | N3 |   |   |   |    |

### Example:

|       |   |   |    |     |    |  |  |  |  |
|-------|---|---|----|-----|----|--|--|--|--|
| SNORM | 3 | 2 | 0. | -1. | 0. |  |  |  |  |
|-------|---|---|----|-----|----|--|--|--|--|

| Describer | Meaning                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GID       | Unique grid point identification number. (Integer > 0)                                                                                                                        |
| CID       | Identification number of coordinate system in which the components of the normal vector are defined. See Remark 3. (Integer ≥ 0; Default = 0 for the basic coordinate system) |
| Ni        | Components of normal vector. The three components of the normal need not define a unit vector. (Real; Default = 0.0)                                                          |

### Remarks:

1. The SNORM Bulk Data entry overrides any unique, internally-generated grid point normals that may have been requested with the user parameter SNORM, described in Chapter 6 of this guide.
2. The normal is used in CQUAD4, CQUADR, CTRIA3, and CTRIAR shell elements. For all other elements, the normal is ignored.
3. If CID is a cylindrical or spherical coordinate system, the components Ni are in the local tangent system at grid GID. For example, if CID=10 is a spherical coordinate system and normals must be defined pointing outwards in the radial direction of the sphere, see , then the SNORM entries for all grids GID on the sphere are simply  
SNORM, GID, 10, 1., 0., 0.

Figure 9-144

## SPBLND1 Strip Based Spline Blending

Defines a strip based blending of two splines.

### Format:

| 1       | 2   | 3    | 4    | 5   | 6  | 7   | 8  | 9  | 10 |
|---------|-----|------|------|-----|----|-----|----|----|----|
| SPBLND1 | SID | SID1 | SID2 | OPT | W1 | GID | D1 | D2 |    |
|         | X1  | X2   | X3   | CID |    |     |    |    |    |

### Example:

|         |     |     |     |     |  |     |      |      |  |
|---------|-----|-----|-----|-----|--|-----|------|------|--|
| SPBLND1 | 130 | 110 | 120 | CUB |  | 227 | 4.05 | 4.05 |  |
|         | 1.0 | 0.0 | 0.0 | 110 |  |     |      |      |  |

| Describer  | Meaning                                                                                                                                                          |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID        | Identification number of blended spline. (Integer > 0)                                                                                                           |
| SID1       | Identification number of first spline (may be a blended spline). (Integer > 0)                                                                                   |
| SID2       | Identification number of second spline (may be a blended spline). (Integer > 0)                                                                                  |
| OPT        | Blending Option:<br>WAVG      Weighted Average (Default)<br>LIN        Linear Blending Functions<br>CUB        Cubic Blending Functions                          |
| W1         | Weight to be used with first spline. ( $0.0 < \text{Real} \leq 1.0$ ; Default = 0.5) (Used only with option WAVG)                                                |
| GID        | Identification number of an aerodynamic grid to be used as reference grid. (Integer>0)                                                                           |
| D1         | Blending Depth of first spline. (Real > 0.0)                                                                                                                     |
| D2         | Blending Depth of second spline. (Real > 0.0)                                                                                                                    |
| X1, X2, X3 | Components of a direction vector $v$ , in the coordinate system defined by CID, which is used to measure the distance from the reference grid. (See Remark 3.)   |
| CID        | Identification number of a rectangular coordinate system used to define the direction vector. (Integer > 0; Default = 0; indicating the basic coordinate system) |

### Remarks:

1. The blending depth defines the maximum distance from the reference grid point of an aerodynamic grid point to be used in blending. It is also needed to evaluate the blending functions.
2. With option WAVG, the definition of GID, D1, D2 and the direction vector is optional. The weight W2 to be used with the second spline is computed from  $W2 = 1 - W1$ .

3. The blended displacement is computed from

$$u_b = f_1(x)u_1 + f_2(x)u_2$$

where  $f_1(x)$  and  $f_2(x)$  are the blending functions (see Figure 9-145) and  $x$  is the distance from the reference grid point, measured in the direction of the direction vector  $\mathbf{v}$ . Functions  $f_1(x)$  and  $f_2(x)$  sum up to 1.

Figure 9-145 Blending Functions

4. If the overlap region extends beyond  $-D1 < x < D2$ , then
- $$f_1(x) = 1.0 \text{ and } f_2(x) = 0 \text{ for } x < -D1$$
- $$f_1(x) = 0 \text{ and } f_2(x) = 1.0 \text{ for } x > D2$$
5. The referenced splines must have the same USAGE flag. This USAGE flag defines the USAGE flag of the blended spline.
6. If the splined aero components are of type CAERO, a MDLPRM,MLTSPLIN,1 entry must be used to enable blending. This is not required with AEGRID based aerodynamics.

## SPBLND2 Curve Based Spline Blending

Defines a curve based blending of two splines.

### Format:

| 1       | 2   | 3    | 4    | 5   | 6      | 7  | 8  | 9 | 10 |
|---------|-----|------|------|-----|--------|----|----|---|----|
| SPBLND2 | SID | SID1 | SID2 | OPT | AELIST | D1 | D2 |   |    |

### Example:

|         |     |     |     |     |   |     |     |  |  |
|---------|-----|-----|-----|-----|---|-----|-----|--|--|
| SPBLND2 | 130 | 110 | 120 | LIN | 4 | 1.5 | 2.5 |  |  |
|---------|-----|-----|-----|-----|---|-----|-----|--|--|

| Describer | Meaning                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------|
| SID       | Identification number of blended spline. (Integer > 0)                                                                    |
| SID1      | Identification number of first spline (may be a blended spline). (Integer > 0)                                            |
| SID2      | Identification number of second spline (may be a blended spline). (Integer > 0)                                           |
| OPT       | Blending Option:<br>LIN      Linear Blending Functions (Default)<br>CUB      Cubic Blending Functions                     |
| AELIST    | Identification number of an AELIST entry listing the aerodynamic grid points that define a reference curve. (Integer > 0) |
| D1        | Blending Depth of first spline. (Real > 0.0)                                                                              |
| D2        | Blending Depth of second spline. (Real > 0.0)                                                                             |

### Remarks:

1. The blending depth defines the maximum value of the distance of an aerodynamic grid point from the reference curve. It is also needed to evaluate the blending functions.
2. Blending functions are evaluated based on the distance of an aerodynamic grid point from the reference curve.
3. The reference curve is approximated by a polygon through the grid points listed on the AELIST entry referenced by AELIST. The list may contain coincident grid points. The order of the grid points is arbitrary.
4. The referenced splines must have the same USAGE flag. This USAGE flag defines the USAGE flag of the blended spline.
5. If the splined aero components are of type CAERO, a MDLPRM,MLTSPLIN,1 entry must be used to enable blending. This is not required with AEGRID based aerodynamics.

**SPC****Single-Point Constraint**

Defines a set of single-point constraints and enforced motion (enforced displacements in static analysis and enforced displacements, velocities or acceleration in dynamic analysis).

**Format:**

| 1   | 2   | 3  | 4  | 5  | 6  | 7  | 8  | 9 | 10 |
|-----|-----|----|----|----|----|----|----|---|----|
| SPC | SID | G1 | C1 | D1 | G2 | C2 | D2 |   |    |

**Example:**

|     |   |    |   |      |   |  |  |  |  |
|-----|---|----|---|------|---|--|--|--|--|
| SPC | 2 | 32 | 3 | -2.6 | 5 |  |  |  |  |
|-----|---|----|---|------|---|--|--|--|--|

| Describer | Meaning                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Identification number of the single-point constraint set. (Integer > 0)                                                                                                                                                                 |
| Gi        | Grid or scalar point identification number. (Integer > 0)                                                                                                                                                                               |
| Ci        | Component number. See Remark 8. ( $0 \leq \text{Integer} \leq 6$ ; up to six Unique Integers, 1 through 6, may be placed in the field with no embedded blanks. 0 or 1 applies to scalar points and 1 through 6 applies to grid points.) |
| Di        | Value of enforced motion for components Gi at grid Ci. (Real; Default = 0.0)                                                                                                                                                            |

**Remarks:**

1. Single-point constraint sets must be selected with the Case Control command SPC = SID.
2. Degrees-of-freedom specified on this entry form members of the mutually exclusive s-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
3. Single-point forces of constraint are recovered during stress data recovery.
4. From 1 to 12 degrees-of-freedom may be specified on a single entry.
5. Degrees-of-freedom on this entry may be redundantly specified as permanent constraints using the PS field on the GRID entry.
6. For reasons of efficiency, the SPCD entry is the preferred method for applying enforced motion rather than the Di field described here.
7. For SOL 400, the SPC entry requests enforced total displacement (Di) while the SPC1 entry requests null enforced relative displacements for a step. See the SPCD and SPCR entries for additional information.

| Enforced Relative Displacement |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| SPCR                           | associated with SPC1 or GRID/PS                                       |
| Enforced Total Displacement    |                                                                       |
| SPCD                           | associated with SPC and overwrite the value of enforced motion on SPC |
| SPCD                           | associated with SPC1 or GRID/PS                                       |
| SPC                            | No association required                                               |

In SOL 400, when a GRID has an applied load associated with it in the previous STEP and the user wishes to pick up the resulting displacement as an enforced displacement in the current STEP, then the recommended procedure is to use the SPCR. Alternatively, the user may apply instead an SPC1 to the GRID to lock in the position of the grid from the previous STEP.

For SOL 600, the SPC entry requests enforced total displacement just like SPCD, however SPC may only be used in SOL 600 to enforce displacements if there is just one subcase in the analysis. If two or more subcases exist, SPCD or SPCR must be used to prescribe the enforced motion.

8. For heat shell element with linear or quadratic nodal distribution (see option TEMPP for NLMOPTS entry 1=TOP, 2=BOT or 3=MID.)
9. In thermal analysis, this entry specifies a constant temperature boundary condition applied on the selected grid or scalar point. For SOL 400, transient thermal analysis with any time-varying boundary condition, a constant temperature condition should be specified using the SPCD and SPC1 Bulk Data entries. For SOLs 153 and 159 thermal analysis, no TEMPBC Bulk Data entries with TYPE="STAT" may be specified with this entry.
10. SOL129 transient analysis does not support Di option for enforced motion. Use SOL400.

## SPC1 Single-Point Constraint, Alternate Form

Defines a set of single-point constraints.

### Format:

| 1    | 2   | 3  | 4  | 5      | 6  | 7  | 8  | 9  | 10 |
|------|-----|----|----|--------|----|----|----|----|----|
| SPC1 | SID | C  | G1 | G2     | G3 | G4 | G5 | G6 |    |
|      | G7  | G8 | G9 | -etc.- |    |    |    |    |    |

### Example:

|      |   |   |   |   |    |   |   |   |  |
|------|---|---|---|---|----|---|---|---|--|
| SPC1 | 3 | 2 | 1 | 3 | 10 | 9 | 6 | 5 |  |
|      | 2 | 8 |   |   |    |   |   |   |  |

### Alternate Format and Example:

|      |     |       |    |        |    |  |  |  |  |
|------|-----|-------|----|--------|----|--|--|--|--|
| SPC1 | SID | C     | G1 | “THRU” | G2 |  |  |  |  |
| SPC1 | 313 | 12456 | 6  | THRU   | 32 |  |  |  |  |

| Describer | Meaning                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Identification number of single-point constraint set. (Integer > 0)                                                                                                                         |
| C         | Component numbers. See Remark 7. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points. This number must be Integer 0, 1 or blank for scalar points.) |
| Gi        | Grid or scalar point identification numbers. (Integer > 0 or “THRU”; For “THRU” option, G1 < G2.)                                                                                           |

### Remarks:

1. Single-point constraint sets must be selected with the Case Control command SPC = SID.
2. Enforced displacements are available via this entry when used with the recommended SPCD entry.
3. Degrees-of-freedom specified on this entry form members of the mutually exclusive s-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
4. Degrees-of-freedom on this entry may be redundantly specified as permanent constraints using the PS field on the GRID entry.
5. If the alternate format is used, points in the sequence G1 through G2 are not required to exist. Points that do not exist will collectively produce a warning message but will otherwise be ignored.
6. For SOL 400, the SPC1 entry requests null enforced relative displacement for a step while the SPC entry requests enforced total displacements. SPC1 can always hold the displacement from the previous STEP. See the SPC, SPCD and SPCR entries for additional information.

| Enforced Relative Displacement                                                                                                                                                                                                                                                                                                                         |                         |                 |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|-----------------|
| SPCR                                                                                                                                                                                                                                                                                                                                                   | associated              | SPC1 or GRID/PS |
| Enforced Total Displacement                                                                                                                                                                                                                                                                                                                            |                         |                 |
| SPCD                                                                                                                                                                                                                                                                                                                                                   | associated              | SPC             |
| SPCD                                                                                                                                                                                                                                                                                                                                                   | associated              | SPC1 or GRID/PS |
| SPC                                                                                                                                                                                                                                                                                                                                                    | No association required |                 |
| <p>In SOL 400 if a “control” GRID has an applied load associated with it in the previous STEP and if the user wishes to pick up the resulting displacement as an enforced displacement in the current STEP, then the recommended procedure is still to use the SPCR, however, the user may apply instead an SPC1 containing the “control” grid ID.</p> |                         |                 |

7. For heat shell element with linear or quadratic nodal distribution (see option TEMPP for NLMOPTS entry 1=TOP, 2=BOT or 3=MID.)
8. In thermal analysis, this entry is used with SPCD to specify a temperature boundary condition applied on the selected grid or scalar point. To define time-varying boundary conditions, the user should specify SPC1 and SPC Bulk Data entries for SOL 400 while using TEMPBC Bulk Data entries with TYPE=“TRAN” for SOL 159.

## SPCADD

## Single-Point Constraint Set Combination

Defines a single-point constraint set as a union of single-point constraint sets defined on SPC or SPC1 entries.

### Format:

|        |     |    |        |    |    |    |    |    |    |
|--------|-----|----|--------|----|----|----|----|----|----|
| 1      | 2   | 3  | 4      | 5  | 6  | 7  | 8  | 9  | 10 |
| SPCADD | SID | S1 | S2     | S3 | S4 | S5 | S6 | S7 |    |
|        | S8  | S9 | -etc.- |    |    |    |    |    |    |

### Example:

|        |     |   |   |   |   |  |  |  |  |
|--------|-----|---|---|---|---|--|--|--|--|
| SPCADD | 101 | 3 | 2 | 9 | 1 |  |  |  |  |
|--------|-----|---|---|---|---|--|--|--|--|

| Describer | Meaning |
|-----------|---------|
|-----------|---------|

|     |                                                                                                          |
|-----|----------------------------------------------------------------------------------------------------------|
| SID | Single-point constraint set identification number. (Integer > 0)                                         |
| Si  | Identification numbers of single-point constraint sets defined via SPC or by SPC1 entries. (Integer > 0) |

### Remarks:

1. Single-point constraint sets must be selected with the Case Control command SPC = SID.
2. No Si may be the identification number of a single-point constraint set defined by another SPCADD entry.
3. The Si values must be unique.
4. If Modules are present then this entry may only be specified in the main Bulk Data section.
5. SPCADD entries take precedence over SPC entries. If both have the same SID, only the SPCADD entry will be used.

## SPCAX Conical Shell Single-Point Constraint

Defines a set of single-point constraints or enforced displacements for conical shell coordinates.

### Format:

| 1     | 2   | 3   | 4   | 5 | 6 | 7 | 8 | 9 | 10 |
|-------|-----|-----|-----|---|---|---|---|---|----|
| SPCAX | SID | RID | HID | C | D |   |   |   |    |

### Example:

|       |   |   |   |    |     |  |  |  |  |
|-------|---|---|---|----|-----|--|--|--|--|
| SPCAX | 2 | 3 | 4 | 13 | 6.0 |  |  |  |  |
|-------|---|---|---|----|-----|--|--|--|--|

| Describer | Meaning                                                                                |
|-----------|----------------------------------------------------------------------------------------|
| SID       | Identification number of a single-point constraint set. (Integer > 0)                  |
| RID       | Ring identification number. See RINGAX entry. (Integer ≥ 0)                            |
| HID       | Harmonic identification number. (Integer ≥ 0)                                          |
| C         | Component identification number. (Any unique combination of the Integers 1 through 6.) |
| D         | Enforced displacement value. (Real)                                                    |

### Remarks:

1. SPCAX is allowed only if an AXIC entry is also present.
2. Single-point constraint sets must be selected with the Case Control command SPC = SID.
3. Coordinates appearing on SPCAX entries may not appear on MPCAX, SUPAX, or OMITAX entries.
4. For a discussion of the conical shell problem, see [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide*.

**SPCD**                      Enforced Motion Value

Defines an enforced displacement value for static analysis and an enforced motion value (displacement, velocity or acceleration) in dynamic analysis.

**Format:**

| 1    | 2   | 3  | 4  | 5  | 6  | 7  | 8  | 9 | 10 |
|------|-----|----|----|----|----|----|----|---|----|
| SPCD | SID | G1 | C1 | D1 | G2 | C2 | D2 |   |    |

**Example:**

|      |     |    |   |      |   |  |     |  |  |
|------|-----|----|---|------|---|--|-----|--|--|
| SPCD | 100 | 32 | 3 | -2.6 | 5 |  | 2.9 |  |  |
|------|-----|----|---|------|---|--|-----|--|--|

| Describer | Meaning                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Set identification number of the SPCD entry. (Integer > 0)                                                                                                                                            |
| Gi        | Grid or scalar point identification number. (Integer > 0)                                                                                                                                             |
| Ci        | Component numbers. See Remark 10. ( $0 \leq \text{Integer} \leq 6$ ; any unique combination of Integers 1 through 6 with no embedded blanks for grid points; Integer 0, 1 or blank for scalar points) |
| Di        | Value of enforced motion for components Ci at grid Gi. (Real)                                                                                                                                         |

**Remarks:**

- In the static solution sequences, the set ID of the SPCD entry (SID) is selected by the LOAD Case Control command. For SOL 600, it may also be selected by Li on the Bulk Data entry LOAD.
- In dynamic analysis, the selection of SID is determined by the presence of the LOADSET request in Case Control as follows:
  - There is no LOADSET request in Case Control  
SID is selected by the EXCITEID field of an RLOAD1, RLOAD2, TLOAD1 or TLOAD2 Bulk Data entry that has enforced motion specified in its TYPE field
  - There is a LOADSET request in Case Control  
SID is selected by LID in the selected LSEQ entries that correspond to the EXCITEID entry of an RLOAD1, RLOAD2, TLOAD1 or TLOAD2 Bulk Data entry that has enforced motion specified in its TYPE field.
- Enforced Motion is not supported for dynamic subcases in SOL 200 (ANALYSIS=MTRAN,DFREQ or MFREQ).
- A global coordinate (Gi and Ci) referenced on this entry must also be referenced on a SPC or SPC1 Bulk Data entry and selected by the SPC Case Control command. This requirement is optional for SOL 600.

5. Enforced motion may be specified on both SPCD and SPC Bulk Data entries. The SPCD entry is selected according to Remark 2. and the SPC entry is selected by the SPC Case Control command. The Di values from both of the selected SPCD and SPC entries will be combined to form a static (or spatial) loading condition. But if a degree-of-freedom is duplicated on both SPCD and SPC then the value of Di on the selected SPCD entry will override the value of Di on the selected SPC entry. In addition, any degrees-of-freedom from the selected SPC entries and not duplicated will still be included in the loading condition. This is illustrated in the examples below.

- Static analysis: In the example below in SUBCASE 11, D=1.0 at GRID 101 overrides D=1.2 on the SPC entry. But GRID 201 is not specified on the selected SPCD and therefore D=1.2 from the SPC entry is also enforced. Similarly, in subcase 12, D=1.0 is enforced at GRID 201 and D=1.2 at GRID 101.

```

SPC=77
SUBCASE 11
LOAD=701
SUBCASE 12
LOAD=702
BEGIN BULK
SPCD,701,101,2,1.0
SPCD,702,201,2,1.0
SPC ,77 ,101,2,1.2
SPC ,77 ,201,2,1.2

```

- Dynamic analysis: In the example below, there are two unique EXCITEIDs specified on TLOAD2 and thusly two static loading conditions are created and identical to the conditions created in the static analysis example above.

```

SPC=77
DLOAD=201
BEGIN BULK
DLOAD,201,1.0,1.0,401,1.0,402
TLOAD2, 401, 701, , DISP, 0., 10.0, 60.,90.
TLOAD2, 402, 702, , DISP, 0., 10.0, 20.,270.
SPCD,701,101,2,1.0
SPCD,702,201,2,1.0
SPC ,77 ,101,2,1.2
SPC ,77 ,201,2,1.2

```

6. The LOAD Bulk Data entry will not combine an SPCD load entry except for SOL 600.
7. In static analysis, this method of applying enforced displacements is more efficient than the SPC entry when more than one enforced displacement condition is applied. It provides equivalent answers.

8. In dynamic analysis, this direct method of specifying enforced motion is more accurate, efficient and elegant than the large mass and Lagrange multiplier techniques.
9. For SOL 400, the SPCD entry requests enforced total displacement for a STEP while the SPCR entry requests enforced relative displacements. SPCD is the position at the end of the applied STEP for ANALYSIS=NLSTAT.

| Enforced Relative Displacement                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                                                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------|
| SPCR                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | associated with SPC1 or GRID/PS                                       |
| Enforced Total Displacement                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                                                       |
| SPCD                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | associated with SPC and overwrite the value of enforced motion on SPC |
| SPCD                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | associated with SPC1 or GRID/PS                                       |
| SPC                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | No association required                                               |
| <p>In SOL 400, when a GRID has an applied load associated with it in the previous STEP and the user wishes to pick up the resulting displacement as an enforced displacement in the current STEP, then the recommended procedure is to use the SPCR. Alternatively, the user may apply instead an SPC1 to the GRID to lock in the position of the grid from the previous STEP.</p> <p>For SOL 600, the SPCD entry requests enforced total displacement for the subcase and is the position at the end of the SUBCASE. SPCR requests displacement or rotation for the current subcase relative to that of the previous subcase. SPCD may be used for nonlinear statics or dynamics and does not need to be associated with SPC, SPC1 or GRID/PS. In other words, the association can be made but is not required for SOL 600.</p> |                                                                       |

10. For SOL 400 using heat shell element with linear or quadratic nodal distribution, see option TEMPP for NLMOPTS entry 1=TOP, 2=BOT or 3=MID).
11. In thermal analysis, this entry is used with SPC1 to specify a temperature boundary condition applied on the selected grid or scalar point. To define time-varying boundary conditions, the user should specify SPC1 and SPCD Bulk Data entries for SOL 400 while using TEMPBC Bulk Data entries with TYPE="TRAN" for SOL 159 and SOL 600.
12. If it is desired to enforce motion on the boundary point (a-set) of a superelement then define a high stiffness element attached to the boundary point and apply the SPCD to the opposite point of the high stiffness element. High stiffness elements may be easily defined with CBUSH or CBAR.
13. SOL129 transient analysis does not support Di option for enforced motion. Use SOL400.

**SPCOFF****Excludes Degrees-of-Freedom from the AUTOSPC Operation**

Defines a set of degrees-of-freedom to be excluded from the AUTOSPC operation. See [Constraint and Mechanism Problem Identification in SubDMAP SEKR](#) in the *MSC Nastran Reference Guide* for a description of the AUTOSPC operation.

**Format:**

| 1      | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 |
|--------|----|----|----|----|----|----|----|----|----|
| SPCOFF | G1 | C1 | G2 | C2 | G3 | C3 | G4 | C4 |    |

**Example:**

|        |    |     |   |   |  |  |  |  |  |
|--------|----|-----|---|---|--|--|--|--|--|
| SPCOFF | 32 | 436 | 5 | 1 |  |  |  |  |  |
|--------|----|-----|---|---|--|--|--|--|--|

| Describer | Meaning                                                                                                                     |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|
| Gi        | Grid or scalar point identification number. (Integer > 0)                                                                   |
| Ci        | Component numbers. (Integer 0, 1 or blank for scalar points; Integers 1 through 6 with no embedded blanks for grid points.) |

**Remarks:**

1. Degrees-of-freedom specified on this entry are to be excluded from the AUTOSPC operation. If any degree-of-freedom in this set is found to be singular, a warning message is issued and no constraint is applied.
2. Degrees-of-freedom that are specified as both SPC and SPCOFF will be considered as SPC.

## SPCOFF1

Excludes DOF's from AUTOSPC Processing, Alternate Form

Defines a set of degrees-of-freedom to be excluded from the AUTOSPC operation. See [Constraint and Mechanism Problem Identification in SubDMAP SEKR](#) in the *MSC Nastran Reference Guide* for a description of the AUTOSPC operation.

### Format:

|         |    |    |        |    |    |    |    |    |    |
|---------|----|----|--------|----|----|----|----|----|----|
| 1       | 2  | 3  | 4      | 5  | 6  | 7  | 8  | 9  | 10 |
| SPCOFF1 | C  | G1 | G2     | G3 | G4 | G5 | G6 | G7 |    |
|         | G8 | G9 | -etc.- |    |    |    |    |    |    |

### Example:

|         |   |   |   |    |   |   |   |   |  |
|---------|---|---|---|----|---|---|---|---|--|
| SPCOFF1 | 2 | 1 | 3 | 10 | 9 | 6 | 5 | 4 |  |
|         | 8 |   |   |    |   |   |   |   |  |

### Alternate Format and Example:

|         |       |    |        |    |  |  |  |  |  |
|---------|-------|----|--------|----|--|--|--|--|--|
| SPCOFF1 | C     | G1 | "THRU" | G2 |  |  |  |  |  |
| SPCOFF1 | 12456 | 6  | THRU   | 32 |  |  |  |  |  |

| Describer | Meaning                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| C         | Component numbers. (Any unique combination of the Integers 1 through 6 with no embedded blanks for grid points; Integer 0, 1 or blank for scalar points.) |
| Gi        | Grid or scalar point identification numbers. (Integer > 0 or "THRU"; for "THRU" option, G1 < G2.)                                                         |

### Remarks:

1. Degrees-of-freedom specified on this entry are to be excluded from the AUTOSPC operation. If any degree-of-freedom in this set is found to be singular, a warning message is issued and no constraint is applied.
2. Degrees-of-freedom that are both specified as SPC and SPCOFF will be considered as SPC.
3. If the alternate format is used, points in the sequence G1 through G2 are not required to exist. Points which do not exist will collectively produce a warning message but will otherwise be ignored.

## SPCR Enforced Relative Motion Value

Defines an enforced relative displacement value for a load step in SOL 400 and SOL 600.

### Format:

| 1    | 2   | 3  | 4  | 5  | 6  | 7  | 8  | 9 | 10 |
|------|-----|----|----|----|----|----|----|---|----|
| SPCR | SID | G1 | C1 | D1 | G2 | C2 | D2 |   |    |

### Example:

|      |     |    |     |      |   |  |     |  |  |
|------|-----|----|-----|------|---|--|-----|--|--|
| SPCR | 100 | 32 | 436 | -2.6 | 5 |  | 2.9 |  |  |
|------|-----|----|-----|------|---|--|-----|--|--|

| Describer | Meaning                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Set identification number of the SPCR entry. (Integer > 0)                                                                                                                 |
| Gi        | Grid or scalar point identification number. (Integer > 0)                                                                                                                  |
| Ci        | Component number. ( $0 \leq \text{Integer} \leq 6$ ; up to six unique Integers may be placed in the field with no embedded blanks, a blank or 0 is treated the same as 1.) |
| Di        | Value of enforced motion for Gi and Ci. (Real)                                                                                                                             |

### Remarks:

1. SPCR requests relative motion for a load step with respect to the previous step in SOL 400 or subcase in SOL 600. SPCR is the companion entry to SPCD. SPCD requests total motion while SPCR requests relative motion. SPCR is the position at activation of the boundary condition.

| Enforced Relative Displacement |                                                                       |
|--------------------------------|-----------------------------------------------------------------------|
| SPCR                           | associated with SPC1 or GRID/PS                                       |
| Enforced Total Displacement    |                                                                       |
| SPCD                           | associated with SPC and overwrite the value of enforced motion on SPC |

### Enforced Relative Displacement

|      |                                 |
|------|---------------------------------|
| SPCD | associated with SPC1 or GRID/PS |
| SPC  | No association required         |

In SOL 400, when a GRID has an applied load associated with it in the previous STEP and the user wishes to pick up the resulting displacement as an enforced displacement in the current STEP, then the recommended procedure is to use the SPCR. Alternatively, the user may apply instead an SPC1 to the GRID to lock in the position of the grid from the previous STEP.

For SOL 600, the SPCR entry requests displacement or rotation for the current subcase relative to that of the previous subcase. The SPCD requests enforced total displacement for the subcase and is the position at the end of the SUBCASE. SPCR may be used for nonlinear statics or dynamics and does not need to be associated with SPC, SPC1 or GRID/PS. In other words, the association can be made but is not required for SOL 600.

2. The enforced motion for a step, for SOL 400 or subcase for SOL 600, can be either total value or relative value. For SOL 400, SPC and SPCD request total enforced motion. SPC1 and SPCR request the relative value. For example, if a DOF is specified on a SPCR with 0.0 for step 2, the relative displacement of this DOF for step 2 with respect to step 1 is 0.0. The total displacement of step 2 is 0.2 if the solution of step 1 for this DOF is 0.2.
3. The SPCD and SPCR entries can have the same SID, but they cannot be specified on the same DOF. A user fatal error will be issued if SPCD and SPCR are specified on the same DOF.
4. In the static solution sequences, the SID of the SPCR entry (SID), same as SPCD, is selected by the LOAD Case Control command.
5. For SOL 400, a global coordinate (Gi and CI) referenced on this entry must also be referenced on a SPC1 Bulk Data entry and selected by the SPC Case Control command. Please note that, for this purpose, SPC cannot be used together with SPCR. If SPC is used, a user fatal error will be issued.
6. For SOL 400, the LOAD Bulk Data entry will not combine an SPCR load entry.
7. For SOL 600 if SPCR is entered, PARAM,MARCTOTT,1 must also be entered.

**SPHERE**

Defines the Shape of a Sphere

Spherical shape used in the initial condition definition on the TICEUL1 entry. Used in SOL 700 only.

**Format:**

|        |     |   |   |   |   |        |   |   |    |
|--------|-----|---|---|---|---|--------|---|---|----|
| 1      | 2   | 3 | 4 | 5 | 6 | 7      | 8 | 9 | 10 |
| SPHERE | VID |   | X | Y | Z | RADIUS |   |   |    |

**Example:**

|        |     |  |    |    |    |    |  |  |  |
|--------|-----|--|----|----|----|----|--|--|--|
| SPHERE | 100 |  | 1. | 1. | 1. | .5 |  |  |  |
|--------|-----|--|----|----|----|----|--|--|--|

| Describer | Meaning                                                        |
|-----------|----------------------------------------------------------------|
| VID       | Number of the sphere. (Integer > 0; Required)                  |
| X, Y, Z   | Coordinates of the center of the sphere. (Real; Default = 0.0) |
| RADIUS    | Radius of the sphere. (Real > 0; Required)                     |

**SPLINE1**

## Surface Spline Methods

Defines a surface spline for interpolating motion and/or forces for aeroelastic problems on aerodynamic geometries defined by regular arrays of aerodynamic points.

**Format:**

| 1       | 2     | 3     | 4    | 5    | 6    | 7  | 8    | 9     | 10 |
|---------|-------|-------|------|------|------|----|------|-------|----|
| SPLINE1 | EID   | CAERO | BOX1 | BOX2 | SETG | DZ | METH | USAGE |    |
|         | NELEM | MELEM |      |      |      |    |      |       |    |

**Example:**

|         |   |     |     |     |    |    |  |  |  |
|---------|---|-----|-----|-----|----|----|--|--|--|
| SPLINE1 | 3 | 111 | 115 | 122 | 14 | 0. |  |  |  |
|---------|---|-----|-----|-----|----|----|--|--|--|

| Describer  | Meaning                                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EID        | Unique spline identification number. (Integer > 0)                                                                                                                                          |
| CAERO      | Aero-element (CAEROi entry ID) that defines the plane of the spline. (Integer > 0)                                                                                                          |
| BOX1, BOX2 | First and last box with motions that are interpolated using this spline; see Remark 3. when using Mach Box method. (Integer > 0; BOX2 ≥ BOX1)                                               |
| SETG       | Refers to the SETi entry that lists the structural grid points to which the spline is attached. (Integer > 0)                                                                               |
| DZ         | Linear attachment flexibility. (Real ≥ 0.0; Default = 0.0)                                                                                                                                  |
| METH       | Method for the spline fit. IPS, TPS or FPS. See Remark 1. (Character; Default = IPS)                                                                                                        |
| USAGE      | Spline usage flag to determine whether this spline applies to the force transformation, displacement transformation or both. FORCE, DISP or BOTH. See Remark 5. (Character; Default = BOTH) |
| NELEM      | The number of FE elements along the local spline x-axis if using the FPS option. (Integer > 0; Default = 10)                                                                                |
| MELEM      | The number of FE elements along the local spline y-axis if using the FPS option. (Integer > 0; Default = 10)                                                                                |

**Remarks:**

1. The default METHOD will result in the use of the Harder-Desmarais Infinite Plate Spline (IPS). The other options are the Thin Plate Spline (TPS) and the Finite Plate Spline (FPS). The continuation applies only to the FPS option and is required only if the defaults are not adequate.
2. The interpolated points (k-set) will be defined by aero boxes. Figure 9-146 shows the cells for which  $u_k$  is interpolated if BOX1 = 115 and BOX2 = 122.

|     |     |     |     |
|-----|-----|-----|-----|
| 111 | 114 | 117 | 120 |
| 112 | 115 | 118 | 121 |
| 113 | 116 | 119 | 122 |

Figure 9-146 SPLINE1 Entry Example

3. The attachment flexibility (units of area) is used for smoothing the interpolation. If  $DZ = 0.0$ , the spline will pass through all deflected grid points. If  $DZ$  is much greater than the spline area, a least squares plane fit will be applied. Intermediate values will provide smoothing.
4. When using the Mach Box method, BOX1 and BOX2 refer to the ID number of the first and last aerodynamic grids (x,y pairs on the AEFACCT entry) which will be used for interpolation to structural grids. BOX1 and BOX2 do not refer to Mach Boxes.
5. The USAGE field allows you to specify that the particular spline interpolant defined in this entry is to be used for just the force transformation (FORCE) or just the displacement transformation (DISP) or for both (BOTH).

$$Fg = [GPkg]^T \{Pk\} \quad (\text{FORCE/BOTH splines are in the transform})$$

$$Uk = [GDkg] \{Ug\} \quad (\text{DISP/BOTH splines are in the transform})$$

In general, the two transforms are done with distinct matrices. Only when ALL splines are of type BOTH is the familiar transpose relationship  $[GPkg]^T = [GDkg]$  satisfied. The default behavior (BOTH for all splines) is compatible with versions of MSC Nastran prior to Version 70.5.

In general, the USAGE field can be used to apply aerodynamic forces to the structure from aerodynamic panels that are intended NOT to move (USAGE=FORCE) or to apply structural displacements to aerodynamic grids whose forces are not to be applied to the structure (USAGE=DISP). The DISP option is somewhat esoteric in that you are then suggesting that the aeroelastic effect of the surface is important while its forces are not. (In other words, only the forces arising from its effects on other surfaces is important.) While there may be circumstances where this is true, it is unlikely. Take care that you included all the FORCEs from aerodynamic panels that are important by including them in either FORCE or BOTH spline(s). MSC Nastran will NOT issue a warning unless ALL forces are omitted. All displacements may be omitted without warning (and is a means to perform “rigid aerodynamic” analyses).

6. The SPLINE1 EID must be unique with respect to all SPLINEi entries.

**SPLINE2**

## Linear Spline

Defines a beam spline for interpolating motion and/or forces for aeroelastic problems on aerodynamic geometries defined by regular arrays of aerodynamic points.

**Format:**

| 1       | 2    | 3     | 4   | 5     | 6    | 7  | 8    | 9   | 10 |
|---------|------|-------|-----|-------|------|----|------|-----|----|
| SPLINE2 | EID  | CAERO | ID1 | ID2   | SETG | DZ | DTOR | CID |    |
|         | DTHX | DTHY  |     | USAGE |      |    |      |     |    |

**Example:**

|         |    |   |    |    |    |    |     |   |  |
|---------|----|---|----|----|----|----|-----|---|--|
| SPLINE2 | 5  | 8 | 12 | 24 | 60 | 0. | 1.0 | 3 |  |
|         | 1. |   |    |    |    |    |     |   |  |

| Describer  | Meaning                                                                                                                                                                                                                                                       |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EID        | Unique spline identification number. (Integer > 0)                                                                                                                                                                                                            |
| CAERO      | Aero panel or body (CAEROi entry ID) that is to be interpolated. (Integer > 0)                                                                                                                                                                                |
| ID1, ID2   | First and last box or body element whose motions are interpolated using this spline. See Remark 6. when using the Mach Box method. (Integer > 0; ID2 ≥ ID1)                                                                                                   |
| SETG       | Refers to an SETi entry that lists the structural grid points to which the spline is attached. (Integer > 0)                                                                                                                                                  |
| DZ         | Linear attachment flexibility. (Real ≥ 0.0; Default = 0.0)                                                                                                                                                                                                    |
| DTOR       | Torsional flexibility ratio ( $EI/GJ$ ). (Real > 0.0; Default = 1.0; use 1.0 for bodies.)                                                                                                                                                                     |
| CID        | Rectangular coordinate system for which the y-axis defines the axis of the spline. Not used for bodies, CAERO2. (Integer ≥ 0)                                                                                                                                 |
| DTHX, DTHY | Rotational attachment flexibility. DTHX is for rotation about the spline's x-axis (in-plane bending rotations); however, it is not used for bodies. DTHY is for rotation about the spline's y-axis (torsion); however, it is used for slope of bodies. (Real) |
| USAGE      | Spline usage flag to determine whether this spline applies to the force transformation, displacement transformation or both. FORCE, DISP or BOTH. See Remark 9. (Character; Default = BOTH)                                                                   |

**Remarks:**

1. The interpolated points (k-set) will be defined by aero boxes.
2. The spline axis for panels is the projection of the y-axis of coordinate system CID, projected onto the plane of the panel. For bodies, the spline axis is parallel to the x-axis of the aerodynamic coordinate system.

3. The flexibilities DZ, DTHX, and DTHY are used for smoothing. (Zero attachment flexibility values will imply rigid attachment (i.e., no smoothing, whereas negative values of DTHX or DTHY will imply infinity, therefore, no attachment). See the [MSC Nastran Aeroelastic Analysis User's Guide](#) for a discussion of special cases.
4. The continuation entry is required.
5. The SPLINE2 EID must be unique with respect to all SPLINEi entries.
6. When using the Mach Box method, ID1 and ID2 refer to the ID number of the first and last aerodynamic grids (x,y pairs on the AEFACCT entry) which will be used for interpolation to the structural grids. ID1 and ID2 do not refer to Mach Boxes.
7. DTOR is the ratio of rotational to linear deflection and, in lieu of a more accurate estimate, a value of 1.0 is recommended. A different value may be used; e.g., if DTOR is much greater than 1.0, primarily rotational deflection will occur; if DTOR is much less than 1.0, primarily linear deflection will occur.
8. If a SPLINE2 element only references one grid point, the job will fail without a message in the GI Module.
9. The USAGE field allows you to specify that the particular spline interpolant defined in this entry is to be used for just the force transformation (FORCE) or just the displacement transformation (DISP) or for both (BOTH). See Remark 5. of the SPLINE1 Bulk Data entry.

## SPLINE3 Aeroelastic Constraint Equation

Defines a constraint equation for aeroelastic problems. Useful for control surface constraints.

### Format:

| 1       | 2   | 3     | 4     | 5    | 6     | 7  | 8  | 9     | 10 |
|---------|-----|-------|-------|------|-------|----|----|-------|----|
| SPLINE3 | EID | CAERO | BOXID | COMP | G1    | C1 | A1 | USAGE |    |
|         | G2  | C2    | A2    |      | -etc. |    |    |       |    |

### Example:

|         |      |     |      |   |   |   |     |  |  |
|---------|------|-----|------|---|---|---|-----|--|--|
| SPLINE3 | 7000 | 107 | 109  | 6 | 5 | 3 | 1.0 |  |  |
|         | 43   | 5   | -1.0 |   |   |   |     |  |  |

| Describer | Meaning                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EID       | Unique spline identification number. (Integer > 0)                                                                                                                                          |
| CAERO     | Identification number of the macro-element on which the element to be interpolated lies. (Integer > 0)                                                                                      |
| BOXID     | Identification number of the aerodynamic element; i.e., the box number. (Integer > 0)                                                                                                       |
| COMP      | The component of motion to be interpolated. See Remark 4. (One of the Integers 1, 2, 3, 4, 5, or 6.)                                                                                        |
| Gi        | Grid point identification number of the independent grid point. (Integer > 0)                                                                                                               |
| Ci        | Component numbers in the displacement coordinate system. (One of the Integers 1 through 6 for grid points, or 0 for scalar points.)                                                         |
| Ai        | Coefficient of the constraint relationship. (Real)                                                                                                                                          |
| USAGE     | Spline uage flag to determine whether this spline applies to the force transformation, displacement transformation or both. FORCE, DISP or BOTH. See Remark 6. (Character; Default = BOTH). |

### Remarks:

1. The independent grid points and components must refer to degrees-of-freedom in the g-set.
2. The constraint is given by

$$u_d = \sum A_i u_i$$

where:

$u_d$  = value of the dependent component of the aerodynamic element

$u_i$  = displacement at grid Gi, component Ci.

3. The SPLINE3 EID must be unique with respect to all SPLINEi entries.

4. The allowable components by CAEROi entry type are indicated by an “X” in the table below:

| Entry Type  | COMP |   |   |   |   |
|-------------|------|---|---|---|---|
|             | 1    | 2 | 3 | 5 | 6 |
| CAERO1      |      |   | X | X |   |
| CAERO2      |      | X | X | X | X |
| CAERO3      |      |   | X |   |   |
| CAERO4      |      |   | X | X | X |
| CAERO5      |      |   | X | X | X |
| 3D Geometry | X    | X | X | X | X |

COMP = 2: lateral displacement

COMP = 3 transverse displacement

COMP = 5: pitch angle

COMP = 6: relative control angle for CAERO4 and CAERO5 yaw angle for CAERO2.

For general 3D aerodynamic geometries the components numbers refer to axes of the Aerodynamic Coordinate System  $(u_x, u_y, u_z, \theta_x, \theta_y, \theta_z)$ .

5. For Strip theory and Piston theory, the COMP = 6 control surface relative angle is positive when the trailing edge has a negative z-deflection in the element coordinate system (see the [MSC Nastran Aeroelastic Analysis User's Guide](#)).
6. The USAGE field allows you to specify that the particular spline interpolant defined in this entry is to be used for just the force transformation (FORCE) or just the displacement transformation (DISP) or for both (BOTH). See Remark 5. of the SPLINE1 Bulk Data entry.

## SPLINE4 Surface Spline Methods

Defines a curved surface spline for interpolating motion or forces for aeroelastic problems on general aerodynamic geometries.

### Format:

| 1       | 2     | 3     | 4      | 5     | 6    | 7  | 8    | 9     | 10 |
|---------|-------|-------|--------|-------|------|----|------|-------|----|
| SPLINE4 | EID   | CAERO | AELIST |       | SETG | DZ | METH | USAGE |    |
|         | NELEM | MELEM | FTYPE  | RCORE |      |    |      |       |    |

### Example:

|         |   |     |     |  |    |    |     |  |  |
|---------|---|-----|-----|--|----|----|-----|--|--|

|---------|---|-----|-----|--|----|----|-----|--|--|

| Describer | Meaning                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Unique spline identification number. (Integer > 0)                                                                                                                                                           |
| CAERO     | Identification number of aerodynamic component that defines the interpolation surface. (Integer > 0)                                                                                                         |
| AELIST    | Identification of an AELIST entry listing the boxes or aerodynamic grid points to be interpolated using this spline. See Remark 2. (Integer > 0)                                                             |
| SETG      | Identification number of a SET1 entry that lists the structural grid points to which the spline is attached. (Integer > 0)                                                                                   |
| DZ        | Linear attachment flexibility. (Real $\geq 0.0$ ; Default = 0.0)                                                                                                                                             |
| METH      | Spline method:<br>IPS      Infinite Plate Spline (Default)<br>TPS      Thin Plate Spline<br>FPS      Finite Plate Spline<br>RIS      Radial Interpolation Spline                                             |
| USAGE     | Spline usage flag to determine whether this spline applies to the force transformation, displacement transformation or both. Legal values are FORCE, DISP or BOTH. See Remark 3. (Character, Default = BOTH) |
| NELEM     | The number of FE elements along the local x-axis if using the FPS option. (Integer > 0; Default = 10)                                                                                                        |
| MELEM     | The number of FE elements along the local y-axis if using the FPS option. (Integer > 0; Default = 10)                                                                                                        |
| FTYPE     | Selects the radial interpolation function to be used with the RIS option:<br>WF0      C0 continuous Wendland function                                                                                        |

| Describer | Meaning                                                                      |
|-----------|------------------------------------------------------------------------------|
|           | WF2      C2 continuous Wendland function (Default)                           |
| RCORE     | Radius of support of radial interpolation function. (Real > 0.0; no Default) |

**Remarks:**

1. The attachment flexibility (units of area) is used for smoothing the interpolation. If DZ = 0.0, the spline will pass through all deflected grid points. If DZ is much greater than the spline area, a least squares plane fit will be applied. Intermediate values will provide smoothing.
2. For aerodynamic meshes input using AEGRID/AEQUAD4/AETRIA3 entries, the AELIST items are AEGRIDS. For the Mach Box method, the AELIST refers to the aerodynamic grids (x,y pairs on the AEFACCT entry). For all other aero methods, the AELIST items are box id's.
3. The USAGE field allows you to specify that the particular spline interpolant defined in this entry is to be used for just the force transformation (FORCE) or just the displacement transformation (DISP) or for both (BOTH). See Remark 5. of the SPLINE1 Bulk Data entry.
4. NELEM and MELEM are used only for the METH=FPS and are required only when the defaults are not adequate.
5. FTYPE and RCORE used only with METH=RIS. FTYPE=WF0 uses a Wendland function:

$$\phi\left(\frac{r}{r_c}\right) = \left(1 - \frac{r}{r_c}\right)_t^2$$

while FTYPE = WF2 uses

$$\phi\left(\frac{r}{r_c}\right) = \left(1 - \frac{r}{r_c}\right)_t^4 \left(4\frac{r}{r_c} + 1\right)$$

where

$$(y)_t = \begin{cases} y & \text{if } y > 0 \\ 0 & \text{if } y < 0 \end{cases}$$

**SPLINE5**

## Linear Spline

Defines a 1D beam spline for interpolating motion and/or forces for aeroelastic problems on aerodynamic geometries.

**Format:**

| 1       | 2    | 3     | 4      | 5     | 6    | 7  | 8     | 9     | 10 |
|---------|------|-------|--------|-------|------|----|-------|-------|----|
| SPLINE5 | SID  | CAERO | AELIST |       | SETG | DZ | DTOR  | CID   |    |
|         | DTHX | DTHY  |        | USAGE | METH |    | FTYPE | RCORE |    |

**Example:**

|         |    |   |    |      |    |  |  |   |  |
|---------|----|---|----|------|----|--|--|---|--|
| SPLINE5 | 5  | 8 | 12 |      | 60 |  |  | 3 |  |
|         | 1. |   |    | BOTH |    |  |  |   |  |

| Describer     | Meaning                                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID           | Unique spline identification number (Integer > 0)                                                                                                                                                                      |
| CAERO         | Identification number of aerodynamic component that defines the interpolation surface. (Integer > 0)                                                                                                                   |
| AELIST        | Identification of an AELIST entry listing the boxes or aerodynamic grid points to be interpolated using this spline. See Remark 6. (Integer > 0)                                                                       |
| SETG          | Refers to an SETi entry that lists the structural grid points to which the spline is attached. (Integer > 0)                                                                                                           |
| DZ            | Linear attachment flexibility. (Real $\geq$ 0.0; Default = 0.0)                                                                                                                                                        |
| DTOR          | Torsional flexibility ratio (EI/GJ) for the bending in the zy-plane. This value is ignored for slender bodies since they have no torsion; see Remark 7. (Real > 0.0; Default = 1.0; ignored for CAERO2 bodies.)        |
| CID           | Rectangular coordinate system that defines the y-axis of the spline and the xy- and yz-planes for bending. Not used for bodies, CAERO2. (Integer $\geq$ 0)                                                             |
| DTHX,<br>DTHY | Rotational attachment flexibility. DTHX is for rotation about the spline's x-axis (the bending rotations). DTHY is for rotation about the spline's y-axis (torsion); however, it is used for bending of bodies. (Real) |
| USAGE         | Spline usage flag to determine whether this spline applies to the force transformation, displacement transformation or both. FORCE, DISP or BOTH. See Remark 8. (Character; Default = BOTH)                            |
| METH          | Spline method:<br>BEAM          Beam Spline (Default)<br>RIS            Radial Interpolation Spline                                                                                                                    |
| FTYPE         | Selects the radial interpolation function to be used with the RIS option:                                                                                                                                              |

| Describer | Meaning                                                                      |
|-----------|------------------------------------------------------------------------------|
|           | WF0            C0 continuous Wendland function                               |
|           | WF2            C2 continuous Wendland function. (Default)                    |
| RCORE     | Radius of support of radial interpolation function. (Real > 0.0; no Default) |

**Remarks:**

1. The interpolated points (k-set) will be defined by aero boxes.
2. The spline axis for panels is the projection of the y-axis of coordinate system CID, projected onto the plane of the panel. For bodies, the interpolating beam (y-axis) is parallel to the x-axis of the aerodynamic coordinate system; the z-axis is taken from the referenced CID and x is made orthogonal.
3. The flexibilities DZ, DTHX and DTHY are used for smoothing. (Zero attachment flexibility values imply rigid attachment; i.e., no smoothing, whereas negative values of DTHX or DTHY imply infinity, therefore, no attachment.) See the [MSC Nastran Aeroelastic Analysis User's Guide](#) for a discussion of special cases.
4. The continuation entry is required.
5. The SPLINE5 EID must be unique with respect to all SPLINEi entries.
6. For aerodynamic meshes input using AEGRID/AEQUAD4/AETRIA3 entries, the AELIST items are AEGRIDS. For the Mach Box method, the AELIST refers to the aerodynamic grids (x,y pairs on the AEFAC entry). For all other aero methods, the AELIST items are box id's.
7. DTOR is the ratio of axial rotational to bending deflection and, in lieu of a more accurate estimate, a value of 1.0 is recommended. A different value may be used; e.g., if DTOR is much greater than 1.0, primarily rotational deflection will occur; if DTOR is much less than 1.0, primarily linear deflection will occur. The values will affect the results only if the structural grids over constrain the motion of the interpolating beam. Slender bodies have no torsional motion, so these values will not be used for CAERO2 entries.
8. The USAGE field allows you to specify that the particular spline interpolant defined in this entry is to be used for just the force transformation (FORCE) or just the displacement transformation (DISP) or for both (BOTH). See Remark 5. of the SPLINE1 Bulk Data entry.
9. FTYPE and RCORE are only used for METHOD=RIS. See Remark 5. on the SPLINE 4 entry for descriptions of the Wendland functions.

## SPLINE6

### 3D Finite Surface Spline

Defines a 6DOF or 3DOF finite surface spline for interpolating motion and/or forces between two meshes.

#### Format:

| 1       | 2      | 3      | 4      | 5      | 6      | 7   | 8       | 9     | 10 |
|---------|--------|--------|--------|--------|--------|-----|---------|-------|----|
| SPLINE6 | EID    | CAERO  | AELIST |        | SETG   | DZ  | METHOD  | USAGE |    |
|         | VSTYPE | VSLIST | I2VNUM | D2VNUM | METHVS | DZR | METHCON | NGRID |    |
|         | ELTOL  | NCYCLE | AUGWEI |        |        |     |         |       |    |

#### Example:

|         |      |   |    |   |     |  |      |      |  |
|---------|------|---|----|---|-----|--|------|------|--|
| SPLINE6 | 5    | 8 | 12 |   | 60  |  | FPS6 | DISP |  |
|         | AERO | 2 | 4  | 4 | VS6 |  |      |      |  |

| Describer | Meaning                                                                                                                                                                                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EID       | Unique spline identification number. (Integer > 0)                                                                                                                                                                                                              |
| CAERO     | Aero panel (CAEROi entry ID) that is to be interpolated. See Remarks 2. and 4. (Integer > 0 or blank)                                                                                                                                                           |
| AELIST    | Identification of an AELIST entry listing the boxes or aerodynamic grid points to be interpolated using this spline. See Remark 2. (Integer > 0)                                                                                                                |
| SETG      | Refers to an SETi entry that lists the structural grid points to which the spline is attached. (Integer > 0)                                                                                                                                                    |
| DZ        | Linear attachment flexibility. (Real $\geq 0.0$ ; Default = 0.0)                                                                                                                                                                                                |
| METHOD    | Method for the spline fit. Either FPS3 or FPS6. See Remark 5. (Character; Default = FPS6)                                                                                                                                                                       |
| USAGE     | Spline usage flag to determine whether this spline applies to the force transformation, displacement transformation or both. FORCE, DISP or BOTH. See Remark 3. (Character; Default = BOTH)                                                                     |
| VSTYPE    | Virtual surface connectivity type. Either AERO or STRUC. (Character; Default = AERO)                                                                                                                                                                            |
| VSLIST    | Identification number of an AELIST entry listing quadrilateral and/or triangular shell elements of the VSTYPE mesh which define the connectivity of the virtual surface mesh. See Remark 2. (Integer > 0 or can be blank if CAERO is not blank and VSTYPE=AERO) |
| I2VNUM    | The minimum number of structural mesh points to connect to each virtual mesh point. See Remarks 7., 8. and 9. (0 < Integer; Default = 3)                                                                                                                        |
| D2VNUM    | The minimum number of aero mesh points to connect to each virtual mesh point. See Remarks 7., 8. and 9. (0 < Integer; Default = 3)                                                                                                                              |

| Describer | Meaning                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| METHVS    | Similar to METHOD, this field chooses whether or not to include the rotational degrees-of-freedom of virtual surface. Either VS6 or VS3. See Remark 5. (Character, Default VS6)                        |
| DZR       | Rotational attachment flexibility. (Real $\geq$ 0.0; Default = 0.0)                                                                                                                                    |
| METHCON   | Method used to determine RBE3 connecting points between the meshes. Either NODEPROX or CIRCBIAS. See Remarks 7., 8. and 9. (Character; Default = NODEPROX)                                             |
| NGRID     | Number of closest grids that are used to determine the element list that is used to define the RBE3 elements. Only valid for METHCON=CIRCBIAS. See Remarks 7. and 9. (Integer > 0; Default = 1)        |
| ELTOL     | Tolerance used to determine whether or not a node projects onto an element of the mesh. Specified as % of element size. Only valid for METHCON=CIRCBIAS. See Remarks 7. and 9. (Real; Default = 100.0) |
| NCYCLE    | Maximum number of cycles used to find elements onto which the nodes project. Only valid for METHCON=CIRCBIAS. See Remark 7. and 9. (Integer > 0; Default = 3)                                          |
| AUGWEI    | RBE3 weighting factor augmentation parameter. Only valid for METHCON=CIRCBIAS. See Remarks 7. and 9. (Real $\geq$ 0.0; Default = 0.0)                                                                  |

**Remarks:**

1. The flexibilities DZ and DZR are used for smoothing. (Zero attachment flexibility values will imply rigid attachment (i.e., no smoothing). The DZ and DZR values are used to derive stiffness of the translational and rotational (respectively) bushing stiffnesses. Bushing elements are placed between the interpolating surface and the connections to the dependent and independent grids.
2. If an aerodynamic mesh is entered using AEGRID/AETRIA3/AEQUAD4 entries, the CAERO ID is not required and the AELIST refers to the element ID's of the aero mesh. In this scenario, if VSTYPE=AERO, VSLIST must point to an AELIST that defines the virtual surface mesh by identifying the aerodynamic elements that make up the surface. For the Mach Box method, the AELIST refers to the aerodynamic grids (x,y pairs on the AEFAC entry). For all other aero methods, the AELIST items are box id's.
3. The USAGE field allows you to specify that the particular spline interpolant defined in this entry is to be used for just the force transformation (FORCE) or just the displacement transformation (DISP) or for both (BOTH). See Remark 5. of the SPLINE1 Bulk Data entry.
4. CAERO2 entries are not supported. The CAERO entry may be blank unless points from a CAERO4 or a CAERO5 are specified. The list of splined points may span multiple aerodynamic components. If the spline defines points from multiple CAERO4 or CAERO5 entries, then any one of the referenced CAERO IDs is valid input.
5. The METHOD option provides a choice in using all 6 degrees of freedom (FPS6) on the independent points or only the translational degrees of freedom (FPS3) in connecting between the virtual surface and the independent points. Similarly, there is a choice in connecting the virtual surface to the dependent points (METHVS).

6. The connection between the independent points (structural) and the dependent points (aero) is made through a virtual surface whose mesh is defined by elements listed in the VSLIST (these are either AERO box id's or STRUCtural shell elements (CQUAD4, CQUADR, CTRIA3 ,CTRIAR).
7. To bind the points to the virtual surface, a connection is made between the points and the surface using automatically generated virtual RBE3 elements. Two methods exist to choose which independent mesh points are connected to each dependent mesh point: nodal-proximity (NODEPROX) and circular bias (CIRCBIAS).
8. The nodal proximity method selects the closest independent mesh points to each dependent mesh point. The actual number of points will depend on the user inputs I2VNUM and D2VNUM as well as collinearity checks. Larger values will spread the connectivity (smearing). Smaller values allow for more concentration (with additional points added as necessary for collinearity).
9. The circular bias method uses elements of the virtual mesh in an attempt to select independent mesh points that encircle each dependent mesh point. This method will be restricted to the case where the virtual mesh is the target mesh.

This method will do the following:

- For each splined dependent mesh node, find the closest NGRID splined independent mesh node(s).
- Assemble the list of virtual mesh elements that use the closest node(s).
- Check each of these elements to see if the dependent node projects onto the element in the element's mean plane normal direction. Note that this check may be computationally expensive, so it is performed only to the "possible" elements, not the entire virtual mesh. The projection check will contain a user-defined tolerance, ELTOL, to expand the area of the element that is acceptable for a match.
- If the dependent node does not project onto any element, use the candidate element's nodes to expand the list of elements to check. Repeat the projection check (the original elements will not be rechecked). Repeat this process up to NCYCLE times.
- All elements that are found to encompass the dependent node (and there may be more than one due to curvature) will be selected to move forward.
- Assemble the list of all splined nodes that connect the selected elements.
- Generate RBE3 elements based on this node list. An optional user-defined input parameter, AUGWEI, will be used to augment the RBE3 weighting factors with the following formula:  
$$\text{weight} = (\text{NE} - 1) \cdot \text{AUGWEI} + 1$$

where NE is the number of elements that are connected with the RBE3 node.

## SPLINE7 Finite Beam Spline

Defines a 6DOF finite beam spline for interpolating motion and/or forces between two meshes.

### Format:

| 1       | 2   | 3     | 4      | 5     | 6      | 7   | 8    | 9     | 10 |
|---------|-----|-------|--------|-------|--------|-----|------|-------|----|
| SPLINE7 | EID | CAERO | AELIST |       | SETG   | DZ  | DTOR | CID   |    |
|         |     |       |        | USAGE | METHOD | DZR | IA2  | EPSBM |    |

### Example:

|         |   |   |    |      |      |  |  |   |  |
|---------|---|---|----|------|------|--|--|---|--|
| SPLINE7 | 5 | 8 | 12 |      | 60   |  |  | 3 |  |
|         |   |   |    | BOTH | FBS6 |  |  |   |  |

| Describer | Meaning                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EID       | Unique spline identification number. (Integer > 0)                                                                                                                                          |
| CAERO     | Aero panel (CAEROi entry ID) that is to be interpolated. See Remark 6. (Integer > 0 or blank)                                                                                               |
| AELIST    | Identification of an AELIST entry listing the boxes or aerodynamic grid points to be interpolated using this spline. See Remark 2. (Integer > 0)                                            |
| SETG      | Refers to an SETi entry that lists the structural grid points to which the spline is attached. (Integer > 0)                                                                                |
| DZ        | Linear attachment flexibility. (Real $\geq$ 0.0; Default = 0.0)                                                                                                                             |
| DTOR      | Ratio of the beam bending stiffness to the beam torsional stiffness. See Remark 3.. (Real > 0.0; Default = 1.0)                                                                             |
| USAGE     | Spline usage flag to determine whether this spline applies to the force transformation, displacement transformation or both. FORCE, DISP or BOTH. See Remark 4. (Character, Default = BOTH) |
| CID       | Rectangular coordinate system that defines the y-axis of the spline and the xy- and yz-planes for bending. Not used for bodies, CAERO2. (Integer $\geq$ 0)                                  |
| METHOD    | Method for the spline fit. Either FBS3 or FBS6. See Remark 5. (Character; Default = FBS6)                                                                                                   |
| DZR       | Rotational attachment flexibility. (Real $\geq$ 0.0; Default = 0.0)                                                                                                                         |
| IA2       | Ratio of the beam bending stiffness to the beam extensional stiffness. (Real > 0.0; Default = 1.0)                                                                                          |
| EPSBM     | Ratio of the minimum beam length to the total beam length. See Remark 7. (Real > 0.0; Default = 0.01)                                                                                       |

**Remarks:**

1. The flexibilities DZ and DZR are used for smoothing. (Zero attachment flexibility values will imply rigid attachment (i.e., no smoothing). The DZ and DZR values are used to derive stiffness of the translational and rotational (respectively) bushing stiffnesses. Bushing elements are placed between the interpolating beam and the connections to the dependent and independent grids.
2. For aerodynamic meshes input using AEGRID/AEQUAD4/AETRIA3 entries, the AELIST items are AEGRIDS. For the Mach Box method, the AELIST refers to the aerodynamic grids (x,y pairs on the AEFAC entry). For all other aero methods, the AELIST items are box id's.
3. DTOR is the ratio of axial rotational to bending deflection and, in lieu of a more accurate estimate, a value of 1.0 is recommended. A different value may be used; e.g., if DTOR is much greater than 1.0, primarily rotational deflection will occur; if DTOR is much less than 1.0, primarily translational deflection will occur. The values will affect the results only if the structural grids over constrain the motion of the interpolating beam. Slender bodies have no torsional motion, so these values will not be used for CAERO2 entries.
4. The USAGE field allows you to specify that the particular spline interpolant defined in this entry is to be used for just the force transformation (FORCE) or just the displacement transformation (DISP) or for both (BOTH). See Remark 5. of the SPLINE1 Bulk Data entry.
5. The FBS3 method will map only the three translational degrees of freedom. The FBS6 method will map all six degrees of freedom.
6. CAERO2 entries are not supported. The CAERO entry may be blank unless points from a CAERO4 or a CAERO5 are specified. The list of splined points may span multiple aerodynamic components. If the spline defines points from multiple CAERO4 or CAERO5 entries, then any one of the referenced CAERO IDs is valid input.
7. EPSBM is the minimum length of a SPLINE7 beam as a fraction of the total SPLINE7 FEM length. Thus, an EPSBM value of 0.01 (Default), would produce a minimum beam length that is 1% of the total FEM length. Defining a value of EPSBM that is smaller than 0.01 will decrease the minimum length and potentially increase the number of beams used to define the SPLINE7 FEM.

## SPLINEX

## Externally-Evaluated Spline

Defines the input for a spline that will be evaluated with a user-supplied procedure.

### Format:

| 1       | 2      | 3      | 4       | 5      | 6      | 7      | 8 | 9     | 10 |

### Describer

### Meaning

|         |                                                                                                                                                                                             |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EID     | Element identification number. (Integer > 0)                                                                                                                                                |
| GROUP   | Group name to which the external spline type belongs. (Character; no Default)                                                                                                               |
| DGCOMP  | The name of an AECOMP or AECOMPL entry that defines the set of points for the dependent mesh. See Remarks 3. and 4. (Character; Default = Blank).                                           |
| IGCOMP  | The name of an AECOMP or AECOMPL entry that defines the set of points for the independent mesh. See Remarks 3. and 4. (Character; Default = Blank).                                         |
| DECOMP  | The name of an AECOMP or AECOMPL entry that defines the set of elements for the dependent mesh. See Remarks 3., 4. and 5. (Character; Default = Blank).                                     |
| IECOMP  | The name of an AECOMP or AECOMPL entry that defines the set of elements for the independent mesh. See Remarks 3., 4. and 5. (Character; Default = Blank).                                   |
| USAGE   | Spline usage flag to determine whether this spline applies to the force transformation, displacement transformation or both. FORCE, DISP or BOTH. See Remark 2. (Character; Default = BOTH) |
| AELIST  | ID of an AELIST that contains a list of user-defined integer data. See Remark 6. (Integer; no Default).                                                                                     |
| AEFACT  | ID of an AEFACT that contains a list of user-defined real data. See Remark 6. (Integer; no Default).                                                                                        |
| AELISTC | ID of an AELISTC that contains a list of user-defined character data. See Remark 6. (Integer; no Default).                                                                                  |

### Remarks:

1. The SPLINEX EID must be unique with respect to all SPLINEi entries.

- The USAGE field allows you to specify that the particular spline interpolant defined in this entry is to be used for just the force transformation (FORCE) or just the displacement transformation (DISP) or for both (BOTH).

$$Fg = [GPkg]^T \{Pk\} \quad (\text{FORCE/BOTH splines are in the transform})$$

$$Uk = [GDkg] \{Ug\} \quad (\text{DISP/BOTH splines are in the transform})$$

In general, the two transforms are done with distinct matrices. Only when ALL splines are of type BOTH is the familiar transpose relationship  $[GPkg]^T = [GDkg]$  satisfied. The default behavior (BOTH for all splines) is compatible with version of MSC Nastran prior to Version 70.5.

In general, the USAGE field can be used to apply aerodynamic forces to the structure from aerodynamic panels that are intended NOT to move (USAGE=FORCE) or to apply structural displacements to aerodynamic grids whose forces are not to be applied to the structure (USAGE=DISP). The DISP option is somewhat esoteric in that you are then suggesting that the aeroelastic effect of the surface is important while its forces are not. (In other words, only the forces arising from its effects on other surfaces is important.) While there may be circumstances where this is true, it is unlikely. Take care that you included all the FORCES from aerodynamic panels that are important by including them in either FORCE or BOTH spline(s). Nastran will NOT issue a warning unless ALL forces are omitted. All displacements may be omitted without warning (and is a means to perform “rigid aerodynamic” analyses).

- Typically, for aero-to-structure splines “dependent” means “aerodynamic”, and “independent” means “structural”.
- If the component defines a structural mesh, then the grid component may be left blank and the list of grids will be obtained from the element component member’s connectivity. Both may not be left blank.
- Structural elements referenced by DECOMP and IECOMP are limited to the following element types: CQUAD4, CQUADR, CTRIA3, CTRIAR. In one list, elements from the different types may not share the same ID.
- The data that are defined on the AELIST, AEFACT, and AELISTC have no meaning to Nastran. These lists are generic containers for data that has meaning to the spline server. Note that the AELIST is limited to numbers greater than zero.

## SPLINRB Rigid Body Spline

Defines a rigid body spline for interpolating motion or forces for aeroelastic problems on general aerodynamic geometries.

### Format:

|         |     |       |        |       |    |    |    |    |    |
|---------|-----|-------|--------|-------|----|----|----|----|----|
| 1       | 2   | 3     | 4      | 5     | 6  | 7  | 8  | 9  | 10 |

|         | G3  | C3    | G4     | C4    | G5 | C5 | G6 | C6 |    |

### Example:

|         |     |    |   |      |      |        |  |  |  |
|---------|-----|----|---|------|------|--------|--|--|--|
| SPLINRB | 110 | 20 | 2 | BOTH | 1093 | 123456 |  |  |  |
|---------|-----|----|---|------|------|--------|--|--|--|

| Describer | Meaning                                                                                                                                                                                        |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Unique spline identification number. (Integer > 0)                                                                                                                                             |
| CAERO     | Identification number of aerodynamic component that defines the interpolation surface. (Integer > 0 or blank)                                                                                  |
| AELIST    | Identification of an AELIST entry listing the boxes or aerodynamic grid points to be interpolated using this spline. See Remark 3. (Integer > 0)                                               |
| USAGE     | Spline usage flag to determine whether this spline applies to the force transformation, displacement transformation or both. Legal values are FORCE, DISP or BOTH. (Character; Default = BOTH) |
| Gi        | Identification number of a structural grid point. (Integer > 0)                                                                                                                                |
| Ci        | Component numbers: Any unique combination of the Integers 1 through 6 with no embedded blanks.                                                                                                 |

### Remarks:

1. Up to six structural grid points can be used to select exactly 6 structural degrees-of-freedom that define the motion of the rigid body.
2. The selected degrees-of-freedom must define statically determinate supports of the rigid body.
3. For aerodynamic meshes input using AEGRID/AEQUAD4/AETRIA3 entries, the AELIST items are AEGRIDS. For the Mach Box method, the AELIST refers to the aerodynamic grids (x,y pairs on the AEFACT entry). For all other aero methods, the AELIST items are box id's.

## SPOINT

### Scalar Point Definition

Defines scalar points.

#### Format:

|        |     |     |     |     |     |     |     |     |    |

| 1      | 2   | 3   | 4   | 5   | 6   | 7   | 8   | 9   | 10 |
| SPOINT | ID1 | ID2 | ID3 | ID4 | ID5 | ID6 | ID7 | ID8 |    |

#### Example:

|        |   |    |   |   |    |   |  |  |  |
|--------|---|----|---|---|----|---|--|--|--|
| SPOINT | 3 | 18 | 1 | 4 | 16 | 2 |  |  |  |
|--------|---|----|---|---|----|---|--|--|--|

#### Alternate Format and Example:

|        |     |        |     |  |  |  |  |  |  |
|--------|-----|--------|-----|--|--|--|--|--|--|
| SPOINT | ID1 | “THRU” | ID2 |  |  |  |  |  |  |
| SPOINT | 5   | THRU   | 649 |  |  |  |  |  |  |

| Describer | Meaning                                                                                       |
|-----------|-----------------------------------------------------------------------------------------------|
| IDi       | Scalar point identification number. (0 < Integer < 100,000,000; For “THRU” option, ID1 < ID2) |

#### Remarks:

1. A scalar point defined by its appearance on the connection entry for a scalar element (see the CELASi, CMASSi, and CDAMPi entries) need not appear on an SPOINT entry.
2. All scalar point identification numbers must be unique with respect to all other structural, scalar, fluid and extra (EPOINT) points. However, duplicate scalar point identification numbers are allowed in the input.
3. This entry is used primarily to define scalar points appearing in single-point or multipoint constraint equations to which no scalar elements are connected.
4. If the alternate format is used, all scalar points ID1 through ID2 are defined.
5. For a discussion of scalar points, see [Scalar Elements \(CELASi, CMASSi, CDAMPi\)](#) in the *MSC Nastran Reference Guide*.

## SPRELAX Spline Relaxation

Defines relaxation of a spline based on an adjacent spline.

### Format:

| 1       | 2    | 3    | 4     | 5    | 6     | 7 | 8 | 9 | 10 |
|---------|------|------|-------|------|-------|---|---|---|----|
| SPRELAX | SID1 | SID2 | LIST2 | DREF | LIST1 |   |   |   |    |

### Example:

|         |     |     |    |     |  |  |  |  |  |
|---------|-----|-----|----|-----|--|--|--|--|--|
| SPRELAX | 140 | 130 | 50 | 5.0 |  |  |  |  |  |
|---------|-----|-----|----|-----|--|--|--|--|--|

| Describer | Meaning                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID1      | Identification number of spline to be modified (may be a blended spline and need not be unique). (Integer > 0)                                               |
| SID2      | Identification number of adjacent spline (may be a blended spline). (Integer > 0)                                                                            |
| LIST2     | Identification of an AELIST entry listing aerodynamic grid points that define the curve used in the relaxation . (Integer > 0) (See Remark 1.)               |
| DREF      | Reference Distance (Real > 0.) (See Remark 2.)                                                                                                               |
| LIST1     | Identification number of an AELIST entry listing aerodynamic grid points of the spline to be modified (optional). (Integer > 0; Default = 0) (See Remark 3.) |

### Remarks:

1. The aerodynamic grid points referenced by LIST2 have to define a curve. The curve need not be contiguous, i.e., coincident grid points are allowed. The order of the grid points is arbitrary.
2. Displacements of spline 1 are modified according to

$$u_{1mod} = u_1 + f\left(\frac{r}{DREF}\right)(u_2 - u_1)$$

where  $r$  is the shortest distance of the aerodynamic grid point considered from the curve,  $u_2$  is the displacement from spline 2, interpolated to the position on the curve which is closest to the aerodynamic grid point considered, and function  $f$  is defined by

$$f(x) = \begin{cases} 1 - x & \text{if } x \leq 1 \\ 0 & \text{if } x > 1 \end{cases}$$

3. If LIST1 is defined, only aerodynamic grid points contained in the referenced list are processed. Otherwise, all aerodynamic grid points of spline 1 are processed.

## STOCHAS

## Randomization of Model Parameters

Specifies statistics used in randomization selected model parameters.

### Format:

| 1       | 2   | 3      | 4   | 5   | 6 | 7 | 8 | 9 | 10 |
|---------|-----|--------|-----|-----|---|---|---|---|----|
| STOCHAS | SID | PENTRY | CDF | CoV | m |   |   |   |    |
|         |     | MENTRY | CDF | CoV | m |   |   |   |    |
|         |     | CENTRY | CDF | CoV | m |   |   |   |    |
|         |     | LOADS  | CDF | CoV | m |   |   |   |    |
|         |     | SPCD   | CDF | CoV | m |   |   |   |    |

### Example 1: (Randomize all element and material properties with the default settings.)

|         |     |        |  |  |  |  |  |  |  |
|---------|-----|--------|--|--|--|--|--|--|--|
| STOCHAS | 100 | PENTRY |  |  |  |  |  |  |  |
|         |     | MENTRY |  |  |  |  |  |  |  |

### Example 2: (Randomize material properties with CoV = 0.1 and loadings with CoV = 0.3 and default multipliers of standard deviations.)

|         |     |        |       |     |  |  |  |  |  |
|---------|-----|--------|-------|-----|--|--|--|--|--|
| STOCHAS | 200 | LOADS  | GAUSS | 0.3 |  |  |  |  |  |
|         |     | MENTRY | GAUSS | 0.1 |  |  |  |  |  |

| Describer | Meaning                                                                                              |
|-----------|------------------------------------------------------------------------------------------------------|
| SID       | Unique identification number that is selected by the STOCHASTICS Case Control command. (Integer > 0) |
| “PENTRY”  | Flag for randomizing real values on all the element property entries. (Character)                    |
| “MENTRY”  | Flag for randomizing real values on all the independent material property entries. (Character)       |
| “CENTRY”  | Flag for randomizing real values on all the connectivity entries. (Character)                        |
| “LOADS”   | Flag for randomizing real values on all the load entries. (Character)                                |
| “SPCD”    | Flag for randomizing real values on all the SPCD entries. (Character)                                |
| CDF       | Name of a cumulative distribution function. See Remark 2. (Character; Default = GAUSSIANS or blank). |
| CoV       | Coefficient of variance. (Real > 0; Default = 0.05)                                                  |
| m         | Number of standard deviations. See Remark 3. (Real > 0; Default = 3.0)                               |

### Remarks:

1. At least one flag must exist but they can be placed in any order.
2. Currently, only Gaussian distributions are supported.

3. The range of a random variable is defined as  $(\mu - m \cdot \sigma, \mu + m \cdot \sigma)$  where  $\mu$  is the mean of the random variable (or the value of one analysis model parameter on a Bulk Data entry),  $\sigma$  is the standard deviation that is related to  $\mu$ , CoV by  $\sigma = \text{CoV} \cdot \mu$  and  $m$  is the multiplier of the standard deviations.
4.  $m \cdot \text{CoV}$  must be  $< 1.0$ .

## SUPAX

## Conical Shell Fictitious Support

Defines determinate reaction degrees-of-freedom in free bodies for conical shell analysis.

### Format:

| 1     | 2    | 3    | 4  | 5    | 6    | 7  | 8 | 9 | 10 |
|-------|------|------|----|------|------|----|---|---|----|
| SUPAX | RID1 | HID1 | C1 | RID2 | HID2 | C2 |   |   |    |

### Example:

|       |   |   |   |  |  |  |  |  |  |
|-------|---|---|---|--|--|--|--|--|--|
| SUPAX | 4 | 3 | 2 |  |  |  |  |  |  |
|-------|---|---|---|--|--|--|--|--|--|

| Describer | Meaning                                                                                        |
|-----------|------------------------------------------------------------------------------------------------|
| RIDi      | Ring identification number. (Integer > 0)                                                      |
| HIDi      | Harmonic identification number. (Integer ≥ 0)                                                  |
| Ci        | Conical shell degree-of-freedom numbers. (Any unique combination of the Integers 1 through 6.) |

### Remarks:

1. SUPAX is allowed only if an AXIC entry is also present.
2. Up to 12 degrees-of-freedom may appear on a single entry.
3. Degrees-of-freedom appearing on SUPAX entries may not appear on MPCAX, SPCAX, or OMITAX entries.
4. For a discussion of conical shell analysis, see [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide*.

## SUPPORT Fictitious Support

Defines determinate reaction degrees-of-freedom in a free body.

### Format:

| 1       | 2   | 3  | 4   | 5  | 6   | 7  | 8   | 9  | 10 |
|---------|-----|----|-----|----|-----|----|-----|----|----|
| SUPPORT | ID1 | C1 | ID2 | C2 | ID3 | C3 | ID4 | C4 |    |

### Example:

|         |    |     |  |  |  |  |  |  |  |
|---------|----|-----|--|--|--|--|--|--|--|
| SUPPORT | 16 | 215 |  |  |  |  |  |  |  |
|---------|----|-----|--|--|--|--|--|--|--|

| Describer       | Meaning                                                                                                                                                |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID <sub>i</sub> | Grid or scalar point identification number. (Integer > 0)                                                                                              |
| C <sub>i</sub>  | Component numbers. (Integer 0 or blank for scalar points. Any unique combination of the Integers 1 through 6 for grid points with no embedded blanks.) |

### Remarks:

1. The SUPPORT entry specifies reference degrees-of-freedom for rigid body motion. It is not intended to be used in place of a constraint (i.e., SPC<sub>i</sub> entry or PS on the GRID entry).
2. SUPPORT and/or SUPPORT1 entries are required to perform inertia relief in static analysis (SOL 101) if PARAM,INREL,-1 is specified. But if PARAM,INREL,-2 is specified, then SUPPORT and/or SUPPORT1 entries are not required.
3. Be careful not to spell SUPPORT with two Ps.
4. Degrees-of-freedom specified on this entry form members of the mutually exclusive r-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
5. From 1 to 24 support degrees-of-freedom may be defined on a single entry.
6. See [Rigid Body Supports](#) in the *MSC Nastran Reference Guide* for a discussion of supported degrees-of-freedom (members of the r-set).
7. An alternative to SUPPORT is the SUPPORT1 entry, which is requested by the SUPPORT1 Case Control command.
8. The SUPPORT entry is not allowed in SOLs 106 and 129. SOL 400 does not support ASET<sub>i</sub>, OMIT<sub>i</sub>, BSET<sub>i</sub>, CSET<sub>i</sub>, SUPORT<sub>i</sub>, and QSET<sub>i</sub> except in the following situations:
  - a. Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding "Standard linear physics". This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
  - b. Linear perturbation with:

- i. EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
    - ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
  - c. Superelements defined with BEGIN SUPER may contain ASETi, OMITi, BSETi, CSETi, and QSETi entries.
9. The SUPPORT entry may not be used in contact in SOL 101 as this is tantamount to executing SOL 400. Additionally, INREL, -2 will not in general converge in SOL101 if run with contact. Inertial Relief is supported in SOL400 and invoked with the Case Control Command IRLOAD. Therefore, SOL101 runs with contact should be converted over to SOL400.

## SUPPORT1 Fictitious Support, Alternate Form

Defines determinate reaction degrees-of-freedom (r-set) in a free body-analysis. SUPPORT1 must be requested by the SUPPORT1 Case Control command.

### Format:

| 1        | 2   | 3   | 4      | 5   | 6  | 7   | 8  | 9 | 10 |
|----------|-----|-----|--------|-----|----|-----|----|---|----|
| SUPPORT1 | SID | ID1 | C1     | ID2 | C2 | ID3 | C3 |   |    |
|          | ID4 | C4  | -etc.- |     |    |     |    |   |    |

### Example:

|          |   |    |     |  |  |  |  |  |  |
|----------|---|----|-----|--|--|--|--|--|--|
| SUPPORT1 | 5 | 16 | 215 |  |  |  |  |  |  |
|----------|---|----|-----|--|--|--|--|--|--|

| Describer | Meaning                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Identification number of the support set. See Remark 1. (Integer > 0)                                                                                  |
| Idi       | Grid or scalar point identification number. (Integer > 0)                                                                                              |
| Ci        | Component numbers. (Integer 0 or blank for scalar points. Any unique combination of the Integers 1 through 6 for grid points with no embedded blanks.) |

### Remarks:

- The SUPPORT1 entry specifies reference degrees-of-freedom for rigid body motion. It is not intended to be used in place of a constraint; (i.e., SPCi entry or PS on the GRID entry).
- SUPPORT and/or SUPPORT1 entries are required to perform inertia relief in static analysis (SOL 101) if PARAM,INREL,-1 is specified. But if PARAM,INREL,-2 is specified, then SUPPORT and/or SUPPORT1 entries are not required.  
In SOL 101, PARAM,INREL,-1 must also be specified or the SUPPORTi entries will be treated as constraints.
- SUPPORT1 must be requested by the SUPPORT1 Case Control command. The degrees-of-freedom specified on SUPPORT1 will be combined with those on the SUPPORT entry.
- Be careful not to spell SUPPORT with two Ps.
- Degrees-of-freedom specified on this entry form members of the mutually exclusive r-set. They may not be specified on other entries that define mutually exclusive sets. See [Degree-of-Freedom Sets](#) for a list of these entries.
- From 1 to 18 support degrees-of-freedom may be defined on a single entry.
- See [Rigid Body Supports](#) in the *MSC Nastran Reference Guide* for a discussion of supported degrees-of-freedom (members of the r-set).
- In superelement analysis, SUPPORT1 may be specified for points belonging to the residual structure only.

9. The SUPORT entry is not allowed in SOLs 106 and 129. SOL 400 does not support ASETi, OMITi, BSETi, CSETi, SUPORTi, and QSETi except in the following situations:
  - a. Multidisciplinary (linear) analysis. See Remark 3-e. under the ANALYSIS Case Control command regarding “Standard linear physics”. This means there are no subcases for nonlinear analysis using ANALYSIS=NLSTATICS, NLTRAN, HSTAT or HTRAN.
  - b. Linear perturbation with:
    - i. EXTSEOUT Case Control command for external superelement creation. This includes runs with AVLEXB Case Control command.
    - ii. ADAMSMNF Case Control command. These entries must be specified in the BEGIN BULK FLXBDY section. See Remark 21. under the ADAMSMNF Case Control command.
  - c. Superelements defined with BEGIN SUPER may contain ASETi, OMITi, BSETi, CSETi, and QSETi entries.
10. The SUPORT1 entry may not be used in contact in SOL 101 as this is tantamount to executing SOL 400. Additionally, INREL, -2 will not in general converge in SOL101 if run with contact. *Inertial Relief is supported in SOL400 and invoked with the Case Control Command IRLOAD.* Therefore, SOL101 runs with contact should be converted over to SOL400.

## SUPPORT6

## Inertia Relief for SOL 600

Inertia relief used in SOL 600 only.

### Format:

| 1        | 2   | 3    | 4      | 5 | 6 | 7 | 8    | 9 | 10 |
|----------|-----|------|--------|---|---|---|------|---|----|
| SUPPORT6 | SID | METH | IREMOV |   |   |   | IDS1 |   |    |

### Example:

|          |   |   |    |  |  |  |     |  |  |
|----------|---|---|----|--|--|--|-----|--|--|
| SUPPORT6 | 0 | 3 | 1  |  |  |  | 101 |  |  |
| SUPPORT6 | 4 | 3 | -2 |  |  |  |     |  |  |

| Describer | Meaning                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Set ID corresponding to a Case Control SUPPORT1 entry or zero. (Integer; Default = 0)                                                                                                             |
|           | 0 If this is the only SUPPORT6 entry, use this SUPPORT6 entry for all subcases. If there are multiple SUPPORT6 entries, use the one with SID=0 for Marc increment zero.                           |
|           | N Use this SUPPORT6 entry for the subcase specified by Case Control SUPPORT1=N.                                                                                                                   |
|           | Different SUPPORT6 entries can be used for each subcase if desired and different subcases can use different methods.                                                                              |
|           | If there is only one SUPPORT6 entry (with SID=0), no Case Control SUPPORT1 entries are necessary.                                                                                                 |
| METH      | Method to use (Integer; Default = 0)                                                                                                                                                              |
|           | 0 Inertia relief is not active for this subcase.                                                                                                                                                  |
|           | 3 Use the "Support Method", usually specified using param,inrel,-1 for other solution sequences. (See Remark 1.) Input will come from all SUPPORT entries and those SUPPORT1 entries with ID=SID. |
| IREMOV    | Method to retain or remove inertia relief from a previous subcase (Integer; Default = 1).                                                                                                         |
|           | 1 Retain inertia relief conditions from previous subcase.                                                                                                                                         |
|           | -1 Remove inertia relief loads immediately.                                                                                                                                                       |
|           | -2 Remove inertia relief loads gradually                                                                                                                                                          |

| Describer | Meaning                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IDS1      | <p>IREMOV should be blank or 1 unless METH is 0.</p> <p>ID of SUPORT1 entries to be used if METH=3 and SID=0 (Integer; no Default).</p> <p>For METH=3, only SUPORT1 entries with ID=IDS1 will be used in Marc increment zero. All SUPORT entries will be used.</p> <p>(Used for METH=3 when SID=0 ONLY.)</p> |

**Remark:**

1. The parameter INREL is ignored by SOL 600.

## SURFINI

## Eulerian Initialization Surface

Defines a surface that is used for initialization of regions of an Eulerian mesh. Used in SOL 700 only.

### Format:

|         |     |      |       |         |       |   |   |   |    |
|---------|-----|------|-------|---------|-------|---|---|---|----|
| 1       | 2   | 3    | 4     | 5       | 6     | 7 | 8 | 9 | 10 |
| SURFINI | VID | BSID | COVER | REVERSE | CHECK |   |   |   |    |

### Example:

|         |     |    |  |  |  |  |  |  |  |
|---------|-----|----|--|--|--|--|--|--|--|
| SURFINI | 100 | 37 |  |  |  |  |  |  |  |
|---------|-----|----|--|--|--|--|--|--|--|

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VID       | Unique number of an SURFINI region entry. Referenced from TICEUL1. (Integer > 0; Required)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| BSID      | ID of a BSURF entry defining the initialization surface. (Integer > 0; Required)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| COVER     | The processing strategy for Eulerian elements inside and outside of the initialization surface. (Character; Default = INSIDE)<br><br><div style="display: flex; justify-content: space-between;"> <div style="width: 15%;">INSIDE</div> <div>The part of the Eulerian elements that lie inside the closed volume of the initialization surface will obtain the initial conditions belonging to that surface.</div> </div> <div style="display: flex; justify-content: space-between; margin-top: 10px;"> <div style="width: 15%;">OUTSIDE</div> <div>The part of the Eulerian elements that lie outside the closed volume of the initialization surface will obtain the initial conditions that belong to that surface</div> </div> |
| REVERSE   | Auto reverse switch for SURFINI surface segments. (Character; Default = ON)<br><br><div style="display: flex; justify-content: space-between;"> <div style="width: 15%;">ON</div> <div>If necessary, the normals of the SURFINI surface segments are automatically reversed so that they all point in the same general direction and give a positive closed volume.</div> </div> <div style="display: flex; justify-content: space-between; margin-top: 10px;"> <div style="width: 15%;">OFF</div> <div>The segments normals are not automatically reversed.</div> </div>                                                                                                                                                           |
| CHECK     | Checking switch for SURFINI surface segments. (Character; Default = ON)<br><br><div style="display: flex; justify-content: space-between;"> <div style="width: 15%;">ON</div> <div>The normals of the segments are checked to see whether they all point in the same general direction and give a positive closed volume.</div> </div> <div style="display: flex; justify-content: space-between; margin-top: 10px;"> <div style="width: 15%;">OFF</div> <div>The segment normals are not checked.</div> </div> <p>When “REVERSE” is set to “ON”, “CHECK” is automatically set to “ON”.</p>                                                                                                                                         |

### Remarks:

1. All initialization surfaces must form a multifaceted closed volume.

2. An initialization surface can only be used to initialize regions in a Eulerian mesh with appropriate initial conditions. An initialization surface cannot be used as a coupling surface, contact surface or rigid surface.
3. The normal vectors of all segments that form the initialization surface must point in the same general direction, and result in a positive, closed volume. Setting the “REVERSE” option to “ON” ensures that this condition is satisfied, regardless of how segments are initially defined.
4. The “COVER” option determines how Eulerian elements that are (partially) inside or outside of the initialization surface are processed.

## SWLDPRM

### Parameters for CFAST, CWELD, and CSEAM Connector Elements

Overrides default values of parameters for CFAST, CWELD, and CSEAM connectivity search.

**Format:**

| PARAMi                    | Name of the connector parameter. Allowable names are listed in <a href="#">Table 9-39</a> . (Real or Integer)                                                  |
| VALi                      | Value of the parameter. See <a href="#">Table 9-39</a> (Real or Integer)                                                                                       |
| CFAST,<br>CWELD,<br>CSEAM | Keywords to control element type specific parameters. Any parameter following a keyword is applied only to that element type. See Remarks 2 and 3. (Character) |

Table 9-39 PARAMi Names and Descriptions

| Name                 | Type                                          | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|-----------------------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACTVTOL<br>(SOL 600) | Integer $\geq 0$<br>Integer $\leq 2211$       | 1111    | Parameter controlling the behavior of PROJTOL for the different CWELD connection methods. This parameter is entered as an integer and is converted to a four-character string. If its value is less than 1000, the string will be prepended with zeros. The first character (from the left) controls the behavior when method PARTPAT is used. The second controls the behavior when method ELPAT is used. The third controls the behavior when method ELEMID is used and the fourth controls the behavior when method GRIDID is used. For ALIGN the PROJTOL tolerance has no significance. Each digit ( $d_i$ ) in the string can have the value 0 or 1 or 2, where the value 2 only has significance for the methods ELPAT or PARTPAT. The values have the following meaning:<br>0 = PROJTOL is completely deactivated<br>1 = PROJTOL is activated for ELEMID and GRIDID, PROJTOL is activated in initial projections for ELPAT, PROJTOL is only activated over free edges of the patch in auxiliary projections for ELPAT and in initial and auxiliary projections for PARTPAT. Free edges have no neighbors within the set that defines the complete surface.<br>2 = PROJTOL is always activated |
| CHKRUN               | Integer 0, 1, 2                               | 0       | Stop run or allow run to continue after the connectivity elements are generated.<br>0=abort on first error;<br>1=stop after connectivity has been checked; 2=continue run if no errors are found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| CNRAGLI              | $90.0 \leq \text{Real} \leq 180.0$<br>or -1.0 | 160.0   | CSEAM only. Minimum angle allowed between the free edges of shell elements EIDSA and EIDEA or shell elements EIDSB and EIDEB. The CSEAM will not be generated if the angle is less than the value of CNRAGLI. If set to -1.0, the check will be skipped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| CNRAGLO              | $0.0 \leq \text{Real} \leq 90.0$ or<br>-1.0   | 20.0    | CSEAM only. Maximum angle allowed between the normal vectors of shell elements EIDSA and EIDEA or shell elements EIDSB and EIDEB. The CSEAM will not be generated if the angle is greater than the value of CNRAGLO. | DLDMIN<br>(SOL 600) | Real > 0.0                       | 0.2     | Default value for LDMIN, the smallest ratio of length to characteristic diameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DRATIO              | $1.0 \leq \text{Real} \leq 10.0$ | 1.0     | CFAST or CWELD (PARTPAT and ELPAT) only. Increases the Connector patch diameter and is used to stiffen the connector patch when a loss of stiffness occurs for the FEM model as mesh size is made smaller. See Remark 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| EPSITR<br>(SOL 600) | Real > 0.0                       | 1.0E-5  | Tolerance to terminate the iteration process for finding the projection on a patch. If the parametric coordinate change in an iteration is less than EPSITR the projection is accepted as converged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| GMCHK               | Integer 0, 1, 2, 3               | 0       | <p>For CSEAM, CWELD with ELPAT or PARTPAT format, and CFAST only.</p> <p>0=no geometry error checks;</p> <p>1=check errors of the CSEAM across a cutout or over a corner with patch elements in plane or out of plane;</p> <p>2=check errors of CSEAM and output all candidate shell elements if an error is encountered.</p> <p>If GMCHK=1 or 2 and an error is detected, the program will loop back to search for next candidate element until a good pair of connection is found or all adjacent elements have been checked. In the latter case, a user fatal message 7595, 7638, or 7667 will be issued. A UFM 7595 is issued if the normal angles between the patches at end GS or the patches at end GE exceed the value of GSPROJ; a UFM 7638 is issued if either the length of the seam spans more than three elements or the seam spans a cutout; a UFM 7667 is issued if the normal angles between the top patches at GS and GE or the normal angles between the bottom patches at GS and GE exceeds CNRAGLO or if the angle between the free edges of the shell elements onto which GS and GE are projected is less than CNRAGLI.</p> <p>3=check backward projections for CWELD with ELPAT or PARTPAT format and CFAST. See Remark 8.</p> |

| GSPROJ              | $0.0 \leq \text{Real} \leq 90.0$<br>or -1.0 | 20.0<br>(-89.0 for SOL 600) | Maximum angle allowed between the normal vectors of shell A and shell B. The connector element will not be generated if the angle between these two normal vectors is greater than the value of GSPROJ. For CSEAM, see also GMCHK for additional error checks using GSPROJ. If GSPROJ is set to -1.0 (or -89.0 for SOL 600), the program will skip the checking of GSPROJ.                                                                                                                                                                                                                 |
| GSTOL               | $\text{Real} \geq 0.0$                      | 0.0                         | For CFAST or CWELD (PARTPAT and ELPAT only), if $\text{GSTOL} > 0.0$ and the distance between GS and the projected point GA or GB is greater the GSTOL, a UFM 7549 is issued and the CFAST or CWELD is rejected. For CSEAM, if $\text{GSTOL} > 0.0$ and the distance between GS and the projected point GSA or GSB or the distance between GE and the projected point GEA or GEB is greater than the GSTOL, a UFM 7549 is issued and the CSEAM is rejected.                                                                                                                                |
| MAXEXP<br>(SOL 600) | Integer > 0                                 | 2                           | Parameter to control the maximum number of expansions in the search for projections of the auxiliary nodes. First the master patch will be searched. If no projection is found on the master patch a first expansion will be made including all neighboring patches of the master patch. If no projection is found on any of the new patches a second expansion will be made including all neighbors of the patches tried so far. This process continues until the number of expansions exceeds MAXEXP. Two patches are neighbors if they share at least one node in their connectivities. |

| MAXITR<br>(SOL 600) | Integer > 0                       | 20                          | The maximum number of iterations allowed in the iteration process for finding the projection on a patch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| NREDIA              | Integer 0, 1, 2, 3, 4, 5, 6, 7, 8 | 0                           | CFAST or CWELD (PARTPAT and ELPAT) only. Maximum number of times the diameter D is reduced in half in case a complete projection of all points has not been found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| PROJTOL             | $0.0 \leq  \text{Real}  \leq 1.0$ | 0.02<br>(0.199 for SOL 600) | <p>For CFAST or CWELD, tolerance to accept the projected point GA or GB if the computed coordinates of the projection point lie outside the shell element but is located within <math> \text{PROJTOL} </math>*(dimension of the shell element forming the patch). For the CSEAM, a projection from GS/GE will always be attempted as if <math>\text{PROJTOL}=0.0</math> and if one cannot be found then the non-zero value of <math> \text{PROJTOL} </math> will be used.</p> <p>Regardless of the value of SWLDPRM PROJTOL, the algorithm starts by assuming a zero projection tolerance for the projections of GA/GB for the CWELD option "PARTPAT" or the CFAST option "PROP" and for GAHi/GBHi for the CWELD options "PARTPAT" and "ELPAT" and any CFAST option. The tolerance is increased by 0.02 until a projection is found or the PROJTOL value is reached.</p> <p>This can be turned off while computing the auxiliary grid projection onto EIDA/EIDB or onto the adjacent elements of EIDA/EIDB by setting <math>\text{PROJTOL} = -\text{value}</math> where <math>0.0 \leq \text{value} \leq 1.0</math>. In this case, the projection calculation starts at tolerance = <math> \text{PROJTOL} </math>. For the rest of the projection search, the algorithm reverts back to the iteration starting at tolerance = 0.0.</p> |
| WMASS               | Integer 0, 1                      | 0                           | For CWELD to react to a non-zero density 1 value is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

The default results in uniform weighting ( $f_1 = 1$ ).                                                                                                                                                                                                                                                    |

Table 9-39 PARAMi Names and Descriptions

| Name                | Type                     | Default | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|--------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GSCURV<br>(SOL 600) | $-90 < \text{Real} < 90$ | 20.0    | <p>Maximum angle allowed between the normal vectors of a patch to which an auxiliary node projects and its corresponding auxiliary and master patches. It provides a measure to monitor the curvature of a surface and to recognize patches that belong to, for example, stiffeners. A connection is not generated if the angle between the normal vectors is greater than <math>90 - \text{GSCURVE}</math> meaning that the patches are almost normal to each other. In that case, the patch is reflected and the search proceeds to the next patch in the list. If the angle is between zero and GSCURV, no message is displayed. If the angle is between GSCURV and <math>90 - \text{GSCURV}</math>, a large angle warning is displayed. The following three tests are performed in the order given below when GSCURV is positive:</p> <p>If <math>0 &lt; \text{angle} &lt; \text{GSCURVE} \geq \text{OK}</math><br/> If <math>\text{GSCURVE} &lt; \text{angle} &lt; 90 - \text{GSCURV} &gt;</math> trigger a warning.<br/> If <math>\text{angle} &gt; 90 - \text{GSCURV} \geq \text{reject}</math>.</p> <p>Note that the warning condition is never triggered when <math>\text{GSCURV} &gt; 45</math> as it is overruled by the reject condition.</p> <p>If GSCURV is negative, the projection is always accepted and a warning is issued when the angle is larger than <math> \text{GSCURV} </math>.</p> |
| SCLSKIN             | $\text{Real} \geq 0.0$   | 0.0     | <p>CFAST or CWELD (PARTPAT and ELPAT) only. If set to a value <math>&gt; 0.0</math> the CFAST or CWELD connector will be stiffened by increasing the bending moment of inertia ratio by SCLSKIN of the shell elements involved in the connector patch. SCLSKIN is Factor used to stiffen the connector patch when a loss of stiffness occurs for the FEM model as mesh size is made smaller. An initial recommended value is 0.1; See Remark 10..</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Remarks:**

1. This entry changes the default settings of control variables for the CFAST, CWELD, and CSEAM connector elements. None of the parameters of this entry are required. Only one SWLDPRM entry is allowed in the Bulk Data Section.

2. If any of the key words CFAST, CWELD, and CSEAM does not appear on this entry, then a parameter set on this entry is considered “global” and applies to all the connector elements in the model. Any parameter set on this entry that comes before a key word CFAST, CWELD, or CSEAM is considered global.
3. Any parameter set on the entry that comes after a key word such as CFAST will only apply to that connector element type until another key word such as CSEAM is encountered. If a parameter is defined for a specific connector type that does not apply to that connector type then it will be ignored.
4. Blank fields are allowed for readability. However, a parameter name must be followed in the immediately following field by the corresponding parameter value. If the parameter name falls in the field just before a continuation field, then its parameter value must be placed in the first field after the continuation marker of the continuation entry.
5. Connectivity information is generated for the CFAST and CSEAM elements. For the CWELD elements, connectivity information is only generated for the PARTPAT, ELPAT, ELEMID, and GRIDID options.
6. The details of individual connector connectivity can be found on the appropriate CFAST, CWELD, and CSEAM Bulk Data entries.
7. The CHKRUN parameter must be global.
8. Backward connections sometimes occur if the patch is near the boundary of a structure and there is a "vertical" flange associated with the patch elements. In this case GMCHK=3 may be used to prevent backward projection. See the figure below. If GMCHK=3 and a backward projection is detected, the program will not connect this projected shell element. Instead, it will continue searching iterations until a satisfying connection is reached.

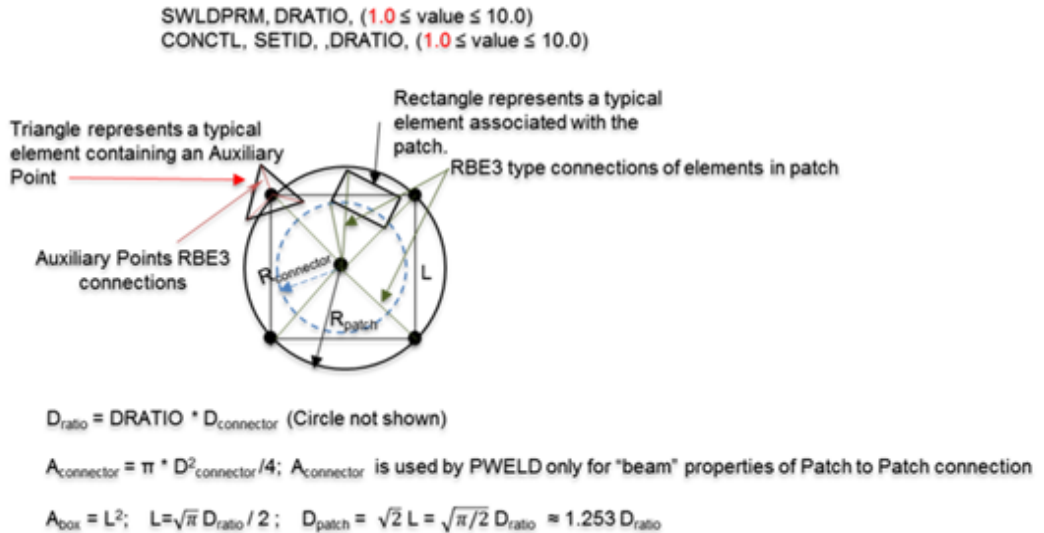

9. If the GSMOVE specification limit is reached for the CFAST or the CWELD with options "PARTPAT" and "ELPAT" and SWLDPRM NREDIA  $\geq 0$ ; then the diameter of the connector will be reduced by half to compute new locations of auxiliary grids. If necessary this is repeated until the NREDIA specified value is reached.
  - a. When the NREDIA  $\neq 0$  is initiated, the GS at its current location is used for GSMOVE  $\geq 0$ .
  - b. When the NREDIA  $\neq 0$  is initiated, the GS at its original location is used for the new option GSMOVE  $< 0$ .

- Connector contribution to a structural model's overall stiffness is sensitive to the model's mesh size and the orientation of the connector relative to the mesh. Thus, the discretization process itself may cause, for example, a model using a fine mesh to be stiffer in torsion than a corresponding model using a coarse mesh. Also for production models that correlate well with test, refining the mesh may cause an inherent overall loss of stiffness due to mesh refinement and hence loss of correlation.

To allow the user some control over model stiffness, the new connectors (CWELD with ELPAT or PARTPAT or CFAST) are provided with two options to provide additional connector stiffness. The two options may be used individually or in combination.

The first stiffening technique is activated by "SWLDPRM, DRATIO, (1.0 ≤ value ≤ 10.0)" or "CONCTL, SETID, ,DRATIO, (1.0 ≤ value ≤ 10.0)". For this option the diameter,  $D_{ratio}$ , is defined as  $D_{ratio} = DRATIO * D_{connector}$ . This results in the diameter of the patch taking a value of  $D_{patch} = \sqrt{\pi/2} D_{ratio}$ . The default of DRATIO is a value=1.0 which implies the diameter of the patch is computed in the standard fashion. For the patch to patch connection for the "beam" properties of the CWELD, the area is still computed as  $A_{connector} = \pi D_{connector}^2 / 4$  as defined in the PWELD entry.

A *disadvantage* of this method is that as DRATIO is increased using the global command SWLDPRM, DRATIO, *value*?; some connector elements may begin to fail because they may no longer be able to find a patch projection.

To overcome this, the "SWLDPRM, NREDIA, *Integer\_value*" can be increased to a value as high as *Integer\_value* = 8 to allow failing welds to halve their patch diameters up to eight times. Whenever a connector has its diameter reduced a message such as: "DA IS REDUCED BY HALF TO 8.8623E+00" when PRTSW diagnostic output is requested. In this message the DA is computed as : DA = L/2.

If the "SWLDPRM, NREDIA, *Integer\_value*" is not an approach the user wishes to pursue, then for these failing elements, the bulk data entry CONCTL, SETID, ,DRATIO, value can be used to define a set for failing connectors and set a value of DRATIO for these connectors that allows them to find a projection.

The second stiffening algorithm attempts, based on the diameter of the connector, to determine a measure of the mesh discretization.

This feature is activated by setting "SWLDPRM, SCLSKIN > 0.0" or "CONCTL, SETID, SCLSKIN > 0.0". The default is a value = 0.0 which implies no stiffening. When activating the "SWLDPRM, SCLSKIN, real value" option for the first time with a new FEM, it is recommended that an initial value = 0.1 be used.

Depending on the complexity of the model and the overall mesh size and the number of connectors within the model and the diameter of the connectors relative to the mesh, the *default value* tends to stiffen a structural model from about 0.4% to about 4%. A value of SCLSKIN=10.0 stiffens coarser mesh models by about 10% to 11% and finer mesh models by about 2% to 6%.

The contribution of the stiffening algorithm to the overall stiffness of the FEM model eventually reaches a limit. For example, a very large value SCLSKIN=100 increases the stiffness of the models overall by only about 0.1% to 2% over the stiffness obtained for SCLSKIN=10.

For a correlated structural model evaluated at a specific mesh size, *with an aim to refine the mesh for some portion of this model containing connectors*, while leaving other portions containing connectors with an unmodified mesh, it is recommended that the "SCLSKIN, *real value*" be entered on the CONCTL bulk data entry referring to the connectors within the area of the refined mesh. Different refined mesh areas within the structural model can have different values of SCLSKIN associated to the specific connectors in each refined region.

For post processing affected shell elements, an updated EPT table is available after module MODGM2. It contains the PSKNSHL record that correlates the property data of the shells involved and a list of shell elements for each patch modified.

Neither of these stiffening methods have any effect on the mass computations of the model.

11. This entry is ignored in part super-elements. Inside the part super-elements, the default settings will be applied.
12. If Modules are present then this entry may only be specified in the main Bulk Data section.

## Entries T-Y

### TABD1MD TABLED1 entries internal modification in SOL 600

Defines how TABLED1 entries are internally modified in SOL 600.

SOL 600 usually requires that the first point of all TABLED1 entries used to describe time histories start with time/amplitude of (0.0, 0.0). If the user omits this entry, all TABLED1 entries that do not start with (0.0, 0.0) will be modified internally to add two points at the start, the first at (0.0, 0.0) and the second at (0.001, V1) where V1 is the first amplitude of the original TABLED1 entry for that curve.

#### Format

| 1       | 2    | 3    | 4   | 5   | 6  | 7  | 8  | 9 | 10 |
|---------|------|------|-----|-----|----|----|----|---|----|
| TABD1MD | TID1 | THRU | ID2 | MOD | T2 | A2 | T3 |   |    |

#### Example:

|         |   |      |   |   |      |     |      |  |  |
|---------|---|------|---|---|------|-----|------|--|--|
| TABD1MD | 1 | THRU | 5 | 1 | .002 | 1.0 | .003 |  |  |
|---------|---|------|---|---|------|-----|------|--|--|

| Descriptor | Meaning                                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID1        | First TABLED1 ID. (Integer > 0; no Default required)                                                                                                                |
| ID2        | Last TABLED1 ID to which MOD, T1 and A1 apply. See Remark 2. (Integer; Default = ID1)                                                                               |
| MOD        | Flag indicating whether or not to modify TABLED1 entries with ID in the range ID1 to ID2. (Integer; Default = 1)<br>0 Do not modify the table<br>1 Modify the table |
| T1         | New time for the second point. See Remark 1. (Real; Default = 0.001)                                                                                                |
| A1         | New amplitude of the second point. See Remark 2. (Real; Default = 1.0)                                                                                              |
| T2         | New time for the third point. See Remark 1. (Real; Default = 0.002)                                                                                                 |

#### Remarks:

1. If MOD=1, all TABLED1 entries with ID's in described by ID1 to ID2 will be modified to add two points to the beginning of the each table. The first point will be at (0.0, 0.0) the second point will be at (T1,A1). The original first point will be modified to be at time T3.
2. All TABLED1 entries in the range ID1 to ID2 will be modified as indicated. Repeat this entry as many times as necessary to specify all TABLED1 ID's that should either be modified or not be modified.
3. Make sure to set MOD=0 to all TABLED1 entries that are not used to describe time history loading.
4. The ID1 to ID2 range may include values that do not have any TABLED1 ID's in the model.

5. If all TABLED1 entries are to be modified or if they do not all start with the same T2, A2, T3 values, PARAM,MTALBD1M PARAM,MTALBD1T may be entered.

## TABDMP1 Modal Damping Table

Defines modal damping as a tabular function of natural frequency.

Format:

| 1       | 2   | 3    | 4  | 5  | 6  | 7  | 8      | 9 | 10 |
|---------|-----|------|----|----|----|----|--------|---|----|
| TABDMP1 | TID | TYPE |    |    |    |    |        |   |    |
|         | f1  | g1   | f2 | g2 | f3 | g3 | -etc.- |   |    |

Example:

|         |     |        |     |        |      |  |  |  |  |
|---------|-----|--------|-----|--------|------|--|--|--|--|
| TABDMP1 | 2   |        |     |        |      |  |  |  |  |
|         | 2.5 | .01057 | 2.6 | .01362 | ENDT |  |  |  |  |

| Describer      | Meaning                                                                 |
|----------------|-------------------------------------------------------------------------|
| TID            | Table identification number. (Integer > 0)                              |
| TYPE           | Type of damping units. (Character: “G”, “CRIT”, or “Q”; Default is “G”) |
| f <sub>i</sub> | Natural frequency value in cycles per unit time. (Real ≥ 0.0)           |
| g <sub>i</sub> | Damping value. (Real)                                                   |

Remarks:

1. Modal damping tables must be selected with the Case Control command SDAMPING = TID.
2. The frequency values, f<sub>i</sub>, must be specified in either ascending or descending order, but not both.
3. Discontinuities may be specified between any two points except the two starting points or two end points. For example, in [Figure 9-146](#) discontinuities are allowed only between points f<sub>2</sub> through f<sub>7</sub>. Also, if g is evaluated at a discontinuity, then the average value of g is used. In [Figure 9-146](#), the value of g at f = f<sub>3</sub> is  $g = (g_3 + g_4)/2$ .
4. At least one continuation entry must be specified.
5. Any f<sub>i</sub> or g<sub>i</sub> entry may be ignored by placing “SKIP” in either of the two fields used for that entry.
6. The end of the table is indicated by the existence of “ENDT” in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag “ENDT”.
7. The TABDMP1 uses the algorithm

$$g = g_T(f)$$

where  $f$  is input to the table and  $g$  is returned. The table look-up  $g_T(f)$  is performed using linear interpolation within the table and linear extrapolation outside the table using the last two end points. See [Figure 9-146](#). No warning messages are issued if table data is input incorrectly. See Remark 11.

Figure 9-146 Example of Table Extrapolation and Discontinuity

8. This form of damping is used only in modal formulations of complex eigenvalue analysis, frequency response analysis, or transient response analysis. The type of damping used depends on the solution sequence (structural damping is displacement-dependent, and viscous damping is velocity-dependent). See [Formulation of Dynamic Equations in SubDMAP GMA](#) in the *MSC Nastran Reference Guide* for the equations used.
9. PARAM,KDAMP may be used in solution sequences that perform modal frequency and modal complex analysis, to select the type of damping.

| KDAMP       | Result      |
|-------------|-------------|
| 1 (Default) | $B$ Matrix  |
| -1          | $(1 + ig)K$ |

See [Formulation of Dynamic Equations in SubDMAP GMA](#) in the *MSC Nastran Reference Guide* for a full explanation.

10. If TYPE is “G” or blank, the damping values  $g_i$ , etc., are in units of equivalent viscous dampers, as follows:

$$b_i = \frac{g_i}{\omega_i} K_i$$

(See [Formulation of Dynamic Equations in SubDMAP GMA](#) in the *MSC Nastran Reference Guide*) If TYPE is “CRIT”, the damping values  $g_i$ , etc., are in the units of fraction of critical damping  $C/C_0$ . If TYPE is “Q”, the damping values  $g_i$  are in the units of the amplification or quality factor,  $Q$ . These constants are related by the following equations:

$$C/C_0 = g/2$$

$$Q = \begin{cases} 1/(2C/C_0) \\ 1/g \end{cases}$$

11. A user warning message is used if either of the following conditions is satisfied:
  - a. The modal damping value is computed as a result of extrapolation.
  - b. The computed modal damping value is negative.

For any modal damping value that satisfies condition a or b, the program lists the cyclic frequency and the corresponding modal damping value and indicates whether this value was computed as a result of interpolation or extrapolation. For the latter case, it also indicates whether the extrapolation was beyond the left end of the table or beyond the right end of the table.

If a modal damping value satisfies *both* of the conditions, a and b above (that is, the modal damping value is computed as a result of extrapolation *and* it is negative), the program terminates the job with a user fatal message.

The user can prevent the program from terminating the job as above by specifying MDAMPEXT=1 [or SYSTEM(426)=1] on the NASTRAN statement. The user fatal message mentioned above does inform the user of this avoidance scheme.

12. The modal damping matrix generated by this approach is not affected by the presence of rotors in the model. Also, the circulation terms are not generated for damping corresponding to rotor degrees of freedom.
13. If Modules are present then this entry may only be specified in the main Bulk Data section.

TABL3D

Multi-Dimensional Table

Specifies a table where an entry can be a function of up to 4 variables such as strain, temperature, strain rate, etc for SOL 600 and SOL 400.

Format 0: Simple Table Type 0 - entry is a function of only one variable:

| 1       | 2    | 3  | 4      | 5     | 6     | 7     | 8  | 9  | 10 |
|---------|------|----|--------|-------|-------|-------|----|----|----|
| TABL3D0 | ITID |    | KIND   | EXTRP | ITIDS | ITIDB | SM |    |    |
|         | X1   | Y1 | X2     | Y2    | X3    | Y3    | X4 | Y4 |    |
|         | X5   | Y5 | -etc.- |       |       |       |    |    |    |

Format 1: Multi-Dimensional Table Type 1 - entry is a function of 2, 3, or 4 variables, data entered one row at a time

| 1       | 2      | 3      | 4      | 5      | 6      | 7      | 8      | 9      | 10                |

| 18                        | arc length                                                       | 43 | $\dot{\epsilon}$ (equivalent creep strain rate)                                        | 68 | magnetic field intensity**                            |
| 19                        | relative density (not available for shells)                      | 44 | minor principal strain                                                                 | 69 | equivalent mechanical strain                          |
| 20                        | $\bar{\sigma}$ (equivalent stress)                               | 45 | distance from neutral axis (-1/2, +1/2)                                                | 70 | 1st strain invariant                                  |
| 21                        | magnetic induction**                                             | 46 | normalized distance from neutral axis (-1, +1)                                         | 71 | 2nd strain invariant                                  |

Table 9-40

| Independent Variable Type |                           |    |                                                                   |    |                           |
|---------------------------|---------------------------|----|-------------------------------------------------------------------|----|---------------------------|
| 22                        | velocity                  | 47 | local x-coordinate of layer point for open or closed section beam | 72 | 3rd strain invariant      |
| 23                        | parameter diameter**      | 48 | local y-coordinate of layer point for open or closed section beam | 73 | local strain component    |
| 24                        | X <sub>0</sub> coordinate | 49 | not available                                                     | 74 | damage                    |
| 25                        | Y <sub>0</sub> coordinate | 50 | not available                                                     | 75 | accumulated crack growth  |
|                           |                           |    |                                                                   | 76 | relative sliding velocity |

## Remarks (General):

1. Independent Variable Types marked as 'NOT AVAILABLE' are not available in either SOL 600 or SOL 400. Independent variable types marked with \* are only available in SOL 600. Independent variable types marked with \*\* are only available in SOL 600 through hand-editing of the Marc input file. The rest are available in SOL 600 and SOL 400.
2. Dependent quantities cannot be arbitrary functions of the Independent Variable Types shown in Table 9-40. For e.g., Young's Modulus can be varied with Temperature and Space but cannot be varied with Time. Incorrect tabular settings that are not allowed will be errored out by the program.
3. For time-independent materials, dependent variables (i.e., yield stress) can typically be defined only as a function of temperature, stress/strain data or coordinates. For time-dependent materials, (e.g., creep coefficient), properties can also be defined as a function of time.
4. For contact dependent variables, (i.e., friction coefficient) can typically be defined as a function of temperature, contact body quantities like normal stress, body force, distance from body, relative velocity, etc.
5. If the independent variable is out of range of the table, the user can indicate if the last point in the table should be used or if the table should be extrapolated. Extrapolation means the table is continued with its first or last slope. Care should be taken with extrapolation, particularly for material properties.
6. Independent variable types for coordinates (5, 6, 7) depend on the type of analysis flagged. For a small strain or Total Lagrange or non-mechanical analysis, these coordinates refer to the original coordinates. For Updated Lagrange mechanical analysis, these coordinates refer to the updated
7. At present, options to specify additional tables using ITIDS, ITIDB, ITIDS1, ITIDB1, ... ITIDS4, ITIDB4 are not active and will be ignored if entered.

## Remarks (for SOL 600 only):

1. The function is read by giving NW1 data points (NW4\*NW3\*NW2) times. The program reads the data using the following method.

```
do k4=1, nw4
  do k3=1, nw3
    do k2=1, nw2
      read nw1 values f(X1, K2, K3, K4)
    enddo
  enddo
enddo
```

2. The function is read one value at a time. There are  $NW1 * NW2 * NW3 * NW4$  values. The program uses the values as follows:

```
do k4=1, nw4
  do k3=1, nw3
    do k2=1, nw2
      do k1=1, nw1
        read one value f(K1, K2, K3, K4)
      enddo
    enddo
  enddo
enddo
```

3. The formula can extend from field 2 through field 9 and must be comprised of the items listed previously.
4. This parameter may also be used to control the BOLT entry. For BOLT, the default for  $MMBOLTUS=1$  to achieve the same results as SOL 400. If the results appear to be backwards, set  $MMBOLTUS=-1$ . BOLT and MBOLTUS may not both be entered in the same model.

#### Remarks for SOL 400 only:

1. Independent variable types are typically specified for materials or contact. When material properties are varied through TABL3DX, the tables are honored only for elements with property extensions. For e.g., if TABL3D0 is used in conjunction with MATEP for a CHEXA mesh with PSOLID properties, then the elements should be given the PSLDN1 property extension for the table to be valid. Note that, with default property mapping (NLMOPTS,SPROPMAP,0), the property extensions will be added automatically based on the rules specified in Remark 9. of the NLMOPTS entry.
2. The strains and stresses identified as independent variables depend on the parameters flagged for large displacement.
  - a. For PARAM,LGDISP,-1, the strains and stresses are engineering quantities.
  - b. For PARAM,LGDISP,n ( $n > 0$ ) or with NLMOPTS,LRGSTRN,n ( $n > 0$ ), the strains are typically Logarithmic strains and the stresses are Cauchy Stresses.

**TABLE3D** Tabular Function with Three Variables

Specify a function of three variables for the CORD3G entry only.

Format:

|         |        |      |    |    |    |    |    |    |    |
|---------|--------|------|----|----|----|----|----|----|----|
| 1       | 2      | 3    | 4  | 5  | 6  | 7  | 8  | 9  | 10 |
| TABLE3D | TID    | X0   | Y0 | Z0 | F0 |    |    |    |    |
|         | X1     | Y1   | Z1 | F1 | X2 | Y2 | Z2 | F2 |    |
|         | X3     | Y3   | Z3 | F3 | X4 | Y4 | Z4 | F4 |    |
|         | -etc.- | ENDT |    |    |    |    |    |    |    |

Example:

|         |      |     |     |       |      |      |      |       |  |
|---------|------|-----|-----|-------|------|------|------|-------|--|
| TABLE3D | 128  | 0.  | 0.  | 1.    |      |      |      |       |  |
|         | 7.   | 8.  | 9.  | 100.  | 12.  | 14.  | 11.  | 200.  |  |
|         | 17.  | 18. | 19. | 1100. | 112. | 114. | 111. | 1200. |  |
|         | ENDT |     |     |       |      |      |      |       |  |

| Describer | Meaning                              | Type        | Default  |
|-----------|--------------------------------------|-------------|----------|
| TID       | Table identification number.         | Integer > 0 | Required |
| X0,Y0,Z0  | Offset of the independent variables. | Real        | 0.0      |
| F0        | Offset of the dependent variables.   | Real        | 0.0      |
| Xi,Yi,Zi  | Independent variables.               | Real        | 0.0      |
| Fi        | Dependent variable.                  | Real        | 0.0      |

Remarks:

1. At least two continuation entries must be specified.
2. The value of the function at  $(x,y,z)$  is calculated as

$$f = \frac{\sum_{i=1}^4 \frac{Fi - F0}{d_i}}{\sum_{i=1}^4 \frac{1}{d_i}}$$

where  $f$  are the function values at the four points with the lowest value of

$$d_i^2 = (x - X0 - Xi)^2 + (y - Y0 - Yi)^2 + (z - Z0 - Zi)^2$$

## TABLED1      Dynamic Load Tabular Function, Form 1

Defines a tabular function for use in generating frequency-dependent and time-dependent dynamic loads.

Format:

|         |     |       |       |    |    |    |        |        |    |
|---------|-----|-------|-------|----|----|----|--------|--------|----|
| 1       | 2   | 3     | 4     | 5  | 6  | 7  | 8      | 9      | 10 |
| TABLED1 | TID | XAXIS | YAXIS |    |    |    |        |        |    |
|         | x1  | y1    | x2    | y2 | x3 | y3 | -etc.- | “ENDT” |    |

Example:

|         |      |     |     |     |     |     |      |  |  |
|---------|------|-----|-----|-----|-----|-----|------|--|--|
| TABLED1 | 32   |     |     |     |     |     |      |  |  |
|         | -3.0 | 6.9 | 2.0 | 5.6 | 3.0 | 5.6 | ENDT |  |  |

| Describer | Meaning                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------|
| TID       | Table identification number. (Integer > 0)                                                                                                |
| XAXIS     | Specifies a linear or logarithmic interpolation for the x-axis. See Remarks 6. and 10. (Character: “LINEAR” or “LOG”; Default = “LINEAR”) |
| YAXIS     | Specifies a linear or logarithmic interpolation for the y-axis. See Remarks 6. and 10. (Character: “LINEAR” or “LOG”; Default = “LINEAR”) |
| xi, yi    | Tabular values. (Real)                                                                                                                    |
| “ENDT”    | Flag indicating the end of the table.                                                                                                     |

Remarks:

1. xi must be in either ascending or descending order, but not both.
2. Discontinuities may be specified between any two points except the two starting points or two end points. For example, in [Figure 9-147](#) discontinuities are allowed only between points x2 through x7. Also, if y is evaluated at a discontinuity, then the average value of y is used. In [Figure 9-147](#), the value of y at  $x = x3$  is  $y = (y3 + y4)/2$ . If the y-axis is a LOG axis then the jump at the discontinuity is evaluated as  $y = \sqrt{y3y4}$ .
3. At least one continuation must be specified.
4. Any xi-yi pair may be ignored by placing the character string “SKIP” in either of the two fields.
5. The end of the table is indicated by the existence of the character string “ENDT” in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag “ENDT”.
6. TABLED1 uses the algorithm

$$y = y_T(x)$$

where  $x$  is input to the table and  $y$  is returned. The table look-up is performed using interpolation within the table and extrapolation outside the table using the two starting or end points. See Figure 9-147. The algorithms used for interpolation or extrapolation are:

| AXIS   | YAXIS  | $y_f(x)$                                                                                             |
|--------|--------|------------------------------------------------------------------------------------------------------|
| LINEAR | LINEAR | $\frac{x_j - x}{x_j - x_i} y_i + \frac{x - x_i}{x_j - x_i} y_j$                                      |
| LOG    | LINEAR | $\frac{\ln(x_j/x)}{\ln(x_j/x_i)} y_i + \frac{\ln(x/x_i)}{\ln(x_j/x_i)} y_j$                          |
| LINEAR | LOG    | $\exp\left[\frac{x_j - x}{x_j - x_i} \ln y_i + \frac{x - x_i}{x_j - x_i} \ln y_j\right]$             |
| LOG    | LOG    | $\exp\left[\frac{\ln(x_j/x)}{\ln(x_j/x_i)} \ln y_i + \frac{\ln(x/x_i)}{\ln(x_j/x_i)} \ln y_j\right]$ |

where  $x_j$  and  $y_j$  follow  $x_i$  and  $y_i$ .

No warning messages are issued if table data is input incorrectly.

Figure 9-147 Example of Table Extrapolation and Discontinuity

- Linear extrapolation is not used for Fourier transform methods. The function is zero outside the range of the table.

8. For frequency-dependent loads, xi is measured in cycles per unit time.
9. Tabular values on an axis if XAXIS or YAXIS = LOG must be positive. A fatal message will be issued if an axis has a tabular value  $\leq 0$ .
10. LOG is not supported for SOL 600 or SOL 700. Fields 3 and 4 must be blank.
11. RC network solver only supports LINEAR type XAXIS and YAXIS for thermal analysis.
12. The X-Y plot information resulting from a dynamic response solution (like any response versus frequency in SOLs 108/111 or any response versus time in SOLs 109/112) can be generated in TABLED1 format by using the XYTRAN module via DMAP. The 6th parameter of this module, which is an integer value, can be used for this purpose. Details can be obtained by referring to the description of this module in the DMAP Programmer's Guide.

## TABLED2 Dynamic Load Tabular Function, Form 2

Defines a tabular function for use in generating frequency-dependent and time-dependent dynamic loads. Also contains parametric data for use with the table.

Format:

| 1       | 2   | 3  | 4  | 5  | 6  | 7  | 8      | 9 | 10 |
|---------|-----|----|----|----|----|----|--------|---|----|
| TABLED2 | TID | X1 |    |    |    |    |        |   |    |
|         | x1  | y1 | x2 | y2 | x3 | y3 | -etc.- |   |    |

Example:

|         |      |       |     |      |      |     |     |     |  |
|---------|------|-------|-----|------|------|-----|-----|-----|--|
| TABLED2 | 15   | -10.5 |     |      |      |     |     |     |  |
|         | 1.0  | -4.5  | 2.0 | -4.2 | 2.0  | 2.8 | 7.0 | 6.5 |  |
|         | SKIP | SKIP  | 9.0 | 6.5  | ENDT |     |     |     |  |

| Describer | Meaning                                    |
|-----------|--------------------------------------------|
| TID       | Table identification number. (Integer > 0) |
| X1        | Table parameter. See Remark 6. (Real)      |
| xi, yi    | Tabular values. (Real)                     |

Remarks:

1. xi must be in either ascending or descending order, but not both.
2. Discontinuities may be specified between any two points except the two starting points or two end points. For example, in [Figure 9-148](#) discontinuities are allowed only between points  $x_2$  and  $x_7$ . Also if  $y$  is evaluated at a discontinuity, then the average value of  $y$  is used. In [Figure 9-148](#), the value of  $y$  at  $x = x_3$  is  $y = (y_3 + y_4)/2$ .
3. At least one continuation entry must be specified.
4. Any  $x_i$ - $y_i$  pair may be ignored by placing “SKIP” in either of the two fields.
5. The end of the table is indicated by the existence of “ENDT” in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag “ENDT”.
6. TABLED2 uses the algorithm

$$y = y_T(x - X1)$$

where  $x$  is input to the table and  $y$  is returned. The table look-up is performed using linear interpolation within the table and linear extrapolation outside the table using the two starting or end points. See [Figure 9-148](#). No warning messages are issued if table data is input incorrectly.

Figure 9-148 Example of Table Extrapolation and Discontinuity

7. Linear extrapolation is not used for Fourier transform methods. The function is zero outside the range of the table.
8. For frequency-dependent loads,  $X1$  and  $x_i$  are measured in cycles per unit time.

## TABLED3 Dynamic Load Tabular Function, Form 3

Defines a tabular function for use in generating frequency-dependent and time-dependent dynamic loads. Also contains parametric data for use with the table.

Format:

| 1       | 2   | 3  | 4  | 5  | 6  | 7  | 8      | 9 | 10 |
|---------|-----|----|----|----|----|----|--------|---|----|
| TABLED3 | TID | X1 | X2 |    |    |    |        |   |    |
|         | x1  | y1 | x2 | y2 | x3 | y3 | -etc.- |   |    |

Example:

|         |     |       |      |     |     |     |      |  |  |
|---------|-----|-------|------|-----|-----|-----|------|--|--|
| TABLED3 | 62  | 126.9 | 30.0 |     |     |     |      |  |  |
|         | 2.9 | 2.9   | 3.6  | 4.7 | 5.2 | 5.7 | ENDT |  |  |

| Describer | Meaning |
|-----------|---------|
|-----------|---------|

|        |                                            |
|--------|--------------------------------------------|
| TID    | Table identification number. (Integer > 0) |
| X1, X2 | Table parameters. (Real; X2 ≠ 0.0)         |
| xi, yi | Tabular values. (Real)                     |

Remarks:

1. xi must be in either ascending or descending order, but not both.
2. Discontinuities may be specified between any two points except the two starting points or two end points. For example, in [Figure 9-149](#) discontinuities are allowed only between points  $x_2$  and  $x_7$ . Also if  $y$  is evaluated at a discontinuity, then the average value of  $y$  is used. In [Figure 9-149](#), the value of  $y$  at  $x = x_3$  is  $y = (y_3 + y_4)/2$ .
3. At least one continuation entry must be present.
4. Any xi-yi pair may be ignored by placing "SKIP" in either of the two fields.
5. The end of the table is indicated by the existence of "ENDT" in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag "ENDT".
6. TABLED3 uses the algorithm

$$y = y_T \left( \frac{x - X1}{X2} \right)$$

where  $x$  is input to the table and  $y$  is returned. The table look-up is performed using interpolation within the table and linear extrapolation outside the table using the two starting or end points. See [Figure 9-149](#). No warning messages are issued if table data is input incorrectly.

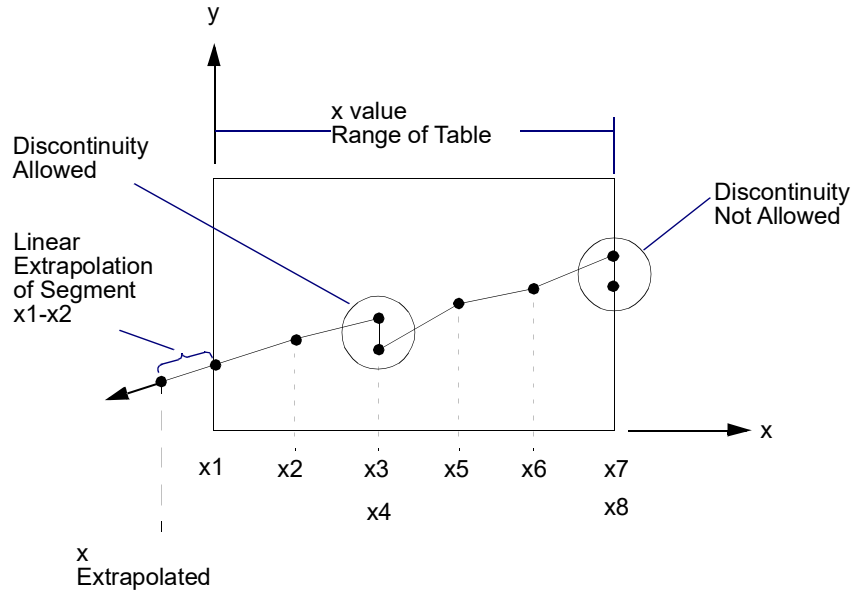

Figure 9-149 Example of Table Extrapolation and Discontinuity

7. Linear extrapolation is not used for Fourier transform methods. The function is zero outside the range of the table.
8. For frequency-dependent loads,  $X_1$ ,  $X_2$ , and  $x_i$  are measured in cycles per unit time.

## TABLED4 Dynamic Load Tabular Function, Form 4

Defines the coefficients of a power series for use in generating frequency-dependent and time-dependent dynamic loads. Also contains parametric data for use with the table.

Format:

|         |     |    |    |    |    |    |        |   |    |
|---------|-----|----|----|----|----|----|--------|---|----|
| 1       | 2   | 3  | 4  | 5  | 6  | 7  | 8      | 9 | 10 |
| TABLED4 | TID | X1 | X2 | X3 | X4 |    |        |   |    |
|         | A0  | A1 | A2 | A3 | A4 | A5 | -etc.- |   |    |

Example:

|         |      |         |        |     |        |      |  |  |  |
|---------|------|---------|--------|-----|--------|------|--|--|--|
| TABLED4 | 28   | 0.0     | 1.0    | 0.0 | 100.   |      |  |  |  |
|         | 2.91 | -0.0329 | 6.51-5 | 0.0 | -3.4-7 | ENDT |  |  |  |

| Describer | Meaning |
|-----------|---------|
|-----------|---------|

|     |                                             |
|-----|---------------------------------------------|
| TID | Table identification number. (Integer > 0)  |
| Xi  | Table parameters. (Real; X2 ≠ 0.0; X3 < X4) |
| Ai  | Coefficients. (Real)                        |

Remarks:

1. At least one continuation entry must be specified.
2. The end of the table is indicated by the existence of “ENDT” in the field following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag “ENDT”.
3. TABLED4 uses the algorithm

$$y = \sum_{i=0}^N A_i \left( \frac{x - X1}{X2} \right)^i$$

where  $x$  is input to the table,  $y$  is returned, and  $N$  is the number of pairs. Whenever  $x < X3$ , use  $X3$  for  $x$ ; whenever  $x > X4$ , use  $X4$  for  $x$ . There are  $N + 1$  entries in the table. There are no error returns from this table look-up procedure.

4. For frequency-dependent loads,  $x_i$  is measured in cycles per unit time.

## TABLED5      Dynamic Load Tabular Function, Form 5

Defines a value as a function of two variables for use in generating frequency-dependent and time-dependent dynamic loads.

Format:

| 1       | 2    | 3      | 4    | 5      | 6    | 7      | 8    | 9      | 10 |
|---------|------|--------|------|--------|------|--------|------|--------|----|
| TABLED5 | TID  |        |      |        |      |        |      |        |    |
|         | X(1) | TID(1) | X(2) | TID(2) | X(3) | TID(3) | X(4) | TID(4) |    |
|         | ...  | ...    | ENDT |        |      |        |      |        |    |

Example:

|         |     |     |      |     |      |     |      |  |  |
|---------|-----|-----|------|-----|------|-----|------|--|--|
| TABLED5 | 52  |     |      |     |      |     |      |  |  |
|         | 0.0 | 101 | 10.0 | 102 | 30.0 | 103 | ENDT |  |  |

| Describer | Meaning                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------|
| TID       | Table identification number. (Integer > 0)                                                                                |
| X(i)      | X value for the function specified by TID(i) (Real; no Default).                                                          |
| TID(i)    | ID of a TABLED1, TABLED2, TABLED3 or TABLED4 defining the function Y for the given value of X. (Integer > 0; no Default). |

Remarks:

1. This table returns a value that is a function of 2 variables  $f(x, y)$ . The first variable value  $x$  is specified on this entry as  $X(i)$ , the function versus  $y$  for the specified value for  $X(i)$  is specified on the referenced table TID(i).
2. When used with the NLRGAP entry to define a frequency dependent gap force as a function of penetration, the frequency values are input as  $X(i)$  and the variation of force vs. penetration is input on a series of TABLED1 entries referenced by the table values TID(i), one for each required change in properties with respect to frequency.
3. 2D linear interpolation is carried out for values of  $(x,y)$  not specified on the tabular entries.
4.  $X(i)$  values must be in ascending order.
5. TABLED5 Usage for frequency as function of temperature:

TABLED5 usage

|         |     |        |     |     |      |   |     |     |  |
|---------|-----|--------|-----|-----|------|---|-----|-----|--|
|         | ID  | E      | G   | NU  |      |   |     | GE  |  |
| MAT1    | 33  | 7.2+10 |     | .3  |      |   |     | .02 |  |
| MAT1F   | 33  | 110    | 111 | 112 |      |   |     | 200 |  |
| TABLED5 | 200 |        |     |     |      |   |     |     |  |
|         | 0.  | 3      | 40. | 4   | 100. | 5 | ... |     |  |
| TABLED1 | 3   | ...    |     |     |      |   |     |     |  |
| TABLED1 | 4   | ...    |     |     |      |   |     |     |  |
| TABLED1 | 5   | ...    |     |     |      |   |     |     |  |

Usage Example

E is dependent only on frequency, therefore points to a TABLED1 entry.

GE is both temperature and frequency dependent and therefore points to a TABLED5 entry

|                                               |     |        |        |        |      |        |      |      |  |
|-----------------------------------------------|-----|--------|--------|--------|------|--------|------|------|--|
|                                               |     | E      | G      | NU     |      |        |      | GE   |  |
| MAT1                                          | 1   | 7.2+10 | 2.8+10 | .3     |      | 2.22-5 |      | 0.02 |  |
| MAT1F                                         | 1   | 110    | 111    | 112    |      |        |      | 200  |  |
| TABLED1                                       | 110 |        |        |        |      |        |      |      |  |
|                                               | 10. | 7.2+10 | 200.   | 7.1+10 | 300. | 6.9+10 | ENDT |      |  |
| TABLED1                                       | 111 |        |        |        |      |        |      |      |  |
|                                               | 10. | 2.8+10 | 200.   | 2.7+10 |      | 2.6+10 | ENDT |      |  |
| TABLED1                                       | 112 |        |        |        |      |        |      |      |  |
|                                               | 10. | .3     | 200.   | .3     |      | .3     | ENDT |      |  |
| GE has frequency as a function of temperature |     |        |        |        |      |        |      |      |  |
| TABLED5                                       | 200 |        |        |        |      |        |      |      |  |
|                                               | 0.  | 3      | 40.    | 4      | 100. | 5      | ENDT |      |  |
| TABLED1                                       | 3   |        |        |        |      |        |      |      |  |
|                                               | 10. | 0.02   | 200.   |        |      | 0.025  | ENDT |      |  |

|         |     |       |      |      |      |       |      |  |  |
|---------|-----|-------|------|------|------|-------|------|--|--|
| TABLED1 | 4   |       |      |      |      |       |      |  |  |
|         | 10. | 0.025 | 200. |      |      | 0.03  | ENDT |  |  |
| TABLED1 | 5   |       |      |      |      |       |      |  |  |
|         | 10. | 0.03  | 200. | 0.04 | 300. | 0.035 | ENDT |  |  |

TABLED1 units are x=frequency, y=material value

TABLED5 input is numerical temperature - frequency table ID

For an element with average temperature of 15.0 degrees the GE value will be selected from TABLED1 ID=3;

For an element with average temperature of 30.0 degrees the GE value will be selected from TABLED1 ID=4;

For an element with average temperature of 20.0 degrees the GE value will be selected from TABLED1 ID=3;

6. TABLED5 in Solution Sequence SOL108, SOL111, SO200, or SOL400 with ANALYSIS=DFREQ or MFREQ:

Example (1): TABLED5 specification using TEMP(INIT) or TEMP(MATE) entry, no TEMP(LOAD) in Case Control section.

```
SOL 108
...
TEMP (INIT) =5
BEGIN BULK
...
TEMP, 5, ...
...
ENDDATA
```

The temperatures specified by TEMP(INIT) will be used for TABLED5 look up

Example (2): TABLED5 specification using TEMP(LOAD) entry.

```
SOL 108
...
TEMP (INIT) =5
SUBCASE 1
TEMP (LOAD) =12
...
```

```
BEGIN BULK
...
TEMP, 5, ...
TEMP, 12, ...
...
ENDDATA
```

The temperatures specified by TEMP(LOAD) will be used for TABLED5 look up.

User is reminded that for dynamic solutions sequences, the above will not apply thermal loading unless there is a DLOAD entry pointing to an RLOAD1 or RLOAD2 referencing TEMP(LOAD) with ID=12 specified.

Example (3): TABLED5 specification using TEMP(LOAD) entry and thermal loading desired.

```
SOL 108
...
TEMP (INIT) =5
SUBCASE 1
TEMP (LOAD) =12
DLOAD = 50
...
BEGIN BULK
...
RLOAD, 50, 12, , , 1.0, , LOAD
...
TEMP, 5, ...
TEMP, 12, ...
...
ENDDATA
```

The temperatures specified by TEMP(LOAD) will be used for TABLED5 look up and will also be used to compute thermal loads in elements.

## TABLEHT Heat Transfer Coefficient Table or Nusselt Number Table with Two Variables

Specifies a function of two variables for convection heat transfer coefficient or Nusselt number.

Format:

| 1       | 2   | 3    | 4  | 5    | 6  | 7     | 8 | 9 | 10 |
|---------|-----|------|----|------|----|-------|---|---|----|
| TABLEHT | TID |      |    |      |    |       |   |   |    |
|         | x1  | TID1 | x2 | TID2 | x3 | -etc. |   |   |    |

Example:

|         |      |     |      |     |      |     |      |  |  |
|---------|------|-----|------|-----|------|-----|------|--|--|
| TABLEHT | 85   |     |      |     |      |     |      |  |  |
|         | 10.0 | 101 | 25.0 | 102 | 40.0 | 110 | ENDT |  |  |

| Describer | Meaning                                                        |
|-----------|----------------------------------------------------------------|
| TID       | Table identification number. (Integer > 0)                     |
| xi        | Independent variables. (Real)                                  |
| TIDi      | Table identification numbers of TABLEH1 entries. (Integer > 0) |

Remarks:

1. xi must be listed in ascending order.
2. At least one continuation entry must be present.
3. The end of the table is indicated by the existence of "ENDT" in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag ENDT.
4. This table is referenced only by PCONV entries that define free convection boundary condition properties. It computes heat transfer coefficient or Nusselt number, depending on the FTYPE of the associated PCONV entry.
  - If FTYPE=1 in PCONV entry: compute heat transfer coefficient.
  - If FTYPE=2 in PCONV entry: compute Nusselt number.

**TABLEH1** Heat Transfer Coefficient Table or Nusselt Number Table, Form 1

Defines a tabular function referenced by TABLEHT for convection heat transfer coefficient or Nusselt number.

Format:

|         |     |    |    |    |    |        |   |   |    |
|---------|-----|----|----|----|----|--------|---|---|----|
| 1       | 2   | 3  | 4  | 5  | 6  | 7      | 8 | 9 | 10 |
| TABLEH1 | TID |    |    |    |    |        |   |   |    |
|         | y1  | f1 | y2 | f2 | y3 | -etc.- |   |   |    |

Example:

|         |      |      |      |      |       |      |      |  |  |
|---------|------|------|------|------|-------|------|------|--|--|
| TABLEH1 | 123  |      |      |      |       |      |      |  |  |
|         | 50.0 | 5.23 | 75.0 | 3.76 | 110.0 | 0.97 | ENDT |  |  |

| Describer | Meaning |
|-----------|---------|
|-----------|---------|

- |     |                                            |
|-----|--------------------------------------------|
| TID | Table identification number. (Integer > 0) |
| yi  | Independent variables. (Real)              |
| fi  | Dependent variable. (Real)                 |

Remarks:

1. yi must be listed in ascending order.
2. At least one continuation entry must be present.
3. Any yi-fi pair may be ignored by placing "SKIP" in either of the two fields used for that entry.
4. The end of the table is indicated by the existence of "ENDT" in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag ENDT.
5. TABLEH1 is used to input a curve in the form of
 
$$f = f(y)$$
 where  $y$  is input to the table and  $f$  is returned. The table look-up is performed using linear interpolation within the table and is evaluated at the starting or end point outside the table. No warning messages are issued if table data is input incorrectly.
6. Discontinuities are not recommended and may lead to unstable results.

## TABLE1 Specifies a Table of Amplitude vs Pseudo-Time for Static Loads Specified in LDTABL Entries

Specifies a table of amplitude vs pseudo-time for static loads specified in LDTABL entries SOL 600 only.

### Format:

| 1      | 2   | 3  | 4  | 5  | 6  | 7  | 8    | 9     | 10 |
|--------|-----|----|----|----|----|----|------|-------|----|
| TABLE1 | TID |    |    |    |    |    |      |       |    |
|        | X1  | Y1 | X2 | Y2 | X3 | Y3 | etc. | "ENT" |    |

### Example:

|        |     |     |     |     |     |     |      |  |  |
|--------|-----|-----|-----|-----|-----|-----|------|--|--|
| TABLE1 | 101 |     |     |     |     |     |      |  |  |
|        | 0.0 | 0.0 | 0.5 | 1.0 | 1.0 | 0.0 | ENDT |  |  |

| Describer | Meaning                                                |
|-----------|--------------------------------------------------------|
| TID       | Table identification number. (Integer > 0; no Default) |
| Xi, Yi    | Tabular values. (Real; no Default)                     |
| "ENDT"    | Flag indicating end of the table. (Character)          |

### Remarks:

1. TABLE1 can only be used in SOL 600.
2. TABLED1 may be used instead of TABLEL1, however, XAXIS and YAXIS must be LINEAR or blank.
3. The TID must be unique among all TABLEL1's and TABLED1's.
4. The string "SKIP" used in TABLED1 may not be used in TABLEL1.
5. Log X and Y is not available in TABLEL1.
6. No blank fields are allowed starting with the second field of the first continuation line until the ENDT string.
7. There must be at least two points in the table.

**TABLEM1** Material Property Table, Form 1

Defines a tabular function for use in generating temperature-dependent material or fatigue related properties.

Format:

|         |     |       |       |    |    |    |        |        |    |
|---------|-----|-------|-------|----|----|----|--------|--------|----|
| 1       | 2   | 3     | 4     | 5  | 6  | 7  | 8      | 9      | 10 |
| TABLEM1 | TID | XAXIS | YAXIS |    |    |    |        |        |    |
|         | x1  | y1    | x2    | y2 | x3 | y3 | -etc.- | “ENDT” |    |

Example:

|         |      |     |     |     |     |     |      |  |  |
|---------|------|-----|-----|-----|-----|-----|------|--|--|
| TABLEM1 | 32   |     |     |     |     |     |      |  |  |
|         | -3.0 | 6.9 | 2.0 | 5.6 | 3.0 | 5.6 | ENDT |  |  |

| Describer | Meaning                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------|
| TID       | Table identification number. See Remark 8. (Integer > 0 or Integer < 0)                                                          |
| XAXIS     | Specifies a linear or logarithmic interpolation for the x-axis. (Character: “LINEAR” or “LOG”; Default = “LINEAR”) See Remark 9. |
| YAXIS     | Specifies a linear or logarithmic interpolation for the y-axis. (Character: “LINEAR” or “LOG”; Default = “LINEAR”) See Remark 9. |
| xi, yi    | Tabular values. (Real)                                                                                                           |
| “ENDT”    | Flag indicating the end of the table.                                                                                            |

Remarks:

- xi must be in either ascending or descending order, but not both.
- Discontinuities may be specified between any two points except the two starting points or two end points. For example, in Figure 9-150 discontinuities are allowed only between points x2 through x7. Also, if y is evaluated at a discontinuity, then the average value of y is used. In Figure 9-150, the value of y at x = x3 is  $y = (y3 + y4)/2$ .
- At least one continuation entry must be specified.
- Any xi-yi pair may be ignored by placing “SKIP” in either of the two fields.
- The end of the table is indicated by the existence of “ENDT” in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag “ENDT”.
- TABLEM1 uses the algorithm  

$$y = y_T(x) \quad (\text{for heat transfer, see Remark 7.})$$

where  $x$  is input to the table and  $y$  is returned. The table look-up is performed using linear interpolation within the table and linear extrapolation outside the table using the two starting or end points. See Figure 9-150. No warning messages are issued if table data is input incorrectly.

Figure 9-150 Example of Table Extrapolation and Discontinuity

- For Nastran heat transfer, the TABLEM1 assumes

$$y = zy_T(x)$$

where  $x$  is input to the table,  $y$  is returned and  $z$  is supplied from MAT4 or MT5 entries.

- A negative TID is used to associate thermal strain  $\epsilon(T)$  ordinate values instead of coefficient of thermal expansion ordinate values to the T(Ai) fields of MATT1, MATT2, or MATT8 Bulk Data entries as described in the remarks of those entries. Internally to Nastran, a negative  $ID_{T(Ai)}$  value will be changed to  $|ID_{T(Ai)}| + 100000000$ .
- Logarithmic XAXIS and YAXIS is only recognized when specifying S-N curves referenced by MATFTG entries for TYPE=TABLE. All other uses use linear and ignore these fields.
- TABLEM1 in RESTART job will cause recalculation of eigenvalues even in the cases where TABLEM1 does not change stiffness and/or mass matrix. An example is SOL 111 RESTART for fatigue analysis with TABLEM1 referenced on MATFTG.

## TABLEM2 Material Property Table, Form 2

Defines a tabular function for use in generating temperature-dependent material properties. Also contains parametric data for use with the table.

Format:

| 1       | 2   | 3  | 4  | 5  | 6  | 7  | 8      | 9 | 10 |
|---------|-----|----|----|----|----|----|--------|---|----|
| TABLEM2 | TID | X1 |    |    |    |    |        |   |    |
|         | x1  | y1 | x2 | y2 | x3 | y3 | -etc.- |   |    |

Example:

|         |      |       |     |      |      |     |     |     |  |
|---------|------|-------|-----|------|------|-----|-----|-----|--|
| TABLEM2 | 15   | -10.5 |     |      |      |     |     |     |  |
|         | 1.0  | -4.5  | 2.0 | -4.5 | 2.0  | 2.8 | 7.0 | 6.5 |  |
|         | SKIP | SKIP  | 9.0 | 6.5  | ENDT |     |     |     |  |

| Describer | Meaning                                                                 |
|-----------|-------------------------------------------------------------------------|
| TID       | Table identification number. See Remark 7. (Integer > 0 or Integer < 0) |
| X1        | Table parameter. (Real)                                                 |
| xi, yi    | Tabular values. (Real)                                                  |

Remarks:

1. xi must be in either ascending or descending order, but not both.
2. Discontinuities may be specified between any two points except the two starting points or two end points. For example, in [Figure 9-151](#), discontinuities are allowed only between points x2 through x7. Also, if y is evaluated at a discontinuity, then the average value of y is used. In [Figure 9-151](#), the value of y at x = x3 is  $y = (y3 + y4)/2$ .
3. At least one continuation entry must be specified.
4. Any xi-yi pair may be ignored by placing “SKIP” in either of the two fields.
5. The end of the table is indicated by the existence of “ENDT” in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag “ENDT”.
6. TABLEM2 uses the algorithm

$$y = zy_T(x - X1)$$

where x is input to the table, y is returned and z is supplied from the MATi entry. The table look-up is performed using linear interpolation within the table and linear extrapolation outside the table using the two starting or end points. See [Figure 9-151](#). No warning messages are issued if table data is input incorrectly.

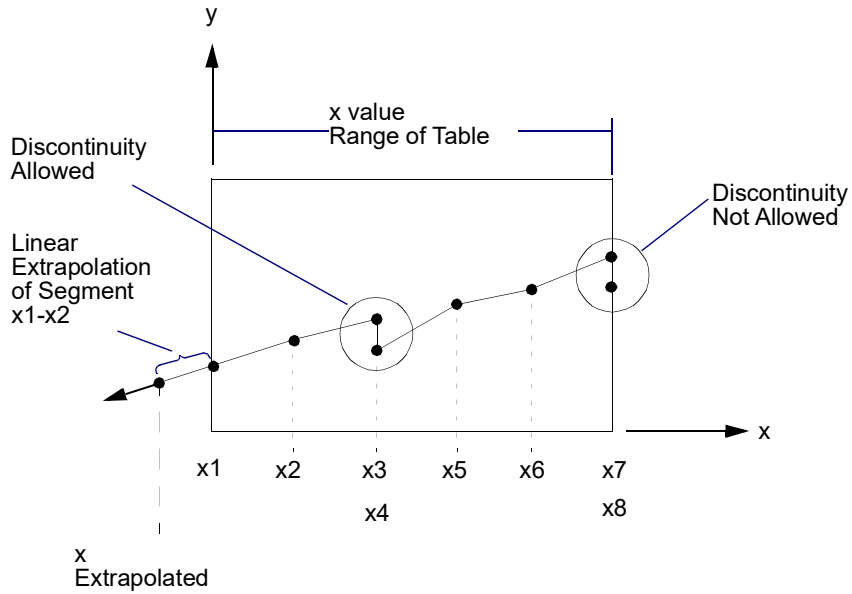

Figure 9-151 Example of Table Extrapolation and Discontinuity

7. A negative TID is used to associate thermal strain  $\epsilon(T)$  ordinate values instead of coefficient of thermal expansion ordinate values to the  $T(A_i)$  fields of MATT1, MATT2, or MATT8 Bulk Data entries as described in the remarks of those entries. Internally to Nastran, a negative  $ID_{T(A_i)}$  value will be changed to  $|ID_{T(A_i)}| + 100000000$ .

**TABLEM3** Material Property Table, Form 3

Defines a tabular function for use in generating temperature-dependent material properties. Also contains parametric data for use with the table.

Format:

|         |     |    |    |    |    |    |        |   |    |
|---------|-----|----|----|----|----|----|--------|---|----|
| 1       | 2   | 3  | 4  | 5  | 6  | 7  | 8      | 9 | 10 |
| TABLEM3 | TID | X1 | X2 |    |    |    |        |   |    |
|         | x1  | y1 | x2 | y2 | x3 | y3 | -etc.- |   |    |

Example:

|         |     |       |      |     |     |     |      |  |  |
|---------|-----|-------|------|-----|-----|-----|------|--|--|
| TABLEM3 | 62  | 126.9 | 30.0 |     |     |     |      |  |  |
|         | 2.9 | 2.9   | 3.6  | 4.7 | 5.2 | 5.7 | ENDT |  |  |

| Describer | Meaning |
|-----------|---------|
|-----------|---------|

- TID Table identification number. See Remark 7. (Integer > 0 or Integer < 0)
- X1, X2 Table parameters. See Remark 6. (Real; X2 ≠ 0.0)
- xi, yi Tabular values. (Real)

Remarks:

1. Tabular values for xi must be specified in either ascending or descending order, but not both.
2. Discontinuities may be specified between any two points except the two starting points or two end points. For example, in Figure 9-152 discontinuities are allowed only between points x2 through x7. Also, if y is evaluated at a discontinuity, then the average value of y is used. In Figure 9-152, the value of y at x = x3 is  $y = (y3 + y4)/2$ .
3. At least one continuation entry must be specified.
4. Any xi-yi pair may be ignored by placing "SKIP" in either of the two fields.
5. The end of the table is indicated by the existence of "ENDT" in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag "ENDT".
6. TABLEM3 uses the algorithm

$$y = zy_T \left( \frac{x - X1}{X2} \right)$$

where x is input to the table, y is returned and z is supplied from the MATi entry. The table look-up is performed using linear interpolation within the table and linear extrapolation outside the table using the two starting or end points. See Figure 9-152. No warning messages are issued if table data is input incorrectly.

Figure 9-152 Example of Table Extrapolation and Discontinuity

7. A negative TID is used to associate thermal strain  $\epsilon(T)$  ordinate values instead of coefficient of thermal expansion ordinate values to the  $T(A_i)$  fields of MATT1, MATT2, or MATT8 Bulk Data entries as described in the remarks of those entries. Internally to Nastran, a negative  $ID_{T(A_i)}$  value will be changed to  $|ID_{T(A_i)}| + 100000000$ .

## TABLEM4 Material Property Table, Form 4

Defines coefficients of a power series for use in generating temperature-dependent material properties. Also contains parametric data for use with the table.

Format:

| 1       | 2   | 3  | 4  | 5  | 6  | 7  | 8      | 9 | 10 |
|---------|-----|----|----|----|----|----|--------|---|----|
| TABLEM4 | TID | X1 | X2 | X3 | X4 |    |        |   |    |
|         | A0  | A1 | A2 | A3 | A4 | A5 | -etc.- |   |    |

Example:

|         |      |         |        |     |        |      |  |  |  |
|---------|------|---------|--------|-----|--------|------|--|--|--|
| TABLEM4 | 28   | 0.0     | 1.0    | 0.0 | 100.   |      |  |  |  |
|         | 2.91 | -0.0329 | 6.51-5 | 0.0 | -3.4-7 | ENDT |  |  |  |

| Describer | Meaning |
|-----------|---------|
|-----------|---------|

|     |                                                                         |
|-----|-------------------------------------------------------------------------|
| TID | Table identification number. See Remark 4. (Integer > 0 or Integer < 0) |
| Xi  | Table parameters. (Real; X2 ≠ 0.0; X3 < X4)                             |
| Ai  | Coefficients. (Real)                                                    |

Remarks:

- At least one continuation entry must be specified.
- The end of the table is indicated by the existence of “ENDT” in the field following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag “ENDT”.
- TABLEM4 uses the algorithm

$$y = z \sum_{i=0}^N Ai \left( \frac{x - X1}{X2} \right)^i$$

where  $x$  is input to the table,  $y$  is returned and  $z$  is supplied from the MATi entry. Whenever  $x < X3$ , use  $X3$  for  $x$ ; whenever  $x > X4$ , use  $X4$  for  $x$ . There are  $N + 1$  entries in the table. There are no error returns from this table look-up procedure.

- A negative TID is used to associate thermal strain  $\epsilon(T)$  ordinate values instead of coefficient of thermal expansion ordinate values to the T(Ai) fields of MATT1, MATT2, or MATT8 Bulk Data entries as described in the remarks of those entries. Internally to Nastran, a negative  $ID_{T(Ai)}$  value will be changed to  $|ID_{T(Ai)}| + 100000000$ .

## TABLES1 Material Property Table, Form 1

Defines a tabular function for stress-dependent material properties such as the stress-strain curve (MATS1 entry), creep parameters (CREEP entry) and hyperelastic material parameters (MATHP entry).

**Format:**

| 1       | 2   | 3    | 4  | 5  | 6  | 7  | 8      | 9      | 10 |
|---------|-----|------|----|----|----|----|--------|--------|----|
| TABLES1 | TID | TYPE |    |    |    |    |        |        |    |
|         | x1  | y1   | x2 | y2 | x3 | y3 | -etc.- | “ENDT” |    |

**Example:**

|         |     |     |     |        |     |        |      |  |  |
|---------|-----|-----|-----|--------|-----|--------|------|--|--|
| TABLES1 | 32  |     |     |        |     |        |      |  |  |
|         | 0.0 | 0.0 | .01 | 10000. | .02 | 15000. | ENDT |  |  |

| Describer | Meaning                                                                                        |
|-----------|------------------------------------------------------------------------------------------------|
| TID       | Table identification number. (Integer > 0)                                                     |
| TYPE      | Flag to define type of the stress-strain curve. See Remark 10. (Integer = 1 or 2; Default = 1) |
| xi, yi    | Tabular values. (Real)                                                                         |
| “ENDT”    | Flag indicating the end of the table.                                                          |

**Remarks:**

1. xi must be in either ascending or descending order, but not both.
2. Discontinuities may be specified between any two points except the two starting points or two end points. For example, in [Figure 9-153](#) discontinuities are allowed only between points x2 through x7. Also, if y is evaluated at a discontinuity, then the average value of y is used. In [Figure 9-153](#), the value of y at x = x3 is  $y = (y3 + y4)/2$ .
3. At least one continuation entry must be present.
4. Any xi-yi pair may be ignored by placing “SKIP” in either of the two fields used for that entry.
5. The end of the table is indicated by the existence of “ENDT” in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag ENDT.
6. TABLES1 is used to input a curve in the form of

$$y = y_T(x)$$

where x is input to the table and y is returned. The table look-up is performed using linear interpolation within the table and linear extrapolation outside the table using the two starting or end points. See [Figure 9-153](#). No warning messages are issued if table data is input incorrectly.

Figure 9-153 Example of Table Extrapolation and Discontinuity

7. Discontinuities are not recommended and may lead to unstable results. Discontinuities are not allowed in nonlinear solution sequences.
8. For SOL 600, general temperature-dependent stress vs. plastic strain curves may be entered using a combination of TABLEST and TABLES1 entries. Each TABLES1 entry is at a constant temperature. All entries must be in the form of stress vs. plastic strain using the stress and strain measures to be incorporated into the analysis. All sets of stress-strain values for a particular TABLES1 entry must be at the same temperature. One set is required for the lowest temperature in the model and another at or above the highest temperature in the model.
9. For SOL 600, the stress and strain values entered here depend on the stress and strain measures selected for the analysis. In addition, the strain is controlled using PARAM,MRTABLS1 which provides several methods of converting an engineering stress-strain curve to a stress vs. plastic strain curve (see MRTABLS1 in the Parameters Section).
10. For SOL 400, TYPE denotes the type of stress-strain curve; 1 - Cauchy (true) stress vs. total true strain; and 2 - Cauchy (true) stress vs. plastic true strain. For MATS1 Bulk Data entry, only TYPE = 1 can be used. A user fatal error will be issued if TYPE = 2 is used. For MATEP Bulk Data entry both TYPE = 1 and 2 can be used.

## TABLEST Material Property Temperature-Dependence Table

Specifies the material property tables for nonlinear elastic temperature-dependent materials.

Format:

|         |     |      |    |      |    |        |   |   |    |
|---------|-----|------|----|------|----|--------|---|---|----|
| 1       | 2   | 3    | 4  | 5    | 6  | 7      | 8 | 9 | 10 |
| TABLEST | TID |      |    |      |    |        |   |   |    |
|         | T1  | TID1 | T2 | TID2 | T3 | -etc.- |   |   |    |

Example:

|         |       |    |       |    |      |  |  |  |  |
|---------|-------|----|-------|----|------|--|--|--|--|
| TABLEST | 101   |    |       |    |      |  |  |  |  |
|         | 150.0 | 10 | 175.0 | 20 | ENDT |  |  |  |  |

| Describer | Meaning                                                        |
|-----------|----------------------------------------------------------------|
| TID       | Table identification number. (Integer > 0)                     |
| Ti        | Temperature values. (Real)                                     |
| TIDi      | Table identification numbers of TABLES1 entries. (Integer > 0) |

Remarks:

1. TIDi must be unique with respect to all TABLES1 and TABLEST table identification numbers.
2. Temperature values must be listed in ascending order.
3. The end of the table is indicated by the existence of ENDT in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag ENDT.
4. This table is referenced only by MATS1 entries that define nonlinear elastic (TYPE = "NLELAST") materials.
5. For SOL 600, this entry provides IDs of TABLES1 curves as a function of temperature for use with Marc's AF\_flowmat. The strains are plastic strain for all curves entered. The first curve must be entered at the lowest temperature encountered in the analysis run. Curves must be defined that equal or exceed the maximum temperature encountered in the run.

## TABLFTG Fatigue Loading Tabular Data

Defines tabular data for specifying fatigue cyclic loading variation.

Format:

| 1       | 2   | 3  | 4  | 5  | 6  | 7  | 8  | 9      | 10 |
|---------|-----|----|----|----|----|----|----|--------|----|
| TABLFTG | TID |    |    |    |    |    |    |        |    |
|         | y1  | y2 | y3 | y4 | y5 | y6 | y7 | "ENDT" |    |

Example:

|         |       |      |     |     |      |  |  |  |  |
|---------|-------|------|-----|-----|------|--|--|--|--|
| TABLFTG | 1     |      |     |     |      |  |  |  |  |
|         | 0.000 | -1.0 | 1.0 | 0.0 | ENDT |  |  |  |  |

| Describer | Meaning                                                  |
|-----------|----------------------------------------------------------|
| TID       | Table identification number. (Integer > 0)               |
| yi        | Y value of each point in the time history curve. (Real). |
| "ENDT"    | Flag indicating the end of the table.                    |

Remarks:

1. The TABLFTG is referenced by a FTGLOAD entry.
2. The x-values are assumed to be in ascending order. For rainflow cycle counting purposes the actual x values are inconsequential.
3. For modal analysis using SOL 103, this would define the modal participation factors for a particular mode.

## TABLRPC

## Dynamic Load Tabular Function Referencing Channel Data File

Defines a tabular function for use in generating time-dependent loads from an externally defined channel data file.

## Format:

| 1       | 2               | 3               | 4               | 5               | 6               | 7               | 8      | 9      | 10 |
|---------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|--------|--------|----|
| TABLRPC | TID             | XAXIS           | YAXIS           | UID             | TYPE            | CHAN            | TOTIM  | PUNCH  |    |
|         | x <sub>i1</sub> | x <sub>j1</sub> | x <sub>i2</sub> | x <sub>j2</sub> | x <sub>i3</sub> | x <sub>j3</sub> | -etc.- | "ENDT" |    |

## Examples:

|         |                  |  |  |    |     |   |  |  |  |
|---------|------------------|--|--|----|-----|---|--|--|--|
| TABLRPC | 32               |  |  | 33 | RPC | 5 |  |  |  |
| UDNAME  | 33               |  |  |    |     |   |  |  |  |
|         | C:\myrpcfile.rsp |  |  |    |     |   |  |  |  |

|         |                  |      |      |      |      |  |  |  |  |
|---------|------------------|------|------|------|------|--|--|--|--|
| TABLRPC | 32               |      |      | 33   | DAC  |  |  |  |  |
|         | 0.0              | 20.0 | 35.0 | 60.0 | ENDT |  |  |  |  |
| UDNAME  | 33               |      |      |      |      |  |  |  |  |
|         | C:\myrpcfile.dac |      |      |      |      |  |  |  |  |

|         |                  |      |      |      |      |   |  |  |  |
|---------|------------------|------|------|------|------|---|--|--|--|
| TABLRPC | 32               |      |      | -33  |      | 5 |  |  |  |
|         | 0.0              | 20.0 | 35.0 | 60.0 | ENDT |   |  |  |  |
| UDNAME  | 33               |      |      |      |      |   |  |  |  |
|         | C:\myrpcfile.rsp |      |      |      |      |   |  |  |  |

| Descriptor | Meaning                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TID        | Table identification number. (Integer > 0, no default)                                                                                                                              |
| XAXIS      | Specifies a linear or logarithmic interpolation for the x-axis. (Character: "LINEAR" or "LOG"; Default = "LINEAR")                                                                  |
| YAXIS      | Specifies a linear or logarithmic interpolation for the y-axis. (Character: "LINEAR" or "LOG"; Default = "LINEAR")                                                                  |
| UID        | Identification number of a UDNAME entry to specify the external file that defines the x-y pair values that define the actual tabular function. Required. (Integer != 0, no default) |
| TYPE       | Type of external file to specify via UID field. (Character: "RPC", or "DAC"; Default = "RPC")                                                                                       |
| CHAN       | Channel number to read for Y (load) values from "RPC" files. Leave blank for "DAC" files. (Integer > 0, Default = 1)                                                                |
| TOTIM      | Total time of the signal defined in channel CHAN. Optional. (Real > 0., Default=Blank). See remarks below.                                                                          |

| Describer | Meaning                                                                                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PUNCH     | Specify whether equivalent TABLED1 entries containing the actual x-y pairs should be written to the PUNCH file. (Character: "YES" or "NO"; Default= "NO")                                                                                                                                       |
| $x_i/x_j$ | x-y pair Filter mechanism. The given $(x_i, x_j)$ pairs reflect the start and end x-values for inclusion from the external file; or if UID is negative, the given pairs reflect the start and end x-values to exclude from reading from the external file. See remarks below. Optional. (Real). |
| "ENDT"    | Flag indicating the end of the table.                                                                                                                                                                                                                                                           |

Remarks:

1. The TABLRPC entry can be referenced by any entry that can reference a TABLED1. The TABLRPC is internally converted to a TABLED1 entry using the channel data specified. This internal TABLED1 entry can be written to the punch (.pch) file if the PUNCH field is set to YES.
2. The CHANnel specified contains the Y (load) data. The X (time) data for each point is automatically extracted from the channel file at each point to create the x-y pairs for a TABLED1 entry. The TOTIM (total time) of the signal can be optionally supplied, in which case the time increment of each point is calculated as TOTIM / (NPNTS-1) where NPNTS are the number of signal points. This will override any time specifications for the points from the original channel file.
3.  $x_i/x_j$  field pairs are purely optional. If not needed, no continuation lines should be present, in which case the entire signal defined in the specified CHANnel is taken.
4. The  $x_i/x_j$  field pairs represent sections of the channel to read and must be in the order in which they appear in the external file. For example, to read from only  $x=0.0$  to  $x=1.0$ , specify  $x_1=0.0$  and  $x_j=1.0$  and  $x_2=ENDT$ . If the first  $x_i$  is left blank, reading begins at the first data point. If the last  $x_j$  value is left blank, then the rest of the data points are read to the end of the channel. If a specified  $x_i$  or  $x_j$  value does not exist, only the points in between are retained or excluded.
5. Any  $x_i/x_j$  field pair may be ignored by placing the character string "SKIP" in either of the two fields.
6. The end of the table is indicated by the existence of the character string "ENDT" in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag "ENDT"
7. As this data is converted to a TABLED1 entry, all comments pertaining to the TABLED1 entry are also valid.

## TABLUDS

## User Defined Failure For Nonlinear Explicit Analysis.

Specifies that a user routine is being used to define an arbitrary function. Use in SOL700 only.

Format:

| 1       | 2   | 3     | 4     | 5 | 6 | 7 | 8 | 9 | 10 |
|---------|-----|-------|-------|---|---|---|---|---|----|
| TABLUDS | TID | GROUP | UNAME |   |   |   |   |   |    |

Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE myfunc 'SCA.MDSolver.Obj.Uds.Dytran.Loads '
```

*In Bulk Data:*

| 1       | 2  | 3      | 4      | 5 | 6 | 7 | 8 | 9 | 10 |
|---------|----|--------|--------|---|---|---|---|---|----|
| TABLUDS | 12 | myfunc | EXFUNC |   |   |   |   |   |    |

| Describer | Meaning                                                                                    |
|-----------|--------------------------------------------------------------------------------------------|
| TID       | Unique output number. (Integer > 0; Required)                                              |
| GROUP     | The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default) |
| UNAME     | User subroutine name associated with the entry. (Character; default=EXFUNC)                |

Remarks:

1. Since tables and user-defined functions belong to the same group, the table numbers must be unique.
2. UNAME can be:

| Subroutine Name | Function                       |
|-----------------|--------------------------------|
| EXFUNC          | Standard user defined function |

## TABRND1 Power Spectral Density Table

Defines power spectral density as a tabular function of frequency for use in random analysis. Referenced by the RANDPS entry.

Format:

|         |     |       |       |    |    |    |        |   |    |
|---------|-----|-------|-------|----|----|----|--------|---|----|
| 1       | 2   | 3     | 4     | 5  | 6  | 7  | 8      | 9 | 10 |
| TABRND1 | TID | XAXIS | YAXIS |    |    |    |        |   |    |
|         | f1  | g1    | f2    | g2 | f3 | g3 | -etc.- |   |    |

Example:

|         |     |        |     |        |      |  |  |  |  |
|---------|-----|--------|-----|--------|------|--|--|--|--|
| TABRND1 | 3   |        |     |        |      |  |  |  |  |
|         | 2.5 | .01057 | 2.6 | .01362 | ENDT |  |  |  |  |

| Describer | Meaning                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------|
| TID       | Table identification number. (Integer > 0)                                                                         |
| XAXIS     | Specifies a linear or logarithmic interpolation for the x-axis. (Character: "LINEAR" or "LOG"; Default = "LINEAR") |
| YAXIS     | Specifies a linear or logarithmic interpolation for the y-axis. (Character: "LINEAR" or "LOG"; Default = "LINEAR") |
| fi        | Frequency value in cycles per unit time. (Real ≥ 0.0)                                                              |
| gi        | Power spectral density. (Real)                                                                                     |

Remarks:

1. The fi must be in either ascending or descending order, but not both.
2. Discontinuities may be specified between any two points except the two starting points or two end points. For example, in [Figure 9-154](#) discontinuities are allowed only between points f2 through f7. Also, if g is evaluated at a discontinuity, then the average value of g is used. In [Figure 9-154](#), the value of g at f = f3 is  $g = (g3 + g4)/2$ . If the y-axis is a LOG axis then the jump at the discontinuity is evaluated as  $y = \sqrt{y3y4}$ .
3. At least two entries must be present.
4. Any fi-gi pair may be ignored by placing "SKIP" in either of the two fields used for that entry.
5. The end of the table is indicated by the existence of "ENDT" in either of the two fields following the last entry. An error is detected if any continuations follow the entry containing the end-of-table flag "ENDT".
6. TABRND1 uses the algorithm

$$g = g_T(f)$$

where  $f$  is input to the table and  $g$  is returned. The table look-up is performed using linear interpolation within the table and linear extrapolation outside the table using the two starting or end points. See Figure 9-154. No warning messages are issued if table data is input incorrectly.

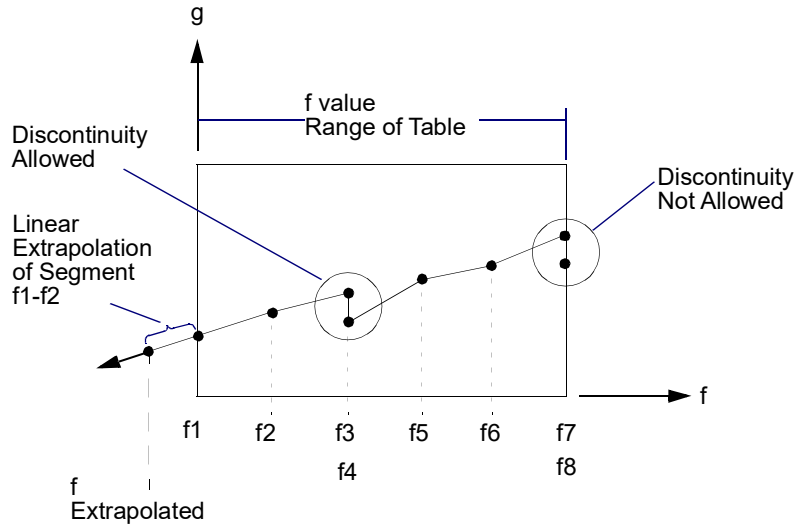

Figure 9-154 Example of Table Extrapolation and Discontinuity

7. For auto spectral density, the value of  $g$  returned must be greater than or equal to zero, as shown in Remark 6.
8. Tabular values on an axis if XAXIS or YAXIS = LOG must be positive. A fatal message will be issued if an axis has a tabular value  $\leq 0$ .
9. The algorithms used are:

| XAXIS  | YAXIS  | $f(x)$                                                                                                             |
|--------|--------|--------------------------------------------------------------------------------------------------------------------|
| LINEAR | LINEAR | $\frac{f_{i+1}-f}{f_{i+1}-f_i}g_i + \frac{f-f_i}{f_{i+1}-f_i}g_{i+1}$                                              |
| LOG    | LINEAR | $\frac{\ln(f_{i+1}/f)}{\ln(f_{i+1}/f_i)}g_i + \frac{\ln(f/f_i)}{\ln(f_{i+1}/f_i)}g_{i+1}$                          |
| LINEAR | LOG    | $\exp\left[\frac{f_{i+1}-f}{f_{i+1}-f_i}\ln g_i + \frac{f-f_i}{f_{i+1}-f_i}\ln g_{i+1}\right]$                     |
| LOG    | LOG    | $\exp\left[\frac{\ln(f_{i+1}/f)}{\ln(f_{i+1}/f_i)}\ln g_i + \frac{\ln(f/f_i)}{\ln(f_{i+1}/f_i)}\ln g_{i+1}\right]$ |

where  $f_i < f < f_{i+1}$ .

10. If Modules are present then this entry may only be specified in the main Bulk Data section.

## TABRNDG Gust Power Spectral Density

Defines the power spectral density (PSD) of a gust for aeroelastic response analysis.

Format:

| 1       | 2   | 3    | 4   | 5  | 6 | 7 | 8 | 9 | 10 |
|---------|-----|------|-----|----|---|---|---|---|----|
| TABRNDG | TID | TYPE | L/U | WG |   |   |   |   |    |

Example:

|         |      |   |     |    |  |  |  |  |  |
|---------|------|---|-----|----|--|--|--|--|--|
| TABRNDG | 1020 | 1 | 1.3 | .1 |  |  |  |  |  |
|---------|------|---|-----|----|--|--|--|--|--|

| Describer | Meaning                                                                              |
|-----------|--------------------------------------------------------------------------------------|
| TID       | Table identification number. (Integer > 0)                                           |
| TYPE      | PSD type: von Karman (TYPE = 1) or Dryden model (TYPE = 2). (Integer = 1 or 2)       |
| L/U       | Scale of turbulence divided by velocity (units of time). See L/U in Remark 2. (Real) |
| WG        | Root-mean-square gust velocity. (Real)                                               |

Remarks:

1. This entry must be referenced by a RANDPS entry.
2. The power spectral density is given by

$$S_q(\omega) = 2(\text{WG})^2(\text{L}/\text{U}) \frac{1 + 2(p+1)k^2(\text{L}/\text{U})^2\omega^2}{[1 + k^2(\text{L}/\text{U})^2\omega^2]^{p+3/2}}$$

where:

| Type          | p   | k     |
|---------------|-----|-------|
| 1= von Karman | 1/3 | 1.339 |
| 2= Dryden     | 1/2 | 1.0   |

and  $\omega = 2\pi f$ . The units of  $S_q(\omega)$  are velocity squared per frequency ( $f$ ).

3. Other power spectral density functions may be defined using the TABRND1 entry.
4. If Modules are present then this entry may only be specified in the main Bulk Data section.

## TABSCTL Load Stepping Control Table - SOL 400

This option allows the user to provide user criteria for load stepping control. It is referred to by an NLSTEP entry. The criteria defined herein are used for controlling the load step size. The criteria come in two flavors as defined in the NLSTEP entry: limit and target. When used as limits, the time step will be reduced if the criterion would be violated. When used as target, the time step will also be increased if the calculated results are less than what is specified by the criteria.

The criteria are calculated for elements or grids as defined below. By default all elements or nodes are used for evaluating the respective criterion, but this can be limited to specific sets. (See the [NLSTEP, 2604](#) entry.)

Format:

| 1       | 2       | 3        | 4     | 5     | 6     | 7     | 8     | 9     | 10 |
|---------|---------|----------|-------|-------|-------|-------|-------|-------|----|
| TABSCTL | TID     |          |       |       |       |       |       |       |    |
|         | ICRIT_1 | SET3_ID1 | YT1_1 | MT1_1 | YT2_1 | MT2_1 | YT3_1 | MT3_1 |    |
|         | YT4_1   | MT4_1    |       |       |       |       |       |       |    |
|         | ICRIT_2 | SET3_ID2 | YT1_2 | MT_2  | YT2_2 | MT2_1 | YT3_2 | MT3_2 |    |
|         | YT4_2   | MT4_2    |       |       |       |       |       |       |    |
|         | ...     | ...      | ...   | ...   |       |       |       |       |    |
|         | ICRIT_n | SET3_IDn | YT1_n | MT1_n | YT1_n | MT2_n | YT3_n | MT3_n |    |
|         | YT4_n   | MT4_n    |       |       |       |       |       |       |    |

Example:

|         |      |     |     |     |     |     |     |  |  |
|---------|------|-----|-----|-----|-----|-----|-----|--|--|
| TABSCTL | 17   |     |     |     |     |     |     |  |  |
|         | ESI  | 84  | .03 | 21. | 0.4 | 55. | 0.6 |  |  |
|         | ESRI | 18  | .03 | 21. |     |     |     |  |  |
|         | EPSI | ALL | 1.1 |     |     |     |     |  |  |

| Describer | Meaning                                                                                    |
|-----------|--------------------------------------------------------------------------------------------|
| TID       | ID of TABSCTL entry. (Integer > 0)                                                         |
| ICRITi    | Type of user criterion to use and the type of entity it refers to: (Character; no Default) |
| ESI       | Element Strain Increment                                                                   |
| EPSI      | Element Plastic Strain Increment                                                           |
| ECSI      | Element Creep Strain Increment                                                             |
| ENCSI     | Element Normalized Creep Strain Increment                                                  |
| ESTRI     | Element STress Increment                                                                   |
| ESRI      | Element Strain Energy Increment                                                            |
| GTI       | Grid Temperature Increment                                                                 |

| Describer | Meaning                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------|
|           | GDI      Grid Displacement Increment                                                                      |
|           | GRI      Grid Rotation Increment                                                                          |
|           | ENSTRI   Element Normalized STress Increment                                                              |
| SET3_IDi  | ID of a SET3 Bulk Data entry. (Integer > 0 or (ALL or BLANK); Default = ALL)                              |
| YT1_i     | First limit or target value for the current criterion i. (Real; no Default)                               |
| MT1_i     | First range or target value for the current criterion i. See Remark 2. (Real-default blank-always active) |
| YT2_i     | Second limit or target value for criterion. (Real; no Default)                                            |
| MT2_i     | Second range of applicability for criterion i. See Remark 2. (Real-default blank-always active)           |

Remarks:

1. This entry is selected by the CRITTID field of the NLSTEP Bulk Data entry.
2. For each criterion ICRIT\_n, up to four ranges of target/limit values can be given. This allows the use of different limit/target values for different ranges of the corresponding total quality. For example, for the first criterion type, YT1\_1 is the strain increment while MT1\_1 is the largest total strain for which YT1\_1 will be used. Typically, the last MTn used should be zero in which case the corresponding YTn will be used for all larger total values.
3. The TID must be unique among all TABSCTL entries.

## TEMP

## Grid Point Temperature Field

Defines temperature at grid points for determination of thermal loading, temperature-dependent material properties, or stress recovery.

Format:

| 1    | 2   | 3  | 4  | 5  | 6  | 7  | 8  | 9 | 10 |
|------|-----|----|----|----|----|----|----|---|----|
| TEMP | SID | G1 | T1 | G2 | T2 | G3 | T3 |   |    |

Example:

|      |   |    |       |    |       |  |  |  |  |
|------|---|----|-------|----|-------|--|--|--|--|
| TEMP | 3 | 94 | 316.2 | 49 | 219.8 |  |  |  |  |
|------|---|----|-------|----|-------|--|--|--|--|

| Describer | Meaning                                              |
|-----------|------------------------------------------------------|
| SID       | Temperature set identification number. (Integer > 0) |
| Gi        | Grid point identification number. (Integer > 0)      |
| Ti        | Temperature. (Real)                                  |

Remarks:

- In the static solution sequences, SID must be selected by the TEMP Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the TID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- Set ID must be unique with respect to all other LOAD type entries if TEMP(Load) is specified in the Case Control Section.
- From one to three grid point temperatures may be defined on a single entry.
- If thermal effects are requested, all elements must have a temperature field defined either directly on a TEMPP1, TEMPP3, or TEMPRB entry or indirectly as the average of the connected grid point temperatures defined on the TEMP or TEMPD entries. Directly defined element temperatures always take precedence over the average of grid point temperatures.
- If the element material is temperature dependent, its properties are evaluated at the average temperature.
- Average element temperatures are obtained as a simple average of the connecting grid point temperatures when no element temperature data are defined. Gauss point temperatures are averaged for solid elements instead of grid point temperature.
- For steady state heat transfer analysis, this entry together with the TEMPD and TEMPN1 entries supplies the initialization temperatures for nonlinear analysis. The Case Control command TEMP(INIT) = SID requests selection of this entry. The temperature values specified here must be coincident with any temperature boundary conditions that are specified.

8. For transient heat transfer analysis, this entry together with the TEMPD and TEMPN1 entries supplies the initial condition temperatures. The Case Control command IC = SID requests selections of this entry. The temperature values specified here must be coincident with any temperature boundary condition specified.
9. In linear and nonlinear buckling analysis, the follower force effects due to loads from this entry are not included in the differential stiffness. See [Buckling Analysis in SubDMAP MODERS](#) and [Nonlinear Static Analysis](#) in the *MSC Nastran Reference Guide*.

## TEMPAX Conical Shell Temperature

Defines temperature sets for conical shell problems.

Format:

| 1      | 2    | 3    | 4    | 5  | 6    | 7    | 8    | 9  | 10 |
|--------|------|------|------|----|------|------|------|----|----|
| TEMPAX | SID1 | RID1 | PHI1 | T1 | SID2 | RID2 | PHI2 | T2 |    |

Example:

|        |   |   |      |       |  |  |  |  |  |
|--------|---|---|------|-------|--|--|--|--|--|
| TEMPAX | 4 | 7 | 30.0 | 105.3 |  |  |  |  |  |
|--------|---|---|------|-------|--|--|--|--|--|

| Describer | Meaning                                                      |
|-----------|--------------------------------------------------------------|
| SIDi      | Temperature set identification number. (Integer > 0)         |
| RIDi      | Ring identification number (see RINGAX entry). (Integer > 0) |
| PHIi      | Azimuthal angle in degrees. (Real)                           |
| Ti        | Temperature. (Real)                                          |

Remarks:

- TEMPAX is allowed only if an AXIC entry is also present.
- SIDi must be unique with respect to all other LOAD type entries if TEMP(LOAD) is specified in the Case Control Section.
- Temperature sets must be selected with the Case Control command TEMP=SID.
- One or two temperatures may be defined on each entry.
- For a discussion of the conical shell problem, see [Conical Shell Element \(RINGAX\)](#) in the *MSC Nastran Reference Guide*.
- TEMP(INIT) is not used with this entry.

## TEMPB3 CBEAM3 Element Temperature Field

Defines a temperature field for the three-node beam element (CBEAM3 entry).

Format:

| 1      | 2      | 3       | 4      | 5     | 6     | 7      | 8      | 9      | 10 |
|--------|--------|---------|--------|-------|-------|--------|--------|--------|----|
| TEMPB3 | SID    | EID     | T(A)   | T(B)  | T(C)  | TPY(A) | TPZ(A) | TPY(B) |    |
|        | TPZ(B) | TPY(C)  | TPZ(C) | TC(A) | TD(A) | TE(A)  | TF(A)  | TC(B)  |    |
|        | TD(B)  | TE(B)   | TF(B)  | TC(C) | TD(C) | TE(C)  | TF(C)  |        |    |
|        |        | Element | ID     | List  |       |        |        |        |    |

Example:

|        |      |     |      |      |      |      |      |      |  |
|--------|------|-----|------|------|------|------|------|------|--|
| TEMPB3 | 101  | 23  | 45.9 | 10.0 | 0.0  | 1.3  | 23.9 | 3.8  |  |
|        |      | 2.5 | 68.0 | 91.0 | 45.0 |      | 48.0 | 80.0 |  |
|        | 20.0 |     | 33.9 |      |      | 45.6 |      |      |  |
|        | 9    | 10  | THRU | 30   | 41   | 51   | 67   | 78   |  |
|        | THRU | 110 | BY   | 2    |      |      |      |      |  |

| Describer       | Meaning                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID             | Temperature set identification number. (Integer > 0; Required)                                                                                                                |
| EID             | Element identification number. (Integer > 0; Required)                                                                                                                        |
| T(j)            | Temperature at j (j=A,B,C) on the neutral axis. (Real; Default = 0.0)                                                                                                         |
| TPi(j)          | Effective linear gradient in local direction i (i = y, z) at j (j = A, B, C). (Real; Default = 0.0)                                                                           |
| Ti(j)           | Temperature at stress recovery point i (i=C, D, E, F) defined in PBEAM3 at location j (j=A, B, C). (Real; Default = 0.0; see Remark 3.)                                       |
| Element ID List | List of CBEAM3 element identification numbers. Character strings "THRU" and "BY" may be used in the list. (Integer > 0; "THRU" or "BY". At least one element ID is required.) |

Remarks:

- In the static solution sequences, SID must be selected by the TEMP Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the TID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- SID must be unique with respect to all other LOAD type entries if TEMP(LOAD) is specified in the Case Control Section.
- If all Ti(j) fields are blank, linear temperature gradients are assumed for stress recovery.

4. Temperature field defined by TEMPB3 entry always takes precedence over the grid point temperatures given by TEMP and TEMPD entries.
5. The effective thermal gradients are defined in the local coordinate system. For their definitions, see Remark 6 of Bulk Data entry TEMPRB for the details.

## TEMPBC      Grid Point Temperatures

Defines the temperature boundary conditions for heat transfer analysis. Applies to steady-state and transient conditions (SOLs 153 and 159 only).

Format:

| 1      | 2   | 3    | 4     | 5    | 6     | 7    | 8     | 9    | 10 |
|--------|-----|------|-------|------|-------|------|-------|------|----|
| TEMPBC | SID | TYPE | TEMP1 | GID1 | TEMP2 | GID2 | TEMP3 | GID3 |    |

Example:

|        |    |      |       |   |       |   |       |   |  |
|--------|----|------|-------|---|-------|---|-------|---|--|
| TEMPBC | 10 | STAT | 100.0 | 1 | 100.0 | 2 | 100.0 | 3 |  |
|--------|----|------|-------|---|-------|---|-------|---|--|

Alternate Format and Example:

|        |     |      |       |      |        |      |      |     |  |
|--------|-----|------|-------|------|--------|------|------|-----|--|
| TEMPBC | SID | TYPE | TEMP1 | GID1 | “THRU” | GID2 | “BY” | INC |  |
|--------|-----|------|-------|------|--------|------|------|-----|--|

|        |    |      |       |   |      |    |    |   |  |
|--------|----|------|-------|---|------|----|----|---|--|
| TEMPBC | 20 | STAT | 100.0 | 4 | THRU | 50 | BY | 2 |  |
|--------|----|------|-------|---|------|----|----|---|--|

| Describer | Meaning                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Temperature set identification number. (Integer > 0)                                                                                                                                        |
| TYPE      | Type of temperature boundary condition. See Remarks. (Character; Default = “STAT”):<br>STAT - Constant temperature boundary condition<br>TRAN - Time-varying temperature boundary condition |
| TEMPi     | Temperature (Real)                                                                                                                                                                          |
| GIDi      | Grid point identification number. (Integer>0 or “THRU” or “BY”)                                                                                                                             |
| INC       | Grid point number increment. (Integer)                                                                                                                                                      |

Remarks:

- For a constant Boundary Condition (TYPE = “STAT”), the temperature boundary load set (SID) is selected in the Case Control Section (SPC = SID). TYPE = “STAT” may be used in both steady-state (SOL 153) and transient analysis (SOL 159).
- For transient analysis (SOL 159), a constant boundary condition should be specified using the SPC Bulk Data entry.
- For a time-varying boundary condition (TYPE = “TRAN”), SID is referenced by a TLOADi Bulk Data entry through the EXCITEID specification. TYPE= “TRAN” is permitted only in transient analysis (SOL 159). A function of time  $F(t - \tau)$  defined on the TLOADi entry multiplies the general load.  $\tau$  provides any required time delay. The load set identifier on the TLOADi entry must be selected in Case Control (DLOAD = SID) for use in transient analysis.

4. In the alternate format, TEMP1 is the nodal temperature for the grid points  $GID1, GID1+INC, \dots, GID2$ . If “BY” and INC are not specified, then the grid point number increment is unity.
5. If TYPE = “STAT”, then no SPCi Bulk Data entries may be specified.
6. If TYPE = “TRAN”, then no CELAS2 or DAREA Bulk Data entries may be specified. Also, “U” must be specified in the CONV field on the entry to obtain accurate results.
7. All TEMPBC entries in the Bulk Data Section must indicate either TYPE = “STAT” or TYPE = “TRAN” but not both.
8. In transient thermal analysis, the TEMPBC option is used to set a grid, known temperature as a function of time. Internally NASTRAN uses SLOAD and CELAS2 entries to enforce the temperature as a function of time. The  $u=P/K$  or temperature is equal to SLOAD divided by CELAS2. The default stiffness for the CELAS2 entry is 1.0E10. This value is fine most of the time. However, if the user desired to run the model using thermal conductivity in the following unit (Btu/sec.inch.F), then it may run into a numerically convergence issue. This is because the thermal conductivity for this unit has conductivity value in the 1.0E-6 range. The avoidance is to set a NASTRAN system cell, TBCMAG to 1.0E2.
9. The TEMPBC with type=TRAN is no longer supported in SOL 400 transient thermal analysis. One should use the SPC1 and SPCD to enforced temperature. For example, convection coefficient as a function of time, mass flow rate as a function of time, or ambient temperature as a function of time all used the TEMPBC,TRAN option to apply a time varying nodal quantity in SOL 159. Following are the procedures for a user to convert SOL 159 into SOL 400 when there is TEMPBC,TRAN entries.

The SPC entry used to fixed a boundary temperature at a particular value at all time. However, if you have a TEMPBC,TRAN in your test file this means that all the permanent SPC must be converted into SPCD and SPC1 with a unit step function on the TABLED1 in SOL 400. The avoidance to this, using a constant temperature with SPC and a time-varying temperature in the same run, is using the large stiffness method to enforced the time varying quantity. The large stiffness used SLOAD and CELAS2 which  $u = P / K$  which  $P = SLOAD$ , and  $K = CELAS2$ , and  $u$  is the desired temperature times the time-varying quantity in the TABLEDx.

To Convert SOL 159 Models to SOL 400 Models:

- a. Executive Control Section - change SOL 159 to SOL 400.
- b. Case Control Section - replace ANALYSIS=HEAT by ANALYSIS=HTRAN, also add SPC if all temperature boundary conditions are transient (the following Case 3b).
- c. Bulk Data Section - replace the “TRAN” type TEMPBC by SPC1 and SPCD. The details are explained below.

If all temperature boundary conditions are constant, no changes are required.

If all temperature boundary conditions are transient, replace TEMPBC by SPC1 and SPCD and modify TLOAD1.

For example, replace the following entries of SOL 159 model:

```
TLOAD1,40,400,,4000
TEMPBC,400,TRAN,300.0,99
```

by

SPC = 111 (Case CC)

:

TLOAD1,40,400,,1,4000

SPCD,400,99,,300.0

SPC1,111,,99

If a model has both constant and transient temperature boundary conditions, all boundary conditions must be converted into SPC1 and SPCD.

For example, replace the following entries of SOL 159 model:

DLOAD,222,1.0,1,0,30,1.0,40

TLOAD1,40,400,,4000

TEMPBC,400,TRAN,300.0,99

SPC,111,98,,20.0

by

DLOAD,222,1.0,1,0,30,1.0,40, 1.0,50

TLOAD1,40,400,,1,4000

SPCD,400,99,,300.0

SPC1,111,,99

TLOAD1,50,500,,1,5000

SPCD,500,98,,20.0

SPC1,111,,98

TABLED1,5000,,,,,,,,

,0.0,1.0,1000.0,1.0,ENDT

10. If TYPE=TRAN and the initial temperature is non zero, then the initial temperature must be supplied. Use case control IC and bulk data TEMP entries.

**TEMPD**

## Grid Point Temperature Field Default

Defines a temperature value for all grid points of the structural model that have not been given a temperature on a TEMP or TEMPN1 (for heat transfer analysis) entries.

Format:

| 1     | 2    | 3  | 4    | 5  | 6    | 7  | 8    | 9  | 10 |
|-------|------|----|------|----|------|----|------|----|----|
| TEMPD | SID1 | T1 | SID2 | T2 | SID3 | T3 | SID4 | T4 |    |

Example:

|       |   |       |  |  |  |  |  |  |  |
|-------|---|-------|--|--|--|--|--|--|--|
| TEMPD | 1 | 216.3 |  |  |  |  |  |  |  |
|-------|---|-------|--|--|--|--|--|--|--|

| Describer | Meaning                                              |
|-----------|------------------------------------------------------|
| SIDi      | Temperature set identification number. (Integer > 0) |
| Ti        | Default temperature value. (Real)                    |

Remarks:

- In the static solution sequences, SID must be selected by the TEMP Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the TID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
- SIDi must be unique with respect to all other LOAD type entries if TEMP(Load) is specified in the Case Control Section.
- From one to four default temperatures may be defined on a single entry.
- If thermal effects are requested, all elements must have a temperature field defined either directly on a TEMPP1, TEMPP3, or TEMPRB entry or indirectly as the average of the connected grid point temperatures defined on the TEMP or TEMPD entries. Directly defined element temperatures always take precedence over the average of grid point temperatures.
- If the element material is temperature dependent, its properties are evaluated at the average temperature.
- Average element temperatures are obtained as a simple average of the connecting grid point temperatures when no element temperature data is defined.
- For steady-state heat transfer analysis, this entry together with the TEMP and TEMPN1 entries supplies the initialization temperatures for nonlinear analysis. The Case Control command TEMP(INIT) = SID requests selection of this entry. The temperature values specified here must be coincident with any temperatures boundary conditions that are specified.

8. For transient heat transfer analysis, this entry together with the TEMP and TEMPN1 entries supplies the initial condition temperatures. The Case Control command IC=SID request selection of this entry. The temperature values specified here must be coincident with any temperature boundary conditions that are specified.
9. In linear and nonlinear buckling analysis, the follower force effects due to loads from this entry are not included in the differential stiffness. See [Buckling Analysis in SubDMAP MODERS](#) and [Nonlinear Static Analysis](#) in the *MSC Nastran Reference Guide*.
10. For partitioned Bulk Data superelements and auxiliary models, TEMPD must be specified in all partitioned Bulk Data Sections.
11. If Modules are present then this entry may only be specified in the main Bulk Data section.

## TEMPN1

## TOP/BOT/MID Grid Point Temperature Field for Heat Shell Element in SOL 400

Defines initial temperature at grid points of heat shell elements with linear or quadratic temperature distribution across the thickness direction.

Format:

| 1      | 2   | 3  | 4  | 5  | 6  | 7  | 8  | 9 | 10 |
|--------|-----|----|----|----|----|----|----|---|----|
| TEMPN1 | SID | G1 | C1 | T1 | G2 | C2 | T2 |   |    |

Example:

|        |    |     |     |       |  |  |  |  |  |
|--------|----|-----|-----|-------|--|--|--|--|--|
| TEMPN1 | 10 | 100 | 123 | 1300. |  |  |  |  |  |
|--------|----|-----|-----|-------|--|--|--|--|--|

| Describer | Meaning                                                                                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Temperature set identification number. (Integer > 0)                                                                                                                                |
| Gi        | Grid point identification number. (Integer > 0)                                                                                                                                     |
| Ci        | Component numbers. ( $0 \leq \text{Integer} \leq 3$ ; up to 3 unique Integers may be placed in the field with no embedded blanks.) 1=TOP, 2=BOT, 3=MID. (Integer > -1; Default = 1) |
| Ti        | Temperature. (Real)                                                                                                                                                                 |

Remarks:

1. This entry is for shell elements defined on a PSHLN1 heat transfer.
2. In the steady-state solution sequences, SID is selected by the LOAD Case Control command.
3. In the transient solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the LID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an ACSRCE, RLOADi or TLOADi entry.
4. The TEMPN1 Bulk Data entry is used to complement the TEMP Bulk Data entry. The TEMP entry will just initiate the TOP grids. This entry allows specifying of the TOP, BOT, and MID or any combination. See the NLMOPTS,TEMGO,vmaptg Bulk Data entry on how to list internally generated grids.
5. For steady-state heat transfer analysis, this entry together with the TEMPD and TEMP entries supplies the initialization temperatures for nonlinear analysis. The Case Control command TEMP(INIT)=SID requests selection of this entry. The temperature values specified here must be coincident with any temperature boundary conditions that are specified.
6. For transient heat transfer analysis, this entry together with the TEMPD and TEMP entries supplies the initial condition temperatures. The Case Control command IC=SID requests selections of this entry. The temperature values specified here must be coincident with any temperature boundary condition specified.

TEMPP1

Plate Element Temperature Field, Form 1

Defines a temperature field for plate, membrane, and combination elements (by an average temperature and a thermal gradient through the thickness) for determination of thermal loading, temperature-dependent material properties, or stress recovery.

Format:

|        |      |      |      |        |      |      |        |   |    |
|--------|------|------|------|--------|------|------|--------|---|----|
| 1      | 2    | 3    | 4    | 5      | 6    | 7    | 8      | 9 | 10 |
| TEMPP1 | SID  | EID1 | TBAR | TPRIME | T1   | T2   |        |   |    |
|        | EID2 | EID3 | EID4 | EID5   | EID6 | EID7 | -etc.- |   |    |

Example:

|        |    |    |      |      |      |      |  |  |  |
|--------|----|----|------|------|------|------|--|--|--|
| TEMPP1 | 2  | 24 | 62.0 | 10.0 | 57.0 | 67.0 |  |  |  |
|        | 26 | 21 | 19   | 30   |      |      |  |  |  |

Alternate Format and Example of Continuation Entry:

|  |      |        |      |      |        |      |  |  |  |
|--|------|--------|------|------|--------|------|--|--|--|
|  | EID2 | “THRU” | EIDi | EIDj | “THRU” | EIDk |  |  |  |
|  | 1    | THRU   | 10   | 30   | THRU   | 61   |  |  |  |

| Describer        | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID              | Temperature set identification number. (Integer > 0)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| EIDi, EIDj, EIDk | Unique element identification number(s). (Integer > 0 or the continuation entries may have “THRU” in fields 3 and/or 6, in which case EID2 < EIDi and EIDj < EIDk.)                                                                                                                                                                                                                                                                                                                                                                                                  |
| TBAR             | Temperature at the element’s reference plane as defined by ZOFFS on the connection entry. (Real, Default 0.0)                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| TPRIME           | Effective linear thermal gradient. Not used for membranes. (Real, Default 0.0)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T1, T2           | Temperatures for stress calculation at points defined on the element property entry. (Z1 and Z2 field on PSHELL entry.) T1 may be specified on the lower surface and T2 on the upper surface for the CQUAD4, CQUAD8, CTRIA3, CTRIA6, CQUADR, and CTRIAR elements. These data are not used for membrane elements. See Remark 9. If both T1 and T2 are blank, they are computed from the equation $T = TBAR + z \cdot TPRIME$ , where $z$ is the distance from the center fiber. The program replaces T1 with a flag, and $z$ is computed in a later operation. (Real) |

Remarks:

1. In the static solution sequences, SID must be selected by the TEMP Case Control command.

In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the TID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry. TBAR and TPRIME are used for the analysis. If both are left blank the elements in essence see no thermal loading. T1 and T2 are used for post analysis for stress calculations.

2. Set ID must be unique with respect to all other LOAD type entries if TEMP(LOAD) is specified in the Case Control Section.
3. If continuation entries are present, EID1 and elements specified on the continuation entry are used. Elements must not be specified more than once.
4. If thermal effects are requested, all elements must have a temperature field defined either directly on a TEMPP1 or TEMPRB entry or indirectly as the average of the connected grid point temperatures defined on the TEMP or TEMPD entries. Directly defined element temperatures always take precedence over the average of grid point temperatures.
5. For temperature field other than a constant gradient, the “effective gradient” for a homogeneous plate is

$$TPRIME = \frac{1}{I} \int_z T(z) z dz$$

where  $I$  is the bending inertia and  $z$  is the distance from the neutral surface in the positive normal direction.

6. The “average” temperature for a homogeneous plate is

$$TBAR = \frac{1}{Volume} \int_{Volume} T dVolume$$

7. If the element material is temperature dependent, its properties are evaluated at the average temperature TBAR.
8. Large “THRU” ranges will lead to System Fatal Message 3008 (“Insufficient Core”) and should be avoided, particularly for open sets.
9. If the element material is nonlinear then T1 and T2 should be left blank (see the MATS1 entry).
10. In linear and nonlinear buckling analysis, the follower force effects due to loads from this entry are not included in the differential stiffness. See [Buckling Analysis in SubDMAP MODERS](#) and [Nonlinear Static Analysis](#) in the *MSC Nastran Reference Guide*.
11. The bending and twisting moments can be reduced to outer fiber stresses and combined with membrane stresses in the composite plate elements. If, in addition, the temperature is specified by the user at a point where outer fiber stresses are calculated, the thermal expansion due to the difference between the specified temperature and the temperature that would be produced by a uniform gradient,  $T'$ , is assumed to be completely restrained. Stated differently, the second and higher order moments of the thermal expansion are assumed to be completely restrained by elastic stiffness. The resulting stress increment is

$$\{\Delta\sigma\} = -[G_e]\{\alpha_e\}(T - T_o - T'z)$$

↑  
— temperature at reference plane

where  $[G_e]$  and  $\{\alpha_e\}$  are evaluated for the average temperature of the element  $\bar{T}$ .

## **TEMPP3**

## Plate Element Temperature Field, Form 3

TEMPP3 is no longer available. Use TEMPP1.

## TEMPRB      One-Dimensional Element Temperature Field

Defines a temperature field for the CBAR, CBEAM, CBEND, CROD, CTUBE, and CONROD elements for determination of thermal loading, temperature-dependent material properties, or stress recovery.

Format:

| 1      | 2    | 3    | 4    | 5    | 6    | 7    | 8      | 9    | 10 |
|--------|------|------|------|------|------|------|--------|------|----|
| TEMPRB | SID  | EID1 | TA   | TB   | TP1A | TP1B | TP2A   | TP2B |    |
|        | TCA  | TDA  | TEA  | TFA  | TCB  | TDB  | TEB    | TFB  |    |
|        | EID2 | EID3 | EID4 | EID5 | EID6 | EID7 | -etc.- |      |    |

Example:

|        |      |      |      |      |      |      |      |     |  |
|--------|------|------|------|------|------|------|------|-----|--|
| TEMPRB | 200  | 1    | 68.0 | 23.0 | 0.0  | 28.0 |      | 2.5 |  |
|        | 68.0 | 91.0 | 45.0 |      | 48.0 | 80.0 | 20.0 |     |  |
|        | 9    | 10   |      |      |      |      |      |     |  |

Alternate Format and Example of Continuation Entry:

|  |      |        |      |      |        |      |  |  |  |
|--|------|--------|------|------|--------|------|--|--|--|
|  | EID2 | “THRU” | EIDi | EIDj | “THRU” | EIDk |  |  |  |
|  | 2    | THRU   | 4    | 10   | THRU   | 14   |  |  |  |

| Describer        | Meaning                                                                                                                                                                                                                 |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID              | Temperature set identification number. (Integer > 0)                                                                                                                                                                    |
| EIDi, EIDj, EIDk | Unique element identification number(s). (Integer > 0 or the second continuation entry may have “THRU” in fields 3 and/or 6 in which case EID2 < EIDi and EIDj < EIDk.)                                                 |
| TA, TB           | Temperature at end A and end B on the neutral axis. (Real, default 0.0)                                                                                                                                                 |
| TPij             | Effective linear gradient in direction i on end j; used with CBAR, CBEAM, and CBEND only. (Real)                                                                                                                        |
| Tij              | Temperature at point i (i=C, D, E, or F) as defined on the PBAR, PBEAM, and PBEND entries at end j (j=A or B). This data is used for stress recovery only with CBAR, CBEAM, and CBEND exclusively. See Remark 3. (Real) |

Remarks:

1. In the static solution sequences, SID must be selected by the TEMP Case Control command.  
In the dynamic solution sequences, if there is a LOADSET Case Control command, then SID must be referenced in the TID field of a selected LSEQ entry. If there is no LOADSET Case Control command, then SID must be referenced in the EXCITEID field of an RLOADi or TLOADi entry.
2. SID must be unique with respect to all other LOAD type entries if TEMP(Load) is specified in the Case Control Section.

3. If at least one nonzero or nonblank  $T_{ij}$  is present, the point temperatures given are used for stress recovery. If no  $T_{ij}$  values are given, linear temperature gradients are assumed for stress recovery. The  $T_{ij}$  values are not used in the calculation of differential stiffness. The default for  $T_{ij}$  for  $j=A$  is  $TA$  and the default for  $T_{ij}$  for  $j=B$  is  $TB$ .
4. If the second (and succeeding) continuation is present, EID1 and elements specified on the second (and succeeding) continuations are used. Elements must not be specified more than once.
5. If thermal effects are requested, all elements must have a temperature field defined either directly on a TEMPP1 or TEMPRB entry or indirectly as the average of the connected grid point temperatures defined on the TEMP or TEMPD entries. Directly defined element temperatures always take precedence over the average of grid point temperatures.
6. The effective thermal gradients in the element coordinate system for the CBAR element are defined by the following integrals over the cross section. For end "A" (end "B" is similar),

$$TA = \frac{1}{A} \int TA(y, z) dA$$

$$TP1A = \frac{I_2}{\Delta} \int_A (y - y_n) TA(y, z) dA - \frac{I_{12}}{\Delta} \int_A (z - z_n) TA(y, z) dA$$

$$TP2A = \frac{I_1}{\Delta} \int_A (z - z_n) TA(y, z) dA - \frac{I_{12}}{\Delta} \int_A (y - y_n) TA(y, z) dA$$

$$\Delta = I_1 I_2 - I_{12}^2$$

$$\text{if } I_{12} = 0$$

$$TP1A = \frac{1}{I_1} \int_A (y - y_n) TA(y, z) dA$$

$$TP2A = \frac{1}{I_2} \int_A (z - z_n) TA(y, z) dA$$

where  $TA(y, z)$  is the temperature at point  $y, z$  (in the element coordinate system) at end "A" of the bar. See the CBAR entry description for the element coordinate system:  $I_1$ ,  $I_2$  and  $I_{12}$  are the moments of inertia about the  $z$  and  $y$  axes, respectively. The temperatures are assumed to vary linearly along the length ( $x$ -axis). Note that if the temperature varies linearly over the cross section, then  $TP1A$ ,  $TP1B$ ,  $TP2A$  and  $TP2B$  are the actual gradients.

7. If the element material is temperature-dependent, the material properties are evaluated at the average temperature  $(TA + TB)/2$ .
8. In linear and nonlinear buckling analysis, the follower force effects due to loads from this entry are not included in the differential stiffness. See [Buckling Analysis in SubDMAP MODERS](#) and [Nonlinear Static Analysis](#) in the *MSC Nastran Reference Guide*.

9. If any  $T_y$  is specified the stresses computed by the effective gradient are corrected by  $\Delta\sigma$  such that:

$$\sigma = \sigma \Big|_{T_A + y^{TP1A} + z^{TP2A}} + \Delta\sigma$$

where  $\Delta\sigma$  is in the form

$$\Delta\sigma = -\alpha E [T_{CA} - T_o - C_1 \cdot TPIA - C_2 \cdot TP2A] \text{ etc}$$

for CBAR and CBEAM

$$\Delta\sigma = -\alpha E [T_{CA} - T_o - (C_1 + \Delta N) \cdot TPIA - C_2 \cdot TP2A] \text{ etc}$$

for CBEND.

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID        | ID corresponding to a Case TERMIN entry. (Integer > 0; no Default)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| NC        | Number of termination conditions to be specified. (Integer > 0; Default = 1; Max number is 10)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| NTYPE     | Termination Criteria Type (Integer; no Default)<br>Enter 1 if termination occurs when a percentage of the boundary nodes are in contact.<br>Enter 2 if termination occurs when the maximum force on a rigid body is exceeded.<br>Enter 3 if termination occurs when the displacement of the rigid body exceeds the allowed displacement.<br>Enter 5 if termination occurs when the distance between the reference points of two rigid bodies is less or greater than the specified value.<br>Enter 6 if termination occurs, when any displacement in body, is greater than the specified value.<br>Enter 7 if termination occurs, when the displacement in the node, is greater than the specified value. |
| NBN       | Body number, for criterion type 7, grid ID (Integer > 0; no Default)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ICRIT     | <p>Criteria specification. (Integer; no Default)</p> <p>For criterion type 1, enter the percentage of nodes to be in contact for termination; default = 100.</p> <p>For criterion type 2, enter direction 1/2/3 for the x, y, z global directions</p> <p>For criterion type 5, enter the second body.</p> <p>For criterion type 6 or 7, enter the degree of freedom.</p> <p>For criterion type 6 or 7, enter -1 if the total translational displacement.</p> <p>For criterion type 6 or 7, enter -2 if the total rotation.</p> |
| VAL       | <p>Termination value. (Real; no Default)</p> <p>For criterion type 2, enter the critical force.</p> <p>For criterion type 3, enter the critical maximum displacement.</p> <p>For criterion type 5, enter the critical distance. If the value is positive, the termination occurs when the distance is less than the value. If the value is negative, the termination occurs when the distance is greater than the value in a positive sign.</p> <p>For criterion type 6 or 7, enter the critical distance (rotation).</p>      |

Remarks:

1. Different TERMIN entries may be used in different subcases.
2. Not all subcases require TERMIN entries if used in other subcases.

## TF Dynamic Transfer Function

Defines a dynamic transfer function of the form

$$(B0 + B1 \cdot p + B2 \cdot p^2)u_d + \sum_i (A0(i) + A1(i)p + A2(i)p^2)u_i = 0 \quad (9-30)$$

Where:

- $U_d$  = dependent coordinate
- $U_i$  = independent degree of freedom
- $p$  = differential operator ( $p=d/dt$ )

Can also be used as a means of direct matrix input. See Remark 4.

Format:

| 1  | 2    | 3    | 4     | 5     | 6     | 7      | 8 | 9 | 10 |
|----|------|------|-------|-------|-------|--------|---|---|----|
| TF | SID  | GD   | CD    | B0    | B1    | B2     |   |   |    |
|    | G(1) | C(1) | A0(1) | A1(1) | A2(1) | -etc.- |   |   |    |

Example:

|    |   |   |     |     |     |     |  |  |  |
|----|---|---|-----|-----|-----|-----|--|--|--|
| TF | 1 | 2 | 3   | 4.0 | 5.0 | 6.0 |  |  |  |
|    | 3 | 4 | 5.0 | 6.0 | 7.0 |     |  |  |  |

| Describer           | Meaning                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------|
| SID                 | Set identification number. (Integer > 0)                                                                                     |
| GD, G(i)            | Grid, scalar, or extra point identification numbers. (Integer > 0)                                                           |
| CD, C(i)            | Component numbers. (Integer zero or blank for scalar or extra points, any one of the Integers 1 through 6 for a grid point.) |
| B0, B1, B2          | Transfer function coefficients. (Real)                                                                                       |
| A0(i), A1(i), A2(i) |                                                                                                                              |

Remarks:

1. Transfer function sets must be selected with the Case Control command TFL = SID.
2. Continuation entries are optional.
3. The matrix elements defined by this entry are added to the dynamic matrices for the problem.

4. The constraint relation given in Eq. (9-30) will hold only if no structural elements or other matrix elements are connected to the dependent coordinate  $u_d$ . In fact, the terms on the left side of Eq. (9-30) are simply added to the terms from all other sources in the row for  $u_d$ .
5. See the [MSC Nastran Dynamic Analysis User's Guide](#) for a discussion of transfer functions.
6. For each SID, only one logical entry is allowed for each GD, CD combination.
7. For heat transfer analysis, the initial conditions must satisfy Eq. (9-30).
8. RC network does not support TF for thermal analysis.
9. For more information see [DMIGs, Extra Points, and Transfer Functions](#) in the *Dynamic Analysis User's Guide*.

## THPAD ROMAC's THPAD User Defined Service Element Property

Allows the user to provide the parameters for a tilting pad bearing for use with ROMAC's THPAD service.

Format:

| 1      | 2           | 3       | 4        | 5             | 6      | 7      | 8      | 9     | 10 |
|--------|-------------|---------|----------|---------------|--------|--------|--------|-------|----|

| Describer | Meaning                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| RID       | ROMAC bearing identification number that matches the property identification number on an ELEMUDS entry as well as a PBUSH2D entry. (Integer > 0) |
| TLIMIT    | Time limit for a call to THPAD. If the call takes longer than this, the service call will be killed. (Real)                                       |
| TITLE1    | User supplied title. (Character)                                                                                                                  |
| TITLE2    | User supplied title. (Character)                                                                                                                  |
| RADIUS    | Journal radius (Real, in)                                                                                                                         |
| CLEAR     | Ground-in pad clearance. (Real, in)                                                                                                               |
| OUTR      | Outer radius of bearing pads. (Real, in)                                                                                                          |
| LENGTH    | Axial length of bearing pads. (Real, in)                                                                                                          |
| E         | Young's modulus for the pads. (Real, psi)                                                                                                         |
| ALPHP     | Pad thermal expansion coefficient. (Real, 1/F)                                                                                                    |
| ALPHJ     | Journal thermal expansion coefficient. (Real, 1/F)                                                                                                |
| ALPHS     | Shell thermal expansion coefficient. (Real, 1/F)                                                                                                  |
| NPADS     | Number of pads. (Integer > 0)                                                                                                                     |
| NEL       | Number of elements per pad. (Integer > 0)                                                                                                         |
| IECC      | Eccentricity variation flag. (Integer)                                                                                                            |
|           | 0 Allow eccentricity variation to match load.                                                                                                     |

| Describer | Meaning                                                           |
|-----------|-------------------------------------------------------------------|
|           | 1 Eccentricity fixed at initial value.                            |
| ARCi      | Arc length for the pad. (Real, deg)                               |
| OFFSETi   | Offset factor for the pad. (Real)                                 |
| PRELOADi  | Preload factor for the pad. (Real)                                |
| PVANGi    | Location of pad pivot angle. (Real, deg)                          |
| IPi       | Pad polar moment. (Real, lb-sec <sup>2</sup> -in)                 |
| KPi       | Pad pivot stiffness. KPi=0 for rigid pivots. (Real, lb/in)        |
| MPi       | Pad mass. (Real, lb-sec <sup>2</sup> /in)                         |
| ITi       | Pad bending inertia. (Real, in <sup>4</sup> )                     |
| KFILM     | Fluid thermal conductivity. (Real, btu/in-sec-F)                  |
| KPAD      | Pad thermal conductivity. (Real, btu/in-sec-F)                    |
| TBACK     | Back of pad temperature. (Real, F)                                |
| TJF       | Temperature of the journal surface. (Real, F)                     |
| PSUMP     | Sump oil pressure. (Real, psi)                                    |
| TIN       | Pad inlet oil temperature. (Real, F)                              |
| KCAV      | Thermal conductivities cavitation ratio. (Real)                   |
| CCAV      | Cavitation latent heat ratio. (Real, btu/sec-in <sup>2</sup> -F)  |
| DENSITY   | Lubricant density. (Real, lbf-sec <sup>2</sup> /in <sup>4</sup> ) |
| SPEC      | Lubricant specific heat. (Real, btu-in/lbf-sec <sup>2</sup> -F)   |
| TA        | First temperature datum. (Real, F)                                |
| MUA       | Viscosity at TA. (Real)                                           |
| TB        | Second temperature datum. (Real, F)                               |
| MUB       | Viscosity at TB. (Real)                                           |
| ESUMP     | Sump heating factor. (Real)                                       |
| TMANU     | Clearance set temperature. (Real, F)                              |
| ERROR     | Error criterion. (Real)                                           |
| XG        | Initial guess of x/cp. (Real)                                     |
| YG        | Initial guess of y/cp. (Real)                                     |
| NAX       | Axial pressure exponent. (Real, 2.0 is recommended)               |
| FACTOR    | Perturbation effect on position iteration. (Real)                 |
| XFACT     | Percentage of cross-coupled terms in position update. (Real)      |
| ITJ       | Journal temperature flag. (Integer)                               |
|           | 0 Journal temperature found as average of film temperature.       |

| Describer | Meaning                                                 |
|-----------|---------------------------------------------------------|
| IBC       | 1 Journal temperature fixed by user.                    |
|           | 2 Journal temperature set for zero heat flux to shaft.  |
|           | Boundary condition flag. (Integer)                      |
| ITUR      | 0 Reynolds boundary condition with flow correction.     |
|           | 1 Not used.                                             |
|           | 2 Reynolds boundary condition for pressure.             |
| IDIM      | Turbulence flag. (Integer)                              |
|           | 0 Laminar solution.                                     |
|           | 1 Turbulence allowed.                                   |
| ICOND     | Dimension flag. (Integer)                               |
|           | 0 Two-dimensional conduction in the pad.                |
|           | 1 Radial conduction in the pad.                         |
| ITB       | Conduction flag. (Integer)                              |
|           | 0 Energy equation includes conduction.                  |
|           | 1 Adiabatic (isothermal) energy equation.               |
| ITG       | Back temperature flag. (Integer)                        |
|           | 0 Pad back temperature equals sump temperature.         |
|           | 1 Pad back temperature fixed by user.                   |
| ICAV      | Groove temperature flag. (Integer)                      |
|           | 0 Groove temperature found iteratively by heat balance. |
|           | 1 Groove temperature fixed at sump temperature.         |
| ICROSS    | Cavitation flag. (Integer)                              |
|           | 0 No cavitation effects in energy equation.             |
|           | 1 Include cavitation effects in energy equation.        |
| IDEF      | Cross-film viscosity flag. (Integer)                    |
|           | 0 Constant cross-film viscosity.                        |
|           | 1 Variable cross-film viscosity.                        |
|           | Deformation flag. (Integer)                             |
| IFLEX     | 0 No pad/pivot deformations.                            |
|           | 1 Pivot deformations.                                   |
|           | 2 Pad, journal and shell thermal deformations.          |
|           | 4 Pad mechanical deformations.                          |
|           | Type of beam bending for pad deformations. (Integer)    |

| Describer | Meaning                                                                        |
|-----------|--------------------------------------------------------------------------------|
|           | 0 Curved beam analysis.                                                        |
|           | 1 Straight beam analysis.                                                      |
|           | 2 Simple curvature calculation.                                                |
| IUN       | Unloaded pads flag. (Integer)                                                  |
|           | 0 Effect of unloaded pads is considered.                                       |
|           | 1 Effect of unloaded pads is neglected.                                        |
| ISUMP     | Sump temperature flag. (Integer)                                               |
|           | 0 Sump temperature set to pad inlet oil temperature.                           |
|           | 1 Sump temperature found iteratively by heat balance.                          |
| KTHETA    | Pivot rotational stiffness. (Real, lb-in, Default = 0.0)                       |
| DELO      | Initial pad angle for moment balance. (Real, rad, Default = 0.0)               |
| HOTOVER   | Percentage of hot oil available carried to the groove. (Real, Default = 100.0) |
| COLDOVER  | Percentage of groove oil made up of inlet oil. (Real, Default = 0.0)           |
| NCASE     | Number of speed/load cases. (Integer > 0)                                      |
| MAXC      | Maximum number of position iterations. (Real, Default = 100)                   |
| IALPH     | New stiffness smoothing factor. (Real)                                         |
| RPMi      | Speed of journal. (Real, rpm)                                                  |
| FXi       | Applied force in the negative x-direction. (Real, lb)                          |
| FYi       | Applied force in the negative y-direction. (Real, lb)                          |
| PGNUi     | Whirl ratio of shaft. (Real)                                                   |
| RELAXi    | Position iteration relaxation factor. (Real)                                   |
| OFLOWi    | Oil flow to bearing. (Real, cips)                                              |
| DERELi    | Relaxation factor for pivot deformation iteration. (Real)                      |

Remarks:

1. This entry triggers the call to the THPAD service. The GROUP must match the GROUP field of the CONNECT SERVICE FMS entry.
2. On the FMS CONNECT entry, only the CONNECT SERVICE can be used with this entry.
3. PID must match an existing ELEMUDS and PBUSH2D PIDs.
4. All units must be in the English system.
5. Refer to <http://www.virginia.edu/romac/> for more information.

6. Use of this entry requires, that the user, has obtained the source for the THPAD routine from the *University of Virginia Rotating Machinery and Controls Laboratory (ROMAC)* and use the MSC Nastran Software Development Kit (SDK) to build it as a User Defined Service (UDS). SDK and UDS build instructions are available in the [MSC Nastran Rotordynamics User's Guide](#).

## TIC Transient Analysis Initial Condition

Defines values for the initial conditions of variables used in structural transient analysis. Both displacement and velocity values may be specified at independent degrees-of-freedom (See Remark 6.). This entry may not be used for heat transfer analysis.

Format:

| 1   | 2   | 3 | 4 | 5  | 6  | 7 | 8 | 9 | 10 |
|-----|-----|---|---|----|----|---|---|---|----|
| TIC | SID | G | C | U0 | V0 |   |   |   |    |

Example:

|     |     |    |   |     |     |  |  |  |  |
|-----|-----|----|---|-----|-----|--|--|--|--|
| TIC | 100 | 10 | 3 | 0.1 | 0.5 |  |  |  |  |
|-----|-----|----|---|-----|-----|--|--|--|--|

| Describer | Meaning                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Set identification number. (Integer > 0)                                                                                                                 |
| G         | Grid, scalar, or extra point or modal coordinate identification number. (Integer > 0). See Remark 4.                                                     |
| C         | Component numbers. (Any one of the integers 1 through 6 for grid points, integer zero or blank for scalar or extra points and -1 for modal coordinates.) |
| U0        | Initial displacement. (Real)                                                                                                                             |
| V0        | Initial velocity. (Real)                                                                                                                                 |

Remarks:

1. Transient analysis initial condition sets must be selected with the IC Case Control command. Note the use of IC in the Case Control command versus TIC on the Bulk Data entry. For heat transfer, the IC Case Control command selects TEMP or TEMPD entries for initial conditions and not the TIC entry.
2. If no TIC set is selected in the Case Control Section, all initial conditions are assumed to be zero.
3. Initial conditions for coordinates not specified on TIC entries will be assumed to be zero.
4. In direct transient analysis (SOL 109 and 129) as well as in modal transient analysis (SOL 112) wherein the TIC Bulk Data entry is selected by an IC or IC(PHYSICAL) Case Control command, G may reference only grid, scalar or extra points. In modal transient analysis (SOL 112) wherein the TIC Bulk Data entry is selected by an IC(MODAL) Case Control command, G may reference only modal coordinates or extra points.
5. The initial conditions for the independent degrees-of-freedom specified by this Bulk Data entry are distinct from, and may be used in conjunction with, the initial conditions for the enforced degrees-of-freedom specified by TLOAD1 and/or TLOAD2 Bulk Data entries.
6. SOL700 does not support U0 (initial displacement).

## TICEL

## Transient Initial Conditions of Elements

Defines the initial values of element variables at the beginning of the analysis. Used in SOL 700 only.

Format:

|       |     |       |       |        |       |        |        |   |    |
|-------|-----|-------|-------|--------|-------|--------|--------|---|----|
| 1     | 2   | 3     | 4     | 5      | 6     | 7      | 8      | 9 | 10 |
| TICEL | SID | SETID | NAME1 | VALUE1 | NAME2 | VALUE2 | -etc.- |   |    |

Example:

|       |   |    |         |      |     |      |  |  |  |
|-------|---|----|---------|------|-----|------|--|--|--|
| TICEL | 3 | 40 | DENSITY | 100. | SIE | 1.E5 |  |  |  |
|-------|---|----|---------|------|-----|------|--|--|--|

| Describer | Meaning                                                                                 |
|-----------|-----------------------------------------------------------------------------------------|
| SID       | Set identification number. (Integer > 0; Required)                                      |
| SETID     | Number of a SET1 entry defining the elements to be initialized. (Integer > 0; Required) |
| NAMEi     | Element variable to be initialized. See Remark 5. (Character; Required)                 |
| VALUEi    | Value of the variable. (Real; Required)                                                 |

Remarks:

1. Initial conditions for elements that are not specified on TICEL entries are assumed to be zero except density, which is set to the reference density.
2. Only initial conditions that are selected in the Case Control Section (IC = SID) will be activated by the solver.
3. As many continuation lines as required can be used to specify all the variables being initialized. A blank field terminates the list.
4. Element variables for Eulerian elements can be initialized with a TICEL or a TICEUL1 entry. The TICEL entry initializes a set of elements, while the TICEUL1 entry initializes either a set of elements or geometrical regions (sphere, cylinder,...). When a Euler element is part of both a TICEL and a TICEUL1 entry, the TICEL entry takes precedence, and overrules the TICEUL1 initialization for the element.
5. The following variables for NAMEi can be used to initialize the Eulerian regions:

|         |                          |
|---------|--------------------------|
| XVEL    | x-velocity               |
| YVEL    | y-velocity               |
| ZVEL    | z-velocity               |
| DENSITY | Density                  |
| SIE     | Specific internal energy |
| Q       | Artificial viscosity     |

|      |                   |
|------|-------------------|
| DIV  | Divergence        |
| VOID | Void fraction     |
| FMAT | Material fraction |
| XMOM | x-momentum        |
| YMOM | y-momentum        |
| ZMOM | z-momentum        |

6. To initialize the pressure use density. And depending on the equation of states also define the specific internal energy (SIE).
7. For the Euler solvers, you can, in addition to the “normal” element variables that the solver has defined, also define an initial radial velocity field. You have to enter the location of the center from where the radial emerges, the velocity to be applied to the element center and the decay coefficient for the velocity field. The center is defined by the keywords “X-CENTER, Y-CENTER, Z-CENTER”, the radial velocity by “R-VEL” and the decay coefficient by "DECAY". You have to input these keywords in the above order, and have every keyword followed by its value.

## TICEUL1

## Transient Initial Conditions of Eulerian Regions

Defines the initial values sets for Eulerian regions. The Eulerian regions are defined by geometric shapes. Used in SOL 700 only.

Format:

| 1       | 2   | 3    | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|---------|-----|------|---|---|---|---|---|---|----|
| TICEUL1 | SID | TSID |   |   |   |   |   |   |    |

Example:

|         |     |     |  |  |  |  |  |  |  |
|---------|-----|-----|--|--|--|--|--|--|--|
| TICEUL1 | 300 | 200 |  |  |  |  |  |  |  |
|---------|-----|-----|--|--|--|--|--|--|--|

| Describer | Meaning                                                                        |
|-----------|--------------------------------------------------------------------------------|
| SID       | Unique TICEUL1 number referenced from a PEULER1 entry. (Integer > 0; Required) |
| TSID      | Group of geometric region TICREG ID. (Integer > 0; Required)                   |

Remarks:

1. Element variables for Eulerian elements can be initialized with a TICEL or a TICEUL1 entry. The TICEL entry initializes a set of elements, while the TICEUL1 entry initializes either a set of elements or geometrical regions (sphere, cylinder, ...). When a Euler element is part of both a TICEL and a TICEUL1 entry, the TICEL entry takes precedence and overrules the TICEUL1 initialization for the element.

## TICEUDS

User-defined Transient Initial Conditions of Euler Elements or Lagrangian grid points.

Defines the initial values of element or grid point variables at the beginning of the analysis by a user written subroutine. Use in SOL700 only.

Format:

| 1       | 2   | 3     | 4     | 5     | 6    | 7 | 8 | 9 | 10 |
|---------|-----|-------|-------|-------|------|---|---|---|----|
| TICEUDS | SID | GROUP | UNAME | SETID | COPT |   |   |   |    |

Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE initex 'SCAI.MDSolver.Obj.Uds.Dytran.InitOut '
```

*In Bulk Data:*

| 1       | 2  | 3      | 4      | 5   | 6    | 7 | 8 | 9 | 10 |
|---------|----|--------|--------|-----|------|---|---|---|----|
| TICEUDS | 12 | initex | EXINIT | 100 | GRID |   |   |   |    |

| Describer | Meaning                                                                                          |
|-----------|--------------------------------------------------------------------------------------------------|
| SID       | Unique output number. (Integer > 0; Required)                                                    |
| GROUP     | The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default)       |
| UNAME     | User subroutine name associated with the entry. (Character; default=EXINIT)                      |
| SETID     | Number of a SET1 entry defining the elements or grids to be initialized. (Integer > 0, Required) |
| COPT      | Flag for assigning initial velocities. (Character; default=Element)                              |
|           | Element            Apply the initial variables on elements                                       |
|           | GRID              Apply the initial variables on grids                                           |

Remarks:

1. Only can be used for SOL 700.
2. Initial conditions to be used must be selected in the Case Control Section (TIC = SID).
3. UNAME=EXINIT can only be used.

## TICREG

## Transient Initial Conditions of Eulerian Regions

Defines the initial values sets for Eulerian regions. The Eulerian regions are defined by geometric shapes. Used in SOL 700 only.

Format:

|        |      |      |      |     |     |      |       |   |    |
|--------|------|------|------|-----|-----|------|-------|---|----|
| 1      | 2    | 3    | 4    | 5   | 6   | 7    | 8     | 9 | 10 |
| TICREG | TRID | TSID | TYPE | VID | MID | TSID | LEVEL |   |    |

Example:

|        |     |     |        |     |     |   |     |  |  |
|--------|-----|-----|--------|-----|-----|---|-----|--|--|
| TICREG | 300 | 200 | SPHERE | 400 | 100 | 3 | 4.0 |  |  |
|--------|-----|-----|--------|-----|-----|---|-----|--|--|

| Describer | Meaning                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------|
| TRID      | Unique TRID number. (Integer > 0; Required)                                                            |
| TSID      | ID of group of Euler regions referenced from the TICEUL1 entry. (Integer > 0; Required)                |
| TYPE      | The type of Eulerian region. (Character; Required)                                                     |
|           | SURF                      Region inside or outside a surface.                                          |
|           | SPHERE                    Region inside a sphere.                                                      |
|           | CYLINDER                Region inside a cylinder.                                                      |
|           | BOX                        Region inside a box.                                                        |
|           | ELEM                      Region defined by list of Euler elements.                                    |
| VID       | ID of a geometric entity. (Integer > 0; Required)                                                      |
|           | <u>Type:</u> <u>Region:</u>                                                                            |
|           | SURF                      SURFINI                                                                      |
|           | SPHERE                  SPHERE                                                                         |
|           | CYLINDER                CYLINDR                                                                        |
|           | BOX                        BCBOX                                                                       |
|           | ELEM                      SET1                                                                         |
| MID       | ID of a MATDEUL entry defining this material. (Integer ≥ 0; Default = 0)                               |
| TSID      | ID of a TICVAL entry containing a list of initial values for this material. (Integer ≥ 0; Default = 0) |
| LEVEL     | Level indicator for this material and initial values. (Real; Default = 0.0)                            |

Remarks:

1. A number of TICREG may exist in the input file with the same TSID. The TICEUI entry will combine all TICREGs with the same TSID into one initial definition for the Euler elements that are referenced from the same PEULER1 definition.
2. When the material number is left blank or zero, the Eulerian elements inside the region will be void. Note that this is not allowed in the Riemann solution-based Euler solvers, as they will not handle void elements. If you define void elements and select either the 1stOrder or 2ndOrder scheme, an error message will be issued and the analysis will stop.
3. All level indicators LEVEL of the same TSID group must have different values. The level indicator can be negative.
4. See also the parameter MICRO for the accuracy of the initial value generation.

## TICVAL

## Transient Initial Condition Set

Defines the initial values of an Eulerian geometric region. Used in SOL 700 only.

Format:

| 1      | 2     | 3      | 4      | 5      | 6     | 7      | 8     | 9      | 10 |
|--------|-------|--------|--------|--------|-------|--------|-------|--------|----|
| TICVAL | TSID  | METHOD | NAME1  | VALUE1 | NAME2 | VALUE2 | NAME3 | VALUE3 |    |
|        | NAMEi | VALUEi | -etc.- |        |       |        |       |        |    |

Example:

|        |      |     |         |      |      |     |     |     |  |
|--------|------|-----|---------|------|------|-----|-----|-----|--|
| TICVAL | 3    |     | DENSITY | 100. | YVEL | 25. | SIE | 3.7 |  |
|        | XVEL | 3.5 |         |      |      |     |     |     |  |

| Describer | Meaning                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TSID      | Unique TICVAL number referenced from a TICEUL entry. (Integer > 0; Required)                                                                                                                                                                |
| METHOD    | Type of input definition. (Character; Default = NORMAL)<br><br>RADIAL     Initializes material with radial profiles. The entries VALUEi are interpreted as TABLED1 IDs. See Remarks 2., 3., and 4.<br><br>NORMAL     Normal initialization. |
| NAMEi     | Variable to be initialized. See TICEL. (Character; Required)                                                                                                                                                                                |
| VALUEi    | Value of the variable. (Real; Required)                                                                                                                                                                                                     |

Remarks:

1. Element variables for Eulerian elements can be initialized with a TICEL or a TICEUL1 entry. The TICEL entry initializes a set of elements, while the TICEUL1 entry initializes either a set of elements or geometrical regions (sphere, cylinder, ...). When an Euler element is part of both a TICEL and a TICEUL1 entry, the TICEL entry takes precedence and overrules the TICEUL1 initialization for the element.
2. METHOD = RADIAL allows to map results of a spherical symmetric 1-D solution onto a full 3-D model. For initialized variables SIE and DENSITY, a 1-D table has to be defined that specifies the variable value for a number of distances from the center. The center is by default (0,0,0) but can be changed by setting X-CENTER, Y-CENTER, Z-CENTER. The velocity is a radial velocity and has to be specified as R-VEL. Its values is also a TABLED1 ID.
3. DYPARAM,SPHERSYM can be used to define a proper 1-D spherical mesh and speeds up the run by taking only the mesh-size in radial direction into account.

4. Radial initialization of JWL is supported. The entries DETSPH and the JWL entry from the 1-D spherical solution stage have to be included in the remap run. Alternatively, the 1-D solution may be run with JWL and the follow-up run with ideal gas, provided that all JWL material has fully ignited. Radial initialization of EOSIG is not supported. In the follow-up run, ideal gas material has to be used instead of IG material.

## TIC3Transient Analysis Initial Velocity with Increment Options

Allows for the definition of a velocity field of grid points consisting of a rotation and a translation specification. Used in SOL 700 only.

Format:

| 1    | 2    | 3    | 4    | 5     | 6    | 7    | 8 | 9 | 10 |
|------|------|------|------|-------|------|------|---|---|----|
| TIC3 | SID  | G    |      | SCALE |      |      |   |   | +  |
| +    | XVEL | YVEL | ZVEL | XROT  | YROT | ZROT |   |   | +  |
| +    | G1   | G2   | THRU | G3    | BY   | G4   |   |   |    |

Example:

|      |       |   |      |      |    |      |  |  |   |
|------|-------|---|------|------|----|------|--|--|---|
| TIC3 | 7     | 5 |      | 10.  |    |      |  |  | + |
| +    | 100.0 |   |      | 5.0  |    | -7.5 |  |  | + |
| +    | 1     | 2 | THRY | 1000 | BY | 23   |  |  |   |

| Describer        | Meaning                                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| SID              | Number of a set of loads. (Integer > 0; Required)                                                                                               |
| G                | Number of a grid point at the center of rotation. (Integer > 0; Required)                                                                       |
| SCALE            | Scale factor of initial velocity. (Real, Default=1.0)                                                                                           |
| XVEL, YVEL, ZVEL | Initial translational velocity components. (Real; Default = 0.0)                                                                                |
| XROT, YROT, ZROT | Initial rotational velocity components. (Real; Default = 0.0)                                                                                   |
| G1, G2, ...      | Grid points to be initialized. THRU indicates a range of grid points. BY is the increment to be used within this range. (Integer > 0; Required) |

Remarks:

1. Any number of TIC3 entries can be used.
2. The rotational velocity components are defined in radians per unit time.
3. For six degree of freedom grid points, the angular velocity components are also initialized.
4. Initial conditions for grid points that are not specified on TICn entries are assumed to be zero.
5. If the THRU specification is used, the grid points in the range definition are required to exist. The BY option enables grid points to be ignored in this range.
6. None of the fields in the list of grid points can be blank or zero, since this indicates the end of the list.
7. The initial conditions to be used in SOL 700 must be selected in the Case Control Section (IC = SID).

8. If grid points are part of a rigid body, it is recommended you enable double precision in SOL700. It is possible that a single precision SOL700 analysis will not assign the correct initial velocities.

## TIM2PSD

## FFT conversion tool for use in random vibration fatigue analysis

Fast Fourier Transformation (FFT) conversion tool for use in SOL 108 or SOL 111 random vibration fatigue analysis. This entry is used to convert time history data into power spectral density (PSD) functions directly input to the fatigue analysis.

## Format:

| 1       | 2        | 3       | 4      | 5      | 6      | 7     | 8     | 9          | 10 |
|---------|----------|---------|--------|--------|--------|-------|-------|------------|----|
| TIM2PSD | ID       | SRATE   | WINDOW | FORMAT | MEANS  | NSKIP |       |            |    |

|         | EVENT  | 80001 |         |     |     |   | 2.0 | 1.0 |  |
|         |        | 80002 |         |     |     |   | 1.0 | 0.5 |  |
|         |        | 80003 |         |     |     |   | 2.0 | 1.0 |  |
|         | DELETE | 80001 | 1.1     | 1.9 |     |   |     |     |  |
|         | MAP    | 1     | 3       | 2   | 5   | 3 | 7   |     |  |

| Describer | Meaning                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID        | Unique identification number referenced by FATIGUE case control, otherwise TIM2PSD entry is ignored (Integer > 0).                                                |
| SRATE     | Number of samples per second (required) - thus $dt = 1/SRATE$ (Real; No Default).                                                                                 |
| WINDOW    | Window function to use. Choices are HANNING or NONE. This is applied to the "block" of data extracted from the total time signal. (Character; Default = HANNING). |

| Descriptor | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FORMAT     | Format of time signal files (RPC or CSV) (Character; Default = CSV). RPC files are binary channel data usually with the .rsp file extension. CSV files are typical MS Excel comma separated files in which the channels are in the columns (i.e. three columns of data is three channels of data - y-values only. x-values assumed to be in ascending order with no regards to length of time between points).                                                                                                                                                                                                                                                                                                                                                                                                                          |
| MEANS      | Used to decide if overall signal mean values are to be calculated (YES or NO) (Character; Default = NO). Currently this is only calculated and not applied in the analysis. Ignored if no mean stress correction specified on FTGPARM entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| NSKIP      | Number of header lines to skip if an FORMAT=CSV file (Integer>=0; Default=0).<br>The next continuation lines are required and repeat for as many Events as necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| EVENT      | Flag indicating that event parameters are to follow (one optional set for each event).<br>EVNTID <sub>i</sub> Number of this Event - must correspond to the TID of a FTGLOAD entry of TYPE=PSD that is referenced by an active FTGEVNT entry. (Note: it is NOT the actual FTGEVNT ID).<br>T <sub>i</sub> Length of window function in time for this Event (Real>0.0; no Default).<br>δ <sub>i</sub> Overlap or gap in time between windows for this Event (real) (+ means overlap) (Real>=0.0; Default = 0.0).<br>The next continuation lines are optional and can repeat for as many Events as necessary.                                                                                                                                                                                                                              |
| DELETE     | Flag indicating that event parameters are to follow for signal deletion. For any Event, time value pairs can be specified for deleting up to three (3) portions of the time signal for each Event.<br>EVNTID <sub>i</sub> Number of this Event - correspond to a previously defined EVNTID <sub>i</sub> in the "EVENT" section above.<br>T <sub>i_1</sub> Used to specify sections in an Event (defined by pairs of time values t1-t2, t3-t4, t5-t6) to delete from Event files before FFT process is applied (Real>0; t1 <= t2 <= t3 < t4 <= ...; no Defaults; if none are specified, entire signal is used). Only three (3) delete pairs per event are currently supported.<br>T <sub>f_i_1</sub><br>The next continuation lines are optional and only necessary if the SUBCASEs corresponding to the channel data is not one-to-one. |
| MAP        | Flag used to map the channel data and load case (SUBCASE) IDs.<br>LCID <sub>i</sub> SUBCASE of transfer function (TF) corresponding to ith load event. SUBCASEs must be in ascending order in the Case Control! There cannot be more SUBCASEs listed than there are channels of data in the CSV/RPC files.<br>CHAN <sub>i</sub> Channel # corresponding to ith load event. Channels must be referenced in ascending order and cannot be repeated.                                                                                                                                                                                                                                                                                                                                                                                       |

Remarks:

1. TIM2PSD bulk data entries are ignored if not selected by a FATIGUE case control.

2. The actual RPC/CSV files are specified with a UDNAME entry referenced by TID field on the FTGLOAD entry for each Event (FTGEVNT). This is a requirement in the presence of a TIM2PSD entry.
3. All events must be in the same format, use the same window function, have the same sample rate, and have the same number and order of channels.
4. Each event can be a different length and can have a different block length and gap.
5. If LOGLVL=1 or 2 on the FTGPARM entry, the input time histories and direct PSD computations are written to CSV files for possible plotting with MS Excel.
6. The TID on the FTGLOAD is also used as the SID of the auto-generated RANDPS entries in this process.
7. A file containing the auto-generated RANDPS and TABRND1 entries is created in the same directory as the referenced UDNAME filename. This file can then be used as an include file for subsequent analyses that use the same generated PSD data rather than using the TIM2PSD entry again in subsequent runs.
8. This process also determines the overall mean values of the time histories for each event. The means are normally thrown away in conversion to PSDs and cross-PSDs. Currently the mean effect is not taken into account in the subsequent fatigue analysis. These means are appended to the end of the file containing the auto-generated RANDPS and TABRND1 entries.
9. MAP flag is not necessary if all channels in RPC/CSV file are used in the exact same order as the SUBCASEs corresponding to the transfer functions. SUBCASE IDs must be in ascending order. Channels must be referenced in ascending order.

## TIRE Selection of Tires used in the Analysis

The TIRE bulk data entry facilitates the selection of all the CDTire/NVH tires to be used in the simulation. This is done by specifying the name of each CDTire/NVH tire that is to be included in the simulation on the tire bulk data entry.

Format:

| 1    | 2        | 3      | 4      | 5                  | 6      | 7      | 8      | 9   | 10  |
|------|----------|--------|--------|--------------------|--------|--------|--------|-----|-----|
| TIRE | ID       |        |        |                    |        |        |        |     |     |
|      | “CDTIRE” | TNAME1 | TNAME2 | TNAME3             | TNAME4 | TNAME5 | TNAME6 | ... | ... |
|      | ...      | ...    | ...    | TNAME <sub>n</sub> |        |        |        |     |     |

where, n is the number of CDTire/NVH tires to be used in the simulation.

Example:

|      |        |       |       |       |       |  |  |  |  |
|------|--------|-------|-------|-------|-------|--|--|--|--|
| TIRE | 100    |       |       |       |       |  |  |  |  |
|      | CDTIRE | TIRFL | TIRFR | TIRRL | TIRRR |  |  |  |  |

| Describer          | Meaning                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID                 | Set identification number referenced by TIRE case control command. (Integer > 0; Required).                                                             |
| “CDTIRE”           | Keyword for indicating that CDTire/NVH tires are used in the model.                                                                                     |
| TNAME <sub>i</sub> | The name of the <sup>i</sup> <sup>th</sup> CDTire/NVH tire. This name is specified in the DTI entry exported by CDTire while generating the tire model. |

## TLOAD1 Transient Response Dynamic Excitation, Form 1

Defines a time-dependent dynamic load or enforced motion of the form

$$\{P(t)\} = \{A\} \cdot F(t - \tau)$$

for use in transient response analysis.

Format:

| 1      | 2   | 3        | 4                 | 5    | 6     | 7   | 8   | 9 | 10 |
|--------|-----|----------|-------------------|------|-------|-----|-----|---|----|
| TLOAD1 | SID | EXCITEID | DELAYI/<br>DELAYR | TYPE | TID/F | US0 | VS0 |   |    |

Example:

|        |   |   |    |      |    |  |  |  |  |
|--------|---|---|----|------|----|--|--|--|--|
| TLOAD1 | 5 | 7 | 15 | LOAD | 13 |  |  |  |  |
|--------|---|---|----|------|----|--|--|--|--|

| Describer | Meaning                                                                                                                                                                              |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Set identification number. (Integer > 0) See Remarks 1. and 5.                                                                                                                       |
| EXCITEID  | Identification number of a static load set or a DAREA or SPCD entry set or a thermal load set (in heat transfer analysis) that defines $\{A\}$ . See Remarks 2. and 3. (Integer > 0) |
| DELAYI    | Identification number of DELAY Bulk Data entry that defines time delay $\tau$ . See Remark 8. and 13. (Integer > 0 or blank)                                                         |
| DELAYR    | Value of time delay $\tau$ that will be used for all degrees-of-freedom that are excited by this dynamic load entry. See Remark 8. and 13. (Real or blank)                           |
| TYPE      | Defines the type of the dynamic excitation. See Remarks 2., 3. and 12. (Integer, character or blank; Default = 0)                                                                    |
| TID/F     | Identification number of TABLEDi entry that gives $F(t)$ . (Integer > 0). Value of F to be used for all times. (Real, non-zero)                                                      |
| US0       | Factor for initial displacements of the enforced degrees-of-freedom. See Remarks 9., 11. and 14. (Real; Default = 0.0)                                                               |
| VS0       | Factor for initial velocities of the enforced degrees-of-freedom. See Remarks 10., 11. and 14. (Real; Default = 0.0)                                                                 |

Remarks:

1. Dynamic excitation sets must be selected with the Case Control command DLOAD = SID.

2. The type of the dynamic excitation is specified by TYPE (field 5) according to the following table:

| TYPE                                                                                                     | TYPE of Dynamic Excitation                                                       |
|----------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| 0, L, LO, LOA or LOAD                                                                                    | Applied load (force or moment) (Default)                                         |
| 1, D, DI, DIS, or DISP                                                                                   | Enforced displacement using large mass or SPC/SPCD data                          |
| 2, V, VE, VEL or VELO                                                                                    | Enforced velocity using large mass or SPC/SPCD data.                             |
| 3, A, AC, ACC or ACCE                                                                                    | Enforced acceleration using large mass or SPC/SPCD data                          |
| 4                                                                                                        | FLOW boundary condition on the face of an Eulerian solid element (SOL 700 only). |
| 12                                                                                                       | Velocity of the center of gravity of a rigid body (SOL 700 only)                 |
| 13                                                                                                       | Force or moment on the center of gravity of a rigid body (SOL 700 only).         |
| For enforced displacement, velocity and acceleration, the large mass method is not supported in SOL 400. |                                                                                  |

The enforced motion options (SPC/SPCD) defined by TYPE=1, 2, 3 are currently used for SOLs 109, 112, 146, 200, and where applicable SOL 400.

3. TYPE (field 5) also determines the manner in which EXCITEID (field 3) is used by the program as described below

Excitation specified by TYPE is applied load

- There is no LOADSET request in Case Control  
 EXCITEID may reference DAREA, static and thermal load set entries
- There is a LOADSET request in Case Control  
 The program may reference DAREA entries as well as static and thermal load set entries specified by the LID and TID fields, respectively, in the selected LSEQ entry corresponding to EXCITEID.

Excitation specified by TYPE is enforced motion

- There is no LOADSET request in Case Control  
 EXCITEID will reference SPCD entries. If such entries indicate null enforced motion, the program will then assume that the excitation is enforced motion using large mass and will reference DAREA and static and thermal load set entries just as in the case of applied load excitation.
- There is a LOADSET request in Case Control  
 The program will reference SPCD entries specified by the LID field in the selected LSEQ entry corresponding to EXCITEID. If such entries indicate null enforced motion, the program will then assume that the excitation is enforced motion using large mass and will reference static and thermal load set entries specified by the LID and TID fields, respectively, in the selected LSEQ entry corresponding to EXCITEID, just as in the case of applied load excitation.

4. EXCITEID may reference sets containing QHBDY, QBDYi, QVECT, QVOL and TEMPBC entries when using the heat transfer option.
5. SID need not be unique for all ACSRCE, RLOAD1, RLOAD2, TLOAD1 and TLOAD2 dynamic load entries. The DLOAD = SID Case Control command will select all dynamic load entries with the set identification of SID.
6. If the heat transfer option is used, the referenced QVECT entry may also contain references to functions of time, and therefore A may be a function of time.
7. If TLOADi entries are selected in SOL 111 or 146 then a Fourier analysis is used to transform the time-dependent loads on the TLOADi entries to the frequency domain and then combine them with loads from RLOADi entries. Then the analysis is performed as a frequency response analysis but the solution and the output are converted to and printed in the time domain. Please refer to [Fourier Transform](#) in the *MSC Nastran Dynamic Analysis User's Guide*.
8. If the DELAYI/DELAYR field is blank or zero,  $\tau$  will be zero.
9. The USO field is used only when the dynamic excitation defined by the TYPE field is enforced velocity or enforced acceleration using SPC/SPCD specification. The initial displacements for the enforced degrees-of-freedom in this case are given by the product  $\{A\}(US0)$  where  $\{A\}$  is defined by the EXCITEID field.
10. The VS0 field is used only when the dynamic excitation defined by the TYPE field is enforced acceleration using SPC/SPCD specification. The initial velocities for the enforced degrees-of-freedom in this case are given by the product  $\{A\}(VS0)$  where  $\{A\}$  is defined by the EXCITEID field.
11. The initial conditions for the enforced degrees-of-freedom implied by the US0 and VS0 fields are distinct from, and may be used in conjunction with, the initial conditions for the independent degrees-of-freedom specified by a TIC Bulk Data entry (which, in turn, is selected by an IC Case Control command).
12. For TYPE=4, TID must be blank if it references a FLOW entry. Use the FLOWT entry to define a time dependent flow boundary on the face of an Eulerian element.
13. For RC network solver in thermal analysis, the DELAY1/DELAYR is ignored.
14. Fields US0 and VS0 are not supported in SOL 700.
15. DELAYI/DELAYR (Integer>0 or Real) is not supported for the follower force in SOL129 and SOL400. The corresponding loads are neglected in the analysis.
16. If Modules are present then this entry may only be specified in the main Bulk Data section.
17. If enforced motion is applied in a modal transient solution the default solution algorithm is the COUPLED method, rather than the UNCOUPLED method. If you wish to use the UNCOUPLED solver in a modal transient solution with enforced motion, specify PARAM,NONCUP,-2 in your input file. When using the COUPLED solver in transient response, it is recommended to have at least two timesteps with 0.0 loading before starting your load.

## TLOAD2

## Transient Response Dynamic Excitation, Form 2

Defines a time-dependent dynamic excitation or enforced motion of the form

$$\{P(t)\} = \begin{cases} 0 & , t < (T1 + \tau) \text{ or } t > (T2 + \tau) \\ \{A\} \tilde{t}^B e^{C\tilde{t}} \cos(2\pi F\tilde{t} + P) & , (T1 + \tau) \leq t \leq (T2 + \tau) \end{cases}$$

for use in a transient response problem, where  $\tilde{t} = t - T1 - \tau$

Format:

| 1      | 2   | 3        | 4                 | 5    | 6  | 7  | 8 | 9 | 10 |
|--------|-----|----------|-------------------|------|----|----|---|---|----|
| TLOAD2 | SID | EXCITEID | DELAYI/<br>DELAYR | TYPE | T1 | T2 | F | P |    |
|        | C   | B        | US0               | VS0  |    |    |   |   |    |

Example:

|        |     |    |     |  |     |     |      |  |  |

| TLOAD2 | 4   | 10 | 5.0 |  | 2.1 | 4.7 | 12.0 |  |  |
|        | 2.0 |    |     |  |     |     |      |  |  |

| Descriptor | Meaning                                                                                                                                                                              |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID        | Set identification number. See Remarks 1. and 6. (Integer > 0)                                                                                                                       |
| EXCITEID   | Identification number of a static load set or a DAREA or SPCD entry set or a thermal load set (in heat transfer analysis) that defines $\{A\}$ . See Remarks 2. and 3. (Integer > 0) |
| DELAYI     | Identification number of DELAY Bulk Data entry that defines time delay $\tau$ . See Remark 5. (Integer > 0 or blank)                                                                 |
| DELAYR     | Value of time delay $\tau$ that will be used for all degrees-of-freedom that are excited by this dynamic load entry. See Remark 5. (Real or blank)                                   |
| TYPE       | Defines the type of the dynamic excitation. See Remarks 2. and 3. (Integer; character or blank; Default = 0)                                                                         |
| T1         | Time constant. (Real $\geq 0.0$ )                                                                                                                                                    |
| T2         | Time constant. (Real; T2 > T1)                                                                                                                                                       |
| F          | Frequency in cycles per unit time. (Real $\geq 0.0$ ; Default = 0.0)                                                                                                                 |
| P          | Phase angle in degrees. (Real; Default = 0.0)                                                                                                                                        |
| C          | Exponential coefficient. (Real; Default = 0.0)                                                                                                                                       |
| B          | Growth coefficient. (Real; Default = 0.0)                                                                                                                                            |

| Describer | Meaning                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| US0       | Factor for initial displacements of the enforced degrees-of-freedom. See Remarks 9, 11, and 16. (Real; Default = 0.0) |
| VSO       | Factor for initial velocities of the enforced degrees-of-freedom. See Remarks 10, 11, and 16. (Real; Default = 0.0)   |

**Remarks:**

- Dynamic excitation sets must be selected with the Case Control command with DLOAD=SID.
- The type of the dynamic excitation is specified by TYPE (field 5) according to the following table:

| TYPE                                                                                                     | TYPE of Dynamic Excitation                                               |
|----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| 0, L, LO, LOA or LOAD                                                                                    | Applied load (force or moment) (Default)                                 |
| 1, D, DI, DIS, or DISP                                                                                   | Enforced displacement using large mass or SPC/SPCD data                  |
| 2, V, VE, VEL or VELO                                                                                    | Enforced velocity using large mass or SPC/SPCD data                      |
| 3, A, AC, ACC or ACCE                                                                                    | Enforced acceleration using large mass or SPC/SPCD data                  |
| 12                                                                                                       | Velocity of the center of gravity of a rigid body. (SOL 700 only)        |
| 13                                                                                                       | Force or moment on the center of gravity of a rigid body. (SOL 700 only) |
| For enforced displacement, velocity and acceleration, the large mass method is not supported in SOL 400. |                                                                          |

The enforced motion options (SPC/SPCD) defined by TYPE=1, 2, 3 are currently used for SOLs 109, 112, 146, 200, and where applicable SOL 400.

- TYPE (field 5) also determines the manner in which EXCITEID (field 3) is used by the program as described below

Excitation specified by TYPE is applied load

- There is no LOADSET request in Case Control  
EXCITEID may reference DAREA, static and thermal load set entries
- There is a LOADSET request in Case Control  
The program may reference DAREA entries as well as static and thermal load set entries specified by the LID or TID fields, respectively, in the selected LSEQ entry corresponding to EXCITEID.

Excitation specified by TYPE is enforced motion

- There is no LOADSET request in Case Control  
EXCITEID will reference SPCD entries. If such entries indicate null enforced motion, the program will then assume that the excitation is enforced motion using large mass and will reference DAREA and static and thermal load set entries just as in the case of applied load excitation.

- There is a LOADSET request in Case Control

The program will reference SPCD entries specified by the LID field in the selected LSEQ entry corresponding to EXCITEID. If such entries indicate null enforced motion, the program will then assume that the excitation is enforced motion using large mass and will reference static and thermal load set entries specified by the LID and TID fields, respectively, in the selected LSEQ entry corresponding to EXCITEID, just as in the case of applied load excitation.

4. EXCITEID (field 3) may reference sets containing QHBDY, QB DYi, QVECT, and QVOL and TEMPBC entries when using the heat transfer option.
5. If the DELAYI/DELAYR field is blank or zero,  $\tau$  will be zero.
6. SID need not be unique for all ACSRCE, RLOAD1, RLOAD2, TLOAD1 and TLOAD2 dynamic load entries. The DLOAD = SID Case Control command will select all dynamic load entries with the set identification of SID.
7. If the heat transfer option is used, the referenced QVECT entry may also contain references to functions of time, and therefore A may be a function of time.
8. If TLOADi entries are selected in SOL 111 or 146 then a Fourier analysis is used to transform the time-dependent loads on the TLOADi entries to the frequency domain and then combine them with loads from RLOADi entries. Then the analysis is performed as a frequency response analysis but the solution and the output are converted to and printed in the time domain. In this case, B will be rounded to the nearest integer. Please refer to [Fourier Transform](#) in the *MSC Nastran Dynamic Analysis User's Guide*.
9. The USO field is used only when the dynamic excitation defined by the TYPE field is enforced velocity or enforced acceleration using SPC/SPCD specification. The initial displacements for the enforced degrees-of-freedom in this case are given by the product  $\{A\}(US0)$  where  $\{A\}$  is defined by the EXCITEID field.
10. The VS0 field is used only when the dynamic excitation defined by the TYPE field is enforced acceleration using SPC/SPCD specification. The initial velocities for the enforced degrees-of-freedom in this case are given by the product  $\{A\}(VS0)$  where  $\{A\}$  is defined by the EXCITEID field.
11. The initial conditions for the enforced degrees-of-freedom implied by the US0 and VS0 fields are distinct from, and may be used in conjunction with, the initial conditions for the independent degrees-of-freedom specified by a TIC Bulk Data entry (which, in turn, is selected by an IC Case Control command).
12. The continuation entry is optional.
13. TYPE=4 (SOL 700) is not supported using TLOAD2.
14. For SOL 700, TLOAD2 is converted to TLOAD1 and a TABLED1 is generated internally.
15. RC network solver does not support TLOAD2 for thermal analysis.
16. Fields US0 and VS0 are not supported in SOL 700.
17. DELAYI/DELAYR (Integer>0 or Real) is not supported for the follower force in SOL129 and SOL400. The corresponding loads are neglected in the analysis.

18. If comparing results between pre-2005 versions and later versions, please note that results are shifted by one time step in later versions. The tload2 should be updated accordingly if there is a need to compare to these pre-2005 versions.
19. If Modules are present then this entry may only be specified in the main Bulk Data section.
20. If enforced motion is applied in a modal transient solution the default solution algorithm is the COUPLED method, rather than the UNCOUPLED method. If you wish to use the UNCOUPLED solver in a modal transient solution with enforced motion, specify PARAM,NONCUP,-2 in your input file. When using the COUPLED solver in transient response, it is recommended to have at least two timesteps with 0.0 loading before starting your load.

## TMPSET

## Temperature Group Set Definition

Define a time-dependent dynamic thermal load group for use in TTEMP Bulk Data entry in SOL 400.

Format:

|        |    |    |    |    |    |    |    |    |    |
|--------|----|----|----|----|----|----|----|----|----|
| 1      | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10 |
| TMPSET | ID | G1 | G2 | G3 | G4 | G5 | G6 | G7 |    |

Alternate Format:

|        |    |    |        |    |      |     |  |  |  |
|--------|----|----|--------|----|------|-----|--|--|--|
| TMPSET | ID | G1 | “THRU” | G2 | “BY” | INC |  |  |  |
|--------|----|----|--------|----|------|-----|--|--|--|

The Continuation Entry formats may be used more than once and in any order. They may also be used with either format above.

Continuation Entry Format 1:

|  |    |    |     |     |        |  |  |  |  |
|--|----|----|-----|-----|--------|--|--|--|--|
|  | G8 | G9 | G10 | G11 | -etc.- |  |  |  |  |
|--|----|----|-----|-----|--------|--|--|--|--|

Continuation Entry Format 2:

|  |    |        |    |      |     |  |  |  |  |
|--|----|--------|----|------|-----|--|--|--|--|
|  | G8 | “THRU” | G9 | “BY” | INC |  |  |  |  |
|--|----|--------|----|------|-----|--|--|--|--|

Example:

|        |    |      |      |    |    |    |  |  |  |
|--------|----|------|------|----|----|----|--|--|--|
| TMPSET | 15 | 5    | THRU | 21 | BY | 4  |  |  |  |
|        | 27 | 30   | 32   | 33 |    |    |  |  |  |
|        | 35 | THRU | 44   |    |    |    |  |  |  |
|        | 67 | 68   | 72   | 75 | 84 | 93 |  |  |  |

| Describer | Meaning                                                       |
|-----------|---------------------------------------------------------------|
| ID        | Temperature group identification number. (Integer > 0)        |
| Gi        | Grid point Identification numbers in the group. (Integer > 0) |

Remarks:

1. This entry is used in SOL 400 only when ANALYSIS=NLTRAN (nonlinear transient analysis) and the temperature load is applied. It only applies to the nonlinear elements in the Residual (SEID=0).
2. GROUP\_ID determines the group of a specified the time-dependent distribution of temperatures. It is used by the TTEMP Bulk Data entry to define the corresponding TABLEDi entry. GROUP\_ID must be unique for all of the other TMPSET entries.
3. The temperature of grid point Gi must be defined using TEMP, TEMPD, TEMPP1, or TEMPRB Bulk Data entry. These bulk data entries must have the same SID as that referenced on the associated TTEMP Bulk Data entry.

**TODYNA****Defines the Start of Direct Text to Dytran**

All bulk data entries between TODYNA and ENDDYNA will be passed directly from SOL 700 to Dytran.  
Used in SOL 700 only.

Format:

| 1      | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|--------|---|---|---|---|---|---|---|---|----|
| TODYNA |   |   |   |   |   |   |   |   |    |

Example:

|        |     |        |  |       |        |  |  |  |  |
|--------|-----|--------|--|-------|--------|--|--|--|--|
| TODYNA |     |        |  |       |        |  |  |  |  |
| MAT1   | 345 | 29.0E6 |  | 0.285 | 0.0004 |  |  |  |  |
| ENDDYN |     |        |  |       |        |  |  |  |  |

## TOMVAR Topometry Design Variable

Defines a design region for topometry optimization (element-by-element optimization).

Format:

| 1      | 2        | 3     | 4   | 5         | 6     | 7   | 8   | 9     | 10 |
|--------|----------|-------|-----|-----------|-------|-----|-----|-------|----|
| TOMVAR | ID       | TYPE  | PID | PNAME/FID | XINIT | XLB | XUB | DELXV |    |
|        | "DLINK"  | TID   | C0  | C1        |       |     |     |       |    |
|        | "DDVAL"  | DSVID |     |           |       |     |     |       |    |
|        | "STRESS" | STLIM |     |           |       |     |     |       |    |

Example:

Design all element's thickness referencing PSHELL ID = 5 with initial design = 10.0 ( $t_0 = 10.0$  input element thickness), lower bound  $0.5 \cdot t_0$  and upper bound  $1.5 \cdot t_0$ .

|        |        |     |        |   |   |      |  |  |  |
|--------|--------|-----|--------|---|---|------|--|--|--|
| TOMVAR | 1      | PS1 | PSHELL | 5 | T | 10.0 |  |  |  |
|        | STRESS | 5.0 |        |   |   |      |  |  |  |

Example:

Design all element's Young Modulus referred by PSHELL ID = 100 with initial design XINIT = 3.E+5, XLB=1.0, and XUB= 1.0E+6.

|        |    |        |     |   |       |     |       |  |  |
|--------|----|--------|-----|---|-------|-----|-------|--|--|
| TOMVAR | 10 | PSHELL | 100 | E | 3.E+5 | 1.0 | 1.E+6 |  |  |
|--------|----|--------|-----|---|-------|-----|-------|--|--|

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID        | Unique topometry design region identification number. (Integer > 0)                                                                                                                                                                                                                                                                                                                                                  |
| TYPE      | Property entry type. Used with PID to identify the elements to be designed. See Remark 2. (Character: "PBAR", "PSHELL", "PSOLID", and "PCOMP", etc.)                                                                                                                                                                                                                                                                 |
| PID       | Property entry identifier (Integer > 0). This PID must be unique for PIDs referenced by other TOPVAR, DVPREL1, DVPREL2, DVMREL1, and DVMREL2 entries. Topometry, topology, and sizing variables cannot share the same properties. (Integer > 0). Combined topometry, topology, topography, sizing, and shape variables are allowed.                                                                                  |
| PNAME/FID | Property name or property material name, such as "T", "A", "E", and "GE", or field position of the property entry or word position in the element property table of the analysis model. Property names that begin with an integer such as 12I/T**3 may only be referenced by field position. Only one property value for each property can be designed by TOMVAR in a job. See Remark 2. (Character or Integer > 0.) |

| Describer | Meaning                                                                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XINIT     | Initial value. (Real or blank, no Default). Typically, XINIT is defined to match the mass target constraint (so the initial design does not have violated constraints) or the analysis model input property value. |
| XLB       | Lower bound. (Real or blank; Default = blank) . The default is $XLB=0.5*XINIT$ .                                                                                                                                   |
| XUB       | Upper bound . (Real or blank; Default = blank). The default is $XLB=1.5*XINIT$ .                                                                                                                                   |
| DELXV     | Fractional change allowed for the design variable during approximate optimization. See Remark 6. (Real > 0.0; Default = 0.5)                                                                                       |
| “DLINK”   | Indicates that this line relates a ply thickness to another ply thickness. See Remark 10.                                                                                                                          |
| TID       | TOMVAR entry identifier. (Integer > 0)                                                                                                                                                                             |
| C0        | Constant term. (Real; Default = 0.0)                                                                                                                                                                               |
| C1        | Coefficient term. (Real; no Default)                                                                                                                                                                               |
| “DDVAL”   | Indicates that this line defines discrete TOMVAR variables.                                                                                                                                                        |
| DSVID     | DDVAL entry identifier. (Integer > 0)                                                                                                                                                                              |
| “STRESS”  | Indicates that this line defines a stress limit.                                                                                                                                                                   |
| STLIM     | Von Mises stress upper bound. See Remark 11. (Real >0.0)                                                                                                                                                           |

### Remarks:

1. Multiple TOMVAR's are allowed in a single file.
2. Property name and FID > 0 can be used for element property values just like the DVPREL1 Bulk Data entry. Only property name can be used for material property values like DVMREL1.
3. Property name “A” is shared by material and property entries. If “A” is used for PNAME, it is a Material. For PROD, PBEAM and PBAR, the integer field ID must be used to point to the area of these entries. TOMVAR supports MAT1 only.
4. PBARL, PBEAML, PBRSECT, PCOMPG and PBMSECT are not supported.
5. For TYPE = PSHELL and PNAME selecting a material property, all the MATi fields on the PSHELL must be the same.
6. Combined topometry, topography, topology, sizing, and shape optimization is supported in a single file. However, topometry and topology cannot reference the same property ID. It is possible to topometry certain elements while sizing others. It is allowed to simultaneously design the same elements with topometry and desvar (sizing and/or shape) variables but topometry and sizing cannot reference the same property name.
7. Topometry optimization with element response constraints is slow due to many design variables. In this case, fully stressed design (FSD) is an alternative for certain problems
8. Parameters DESPCH and DESPCH1 specify when the topometry optimized design values are written to the element result history file jobname.des that can be imported to Patran and other post-processor to view topometry optimized results.
9. The TOMVAR entry cannot be used with thermal loads.

10. The DLINK line can only be used when TYPE=PCOMP. The PID must be the same as the PID given on the TOMVAR referenced by TID and the PNAMEs in the two TOMVAR entries must differ
11. "STRESS" limits can only be used for PTYPE=PSHELL and PNAME= T. The Von Mises stress (at element center) constraints apply to all shell elements in both designed and non-designed regions. All TOMVAR entries must have the same STLIM.

## TOPVAR Topological Design Variable

Define a topology design region for topology optimization.

Format:

| 1      | 2        | 3     | 4     | 5     | 6     | 7     | 8     | 9   | 10 |
|--------|----------|-------|-------|-------|-------|-------|-------|-----|----|
| TOPVAR | ID       | LABEL | PTYPE | XINIT | XLB   | DELXV | POWER | PID |    |
|        | "SYM"    | CID   | MS1   | MS2   | MS3   | CS    | NCS   |     |    |
|        | "CAST"   | CID   | DD    | DIE   | ALIGN |       |       |     |    |

|        | STRESS | 5.0 |        |   |   |      |   |   |  |

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID        | Unique topology design region identification number. (Integer > 0)                                                                                                                                                                                                                                                                                                                                    |
| LABEL     | User-supplied name for printing purpose. (Character)                                                                                                                                                                                                                                                                                                                                                  |
| PTYPE     | Property entry name. Used with PID to identify the elements to be designed. (Character: "PBAR", "PSHELL", "PSOLID", etc.)                                                                                                                                                                                                                                                                             |
| XINIT     | Initial value. (Blank or Real, $XLB < XINIT \leq 1.0$ ; Default = Blank). Typically, XINIT is defined to match the mass constraint on DRESP1=FRMASS, so the initial design does not have violated constraints. In this case, the default is set to the constraint value. If the mass (DRESP1=FRMASS or WEIGHT) is the objective, the default is 0.9. The default of XINIT is 0.6 for the other cases. |
| XLB       | Lower bound to prevent the singularity of the stiffness matrix. (Real; Default = 0.001)                                                                                                                                                                                                                                                                                                               |
| DELXV     | Fractional change allowed for the design variable during approximate optimization. See Remark 3. (Real > 0.0; Default = 0.2)                                                                                                                                                                                                                                                                          |
| POWER     | A penalty factor used in the relation between topology design variables and element Young's modulus. (Real > 1.0; Default = 3.0, or 4.0 if symmetry constraints used). $2.0 \leq POWER \leq 5.0$ is recommended.                                                                                                                                                                                      |
| PID       | Property entry identifier. This PID must be unique for PIDs referenced by other TOPVAR, DVPREL1 and DVPREL2 entries. Topology and sizing variables cannot share the same properties. (Integer > 0)                                                                                                                                                                                                    |
| "SYM"     | Indicates that this line defines symmetry constraints.                                                                                                                                                                                                                                                                                                                                                |

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CID       | Rectangular coordinate system ID used for specifying manufacturing constraints. See Remark 4. (Blank or Integer > 0; Default = blank)                                                                                                                                                                                                                                                                                                                                    |
| MSi       | Mirror symmetry plane. See Remark 5. & 7. (Character, 'XY', 'YZ', or 'ZX')                                                                                                                                                                                                                                                                                                                                                                                               |
| CS        | Cyclic symmetry axis. (character X, Y, Z). See Remark 12.                                                                                                                                                                                                                                                                                                                                                                                                                |
| NCS       | Number of cyclic symmetric segments in 360 degrees (Integer > 0). See Remark 9.                                                                                                                                                                                                                                                                                                                                                                                          |
| “CAST”    | Indicates that this line defines casting constraints (i.e., die draw direction constraints). See Remarks 6., 7., 8., and 10.                                                                                                                                                                                                                                                                                                                                             |
| DD        | Draw Direction. DDi=X, Y, Z or X-, Y-, Z- for a single die option (DIE=1) where X-, Y-, Z- indicates the opposite direction of X, Y, and Z respectively. DDi=X, Y, and Z for two die option (DIE =2) (Character)                                                                                                                                                                                                                                                         |
| DIE       | Die Options. (Blank or integer 1 or 2; Default = 1)<br>= 1 (or blank). A single die will be used and the die slides in the given draw direction (i.e., material grows from the bottom in the draw direction)<br>= 2. Two dies will be used and the dies split apart along the draw direction (i.e., material grows from the splitting plane in opposite direction along the axis specified by the draw direction DDi. The splitting plane is determined by optimization) |
| ALIGN     | Indicates whether the designed property finite element mesh is precisely aligned with the draw direction or extrusion direction. (Character: “YES” or “NO” or Blank; Default = blank = “NO”) See Remark 10.                                                                                                                                                                                                                                                              |
| “EXT”     | Indicates that this line defines extrusion constraints (i.e., enforce constant cross-section) See Remark 6. and 7.                                                                                                                                                                                                                                                                                                                                                       |
| ED        | Extrusion direction. (Character, X, Y, or Z)                                                                                                                                                                                                                                                                                                                                                                                                                             |
| “PRINT”   | Indicates that this line defines overhang constraints (maximum overhang angle is 45 degree). See Remark 12.                                                                                                                                                                                                                                                                                                                                                              |
| CID       | Rectangular coordinate system ID used for specifying overhang constraints.                                                                                                                                                                                                                                                                                                                                                                                               |
| PD        | PRINT Direction. PD =X, Y, Z or X-, Y-, and Z- where X-, Y-, Z- indicates the opposite direction of X, Y, and Z respectively (Character).                                                                                                                                                                                                                                                                                                                                |
| “TDMIN”   | Indicates that this line defines a minimum and/or maximum member size., See remarks 11. and 12.                                                                                                                                                                                                                                                                                                                                                                          |
| TVMIN     | Minimum member size. See Remarks 11. and 12. (Real>=0.0 or blank)                                                                                                                                                                                                                                                                                                                                                                                                        |
| TVMAX     | Maximum member size. See Remarks 11. and 12. (Real > TVMIN or blank)                                                                                                                                                                                                                                                                                                                                                                                                     |
| “STRESS”  | Indicates that this line defines a stress limit.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| STLIM     | Von Mises stress upper bound. See Remark 13.. (Real >0.0)                                                                                                                                                                                                                                                                                                                                                                                                                |

## Remarks:

1. The topologically designable element properties include PROD, PBAR, PBARL, PBEND, PBEAM, PBEAML, PSHELL, PSHEAR, PSOLID, and PWELD. Multiple TOPVAR's are allowed in a single file. Combined topology, topography (BEADVAR), topometry (TOMVAR) sizing, and shape optimization is supported in a single file. However, TOPVAR cannot be used with DVMREL1 and DVMREL2 entries.
2. All designed element properties must refer to a MAT1 entry or MAT9 entry (PSOLID only); therefore, a PCOMP/PCOMPG cannot be used as designed property in topology optimization. PCOMP/PCOMPG's can be used as non-designed properties in a topology optimization job.
3. If DELXV is blank, the default is taken from the specification of DELX parameter on the DOPTPRM entry.
4. Only CORD1R and CORD2R can be used as a referenced coordinate system to specify topology manufacturing constraints. Only one reference coordinate system CID is allowed for each TOPVAR entry.
5. One, two or three different mirror symmetry planes can present (such as MS1=XY, MS2=YZ, and MS3=ZX).
6. Casting ("CAST") and Extrusion ("EXT") manufacturability constraints can be applied to PTYPE="PSOLID" only. Casting constraints cannot be combined with extrusion constraints for the same TOPVAR entry.
7. Some symmetry constraint types can be combined with casting or extrusion constraints. The referenced coordinate system CID must be the same for the combined constraints. Some possible combinations are:
  - For "EXT" constraints, possible combinations are (ED=X, MSi=XY, and/or ZX or CS=X), (ED=Y, MSi=YZ, and/or XY or CS=Y), (ED=Z, MSi=ZX, and/or YZ or CS=Z).
  - For "CAST" constraints, possible combinations are (DD=X or X-, MSi=XY and/or ZX or CS=X), (DD=Y or Y-, MSi=YZ and/or XY or CS=Y), (DD=Z or Z-, MSi=ZX and/or YZ or CS=Z).
8. For two dies option (DIE=2), the splitting plane is optimized. For a single die DIE=1, the parting plane is the bottom surface of the designed part in the draw direction.
9. The first symmetry segment starts at the X-axis when CS = Z (at Z-axis when CS = Y, and at the Y-axis when CS = X). One cycle symmetry can be combined with one mirror symmetry constraint as long as the axis of cyclic symmetry is normal to the plane of mirror symmetry. For example, MSi = YZ and CS = X, MSi = XZ and CS = Y, and MSi = XY and CS = Z. This feature can also be used for < 360 degrees but NCS must be given in 360 degrees.
10. It is recommended to use aligned mesh for casting property due to smaller tolerance used.
11. Without a TDMIN continuation line, the minimum member size constraint is taken from the specification of TDMIN parameter on the DOPTPRM entry. This option is applied on 2 and 3 D elements only. Minimum member size constraints can be used with "SYM", "CAST", and "EXT" constraints.

12. TVMIN and TVMAX are dimensional quantities. A guideline is that TVMIN be at least three times a representative element dimension. TVMAX must be greater than TVMIN and it is recommended that it be twice as big. If TVMAX is blank, no maximum member size is imposed. It is recommended that TVMIN always be used when TVMAX is specified.
13. “STRESS” limits can only be used for PTYPE=PSOLID and PSHELL referencing MAT1 only. The Von Mises stress (at element center) apply to all solid and/or shell elements in both designed and non-designed regions. All TOPVAR entries must have the same STLIM.
14. The TOPVAR entry cannot be used with thermal loads.
15. For normal mode topology optimization, lower and higher mode may switch during optimization. This often occurs while maximizing or constraining the first eigenfrequency. This leads to a diverging solution. A workaround is using the mean value of a few of the lowest eigenfrequency (3-6) by DRESP2.
16. The CASI solver is strongly recommended for solid elements topology problems for efficiency.
17. “PRINT” (overhang constraints) can be used for PTYPE=PSOLID only and limited to one TOPVAR entry. The result is mesh dependent. If used with minimum member size, the location of reference coordinate system may have some influence on the optimal design.

## TRIM Trim Variable Constraint

Specifies constraints for aeroelastic trim variables.

Format:

| 1    | 2      | 3    | 4      | 5      | 6   | 7      | 8   | 9    | 10 |
|------|--------|------|--------|--------|-----|--------|-----|------|----|
| TRIM | SID    | MACH | Q      | LABEL1 | UX1 | LABEL2 | UX2 | AEQR |    |
|      | LABEL3 | UX3  | -etc.- |        |     |        |     |      |    |

Example:

|      |      |     |      |       |     |        |     |     |  |
|------|------|-----|------|-------|-----|--------|-----|-----|--|
| TRIM | 1    | 0.9 | 100. | URDD3 | 1.0 | ANGLEA | 7.0 | 0.0 |  |
|      | ELEV | 0.2 |      |       |     |        |     |     |  |

| Describer | Meaning                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Trim set identification number. (Integer > 0). See remarks 1 and 2.                                                                                 |
| MACH      | Mach number. (Real $\geq 0.0$ and $\neq 1.0$ )                                                                                                      |
| Q         | Dynamic pressure. (Real > 0.0)                                                                                                                      |
| LABELi    | The label identifying aerodynamic trim variables defined on an AESTAT, AESURF or AEPARM entry. (Character)                                          |
| UXi       | The magnitude of the aerodynamic extra point degree-of-freedom. (Real)                                                                              |
| AEQR      | Flag to request a rigid trim analysis (Real $\geq 0.0$ and $\leq 1.0$ ; Default =1.0). A value of 0.0 provides a rigid trim analysis, see Remark 5. |

Remarks:

1. The TRIM entry must be selected with the Case Control command TRIM=SID.
2. The SID must be unique among all the TRIM and TRIM2 entries.
3. The selected TRIM entry specifies the constrained values of the listed extra point degrees-of-freedom ("trim variables") for a particular loading condition. These variables are listed on AESTAT, AESURF and/or AEPARM entries.
4. If MACH is less than 1.0, then the Doublet-Lattice theory is used. If MACH is greater than 1.0, then the ZONA51 theory is used.
5. AEQR=0.0 can be used to perform a rigid trim analysis (ignoring the effects of structural deformation on the loading). AEQR=1.0 provides standard aeroelastic trim analysis. Intermediate values are permissible, but have no physical interpretation (they may be useful for model checkout).

**TRIM2** Trim Variable Definition

Defines the state of the aerodynamic extra points for a trim analysis. All undefined extra points will be set to zero.

Format:

| 1     | 2      | 3      | 4      | 5      | 6      | 7 | 8 | 9    | 10 |
|-------|--------|--------|--------|--------|--------|---|---|------|----|
| TRIM2 | SID    | MACH   | Q      |        |        |   |   | AEQR |    |
|       | LABEL1 | VALUE1 | LABEL2 | VALUE2 | -etc.- |   |   |      |    |

Example:

|       |       |     |        |      |      |     |  |  |  |
|-------|-------|-----|--------|------|------|-----|--|--|--|
| TRIM2 | 1     | 0.9 | 100.   |      |      |     |  |  |  |
|       | URDD3 | 1.0 | ANGLEA | FREE | ELEV | 0.2 |  |  |  |

| Describer | Meaning                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID       | Trim set identification number (Integer>0). See Remarks 1. and 2.                                                                                                          |
| MACH      | Mach number. (Real $\geq 0.0$ and $\neq 1.0$ ). See Remark 5.                                                                                                              |
| Q         | Dynamic pressure. (Real > 0.0)                                                                                                                                             |
| AEQR      | Flag to request a rigid trim analysis (Real $\geq 0.0$ and $\leq 1.0$ ; Default = 1.0). A value of 0.0 provides a rigid trim analysis. See Remark 6.                       |
| LABELi    | The label identifying aerodynamic trim variables defined on an AESTAT, AESURF, or AEPARM entry (Character)                                                                 |
| VALUEi    | The value assigned to LABELi. Either a real number that indicates the variable's fixed value, or one of the following words: FREE, LINKED, or SCHED. See Remarks 3. and 4. |

Remarks:

1. The TRIM2 entry must be selected with the Case Control command TRIM=SID.
2. The SID must be unique among all TRIM and TRIM2 entries.
3. A value of FREE indicates that the controller value will be solved for by the trim process. A value of LINKED indicates that the controller value will be set by an AELINK entry. A value of SCHED indicates that the controller value will be set by a CSSCHD entry. The LINKED and SCHED inputs are optional and provided as a convenience to the user. Nastran will determine the linked and scheduled controller states from the AELINK and CSSCHD entries, respectively.
4. All aerodynamic extra points that have not been defined on a TRIM2, AELINK, or CSSHED entry will be fixed to a value of zero.
5. If MACH is less than 1.0, then the Doublet-Lattice theory is used. If MACH is greater than 1.0, then the ZONA51 theory is used.

6.  $AEQR=0.0$  can be used to perform a rigid trim analysis (ignoring the effects of structural deformation on the loading).  $AEQR=1.0$  provides standard aeroelastic trim analysis. Intermediate values are permissible, but have no physical interpretation (they may be useful for model checkout).

## TRMCPL Trim Component Interface Coupling Parameters

Defines the interface coupling parameters for computing interface coupling matrices.

Format:

| 1      | 2   | 3     | 4     | 5       | 6       | 7       | 8       | 9   | 10 |
|--------|-----|-------|-------|---------|---------|---------|---------|-----|----|
| TRMCPL | TID | CTYPE | PLTOL | GAPTOL1 | GAPTOL2 | GAPTOL3 | GAPTOL4 | RID |    |

Example:

|        |   |        |      |   |  |  |  |  |  |
|--------|---|--------|------|---|--|--|--|--|--|
| TRMCPL | 1 | SGLUED | 0.12 | 5 |  |  |  |  |  |
|--------|---|--------|------|---|--|--|--|--|--|

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TID       | Identification number of trim component. (Integer>0; Required)                                                                                                                                                                                                                                                                                                                                                                                                                           |
| CTYPE     | Interface coupling type; see Remark 2. (Character, “SGLUED”, “SSLIDE”, “SOPEN”, “SIMPER” or “SAIRGAP”; Required)                                                                                                                                                                                                                                                                                                                                                                         |
| PLTOL     | Relative tolerance for in-plane/in-element/normal acceptance with respect to CTYPE. (Real>0.0; Default=0.1)                                                                                                                                                                                                                                                                                                                                                                              |
| GAPTOLx   | <ul style="list-style-type: none"> <li>■ GAPTOL1 Absolute tolerance for extrusion with respect to CTYPE. (Real&gt;0.0; Default=0.01)</li> <li>■ GAPTOL2 Second absolute tolerance for extrusion with respect to CTYPE. (Real&gt;0.0; Default=GAPTOL1)</li> <li>■ GAPTOL3 Third absolute tolerance for extrusion with respect to CTYPE. (Real&gt;0.0; Default=GAPTOL2)</li> <li>■ GAPTOL4 Fourth tolerance for extrusion with respect to CTYPE. (Real&gt;0.0; Default=GAPTOL3)</li> </ul> |
| RID       | ID of a region of a TRMC. (Blank or Integer≥0, default=0)                                                                                                                                                                                                                                                                                                                                                                                                                                |

Remarks:

- For each interface coupling type, CTYPE, this entry is used to compute the interface matrix with incongruent meshes at the interface.
- For the meanings of values on CTYPE, please see Bulk Data entry, ACPMCP for the detailed descriptions.
- TRMCPL is not a required entry for any trim component referenced by TRIMGRP and should be placed in the main bulk data section or under 'BEGIN BULK'.

4. GAPTOL<sub>x</sub> is the absolute tolerance for mapping surfaces of (structure, trim components) and (trim components, cavity). Grids on surfaces that are separated further than GAPTOL<sub>x</sub> will not be considered for coupling. GAPTOL<sub>x</sub> are utilized for successive projections. GAPTOL1 will be used for first projection. Then, GAPTOL2, GAPTOL3 and GAPTOL4, if provided, will be used for subsequent projections for the remaining unprojected grids. GAPTOL<sub>x</sub> is in the same unit as the one used for length.
5. PLTOL is relative tolerance for computing volume contributions. PLTOL is in percentage.

6. TRMCPL entries of a (TID,RID) pair correspond to ACPEMCP with the same (TID,RID) pair.
7. TRMCPL entry with CTYPE specified must have CTYPE field with non-zero input on the corresponding ACPEMCP entry.

## TSTEP Transient Time Step

Defines time step intervals at which a solution will be generated and output in transient analysis.

Format:

| 1     | 2   | 3      | 4   | 5   | 6 | 7 | 8 | 9 | 10 |
|-------|-----|--------|-----|-----|---|---|---|---|----|
| TSTEP | SID | N1     | DT1 | NO1 |   |   |   |   |    |
|       |     | N2     | DT2 | NO2 |   |   |   |   |    |
|       |     | -etc.- |     |     |   |   |   |   |    |

Example:

|       |   |    |      |   |  |  |  |  |  |
|-------|---|----|------|---|--|--|--|--|--|
| TSTEP | 2 | 10 | .001 | 5 |  |  |  |  |  |
|       |   | 9  | 0.01 | 1 |  |  |  |  |  |

| Describer | Meaning                                                                                        |
|-----------|------------------------------------------------------------------------------------------------|
| SID       | Set identification number. (Integer > 0)                                                       |
| Ni        | Number of time steps of value DTi. (Integer $\geq 1$ )                                         |
| DTi       | Time increment. (Real > 0.0)                                                                   |
| NOi       | Skip factor for output. Every NOi-th step will be saved for output. (Integer > 0; Default = 1) |

Remarks:

1. TSTEP entries must be selected with the Case Control command TSTEP = SID.
2. Note that the entry permits changes in the size of the time step during the course of the solution. Thus, in the example shown, there are 10 time steps of value .001 followed by 9 time steps of value .01. Also, the user has requested that output be recorded for  $t = 0.0, .005, .01, .02, .03$ , etc.
3. See [Guidelines and Tools for Effective Dynamic Analysis](#) in *MSC Nastran Dynamic Analysis User's Guide* or a discussion of considerations leading to the selection of time steps.
4. In modal frequency response analysis (SOLs 111 and 146), this entry is required only when TLOADi is requested; i.e., when Fourier methods are selected.
5. The maximum and minimum displacement at each time step and the SIL numbers of these variables can be printed by altering DIAGON(30) before the transient module TRD1 and by altering DIAGOFF(30) after the module. This is useful for runs that terminate due to overflow or excessive run times.
6. For heat transfer analysis in SOL 159, use the entry.
7. If Modules are present then this entry may only be specified in the main Bulk Data section.

## TSTEPNL Parameters for Nonlinear Transient Analysis

Defines parametric controls and data for nonlinear transient structural or heat transfer analysis. is intended for SOLs 129, 159, 600 and SOLs 400 and 700.

Format:

| 1       | 2      | 3      | 4     | 5      | 6      | 7     | 8       | 9       | 10 |
|---------|--------|--------|-------|--------|--------|-------|---------|---------|----|
| TSTEPNL | ID     | NDT    | DT    | NO     | METHOD | KSTEP | MAXITER | CONV    |    |
|         | EPSU   | EPSP   | EPSW  | MAXDIV | MAXQN  | MAXLS | FSTRESS |         |    |
|         | MAXBIS | ADJUST | MSTEP | RB     | MAXR   | UTOL  | RTOLB   | MINITER |    |

Example:

|         |       |       |       |      |       |     |     |    |  |
|---------|-------|-------|-------|------|-------|-----|-----|----|--|
| TSTEPNL | 250   | 100   | .01   | 1    | ADAPT | 2   | 10  | PW |  |
|         | 1.E-2 | 1.E-3 | 1.E-6 | 2    | 10    | 2   | .02 |    |  |
|         | 5     | 5     | 0     | 0.75 | 16.0  | 0.1 | 20. |    |  |

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID        | Identification number. (Integer > 0)                                                                                                                                                                                                                                                                                                                          |
| NDT       | Number of time steps of value DT. See Remark 2. (Integer ≥ 3)                                                                                                                                                                                                                                                                                                 |
| DT        | Time increment. See Remark 2. (Real > 0.0)                                                                                                                                                                                                                                                                                                                    |
| NO        | Time step interval for output. Every NO-th step will be saved for output. See Remark 3. (Integer ≠ 0; Default = 1)                                                                                                                                                                                                                                            |
| METHOD    | Method for stiffness matrix update and the transient time integration schemes. For SOLs 129 and 159, only METHOD=ADAPT is allowed and it is also the default. For SOL 400, all options are allowed. The default is AUTO with non-contact analysis and FNT with contact analysis. See Remark 4. (Character: "AUTO", "ITER", "ADAPT", "SEMI", "FNT", or "PFNT") |
| KSTEP     | KSTEP is the number of converged bisection solutions between stiffness updates for ADAPT method. (Default = 2). It is the number of iterations before stiffness updates for ITER method (Default = 10). See Remarks 18. and 19. (Integer > 0).                                                                                                                |
| MAXITER   | Limit on number of iterations for each time step. See Remarks 5., 6., and 18. (Integer ≠ 0; Default = 10 for ADAPT method and 25 for non-ADAPT methods)                                                                                                                                                                                                       |
| CONV      | Flags to select convergence criteria. See Remarks 7. and 21. (Character; Default = "PW" for SOLs 129 and 159, "UPW" for SOL 400 with non-contact analysis, and "PV" for SOL 400 with contact analysis.)                                                                                                                                                       |
| EPSU      | Error tolerance for displacement (U) criterion. See Remark 20. (Real ≠ 0.0; Default = 1.0E-2 for all methods except PFTN. For PFTN, Default = -1.0E-2)                                                                                                                                                                                                        |
| EPSP      | Error tolerance for load (P) criterion. (Real > 0.0; Default = 1.0E-3 for SOLs 129 and 159, 1.0E-2 for SOL 400)                                                                                                                                                                                                                                               |

| Descriptor | Meaning                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EPSW       | Error tolerance for work (W) or energy criterion. See Remark 20. (Real > 0.0; Default = 1.0E-6 for SOLs 129 and 159, 1.0E-2 for SOL 400 and non-PFNT methods, -1.0E-2 for SOL 400 and PFNT method)                     |
| MAXDIV     | Limit on the number of diverging conditions for a time step before the solution is assumed to diverge. See Remark 8. (Integer ≠ 0; Default = 2)                                                                        |
| MAXQN      | Maximum number of quasi-Newton correction vectors to be saved on the database. See Remark 9. (Integer ≥ 0; Default = 10 for all methods except PFNT. For PFNT, Default = 0)                                            |
| MAXLS      | Maximum number of line searches allowed per iteration. See Remark 9. (Integer ≥ 0; Default = 2 for all methods except PFNT. For PFNT, Default = 0)                                                                     |
| FSTRESS    | Fraction of effective stress ( $\bar{\sigma}$ ) used to limit the subincrement size in the material routines. See Remark 10. (0.0 < Real < 1.0; Default = 0.2)                                                         |
| MAXBIS     | Maximum number of bisections allowed for each time step. See Remark 11. and 12. (-9 ≤ Integer ≤ 9; Default = 5 except for MAXITER < 0 and SOL 400. For MAXITER < 0 and SOL 400, Default = 0)                           |
| ADJUST     | Time step skip factor for automatic time step adjustment. See Remark 13. (Integer ≥ 0; Default = 5)                                                                                                                    |
| MSTEP      | Number of steps to obtain the dominant period response. See Remark 14. (10 ≤ Integer ≤ 200; Default = variable between 20 and 40 for SOL 129 and between 10 and 20 for SOL 400.)                                       |
| RB         | Define bounds for maintaining the same time step for the stepping function during the adaptive process. See Remark 14. (0.1 ≤ Real ≤ 1.0; Default = 0.6)                                                               |
| MAXR       | Maximum ratio for the adjusted incremental time relative to DT allowed for time step adjustment. See Remark 15. (Real ≥ 1.0; Default = 32.0)                                                                           |
| UTOL       | Tolerance on displacement or temperature increment below which a special provision is made for numerical stability. See Remark 16. (0.001 < Real ≤ 1.0; Default = 0.1)                                                 |
| RTOLB      | Maximum value of incremental rotation (in degrees) allowed per iteration to activate bisection. See Remark 17. (Real > 2.0; Default = 20.0)                                                                            |
| MINITER    | Minimum number of iterations for a load increment, SOL 400 only. (Default = 1 except for the contact analysis. For contact analysis, Default = 2) It is recommended to set MINITER = 2 when high accuracy is expected) |

Remarks:

- For SOL 129 and SOL 159, the Bulk Data entry is selected by the Case Control command = ID. Each residual structure subcase requires a entry and either applied loads via TLOADi data or initial values from a previous subcase. Multiple subcases are assumed to occur sequentially in time with the initial values of time and displacement conditions of each subcase defined by the end conditions of the previous subcase.

For SOL 400, the is selected in the STEP ID's listed within a SUBCASE ID. For SOL 400 each SUBCASE is independent of the previous statement.

2. NDT is used to define the total duration for analysis, which is  $NDT * DT$ . Since DT is adjusted during the analysis, the actual number of time steps, in general, will not be equal to NDT). Also, DT is used only as an initial value for the time increment.
3. For printing and plotting the solution with SOLs 129 and 159, data recovery is performed at time 0,  $NO*DT$ ,  $2*NO*DT$ , ..., and the last converged step, where DT is internally computed time increment and may change at every time step. For SOL 400 and  $NO > 0$ , data recovery is performed at time 0,  $NO*DTI$ ,  $2*NO*DTI$ , ..., and the last converged step, where DTI is the user input initial time increment and it is a constant. For SOL 400 thermal analysis and  $NO < 0$ , the SOL 159 scheme is used. For SOL 400 structural analysis and  $NO < 0$ , the SOL 129 scheme is used for SOL 400, i.e., data recovery is performed at time 0,  $|NO|*DT$ ,  $2*|NO|*DT$ , ..., and the converged step. See Remark 13. on how DT is changed.
4. The stiffness update strategy as well as the transient integration method is selected in the METHOD field.
  - a. METHOD="ADAPT": The program automatically adjusts the incremental time and uses bisection. During the bisection process, the stiffness matrix is updated every KSTEPth converged bisection solution. This is the **only** method available for SOLs 129 and 159 and is also their **default**.
  - b. METHOD="AUTO": The stiffness matrix is automatically updated to improve the convergence. Also, the program automatically adjusts the incremental time and uses bisection. The automatic time adjustment can be deselected by using ADJUST=0. KSTEP value is ignored during iteration. This is the **default** method for SOL 400.
  - c. METHOD = "ITER": The stiffness is updated at every KSTEPth iterations. Also, the program automatically adjusts the incremental time and uses bisection. The automatic time adjustment can be deselected by using ADJUST=0.
  - d. METHOD="SEMI": Same as the AUTO method except that the stiffness updated at the first iteration, and then starts the AUTO iteration scheme.
  - e. METHOD = "FNT": This is the Full Newton iteration method; the stiffness is updated at every iteration. In comparison with the PFNT method, the defaults for FNT are EPSU = 0.01, EPSW = 0.01 and MAXLS = 2. See Remark 19.
  - f. METHOD = "PFNT": This is the Pure Full Newton iteration method. The PFNT method is the same as the FNT method except that the defaults for PFNT method are EPSU = -0.01, EPSW = -0.01, and MAXLS = 0. See Remark 19.
5. This remark applies to SOLs 129 or 159 only. The number of iterations for a time step is limited to MAXITER. If MAXITER is negative, the analysis is terminated when the divergence condition is encountered twice during the same time step or the solution diverges for five consecutive time steps. If MAXITER is positive, the program computes the best solution and continues the analysis until divergence occurs again. If the solution does not converge in MAXITER iterations, the process is treated as a divergent process. See Remark 8.

6. This remark applies to SOL 400 only. The number of iterations for a load increment is limited to  $|\text{MAXITER}|$ . If the solution does not converge in  $|\text{MAXITER}|$  iterations, the load increment is bisected and the analysis is repeated. If the load increment cannot be bisected (i.e.,  $\text{MAXBIS}$  is attained or  $\text{MAXBIS} = 0$ ) and  $\text{MAXDIV}$  is positive, the best attainable solution is computed and the analysis is continued to the next time step. Best solutions for 4 time steps are computed. The analysis is terminated if the solution still diverges. If  $\text{MAXDIV}$  is negative, the analysis is terminated immediately.

If  $\text{MAXITER}$  is negative, the solution is continued to the end of the current step, even if the solution is divergent. In this case, the best attainable solution is computed for each time step. The default for  $\text{MAXBIS} = 1$ , if  $\text{MAXITER} < 0$ . Also for SOL 400, the value of  $\text{MAXITER}$  for the AUTO method is an approximation. The program will try to obtain a converged solution if it senses the solution can converge.

7. The convergence test flags (U = displacement error test, P = load equilibrium error test, W = work error test, V = vector component method, N = Length method) and the error tolerances (EPSU, EPSP, and EPSW) define the convergence criteria. All requested criteria (combination of U, P, W, V, and/or N) are satisfied upon convergence. Note that at least two iterations are necessary to check the displacement convergence criterion. For SOL 400, if the U criterion is selected together with P or W, then for the first iteration of a load increment, the U criterion will not be checked. For V and N, see Remark 21.
8.  $\text{MAXDIV}$  provides control over diverging solutions. Depending on the rate of divergence, the number of diverging solutions ( $\text{NDIV}$ ) is incremented by 1 or 2. The solution is assumed to diverge when  $\text{NDIV}$  reaches  $\text{MAXDIV}$  during the iteration. If the bisection option is used (allowed  $\text{MAXBIS}$  times) the time step is bisected upon divergence. Otherwise, the solution for the time step is repeated with a new stiffness based on the converged state at the beginning of the time step. If  $\text{NDIV}$  reaches  $\text{MAXDIV}$  again within the same time step, the analysis is terminated for SOLs 129 and 159. For SOL 400, the termination of analysis is dependent on the sign of  $\text{MAXDIV}$ . If  $\text{MAXDIV}$  is positive, the best attainable solution is computed and the analysis is continued to the next time step. Best solutions for 4 time steps are computed. The analysis is terminated if the solution is still diverges. If  $\text{MAXDIV}$  is negative, the analysis is terminated immediately. See Remark 6.
9. Nonzero values of  $\text{MAXQN}$  and  $\text{MAXLS}$  will activate the quasi-Newton update and the line search process, respectively.
10. The number of subincrements in the material routines is determined such that the subincrement size is approximately  $\text{FSTRESS} \cdot \bar{\sigma}$ .  $\text{FSTRESS}$  is also used to establish a tolerance for error correction in elastoplastic material, i.e., error in yield function  $< \text{FSTRESS} \cdot \text{yield stress}$ .  
If the limit is exceeded at the converging state, the program will terminate with a fatal error message. Otherwise, the stress state is adjusted to the current yield surface, resulting in  $\delta = 0$ .
11. The remark applies to SOLs 129 or 159 only. The bisection process is activated when divergence occurs and  $\text{MAXBIS} \neq 0$ . The number of bisections for a time increment is limited to  $|\text{MAXBIS}|$ . If  $\text{MAXBIS}$  is positive and the solution does not converge after  $\text{MAXBIS}$  bisections, the best solution is computed and the analysis is continued to the next time step. If  $\text{MAXBIS}$  is negative and the solution does not converge in  $|\text{MAXBIS}|$  bisection, the analysis is terminated.

12. This remark applies to SOL 400 only. The bisection process is activated when divergence occurs and  $MAXBIS \neq 0$ . The number of bisections for a time step is limited to the absolute value of  $MAXBIS$ . Different actions are taken when the solution diverges depending on the sign of  $MAXBIS$ . If  $MAXBIS$  is positive, the stiffness is updated on the first divergence, and the load is bisected on the second divergence. If  $MAXBIS$  is negative, the load is bisected every time the solution diverges until the limit on bisection is reached. If the solution does not converge after  $|MAXBIS|$  bisections, the analysis is continued or terminated depending on the sign of  $MAXDIV$ . See Remark 8.
13. **ADJUST** controls the automatic time stepping. Since the automatic time step adjustment is based on the mode of response and not on the loading pattern, it may be necessary to limit the adjustable step size when the period of the forcing function is much shorter than the period of dominant response frequency of the structure. It is the user's responsibility to ensure that the loading history is properly traced with the **ADJUST** option. The **ADJUST** option should be suppressed for the duration of short pulse loading. In particular, for impact problems in SOL 400, it is recommended that the **ADJUST** option be suppressed since the short duration pulses during the impact may not be tracked well by the frequency-based algorithm. It should also be noted that the **TZEROMAX** process (where the step is repeated with the same/smaller time step after the first 2 increments) is not currently available for contact problems. If unsure, start with a value for **DT** that is much smaller than the pulse duration in order to properly represent the loading pattern.
  - If **ADJUST** = 0, then the automatic adjustment is deactivated. This is recommended when the loading consists of short duration pulses.
  - If **ADJUST** > 0, the time increment is continually adjusted for the first few steps until a good value of  $\Delta t$  is obtained. After this initial adjustment, the time increment is adjusted every **ADJUST**-th time step only.
  - For SOL 400, if **ADJUST** > 0 and **NO** > 0 (see Remark 3.), the analysis time step can reduce without limit, but it cannot increase more than  $DT*NO$ . This means that, if **NO** = 1, the analysis time step can only reduce, but cannot increase. The user should use **NO** > 1 to take the advantage of the range of automatic time stepping. If **NO** < 0, the time step can both increase and decrease without limit. But in this case, the user will not know the exact output locations.
  - If **ADJUST** is one order greater than **NDT**, then automatic adjustment is deactivated after the initial adjustment.
14. **MSTEP** and **RB** are used to adjust the time increment during analysis. The recommended value of **MSTEP** is 10 to 40. A larger value (e.g., 40) is required for highly nonlinear problems. By default, the program automatically computes the value of **MSTEP** based on the changes in the stiffness.

The time increment adjustment is based on the number of time steps desired to capture the dominant frequency response accurately. The time increment is adjusted as follows:

$$\Delta t_{n+1} = f(r)\Delta t_n$$

where

$$r = \frac{1}{MSTEP} \left( \frac{2\pi}{\omega_n} \right) \left( \frac{1}{\Delta t_n} \right)$$

where:

|     |      |     |                            |
|-----|------|-----|----------------------------|
| f = | 0.25 | for | $r < 0.5 \cdot RB$         |
| f = | 0.5  | for | $0.5 \cdot RB \leq r < RB$ |
| f = | 1.0  | for | $RB \leq r < 2.0$          |
| f = | 2.0  | for | $2.0 \leq r < 3.0/RB$      |
| f = | 4.0  | for | $r \geq 3.0/RB$            |

15. MAXR is used to define the upper and lower bounds for adjusted time step size, i.e.,

$$\text{MIN}\left(\frac{DT}{2^{\text{MAXBIS}}}, \frac{DT}{\text{MAXR}}\right) \leq \Delta t \leq \text{MIN}(\text{MAXR} \cdot DT, \text{NO} \cdot DT)$$

16. UTOL is a tolerance used to filter undesirable time step adjustments; i.e.,

$$\frac{\|\dot{U}_n\|}{\|\dot{U}\|_{\text{max}}} < \text{UTOL}$$

Under this condition no time step adjustment is performed in a structural analysis (SOL 129). In a heat transfer analysis (SOL 159) the time step is doubled.

17. The bisection is activated if the incremental rotation for any degree-of-freedom ( $\Delta\theta_x, \Delta\theta_y, \Delta\theta_z$ ) exceeds the value specified by RTOLB. This bisection strategy is based on the incremental rotation and controlled by MAXBIS.
18. For non-ADAPT (except FNT and PFNT) methods, the stiffness will be updated at convergence if the number of iterations since last iteration is equal or greater than KSTEP. In addition, for SOL 400 and ADAPT method, the stiffness will be updated if  $3 \cdot \text{MAXITER}$  iterations are performed. For SOL 400 and non-ADAPT methods, the stiffness will be updated if MAXITER iterations are performed.
19. For FNT and PFNT methods, whether the stiffness matrix will be updated between the convergence of a load increment and the start of the next load increment depends on the value of KSTEP. In this case, KSTEP = -1, 'BLANK', or 1. A user fatal error will be issued if other value is input. If KSTEP = 1, the stiffness matrix will not be updated. If KSTEP = 'BLANK', the program will decide whether to update depending element type. If KSTEP = -1, the stiffness matrix will be forced to be updated.
20. If EPSU > 0.0, the displacement error is computed file with respect to the total displacements. If EPSU < 0.0, the displacement error is computed with respect to the delta displacements of a load increment. If EPSW > 0.0, the energy error is computed with respect to the total energy. If EPSW < 0.0, the energy error is computed respect to the delta energy of a load increment. The options EPSU < 0.0 and EPSW < 0.0 are available for SOL 400 only.
21. V and N are additional methods for convergence checking using the displacement (U) and/or load (P) criteria. V stands for vector component checking. In this method, convergence checking is performed on the maximum vector component of all components in the model. N stands for length checking. In this method, the length of a vector at a grid point is first computed by the SRSS (square root of the sum of the squares) method. Then convergence checking is performed on the maximum length of all grid points in the model. For example, if CONV=UV, then V checking method will be

performed with the U criteria, i.e., the maximum displacement component of all displacement components in the model is used for convergence checking. For V and N, the EPSU is always negative, i.e., the error is computed with respect to the delta displacements of a load increment, even if positive value is requested by users. CONV=V is the same as CONV=UPV and CONV=D is the same as CONV=UPD. If both V and N are specified; V will take precedence over N. For example, CONV=VN is the same as CONV=V.

By default, for UPV or UPN, separate checks are made over force and moment vectors, and translation and rotation vectors. While the force/translation check is valid always, the moment or rotation check is only valid for 6 DOF elements (beams, shells, etc.). In certain cases (i.e., simply supported or hinged structures where moments are numerically small, small rotation problems), it may be beneficial to turn off the additional convergence testing done for moments and/or rotations.

22. For SOL 700, only fields ID, NDT, and DT are used.
23. In NLTRAN analysis, the output is also influenced by NLPACK. Please refer to NLPACK for an example.

## TTEMP

## Temperature Distribution of Transient Response

Defines a time-dependent temperature distribution for the nonlinear transient analysis in SOL 400.

$$\{T(t)\} = \{A(T(x)) \cdot F(t)\}$$

where  $A(T(x))$  defines a spatial temperature distribution and  $F(t)$  a time function.  $T(t)$  is the time dependent temperature distribution for use in the nonlinear elements in nonlinear transient analysis.

Format:

| 1     | 2   | 3        | 4   | 5 | 6 | 7 | 8 | 9 | 10 |
|-------|-----|----------|-----|---|---|---|---|---|----|
| TTEMP | SID | GROUP_ID | TID |   |   |   |   |   |    |

Example:

|       |    |     |    |  |  |  |  |  |  |
|-------|----|-----|----|--|--|--|--|--|--|
| TTEMP | 11 | 101 | 31 |  |  |  |  |  |  |
|-------|----|-----|----|--|--|--|--|--|--|

| Descriptor | Meaning                                                                  |
|------------|--------------------------------------------------------------------------|
| SID        | Temperature set identification number. (Integer > 0)                     |
| GROUP_ID   | Temperature group identification number (Integer > 0 or =-1)             |
| TID        | Identification number of TABLEDi entry that gives $F(t)$ . (Integer > 0) |

Remarks:

1. The temperature distribution TTEMP must be selected by a Case Control command TEMP(Load)=SID in order to be used in the nonlinear transient analysis.
2. This command is used in SOL 400 only when ANALYSIS=NLTRAN (nonlinear transient analysis) and the temperature load is applied. It only applies to the nonlinear elements in the Residual (SEID=0). There should be only one temperature set for each STEP.
3. GROUP\_ID determines the distribution of temperatures. It references the TMPSET Bulk Data entry to define all grid points, which reference the same TABLEDi entry. Each grid point can have its own GROUP\_ID if necessary. GROUP\_ID=-1 means all grid points are in one group and reference the same TTEMP Bulk Data entry.
4. If the TEMP(INIT) Case Control command references a TTEMP entry, then only the spatial distribution of the TTEMP will be used as the initial temperature distribution for the TEMP(INIT) command.
5. TTEMP may be used in nonlinear transient analysis in SOL 400. For pure linear analysis in SOL 400, DLOAD/TLOADi has to be used to define a time-dependent temperature distribution.

## UDNAME

### User Defined File Name

Provides the name of a file that can be referenced from other bulk data entries such as FTGLOAD, TABLRPC, and MATDIGI.

Format:

| 1      | 2    | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|--------|------|---|---|---|---|---|---|---|----|
| UDNAME | UDID |   |   |   |   |   |   |   |    |
|        | NAME |   |   |   |   |   |   |   |    |

Example:

|        |            |  |  |  |  |  |  |  |  |
|--------|------------|--|--|--|--|--|--|--|--|
| UDNAME | 10         |  |  |  |  |  |  |  |  |
|        | myfile.dat |  |  |  |  |  |  |  |  |

| Describer | Meaning                                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------|
| UDID      | Unique UDID (Integer>0). See Remark 1.                                                                                                     |
| NAME      | Name of a file (with or without path) such as the external loading time history in DAC or RPC format or DIGIMAT material file (Character). |

Remarks:

1. The UDID is referenced by FTGLOAD, TABLRPC, or MATDIGI entries
2. The NAME is limited to a maximum of 256 characters ( corresponding to 4 lines of data in fields 2-9 ). For Fatigue analysis using .rsp (RPC) files, there is a 128 character limit (corresponding to 2 lines of data in fields 2-9). Embedded blanks are not supported.
3. If only a NAME with no path (e.g., *sine01.dac*) is supplied, the file is assumed to be located in the same directory as the Nastran input file. If an absolute or relative path is supplied (e.g, *//local/user/fatigue/sine01.dac*), it will be used.

**UDSESV** Define the number and names of user state variables for material user subroutines (SOL 400 only)

Define the number and names of the user state variables. Each state variable has default nominal name if a user name is not given. This is a global entry.

Format:

|        |     |          |      |          |     |          |     |          |    |
|--------|-----|----------|------|----------|-----|----------|-----|----------|----|
| 1      | 2   | 3        | 4    | 5        | 6   | 7        | 8   | 9        | 10 |
| UDSESV |     | NSTATS   |      |          |     |          |     |          |    |
|        | SV2 | SV2_NAME | SV3  | SV3_NAME | SV4 | SV4_NAME | SV5 | SV5_NAME |    |
|        | SV6 | SV6_NAME | .ETC |          |     |          |     |          |    |

Example:

|        |     |      |     |      |  |  |  |  |  |
|--------|-----|------|-----|------|--|--|--|--|--|
| UDSESV |     | 3    |     |      |  |  |  |  |  |
|        | SV2 | VAR2 | SV3 | VAR3 |  |  |  |  |  |

| Describer | Meaning                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| NSTATS    | The number of user defined state variables. (Integer >= 1)                                                            |
| SVi       | The default nominal name of state variable (CHARACTER, i >= 1, where i is the index number of the state variable)     |
| SVi_NAME  | The state variable name defined by user (CHARACTER, Default = SVi, where i is the index number of the state variable) |

Remarks:

1. This is a global entry that defines user state variables for material user subroutines. The temperature will always be passed to material use subroutine as the first state variable; its name should not be redefined in this entry.
2. If a state variable is not given a name, SVi will be used as its name. The number i is the index number of the state variable.
3. For output, either state variables names given in UDSESV or default SVi names can be used in NLOUT entry in case control. The state variables names will be used as keywords for output selection.
4. The 1st state variable is always temperature. The remaining user defined state variables are defined and used only by user, Nastran will not use them.
5. This entry only supports UMAT and UCOHES user subroutines, see UNAME in MATUDS
6. This entry is required when MATDIGI is defined to define the number of state variables.
7. The number of state variables is limited to 100 state variables (including temperature) for SOL400.

**UNBALNC****Specifies an Unbalanced Load for Rotordynamic Transient or Frequency Response Analysis**

Used in rotordynamic analyses to specify a rotating unbalance load in terms of a cylindrical system with the rotor rotation as the z-axis.

**Format:**

| 1       | 2       | 3     | 4       | 5                 | 6                  | 7     | 8 | 9 | 10 |
|---------|---------|-------|---------|-------------------|--------------------|-------|---|---|----|
| UNBALNC | SID     | MASS  | GRID    | X1                | X2                 | X3    |   |   |    |
|         | ROFFSET | THETA | ZOFFSET | T/F <sub>on</sub> | T/F <sub>OFF</sub> | CFLAG |   |   |    |
|         | UFT1    | UFT2  | UFT3    | UFR1              | UFR2               | UFR3  |   |   |    |
|         | MCT1    | MCT2  | MCT3    | MCR1              | MCR2               | MCR3  |   |   |    |
|         | SCR1    | SCR2  | SCR3    |                   |                    |       |   |   |    |

**Example:**

|         |      |      |      |      |      |      |  |  |  |
|---------|------|------|------|------|------|------|--|--|--|
| UNBALNC | 100  | 0.1  | 1001 | 0.0  | 1.0  | 0.0  |  |  |  |
|         | 0.02 | 30.0 | 0.5  |      |      | MASS |  |  |  |
|         | 1001 | 1002 | 1003 | 1004 | 1005 | 1006 |  |  |  |
|         | 2001 | 2002 | 2003 | 2004 | 2005 | 2006 |  |  |  |
|         | 3001 | 3003 | 3004 |      |      |      |  |  |  |

| Describer         | Meaning                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SID               | Set identification number. (Integer; Required; no Default)                                                                                                                                               |
| MASS              | Mass of imbalance. See Remark 4. (Real or Integer; if integer must be > 0; Required; no Default)                                                                                                         |
| GRID              | Grid identification number of applying imbalance. See Remark 10. (Integer; Required; no Default)                                                                                                         |
| X1, X2, X3        | Components of the vector, from GRID, in the displacement coordinate system of GRID, which is used to define a cylindrical coordinate system centered at GRID; see Remark 5. (Real; Required; no Default) |
| ROFFSET           | Offset of mass in the radial direction of the unbalance coordinate system. See Remark 4. (Real or Integer; if integer, must be > 0; Default = 1.0)                                                       |
| THETA             | Angular position, in degrees, of the mass in the unbalance coordinate system. (Real; Default = 0.0)                                                                                                      |
| ZOFFSET           | Offset of mass in the z-direction of the unbalance coordinate system. See Remark 4. (Real or Integer; if integer, must be > 0; Default = 0.0)                                                            |
| T/F <sub>ON</sub> | Start time or frequency for applying imbalance load. See Remark 6. (Real ≥ 0.0; Default = 0.0)                                                                                                           |

| Describer          | Meaning                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T/F <sub>OFF</sub> | Stop time or frequency for terminating imbalance load. See Remark 6. (Real > 0.0; Default = 999999.0)                                                                                                                                                                                                            |
| UFT1-3             | EPOINTS to output the unbalanced forces in the T1, T2, and T3 directions. See Remark 6. (Integer > 0)                                                                                                                                                                                                            |
| UFR1-3             | EPOINTS to output the unbalanced forces in the R1, R2, and R3 directions. See Remark 6. (Integer > 0)                                                                                                                                                                                                            |
| MCT1-3             | EPOINTS to output the mass-correction forces in the T1, T2, and T3 directions. See Remark 6. (Integer > 0)                                                                                                                                                                                                       |
| MCR1-3             | EPOINTS to output the mass-correction forces in the R1, T2, and R3 directions. See Remark 6. (Integer > 0)                                                                                                                                                                                                       |
| SCR1-3             | EPOINTS to output the speed-correction forces in the R1, R2, and R3 directions. (Integer > 0)                                                                                                                                                                                                                    |
| CFLAG              | Correct flag to specify whether 1) the mass will be used to modify the total mass in the transient response calculations, 2) the effect of the rotor spin rate change will be included in the transient response calculation, or 3) both; see Remark 7. (Character: NONE, MASS, SPEED, or BOTH, Default = NONE). |

Remarks:

- Multiple UNBALNC entries with the same SID value are allowed.
- UNBALNC can be specified on reference and/or non-reference rotors. For transient response, UNBALNC is specified by the RGYRO Case Control command. For frequency response, it is specified by the DLOAD Case Control command; the RGYRO Case Control command, however, is still required to activate the unbalance information and the rotodynamics capability. For frequency response SYNC analysis, the rotor speed ratio between all rotors should be 1.0. Speed ratio is calculated based on the ratio of SPTID entry of its RSPINR entry to SPDIT field of its reference rotor RSPINR entry. A User Fatal Message will be issued if the ratio is not equal to 1.0.
- The imbalance load will be generated based on the mass value, offset values, and the rotor spin speed.
- If the entry is a real number, the value is considered constant. If the entry is an integer number, the value references a TABLEDi entry that specifies the value as a function of time for transient response or frequency for frequency response.
- A cylindrical coordinate system is used to determine the initial position and rotation direction of the mass unbalance. Theta is measured from the plane defined by the z-axis and the user specified vector (X1, X2, X3). Theta = 0.0 is in the direction of the user-specified vector (X1, X2, X3). Unbalance rotation is in the positive z-direction.
- For frequency response analysis, the EPOINTS and the continuation cards are ignored.
- If the mass loss (increase) is relatively small, the correction may safely be ignored. (CFLAG = NONE). These error corrections terms are applied for analysis in fixed reference frame only.

8. The mass specified on UNBALNC is scaled with PARAM, WTMASS factor for both transient and frequency response analysis. For the rotating reference frame, the unbalance load should be defined through UNBALNC only.

Equations in fixed reference frame:

- a. For Frequency response analysis

$$\begin{Bmatrix} F_x(\omega) \\ F_y(\omega) \end{Bmatrix} = WTMASS \cdot \begin{Bmatrix} mr\omega^2(\cos\theta_k + i\sin\theta_k) \\ mr\omega^2(\sin\theta_k + i\cos\theta_k) \end{Bmatrix}$$

- b. For transient analysis

$$\begin{Bmatrix} F_x(\omega) \\ F_y(\omega) \end{Bmatrix} = WTMASS \cdot \begin{Bmatrix} m(t)r(t)(\Omega_j^2(t)\cos\theta_{jk}(t) + \dot{\Omega}_j(t)\sin\theta_{jk}(t)) \\ m(t)r(t)(\Omega_j^2(t)\sin\theta_{jk}(t) - \dot{\Omega}_j(t)\cos\theta_{jk}(t)) \end{Bmatrix}$$

where,

$m(t)$  Specified by the user (MASS field in UNBALNC)

$r(t)$  Specified by the user (ROFFSET field in UNBALNC)

$\Omega_j(t)$  Specified by the user through RSINT/RSPINR entry

$\dot{\Omega}_j(t)$  Derived from  $\Omega_j(t)$

$\theta_{jk}(t)$  Instantaneous angular location, measured from axis 1 to axis 2 ( $= \int (\Omega_j(t)dt + \theta_k)$ )

$\theta_k$  Specified by the user (THETA field in UNBALNC) 0

j Rotor on which the grid is located

Equations in rotating reference frame:

- c. For frequency response analysis

$$\begin{Bmatrix} F_x(\omega) \\ F_y(\omega) \end{Bmatrix} = WTMASS \bullet \begin{Bmatrix} mr\omega^2(\cos\theta_k) \\ mr\omega^2(\sin\theta_k) \end{Bmatrix}$$

- d. For transient analysis

$$\begin{Bmatrix} F_x(t) \\ F_y(t) \end{Bmatrix} = WTMASS \bullet \begin{Bmatrix} m(t)r(t)\Omega_{jk}^2(t) \cos \theta_k \\ m(t)r(t)\Omega_{jk}^2(t) \sin \theta_k \end{Bmatrix}$$

9. The moment due to ZOFFSET is given by,

$$\begin{Bmatrix} M_x(\omega) \\ M_y(\omega) \end{Bmatrix} = \begin{Bmatrix} -F_y(\omega) \bullet ZOFFSET \\ F_x(\omega) \bullet ZOFFSET \end{Bmatrix}$$

10. The GRID specified on UNBALNC and the GRIDA specified on RSPINR/RSPINT for the same rotor must use the same CD.

**UNGLUE****Defines Grids that Should Be Eliminated From Glued Contact**

This entry may be used in SOLs 101 or 400 but is only necessary if glued contact has been specified and some of the grids should use standard contact instead of glued contact. This option is normally used for crack analysis where the grids along the crack are not glued but all other grids on a contact body have glued contact.

Format:

| 1      | 2   | 3    | 4   | 5    | 6   | 7      | 8 | 9 | 10 |
|--------|-----|------|-----|------|-----|--------|---|---|----|
| UNGLUE | ID  | BID  | ID1 | THRU | ID2 | BY     | N |   |    |
|        | ID3 | THRU | ID4 | ID5  | ID6 | -etc.- |   |   |    |

Example:

|        |    |      |      |      |      |      |      |  |  |
|--------|----|------|------|------|------|------|------|--|--|
| UNGLUE | 10 | 101  | 20   | THRU | 300  | BY   | 2    |  |  |
|        |    | 3457 | 8456 | 4712 | 1000 | THRU | 2000 |  |  |

| Describer | Meaning                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------|
| ID        | Identification number referenced by a SUBCASE or STEP Case Control BCONTACT or UNGLUE command. See Remark 1. (Integer; no Default) |
| BID       | Identification of the specified BCBODY. (Integer > 0; no Default).                                                                 |
| Idi       | ID list of grids. (Integer > 0; no Default).                                                                                       |
| THRU      | Enter THRU if a range of grids is required. (Character)                                                                            |
| BY        | Enter BY if the range of grids is not consecutive. (Character)                                                                     |
| N         | BY increment. (Integer > 0).                                                                                                       |

Remarks:

1. To place an entry in loadcase 0, set ID=0, which does not need any corresponding Case Control command BCONTACT=0 or UNGLUE=0 and is always automatically executed. To place an entry in any physical loadcase (SUBCASE or STEP), ID must be selected by the Case Control command BCONTACT=ID or UNGLUE=ID. Note that UNGLUE Case Control will take precedence over the BCONTACT Case Control for this entry with same ID. UNGLUE is ignored by Permanent contact.
2. This entry may be repeated as many times as necessary to define all subcases and bodies with grids that should not have glued contact.

**UNGLUE** Defines Grids that Should Be Eliminated From Glued Contact in SOL 600

This entry is only necessary if glued contact has been specified and some of the grids should use standard contact instead of glued contact. This option is normally used for crack analysis where the grids along the crack are not glued but all other grids on a contact body have glued contact. SOL 600 only.

| Descriptor | Meaning                                                                                                                                                                                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IDBC       | Identification number of a Case Control BCONTACT command defining the subcase to which these items should be available.<br>Enter 0 if this entry should apply to Marc's increment zero. Enter -9999 if it should apply to all subcases. (Integer; no Default)                              |
| IBOD       | Identification number of a matching BCBODY Bulk Data entry of a flexible surface defining the body with GRIDS to be removed from glued contact. The BCBODY may include additional grids (not included in this entry) that remain glued. (Integer; Default = 1) See Remarks 4. and 5. (3,1) |
| IDi        | ID list of grids. (Integer > 0; no Default).                                                                                                                                                                                                                                               |
| THRU       | Enter THRU if a range of grids is required. (Character)                                                                                                                                                                                                                                    |
| BY         | Enter BY if the range of grids is not consecutive. (Character)                                                                                                                                                                                                                             |
| N          | BY increment. (Integer > 0).                                                                                                                                                                                                                                                               |

Remarks:

1. Repeat the continuation entry until all grids for the particular body are described.
2. This entry may be repeated as many times as necessary to define all subcases and bodies with grids that should not have glued contact.
3. This entry corresponds to Marc's DEACT GLUE option. Items (i,j) indicate the corresponding data block and field.
4. In certain models, there are no BCBODY entries (for example; self contact) because the entire model comprises one body. For such models IBOD may be left blank.

5. If IBOD is a positive number, it will be converted to the body number using the BCBODY entries. To override this conversion and use the body number directly, enter IBOD as a negative number whose magnitude is equal to the body number desired.
6. Multiple UNGLUE entries with the same IDBC are not allowed.

## USET Degree-of-Freedom Set Definition

Defines a degree-of-freedom set.

Format:

| 1    | 2     | 3   | 4  | 5   | 6  | 7   | 8  | 9 | 10 |

|      |    |     |    |    |   |  |  |  |  |
|------|----|-----|----|----|---|--|--|--|--|
| USET | U4 | 333 | 26 | 17 | 0 |  |  |  |  |
|------|----|-----|----|----|---|--|--|--|--|

| Descriptor | Meaning                                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SNAME      | Set name. (One to four characters, or the string "ZERO" followed by the set name.)                                                                           |
| IDI        | Grid or scalar point identification number. (Integer > 0)                                                                                                    |
| CI         | Component number. (Integer zero or blank for scalar points, or any unique combinations of the Integers 1 through 6 for grid points with no embedded blanks.) |

Remarks:

1. SNAME may refer to any of the set names given in [Degree-of-Freedom Sets](#) or their new names on the DEFUSET entry. However, it is recommended that SNAME refer only to the set names U1 through U6 or their new names on the DEFUSET entry. If set names a through v are used then the degrees-of-freedom may also have to be defined in the applicable super sets on other USETi entries.
2. If SNAME = "ZEROi", where i is a set name, then the degrees-of-freedom are omitted from set i.
3. A maximum of 18 degrees-of-freedom may be designated on a single entry.
4. If degrees-of-freedom defined by USET entries are found to be singular and AUTOSPC is requested for a degree-of-freedom that is also in a set that AUTOSPC may change, then the set defined by the USET entry will be removed by the AUTOSPC operation. An avoidance is to use PARAM,AUTOSPC,NO.
5. The USET entry is processed by the GP4 module with its effect appearing in the USET table. User-written DMAPs must therefore include the GP1 and GP4 modules if USET entries are used.
6. If a USETi Bulk Data entry lists a standard degree-of-freedom set, such as S or M, the program may fail in the PARTN module with the message "SYSTEM FATAL MESSAGE 3007, ILLEGAL INPUT TO SUBROUTINE". This entry should only reference new sets defined on DEFUSET Bulk Data entries.

## USET1 Degree-of-Freedom Set Definition, Alternate Form

Defines a degrees-of-freedom set.

Format:

| 1     | 2     | 3   | 4      | 5   | 6   | 7   | 8   | 9   | 10 |
|-------|-------|-----|--------|-----|-----|-----|-----|-----|----|
| USET1 | SNAME | C   | ID1    | ID2 | ID3 | ID4 | ID5 | ID6 |    |
|       | ID7   | ID8 | -etc.- |     |     |     |     |     |    |

Example:

|       |    |     |   |   |    |   |   |   |  |
|-------|----|-----|---|---|----|---|---|---|--|
| USET1 | SB | 345 | 2 | 1 | 36 | 5 | 9 | 7 |  |
|       | 40 |     |   |   |    |   |   |   |  |

Alternate Format and Example:

|       |       |     |     |        |     |  |  |  |  |
|-------|-------|-----|-----|--------|-----|--|--|--|--|
| USET1 | SNAME | C   | ID1 | “THRU” | ID2 |  |  |  |  |
| USET1 | SB    | 123 | 170 | THRU   | 180 |  |  |  |  |

| Describer | Meaning                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SNAME     | Set name. (One to four characters or the word “ZERO” followed by the set name.)                                                                              |
| C         | Component numbers. (Integer zero or blank for scalar points or any unique combinations of the Integers 1 through 6 for grid points with no embedded blanks.) |
| IDI       | Grid or scalar point identification number. (Integer > 0; for “THRU” option, ID1 < ID2.)                                                                     |

Remarks:

1. SNAME may refer to any of the set names given in [Degree-of-Freedom Sets](#) or their new names on the DEFUSET entry. However, it is recommended that SNAME refer only to the set names U1 through U6 or their new names on the DEFUSET entry. If set names a through v are used then the degrees-of-freedom may also have to be defined in the applicable super sets on other USETi entries.
2. If SNAME=“ZEROi”, where i is a set name, then the degrees-of-freedom are omitted from set i.
3. If the alternate format is used, all of the points ID1 through ID2 are assigned to the set.
4. If degrees-of-freedom defined by USET entries are found to be singular and AUTOSPC is requested for a degree-of-freedom that is also in a set that AUTOSPC may change, then the set defined by the USET entry will be removed by the AUTOSPC operation. An avoidance is to use PARAM,AUTOSPC,NO.
5. The USET1 entry is processed by the GP4 module with its effect appearing in the USET table. User-written DMAPs must therefore include the GP1 and GP4 modules if USET entries are used.

6. If a USETi Bulk Data entry lists a standard degree-of-freedom set, such as S or M, the program may fail in the PARTN module with the message “SYSTEM FATAL MESSAGE 3007, ILLEGAL INPUT TO SUBROUTINE”. This entry should only reference new sets defined on DEFUSET Bulk Data entries.

## USRSUB6

## Defines User Subroutines for SOL 600

Defines user subroutines used in SOL 600 only.

Format:

| 1       | 2  | 3   | 4  | 5  | 6  | 7  | 8  | 9  | 10 |
|---------|----|-----|----|----|----|----|----|----|----|
| USRSUB6 | U1 | U2  | U3 | U4 | U5 | U6 | U7 | U8 |    |
|         | U9 | U10 |    |    |    |    |    |    |    |

Examples:

|          |               |       |        |  |  |  |  |  |  |
|----------|---------------|-------|--------|--|--|--|--|--|--|
| USRSUB6  | UDAMAG        | uvoid | TENSOF |  |  |  |  |  |  |
| USRSUB6* | SEPFORBB<br>C |       |        |  |  |  |  |  |  |

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ui        | Name of user subroutine(s) to be included. See Marc Volume D for list of available user subroutines. Do not include the .f extension on this entry, however, the actual file on the disk must have the .f extension. If any user subroutine exceeds 8 characters, use the wide field format for the primary line and all continuation lines. (Character; no Default) |

Notes:

1. All user subroutines must reside in the directory where the Nastran input file resides.
2. All user subroutines on disk must be in lower case and have an extension of .f. The names entered in the bulk data entry may be in upper or lower case. They will be converted to lower case.
3. SOL 600 combines all user subroutines into one large subroutine named u600.f and u600.f is passed to the Marc command line when spawned from Nastran.
4. If only one user subroutine is required, an alternate is to use PARAM,MARCUSUB,name.

## UXVEC

### Control Parameter State

Specification of a vector of aerodynamic control point (extra point) values. These data define the control positions corresponding to user defined nonlinear control forces that have been defined by AEDW, AEPRESS and AEFORCE entries. Only nonzero values need to be defined.

Format:

| 1     | 2      | 3   | 4      | 5   | 6      | 7 | 8 | 9 | 10 |
|-------|--------|-----|--------|-----|--------|---|---|---|----|
| UXVEC | ID     |     |        |     |        |   |   |   |    |
|       | LABEL1 | UX1 | LABEL2 | UX2 | -etc.- |   |   |   |    |

Example:

|       |        |      |        |      |  |  |  |  |  |
|-------|--------|------|--------|------|--|--|--|--|--|
| UXVEC | 1001   |      |        |      |  |  |  |  |  |
|       | THRUST | 1.E4 | ANGLEA | .015 |  |  |  |  |  |

| Describer | Meaning                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------|
| ID        | Control vector identification number, see Remark 1. (Integer > 0)                                                          |
| LABELi    | Controller name. This must correspond to an existing AESURF, AESTAT or AEPARM label or INTERCPT (Character). See Remark 4. |
| UXi       | The magnitude of the aerodynamic extra point degree-of-freedom (Real)                                                      |

Remarks:

1. The ID is referenced by the AEUXREF Case Control command and/or by AEDW, AEPRESS, and/or AEFORCE entries.
2. The units of the user defined AEPARM controllers are implied by their use on this entry and the corresponding values on the force vector definition. The user must be self-consistent in all uses of the same controller. AESURF controllers are expressed in radians as are the rigid body angles ANGLEA and BETA. The rigid body rates, ROLL, PITCH and YAW are nondimensional rates pb/2V, qc/2V, rb/2V; respectively. V is the velocity and b and c are the reference span and chord lengths, respectively.
3. LABELs that are part of the UX vector that are omitted in the UXVEC specification are assigned a value of 0.0.
4. INTERCPT = 1.0 is implied on all UXVEC input.  
INTERCPT = 0.0 indicates that associated load is a perturbation.  
If there are no AESTAT entires, INTERCPT=1.0 must be input on one or more UXVEC entries to establish the intercept aerodynamics.
5. When multiple control point values are listed for a single controller, it is necessary to add an additional AEPARM controller with value fixed to 1.0 to maintain accuracy.

6. If LABEL<sub>i</sub> is AESTAT and UX<sub>i</sub> = 1.0 and INTERCPT is 1.0, either explicit or by default and there are no other LABEL<sub>j</sub>, UX<sub>j</sub> pairs, the term is added to the internal forces for the AESTAT. If LABEL<sub>i</sub> is an AESTAT and UX<sub>i</sub> is not 1.0, it is an error.

VCCT

Virtual Crack Closure Technique - SOL 400

Format:

| 1    | 2      | 3     | 4     | 5     | 6    | 7      | 8        | 9         | 10 |
|------|--------|-------|-------|-------|------|--------|----------|-----------|----|

|      |     | 2000. |   |   |   |   |  |   |  |
|      |     | 0     |   |   |   |   |  |   |  |
|      | 51  | 52    |   |   |   |   |  |   |  |

| Describer | Meaning                                                                                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID        | Identification of a matching Case Control VCCT entry. See Remark 2. (Integer; no Default)                                                                                                                                                                                                                                                   |
| IDCR      | Identification of this particular crack. IDCR must be unique among all VCCT cracks with the same ID but can replace a crack with the same IDCR. (Integer > 0; Default = 1)                                                                                                                                                                  |
| ITYPE     | Type of crack propagation. (Integer; Default = 0)<br>0 No crack propagation<br>2 Direct crack propagation                                                                                                                                                                                                                                   |
| IGROW     | Specifies how the crack grows. (Integer; Default = 2)<br>1 Uses remeshing (not presently available)<br>2 Release user tyings or glued contact                                                                                                                                                                                               |
| INCM      | Specifies the crack growth increment (Integer; Default = 1)<br>1 Uses a fixed increment or a user subroutine                                                                                                                                                                                                                                |
| METHOD    | Specifies the method used for the estimated crack growth direction (Integer; Default=1)<br>1 Maximum hoop stress criterion (Default)                                                                                                                                                                                                        |
| CGI       | Crack growth increment (Real; Default = 0.0). If the option of releasing tyings or glued contact is used, the length of the released element edge is used. Leave blank for fatigue growth defined by the Paris law. (Not presently used)                                                                                                    |
| GC        | Crack growth resistance. (Real; Default = 0.0) Ignored for fatigue growth. If different crack growth resistance values are needed from modes I, II, III, this is the mode I value and modes II and III are entered in fields 8 and 9. For SOL 600, if it is desired that the mode I crack resistance be zero, enter GC as a negative value. |

| Describer | Meaning                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GC-II     | Crack growth resistance, Mode II (Real; Default = 0.0) Ignored for fatigue growth.                                                                                 |
| GC-III    | Crack growth resistance, Mode III (Real; Default = 0.0) Ignored for fatigue growth.                                                                                |
| TABCGI    | TABLEMi or TABL3Di for CGI (crack growth increment). (Integer; Default = 0)                                                                                        |
| TABGC     | TABLEMi or TABL3Di for scaling GC (crack growth resistance). (Integer; Default = 0)                                                                                |
| TABGC-II  | TABLEMi or TABL3Di for scaling GC-II (Integer; Default = 0)                                                                                                        |
| TABGC-III | TABLEMi or TABL3Di for scaling GC-III (Integer; Default = 0)                                                                                                       |
| Gi        | Grids along the crack front – for a shell there is only one node. See Remark 6. (Integer or “THRU” or “BY”; no Default; at least one value, G1, must be provided.) |

**Remarks:**

1. The grids entered on this entry **MUST** be associated with SOL400 elements that have had their capabilities extended by use of either a PSNLN1, PSNLN2, PSLDN1, PLCOMP or PCOMPLS or a combination of these entries.
2. ID corresponds to a Case Control VCCT entry.
3. If tables are not required, enter at least one field with a zero value. Do not enter a blank line.
4. This entry may be repeated as many times as necessary to describe all the cracks in the model.
5. The 4<sup>th</sup> line may be repeated as many times as necessary to describe all grids on the crack front
6. If G1 is negative, the absolute value of G1 is used as the ID of a SET3 entry providing the list of grids. For this case, G2, G3, etc. must be blank (only one SET3 ID per VCCT entry is allowed).
7. The values of the entries on the second line that are not needed should be set to 0.0 or blank. If no tables are required to specify the variation with time, temperature or some other variable, one or all of the table entries on the third line can be set to zero or blank.
8. If TABLEM1 is used, accumulated crack growth will be used for the X coordinates instead of the usual value of temperature.

## VCCT

## Virtual Crack Closure Technique in SOL 600

Provides data to simulate crack growth using virtual crack closure technology methods in SOL 600.

| Describer      | Meaning                                                                                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID             | Identification of a matching Case Control VCCT entry. See Remark 2. (Integer; no Default)                                                                                                                          |
| IDCR           | Identification of this particular crack. IDCR must be unique among all VCCT cracks with the same ID but can replace a crack with the same IDCR and a different ID using the IACT field. (Integer > 0; Default = 1) |
| ITYPE<br>(6-1) | Type of crack propagation. (Integer; Default = 2)<br><br>0 No crack propagation<br>1 Fatigue type crack propagation<br>2 Direct crack propagation                                                                  |
| IGROW<br>(6-2) | How crack grows (Integer; Default = 2)<br><br>1 Uses remeshing (not presently available)                                                                                                                           |

| Describer       | Meaning                                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INCM<br>(6-3)   | 2 Release user tyings or glued contact                                                                                                                                                                                                |
|                 | Specifies the crack growth increment (Integer; Default = 2)                                                                                                                                                                           |
| METHOD<br>(6-4) | 1 Uses a fixed increment or a user subroutine                                                                                                                                                                                         |
|                 | 2 Uses Paris law                                                                                                                                                                                                                      |
| TIME<br>(6-5)   | Specifies the method used for the estimated crack growth direction (Integer; Default=1)                                                                                                                                               |
|                 | 1 Maximum hoop stress criterion (Default)                                                                                                                                                                                             |
| IACT<br>(3-1)   | Time period for fatigue load sequence. (Real; no Default) Only enter if ITYPE=1                                                                                                                                                       |
|                 | Flag for activating or deactivating an existing crack (Integer; Default = 0)                                                                                                                                                          |
| CGI<br>(7-1)    | 0 Leave as is                                                                                                                                                                                                                         |
|                 | 1 Activate                                                                                                                                                                                                                            |
|                 | 2 Deactivate                                                                                                                                                                                                                          |
| GC<br>(7-2)     | Crack growth increment (Real; Default = 0.0). If the option of releasing tyings or glued contact is used, the length of the released element edge is used. Leave blank for fatigue growth defined by the Paris law.                   |
| GTH<br>(7-3)    | Crack growth resistance. (Real; Default = 0.0) Ignored for fatigue growth. If different crack growth resistance values are needed from modes I, II, III, this is the mode I value and modes II and III are entered in fields 8 and 9. |
| C<br>(7-4)      | Paris law energy release rate threshold. (Real; Default = 0.0)                                                                                                                                                                        |
| M<br>(7-5)      | Paris law parameter C. (Real; Default = 0.0) Only enter if INCM=2                                                                                                                                                                     |
| GMIN<br>(7-6)   | Paris law parameter m. (Real; Default = 0.0) Only enter if INCM=2                                                                                                                                                                     |
| GC-II (7-4)     | Minimum growth increment. (Real; Default = 0.0) Only enter if INCM=2                                                                                                                                                                  |
| GC-III          | Crack growth resistance, Mode II (Real; Default = 0.0) Ignored for fatigue growth.                                                                                                                                                    |
| TABCGI<br>(8-1) | Crack growth resistance, Mode III (Real; Default = 0.0) Ignored for fatigue growth.                                                                                                                                                   |
| TABGC<br>(8-2)  | TABLEMi or TABL3Di for CGI (crack growth increment). (Integer; Default = 0)                                                                                                                                                           |
|                 | TABLEMi or TABL3Di for scaling CG (fracture toughness). (Integer; Default = 0)                                                                                                                                                        |

| Describer        | Meaning                                                                                                                                          |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| TABGTH<br>(8-3)  | TABLEMi or TABL3Di for scaling GTH (Paris law energy release rate) (Integer; Default = 0)                                                        |
| TABC<br>(8-4)    | TABLEMi or TABL3Di for scaling C (Paris law parameter C). (Integer; Default = 0)                                                                 |
| TABM<br>(8-5)    | TABLEMi or TABL3Di for scaling M (Paris law parameter m). (Integer; Default = 0)                                                                 |
| TABGMIN<br>(8-6) | TABLEMi or TABL3Di for scaling GMIN (Minimum growth increment). (Integer; Default = 0)                                                           |
| TABGC-II         | TABLEMi or TABL3Di for scaling GC-II (Integer; Default = 0)                                                                                      |
| TABGC-III        | TABLEMi or TABL3Di for scaling GC-III (Integer; Default = 0)                                                                                     |
| Gi<br>(5-i)      | Grids along the crack front – for a shell there is only one node. (Integer; no Default; at least one value, G1, must be provided. See Remark 6.) |

#### Remarks:

1. This entry corresponds to Marc's VCCT model definition and history definition options.
2. (i,j) corresponds to Marc Vol C VCCT entry ith datablock jth field
3. ID corresponds to a Case Control VCCT command. Set ID=0 to enter VCCT entries into Marc's model definition.
4. If tables are not required, enter at least one field with a zero value. Do not enter a blank line.
5. This entry may be repeated as many times as necessary to describe all the cracks in the model.
6. The 4<sup>th</sup> line may be repeated as many times as necessary to describe all grids on the crack front
7. If the Alternate Format is used, entries may only be made in the fields indicated, however this line may be repeated as many times as necessary to describe all grids on the crack front.
8. If G1 is negative, the absolute value of G1 is used as the ID of a SET3 entry providing the list of grids. For this case, G2, G3, etc. must be blank (only one SET3 ID per VCCT entry is allowed).
9. Most analyses do not use all of the entries on the second line, however a meaningful analysis will specify one or more of these values. Those not needed should be set to 0.0 or blank. If no tables are required to specify the variation with time, temperature or some other variable, one or all of the table entries on the third line can be set to zero or blank.
10. If TABLEM1 is used, accumulated crack growth will be used for the X coordinates instead of the usual value of temperature.

## VIEW

## View Factor Definition

Defines radiation cavity and shadowing for radiation view factor calculations.

|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IVIEW     | Identification number. (Integer > 0)                                                                                                                                                                                                                                                                                                 |
| ICAVITY   | Cavity identification number for grouping the radiant exchange faces of CHBDYi elements. (Integer > 0)                                                                                                                                                                                                                               |
| SHADE     | Shadowing flag for the face of CHBDYi element. (Character; Default = "BOTH")<br>NONE means the face can neither shade nor be shaded by other faces.<br>KSHD means the face can shade other faces.<br>KBSD means the face can be shaded by other faces.<br>BOTH means the face can both shade and be shaded by other faces. (Default) |
| NB        | Subelement mesh size in the beta direction. (Integer > 0; Default = 1)                                                                                                                                                                                                                                                               |
| NG        | Subelement mesh size in the gamma direction. (Integer > 0; Default = 1)                                                                                                                                                                                                                                                              |
| DISLIN    | The displacement of a surface perpendicular to the surface. See <a href="#">Figure 9-155</a> . (Real; Default = 0.0)                                                                                                                                                                                                                 |

Remarks:

1. VIEW must be referenced by CHBDYE, CHBDYG, or CHBDYP elements to be used.
2. ICAVITY references the cavity to which the face of the CHBDYi element belongs; a zero or blank value indicates this face does not participate in a cavity.
3. NB, NG, and DISLIN are used in the calculation of view factors by finite difference or contour integration techniques. They are not used with the VIEW3D entry.
4. A summary of the shadowing conditions can be requested by the PARAM,MESH,YES Bulk Data entry.
5. SHADE references shadowing for CHBDYi elements participating in a radiation cavity, the VIEW calculation can involve shadowing.

6. DISLIN should only be used with LINE type CHBDYE and CHBDYP surface elements. DISLIN > 0.0 means into the cavity. See Figure 9-155.

Figure 9-155 DISLIN Convention

7. NB and NG define the subelement mesh refinement when using the VIEW module (as opposed to the VIEW3D module) for the calculation of view factors.

Figure 9-156 Typical AREA4 surface element where NB=2 and NG=4

8. For RC network solver in thermal analysis, the SHADE, NB, NG and DISLIN are ignored.

## VIEW3D

## View Factor Definition - Gaussian Integration Method

Defines parameters to control and/or request the Gaussian Integration method of view factor calculation for a specified cavity.

Format:

| 1      | 2       | 3    | 4    | 5    | 6    | 7    | 8    | 9      | 10 |

| Describer | Meaning                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ICAVITY   | Radiant cavity identification number on RADCAV entry. (Integer > 0)                                                                                                                                          |
| GITB      | Gaussian integration order to be implemented in calculating net effective view factors in the presence of third-body shadowing. (Integer 2, 3, 4, 5, 6 or 10; Default = 4)                                   |
| GIPS      | Gaussian integration order to be implemented in calculating net effective view factors in the presence of self-shadowing. (Integer 2, 3, 4, 5, 6 or 10; Default = 4)                                         |
| CIER      | Discretization level used in the semi-analytic contour integration method. ( $1 \leq \text{Integer} \leq 20$ ; Default = 4)                                                                                  |
| ETOL      | Error estimate above which a corrected view factor is calculated using the semi-analytic contour integration method. (Real $\geq 0.0$ ; Default = 0.1)                                                       |
| ZTOL      | Assumed level of calculation below which the numbers are considered to be zero. (Real $\geq 0.0$ ; Default = 1.E-10)                                                                                         |
| WTOL      | Assumed degree of warpage above which the actual value of $F_{ii}$ will be calculated. ( $0.0 \leq \text{Real} \leq 1.0$ ; Default = 0.01)                                                                   |
| RADCHK    | Type of diagnostic output desired for the radiation exchange surfaces. (Integer; Default = 3)                                                                                                                |
|           | -1 No diagnostic output requested                                                                                                                                                                            |
|           | 1 Grid table and element connectivity                                                                                                                                                                        |
|           | 2 Surface Diagnostics - Surface type, area, skewness, taper, warpage, grid point sequencing, aspect ratio, and shading flags.                                                                                |
|           | 3 Area, view factor, area-view factor product with error estimate, existence flags for partial self-shadowing, third-body shadowing with error estimate, and enclosure summations for view factor. (Default) |
|           | 0 Same as RADCHK = 1, 2, and 3                                                                                                                                                                               |
|           | 12 Same as RADCHK = 1 and 2                                                                                                                                                                                  |

| Describer | Meaning                  |
|-----------|--------------------------|
| 13        | Same as RADCHK = 1 and 3 |
| 23        | Same as RADCHK = 2 and 3 |

**Remarks:**

1. For ETOL, when the error estimate exceeds the value input for the ETOL entry, the contour method is employed to develop an improved view factor.
2. For ZTOL, the use of a geometry scale that results in small numerical values of  $A_i F_{ij}$  should be avoided.
3. When WTOL is exceeded, the actual value of  $F_{ij}$  will be calculated when using the adaptive view module. Warpage will not be considered in the calculation of  $F_{ij}$ .
4. For axisymmetric analysis, RADCHK = -1 or 3 only.

## VIEWEX

## Advanced RC Radiation Solver Parameters - SOL 400

Defines the radiation solver and correlating solver parameters for radiation calculations in RC heat transfer.  
Note: You must have a copy of the external radiation code to use it.

## Format: (NEVADA)

| 1      | 2        | 3                 | 4                  | 5              | 6                       | 7             | 8          | 9            | 10 |

| Describer                | Meaning                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ICAVITY                  | Cavity identification number (Integer > 0; Required)                                                                                                                         |
| Run Interactively        | Run the radiation code interactively (Character; "T" or "F", Default "F")<br>Do not currently have batch mode for Thermica or TSS<br>Do not have interactive mode for TRASYS |
| RADK Distro Method       | How to redistribute RADK onto elements. (Character; "FULL", "AREA", or "DIRECT"; Default "FULL")                                                                             |
| Orbital                  | Use orbital analysis for radiation (Character; "T" or "F"; Default "F")<br>Not supported in SindaRad                                                                         |
| Re-use existing results  | Re-use previous radiation results (Character; "T" or "F"; Default "F")                                                                                                       |
| "NEVADA"                 | Identification that NEVADA will be used (Character)                                                                                                                          |
| RENO Reflection          | Use reflection method of ray tracing for RADK (Character; "T" or "F"; Default "T")                                                                                           |
| Restart                  | Use Restart (Character; "T" or "F"; Default "F")                                                                                                                             |
| Reno Ray count           | Number or rays cast for Reno module (Integer > 0; Default 5000)                                                                                                              |
| Vegas Ray count          | Number or rays cast for Vegas module (Integer > 0; Default 5000)                                                                                                             |
| Energy Cutoff            | Energy cutoff level (Integer; Default -3)                                                                                                                                    |
| Confidence               | Confidence Level % (Real > 0.0; Default 99.0)                                                                                                                                |
| GRID closure             | GRID closure tolerance (Real > 0.0; Default 0.001)                                                                                                                           |
| GRID iterations          | Maximum GRID iterations (Integer > 0; Default 300)                                                                                                                           |
| Time Scale               | Orbital time scale factor, number of time units in an hour. Ex. If using seconds, value would be 3600.0. (Real > 0.0; Default 1.0)                                           |
| RADK cutoff              | RADK filter smallest element (Real ≥ 0.0; Default 1.0e-8)                                                                                                                    |
| "TSS"                    | Identification that TSS will be used (Character)                                                                                                                             |
| "THERMICA"               | Identification that THERMICA will be used (Character)                                                                                                                        |
| Solar Flux               | Quantity of solar flux (Real > 0.0; Default 1380.0 W/m <sup>2</sup> )                                                                                                        |
| Planet Albedo            | Planetary Albedo (Real; Default 0.3; assumes Earth orbit)                                                                                                                    |
| Planet BlackBody         | Planet Blackbody (Real; Default -19.0; assumes Earth orbit)                                                                                                                  |
| Restart                  | Use Restart option (Character, "T" or "F"; Default "F")                                                                                                                      |
| Suppress VF Articulation | Suppress view factor articulation (Character; "T" or "F"; Default "T")                                                                                                       |
| Radiation ray count      | Number or rays cast for radiation calculation (Integer > 0; Default 5000)                                                                                                    |
| Orbital flux ray count   | Number or rays cast for orbital flux (Integer > 0; Default 5000)                                                                                                             |
| Confidence               | Confidence Level % (Real > 0.0; Default 99.0)                                                                                                                                |
| Time Scale               | Orbital time scale factor, number of time units in an hour. Ex. If using seconds, value would be 3600.0. (Real > 0.0; Default 1.0)                                           |

| Describer            | Meaning                                                                                                                            |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| RADK cutoff          | RADK filter smallest element (Real $\geq$ 0.0; Default 1.0e-8)                                                                     |
| “TRASYS”             | Identification that TRASYS will be used (Character)                                                                                |
| Axi Radial mesh      | Axisymmetric element mesh in radial direction (Integer > 0; Default 1)                                                             |
| Axi Axial mesh       | Axisymmetric element mesh in axial direction (Integer > 0; Default 1)                                                              |
| Axi Angular mesh     | Axisymmetric element mesh in angular direction (Integer > 0; Default 4)                                                            |
| Time Scale           | Orbital time scale factor, number of time units in an hour. Ex. If using seconds, value would be 3600.0. (Real > 0.0; Default 1.0) |
| RADK cutoff          | RADK filter smallest element (Real $\geq$ 0.0; Default 1.0e-8)                                                                     |
| “SRR”                | Identification that the SindaRad RADK method will be used (Character)                                                              |
| Gebhart Solver       | Which RADK solver to use (Character; “GS” or “FGS”; Default “GS”)                                                                  |
| Convergence Tol      | Tolerance for convergence of RADK calculation (Real $\geq$ 0.0; Default 1.0e-5)                                                    |
| Max Iter             | Maximum allowable iterations to converge (Integer > 0; Default 50)                                                                 |
| Fij smoothing method | How to filter view factors (Character; “CROP” or “HIGH”; Default “CROP”)                                                           |
| Fij Filter cutoff    | Parameter for filter (Real > 0.0; Default 1.0e-8)                                                                                  |
| Fij Smoothing Tol    | Tolerance for smoothing (Real $\geq$ 0; Default 1.0e-4)                                                                            |
| Fij Smooth Iter      | Maximum allowable iterations to smoothing (Integer > 0; Default 50)                                                                |
| Bij smoothing method | How to filter conductors (Character; “CROP” or “HIGH”; Default “CROP”)                                                             |
| Bij Filter cutoff    | Parameter for filter (Real > 0.0; Default 1.0e-8)                                                                                  |
| Bij Smoothing Tol    | Tolerance for smoothing (Real $\geq$ 0; Default 1.0e-4)                                                                            |
| Bij Max Iter         | Maximum allowable iterations to smoothing (Integer > 0; Default 50)                                                                |
| “SRQ”                | Identification that the SindaRad QRad method will be used (Character)                                                              |
| Flux Solver          | Which QRad solver to use (Character, “GS” or “CG”; Default “GS”)                                                                   |
| Convergence Tol      | Tolerance for convergence of QRad calculation (Real $\geq$ 0.0; Default 1.0e-5)                                                    |
| Max Iter             | Maximum allowable iterations to converge (Integer > 0; Default 50)                                                                 |
| Fij smoothing method | How to filter view factors (Character, “CROP” or “HIGH”; Default “CROP”)                                                           |
| Fij Filter cutoff    | Parameter for filter (Real > 0.0; Default 1.0e-8)                                                                                  |
| Fij Smoothing Tol    | Tolerance for smoothing (Real $\geq$ 0; Default 1.0e-4)                                                                            |
| Fij Smooth Iter      | Maximum allowable iterations to smoothing (Integer > 0; Default 50)                                                                |

#### Remarks:

1. This entry is for RC Network solver only.
2. Each entry type is designed for one specific radiation solver, except the very last two types, which are for SindaRad’s two options.

NEVADA  
TSS  
THERMICA  
TRASYS  
SINDARad RADK method  
SINDARad Q method

3. For more details about the parameters in the entry, please reference SINDA for *Patran User's Guide* and the *SINDARad User's Guide*.
4. MSC provides these radiation programs on Windows only.

## WALL

## Rigid Wall

Defines a rigid plane through which specified Lagrangian grid points cannot penetrate. Finite or infinite size (FINITE), Orthotropic friction (ORTHO) a mass and an initial velocity (MOVING) and Force output option (FORCES) can be defined. Used in SOL 700 only.

Format:

| 1    | 2      | 3  | 4  | 5   | 6  | 7  | 8  | 9      | 10 |
|------|--------|----|----|-----|----|----|----|--------|----|
| WALL | ID     | XP | YP | ZP  | NX | NY | NZ | BCGRID |    |
|      | METHOD | FS | FK | EXP |    |    |    |        |    |

Example:

|      |         |     |  |  |  |  |     |    |  |
|------|---------|-----|--|--|--|--|-----|----|--|
| WALL | 17      |     |  |  |  |  | 1.0 | 21 |  |
|      | PENALTY | 0.2 |  |  |  |  |     |    |  |

| Describer  | Meaning                                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ID         | Unique rigid-wall number. (Integer > 0; Required)                                                                                                                               |
| XP, YP, ZP | Coordinates of the origin of the wall. (Real; Default = 0.0)                                                                                                                    |
| NX, NY, NZ | A vector normal to the wall pointing towards the model. (Real; Default = 0.0)                                                                                                   |
| BCGRID     | Number of a BCGRID entry listing the points that cannot penetrate the wall. (Integer > 0; Required)                                                                             |
| METHOD     | Algorithm for contact processing. (Character; Default = PENALTY)                                                                                                                |
|            | PENALTY      Penalty method, allowing for extra boundary conditions, friction and output.                                                                                       |
|            | KINMATIC      Kinematic method, only included for compatibility reasons with older Dytran versions. This method allows no extra boundary conditions, no friction and no output. |
| FS         | Static coefficient of friction. See Remark 5. (Real $\geq$ 0; Default = 0.0)                                                                                                    |
| FK         | Kinetic coefficient of friction. See Remark 5. (Real $\geq$ 0; Default = 0.0)                                                                                                   |
| EXP        | Exponential decay coefficient. See Remark 5. (Real $\geq$ 0; Default = 0.0)                                                                                                     |

Remarks

1. A rigid plane of infinite size is generated that the grid points cannot penetrate. The plane is fixed in space.
2. The grid points can slide on the wall and separate from it.
3. A (moving) rigid plane of finite size can be modeled by using a rigid surface and a primary-secondary contact.

4. For the wall definition using penalty method, output can be requested by referencing it in a SET command in the Case Control Section. The keywords for output are WALLS and WALLOUT. Please check \$S700.
5. The coefficient of friction is given by:

$$\mu = \mu_k + (\mu_s - \mu_k)e^{-\beta v}$$

where

$\mu_s$  = Static coefficient of friction FS.

$\mu_k$  = Kinetic coefficient of friction FK.

$\beta$  = Exponential decay coefficient EXP.

$v$  = Relative sliding velocity at the point of contact.

## WEAR Specifies Values for Modeling Mechanical Wear in Deformable Contact Bodies

Specifies values for modeling mechanical wear in deformable contact bodies for SOL 600 only.

Format:

| 1    | 2       | 3       | 4       | 5       | 6    | 7    | 8 | 9 | 10 |
|------|---------|---------|---------|---------|------|------|---|---|----|
| WEAR | BID     | Model   | IUPD    |         |      |      |   |   |    |
|      | COEF    | HARD    | SEXP    | VEXP    | B    | SFGU |   |   |    |
|      | T(COEF) | T(HARD) | T(SEXP) | T(VEXP) | T(B) |      |   |   |    |

Example:

|      |     |      |     |     |      |     |  |  |  |
|------|-----|------|-----|-----|------|-----|--|--|--|
| WEAR | 3   | 2    | 1   |     |      |     |  |  |  |
|      | 3.6 | 200. | 1.1 | 1.2 | .087 | 1.0 |  |  |  |
|      | 22  | 23   | 24  | 25  | 26   |     |  |  |  |

| Describer | Meaning                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------|
| BID       | BCBODY ID for which this wear entry applies. (Integer > 0; no Default; see Remark 2)                              |
| MODEL     | Wear model. (Integer > 0; Default = 1, see Remark 1)                                                              |
| IUPD      | Geometry update due to wear flag. (Integer; Default = 0)<br>0 Do not update the geometry<br>1 Update the geometry |
| COEF      | Wear coefficient. (Real; no Default)                                                                              |
| HARD      | Material hardness. (Real; no Default)                                                                             |
| SEXP      | Stress exponent. (Real; Default = 1.0)                                                                            |
| VEXP      | Velocity exponent. (Real; Default = 1.0)                                                                          |
| B         | Thermal activation constant. (Real; Default = 1.0)                                                                |
| SFGU      | Scale factor for geometry update. (Real; Default = 1.0)                                                           |
| T(COEF)   | TABL3D ID for the wear coefficient. (Integer; Default = 0, meaning no table variation)                            |
| T(HARD)   | TABL3D ID for the material hardness. (Integer; Default = 0, meaning no table variation)                           |
| T(SEXP)   | TABL3D ID for the stress exponent. (Integer; Default = 0; meaning no table variation)                             |
| T(VEXP)   | TABL3D ID for the velocity exponent. (Integer; Default = 0, meaning no table variation)                           |
| T(B)      | TABL3D ID for the thermal activation constant. (Integer; Default = 0, meaning no table variation)                 |

## Remarks:

1. The following wear models are available

$$\dot{w} = \frac{K}{H} \sigma v_{rel} \quad \text{Archard base model}$$

$$\dot{w} = \frac{K}{H} \sigma^m v_{rel}^n \quad \text{Archard model; Bayer exponential form}$$

$$\dot{w} = \frac{K}{H} \sigma^m v_{rel}^n e^{\frac{-B}{T}} \quad \text{Archard model; exponential form with thermal activation}$$

2. BID may also point the ID in field 2 of BCPROP, BCMATL or BCBOX.

**WETELME**

Wetted element in OpenFSI by side in SOL 400

Defines a wetted element used in OpenFSI fluid structure interaction simulations in SOL 400 only.

Format:

| 1       | 2    | 3   | 4    | 5 | 6 | 7 | 8 | 9 | 10 |
|---------|------|-----|------|---|---|---|---|---|----|
| WETELME | WEID | EID | SIDE |   |   |   |   |   |    |

Example:

|         |       |    |   |  |  |  |  |  |  |
|---------|-------|----|---|--|--|--|--|--|--|
| WETELME | 10001 | 34 | 3 |  |  |  |  |  |  |
|---------|-------|----|---|--|--|--|--|--|--|

| Describer | Meaning |
|-----------|---------|
|-----------|---------|

WEID      Wetted element identification number. (Integer > 0; no Default)

EID      Structural element identification number, which corresponds to a surface element CQUAD4, CQUAD8, CQUADR, CTRIA3, CTRIA6, CTRIAR; or a solid element CTETRA, CPENTA, or CHEXA. (Integer > 0; no Default)

SIDE      Side identification number of element EID. ( $1 \leq \text{Integer} \leq 6$ ; no Default)

Remarks:

1. Refer to the remarks [6.](#) and [7.](#) for the element side identification of CHBDYE entry.

**WETELMG****Wetted element in OpenFSI by type in SOL 400**

Defines a wetted element used in OpenFSI fluid structure interaction simulations in SOL 400 only.

Format:

| 1       | 2    | 3    | 4  | 5  | 6  | 7  | 8  | 9  | 10 |
|---------|------|------|----|----|----|----|----|----|----|
| WETELMG | WEID | TYPE |    |    |    |    |    |    |    |
|         | G1   | G2   | G3 | G4 | G5 | G6 | G7 | G8 |    |

Example:

|         |       |       |     |    |  |  |  |  |  |
|---------|-------|-------|-----|----|--|--|--|--|--|
| WETELMG | 10001 | QUAD4 |     |    |  |  |  |  |  |
|         | 23    | 35    | 124 | 28 |  |  |  |  |  |

| Describer   | Meaning                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------|
| WEID        | Wetted element identification number. (Integer > 0; no Default)                                              |
| TYPE        | Wetted element type, which can be any of TRIA3, TRIA6, QUAD4, QUAD8, LINE2 or LINE3. (Character; no Default) |
| G1, ..., G8 | Grid point identification numbers for the wetted surface element WEID. (Integer > 0; no Default)             |

## WETLOAD Load set and associated wetted surface for OpenFSI in SOL 400

Defines the load set and associated wetted surface for OpenFSI fluid structure interaction simulations in SOL 400 only.

Format:

| 1       | 2    | 3    | 4       | 5 | 6 | 7 | 8 | 9 | 10 |
|---------|------|------|---------|---|---|---|---|---|----|
| WETLOAD | WLID | WSID | SERV_ID |   |   |   |   |   |    |

Example:

|         |   |      |        |  |  |  |  |  |  |
|---------|---|------|--------|--|--|--|--|--|--|
| WETLOAD | 1 | 1001 | scafsi |  |  |  |  |  |  |
|---------|---|------|--------|--|--|--|--|--|--|

| Describer | Meaning                                                                                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WLID      | Load set ID, referenced by the EXCITEID field in the TLOAD entry. (Integer > 0; no Default)                                                                        |
| WSID      | Wetted surface identification number. The wetted surface must be defined in the WETSURF Bulk Data entry. (Integer > 0; no Default)                                 |
| SERV_ID   | OpenFSI SCA service name associated with the wetted surface loads. The OpenFSI SCA service is defined using the CONNECT SERVICE FMS entry. (Character; no Default) |

Remarks:

1. To activate WETLOAD, the following entries must be present and referenced:
  - a. The load set ID WLID must be referenced by a TLOAD1 entry.
  - b. The TLOAD1 entry must be referenced by a DLOAD Case Control command or a DLOAD Bulk Data entry, which in turn is referenced by a DLOAD Case Control command.
  - c. The TLOAD1 entry must reference a TABLED1 entry.
  - d. The TABLED1 entry must have constant values and be the same for all TLOAD1 entries referenced by the WETLOAD entries used within the same service.

Procedures a ~ d are required in the Nastran load generator processes. Their values do not really influence the load calculation of WETLOAD in OpenFSI. Please refer to the remarks below to apply WETLOAD(s) to OpenFSI.
2. The SERV\_ID string must be 8 characters or less.
3. For multiple WETLOAD entries with same SERV\_ID, the wet surfaces in WSID will be merged together for the service and the WLID in the first WETLOAD entry will replace other entries WLID.
4. In the current implementation, all OpenFSI services in a model are active and participate in the calculation. The TLOAD1 and DLOAD selection in case control are not applied on OpenFSI services.
5. For OpenFSI services, the scale factors in DLOAD are always taken to be constant 1.0.

6. In the FMS Section, the following statement should be included: `CONNECT SERVICE SERV_ID  
ExternalCodeVendor.OpenFSI`

## WETSURF

Wetted surface used in OpenFSI in SOL 400

Defines a wetted surface used in OpenFSI fluid structure interaction simulations in SOL 400 only.

Format:

| 1       | 2     | 3      | 4      | 5     | 6     | 7     | 8     | 9     | 10 |
|---------|-------|--------|--------|-------|-------|-------|-------|-------|----|
| WETSURF | WSID  | WTAG   |        |       |       |       |       |       |    |
|         | WEID1 | WEID2  | WEID3  | WEID4 | WEID5 | WEID6 | WEID7 | WEID8 |    |
|         | WEID9 | WEID10 | -etc.- |       |       |       |       |       |    |

Alternate Format:

|         |       |        |       |      |     |  |  |  |  |
|---------|-------|--------|-------|------|-----|--|--|--|--|
| WETSURF | WSID  | WTAG   |       |      |     |  |  |  |  |
|         | WEID1 | “THRU” | WEID2 | “BY” | INC |  |  |  |  |

Example:

|         |       |       |     |    |    |    |    |    |  |
|---------|-------|-------|-----|----|----|----|----|----|--|
| WETSURF | 10001 | wall1 |     |    |    |    |    |    |  |
|         | 5     | THRU  | 21  | BY | 4  |    |    |    |  |
|         | 27    | 30    | 33  |    |    |    |    |    |  |
|         | 35    | THRU  | 44  |    |    |    |    |    |  |
|         | 67    | 68    | 70  | 72 | 77 | 82 | 86 | 79 |  |
|         | 89    | THRU  | 110 | BY | 3  |    |    |    |  |

| Describer         | Meaning                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| WSID              | Wetted surface identification number. (Integer > 0; no Default)                                                         |
| WTAG              | Wetted surface tag name exported to an external code using the OpenFSI SCA interface. (Character; no Default)           |
| WEID1, WEID2, ... | Wetted element identification numbers defined using the WETELMG or WETELME Bulk Data entries. (Integer > 0; no Default) |
| THRU, BY          | Keywords to specify a range of wetted elements. (Character; no Default)                                                 |
| INC               | Increment to use with the “THRU” and “BY” keywords. (Integer; Default = 1)                                              |

## YLDHY

## Hydrodynamic Yield Model

Defines a yield model with zero yield stress. Used in SOL 700 only.

Format:

| 1     | 2   | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|-------|-----|---|---|---|---|---|---|---|----|
| YLDHY | YID |   |   |   |   |   |   |   |    |

Example:

|       |     |  |  |  |  |  |  |  |  |
|-------|-----|--|--|--|--|--|--|--|--|
| YLDHY | 200 |  |  |  |  |  |  |  |  |
|-------|-----|--|--|--|--|--|--|--|--|

| Describer | Meaning                                                                            |
|-----------|------------------------------------------------------------------------------------|
| YID       | Unique yield-model number referenced from a MATDEUL entry. (Integer > 0; Required) |

Remark:

1. This yield model should be used for fluids that have no shear strength.
2. YID must unique among all YLDxx entries in one model.

## YLDJC

## Johnson-Cook Yield Model

Defines a Johnson-Cook yield model where the yield stress is a function of effective plastic strain, strain rate, and temperature. Used in SOL 700 only.

Format:

| 1     | 2   | 3     | 4     | 5   | 6   | 7   | 8    | 9    | 10 |
|-------|-----|-------|-------|-----|-----|-----|------|------|----|
| YLDJC | YID | A     | B     | n   | C   | m   | EPS0 | CP   |    |
|       | 100 | 200E6 | 50.E6 | 0.1 | .15 | .95 | 1.   | 285. |    |

Example:

|       |       |       |  |  |  |  |  |  |  |
|-------|-------|-------|--|--|--|--|--|--|--|
| YLDJC | TMELT | TROOM |  |  |  |  |  |  |  |
|       | 1500. | 273.  |  |  |  |  |  |  |  |

| Describer | Meaning                                                                            |
|-----------|------------------------------------------------------------------------------------|
| YID       | Unique yield-model number referenced from a MATDEUL entry. (Integer > 0; Required) |
| A         | Static yield stress. (Real ≥ 0.0; Required)                                        |
| B         | Hardening parameter. (Real; Default = 0.0)                                         |
| n         | Hardening exponent. (Real; Default = 1.0)                                          |
| C         | Strain-rate parameter. (Real; Default = 0.0)                                       |
| m         | Temperature exponent. (Real; Default = 1.0)                                        |
| EPS0      | Reference strain rate. (Real > 0.0; Default = 1.0)                                 |
| CP        | Specific heat. (Real > 0.0; Default = 1.E20)                                       |
| TMELT     | Melt temperature. (Real; Default = 1.E20)                                          |
| TROOM     | Room temperature. (Real; Default = 293.0)                                          |

Remark:

1. The yield stress is computed from

$$\sigma_y = (A + B\varepsilon_p^n) \left( 1 + C \ln \left( \frac{\dot{\varepsilon}}{\varepsilon_0} \right) \right) (1 - T^{*m})$$

where

$$\begin{aligned} \varepsilon_p &= \text{effective plastic strain} \\ T^* &= \frac{(T - T_r)}{(T_m - T_r)} \end{aligned}$$

|                    |   |                        |
|--------------------|---|------------------------|
| $\dot{\epsilon}$   | = | effective strain rate  |
| $\dot{\epsilon}_0$ | = | referenced strain rate |
| $T$                | = | temperature            |
| $T_r$              | = | room temperature       |
| $T_m$              | = | melt temperature       |

and  $A$ ,  $B$ ,  $n$ ,  $C$ , and  $m$  are constants.

2. The reference strain rate is per unit time.
3. YID must unique among all YLDxx entries in one model.

## YLDMC

## Mohr-Coulomb Yield Model

Defines a Mohr-Coulomb yield model. Used in SOL 700 only.

Format:

|       |     |    |    |    |   |   |   |   |    |
|-------|-----|----|----|----|---|---|---|---|----|
| 1     | 2   | 3  | 4  | 5  | 6 | 7 | 8 | 9 | 10 |
| YLDMC | YID | Y1 | Y2 | Y3 |   |   |   |   |    |

Example:

|       |   |       |       |      |  |  |  |  |  |
|-------|---|-------|-------|------|--|--|--|--|--|
| YLDMC | 1 | 10.E5 | 20.E5 | 1.E4 |  |  |  |  |  |
|-------|---|-------|-------|------|--|--|--|--|--|

| Describer | Meaning                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------|
| YID       | Unique yield-model number referenced from MATDEUL for Eulerian elements with shear strength. (Integer > 0; Required) |
| Y1        | Cap yield stress. (Real; Required)                                                                                   |
| Y2        | Cohesion. (Real; Required)                                                                                           |
| Y3        | Internal friction angle. (Real; Required)                                                                            |

Remarks:

1. The yield stress depends on the pressure as

$$\sigma_y = \text{MIN}(Y1, (Y2 + Y3 \cdot P))$$

where Y1, Y2, Y3 are constants and  $P$  is the pressure.

2. This yield model is applicable only for Eulerian materials with shear strength.
3. YID must unique among all YLDxx entries in one model.

## YDMSS

## Multi-Surface Yield Model for Snow

Defines the yield model for snow material. This entry must be used in combination with MATDEUL, EOSPOL and SHREL. Used in SOL 700 only.

Format:

| 1     | 2   | 3     | 4  | 5    | 6    | 7   | 8    | 9   | 10 |
|-------|-----|-------|----|------|------|-----|------|-----|----|
| YDMSS | YID | KC    | T  | CC   | AC   | BC  | FC   | FTU |    |
|       | 7   | 0.149 | 82 | 1E-5 | 0.09 | 0.2 | 0.99 | 82  |    |

Example:

|       |       |     |  |  |  |  |  |  |  |
|-------|-------|-----|--|--|--|--|--|--|--|
| YDMSS | ALP0  | DS  |  |  |  |  |  |  |  |
|       | -0.37 | 0.0 |  |  |  |  |  |  |  |

| Describer | Meaning                                                                              |
|-----------|--------------------------------------------------------------------------------------|
| YID       | Unique yield model number referenced from a MATDEUL entry. (Integer > 0; Required)   |
| KC        | Parameter related to the angle of friction. (Real > 0; Required)                     |
| T         | Equivalent value of the snow cohesion. see Remark 5. (Real > 0; Required)            |
| CC        | Shape of the yield surface. See Remark 4. (Real > 0; Required)                       |
| AC        | Hardening parameter for compression. See Remark 4. (Real > 0; Required)              |
| BC        | Hardening parameter for compression. See Remark 4. (Real > 0; Required)              |
| FC        | Factor to avoid singularity. See Remark 4. (0 < Real < 1; Default = 0.99)            |
| FTU       | Hydrostatic tensile strength. See Remark 6. (Real > 0; Default = T/3)                |
| ALP0      | Initial compressive volumetric plasticity strain. See Remark 4. (Real < 0; Required) |
| DS        | Softening modulus. See Remark. (Real ≥ 0; Default = 0.0)                             |

Remarks:

1. This material model can be used to model Snow material.
2. In addition to deviatoric plastic strain there is also volumetric plastic strain. This volumetric strain is stored in the output variable VOLPLS. The deviatoric strain is stored in the variable EFFPLS.
3. For detail description of each parameter in this model, the user should refer to the Theory Manual in which the mechanical properties of snow are described.
4. If CC is set to zero then the material behaves as a Drucker-Prager model. Ac, Bc, Fc\* and ALP0 will be ignored.

5. The T value must be consistently converted from the cohesion data,  $C_{DP}$ , of the Drucker-Prager model as follows:

$$T = C_{DP}/K_C$$

6. FTU, hydrostatic tensile strength, may not be greater than T divided by 3. Otherwise it will be set to that value.
7. The softening modulus is used to update the hardening parameter  $q_t$ , see Theory Manual. It can be requested as output using FTU variable. The corresponding accumulated-plastic-volumetric-tensile-strain variable is SOFTE.
8. This material model is valid for the Euler with Strength solver and the Multi-material Euler with Strength solver.
9. YID must unique among all YLDxx entries in one model.

## YLDAPOL

## Polynomial Yield Model

Defines a polynomial yield model where the yield stress is a function of effective plastic strain. Used in SOL 700 only.

Format:

| 1       | 2   | 3 | 4 | 5 | 6 | 7 | 8 | 9    | 10 |
|---------|-----|---|---|---|---|---|---|------|----|
| YLDAPOL | YID | A | B | C | D | E | F | SMAX |    |

Example:

|         |   |        |  |  |  |  |  |  |  |
|---------|---|--------|--|--|--|--|--|--|--|
| YLDAPOL | 7 | 180.E6 |  |  |  |  |  |  |  |
|---------|---|--------|--|--|--|--|--|--|--|

| Descriptor | Meaning                                                                    |
|------------|----------------------------------------------------------------------------|
| YID        | Unique yield model number referenced from MATDEUL. (Integer > 0; Required) |
| A          | Initial yield parameters. (Real > 0; Required)                             |
| B          | Coefficient B. (Real; Default = 0.0)                                       |
| C          | Coefficient C. (Real; Default = 0.0)                                       |
| D          | Coefficient D. (Real; Default = 0.0)                                       |
| E          | Coefficient E. (Real; Default = 0.0)                                       |
| F          | Coefficient F. (Real; Default = 0.0)                                       |
| SMAX       | Maximum yield stress. (Real; Default = 1.E20)                              |

Remarks:

- The yield stress is computed from

$$\sigma_y = \text{MIN}(\sigma_{\max}, A + B\varepsilon_p + C\varepsilon_p^2 + D\varepsilon_p^3 + E\varepsilon_p^4 + F\varepsilon_p^5)$$

where

$$\begin{aligned} \varepsilon_p &= \text{effective plastic strain} \\ \sigma_{\max} &= \text{maximum yield stress} \end{aligned}$$

and  $A$ ,  $B$ ,  $C$ ,  $D$ ,  $E$  and  $F$  are constants.

- YID must be unique among all YLDxx entries in one model.

## YLDRPL

## Rate Power Law Yield Model

Defines a rate power law yield model where the yield stress is a function of effective plastic strain and strain rate. Used in SOL 700 only.

Format:

| 1      | 2   | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|--------|-----|---|---|---|---|---|---|---|----|
| YLDRPL | YID | A | B | n | m | C |   |   |    |

Example:

|        |   |        |  |  |  |  |  |  |  |
|--------|---|--------|--|--|--|--|--|--|--|
| YLDRPL | 7 | 180.E6 |  |  |  |  |  |  |  |
|--------|---|--------|--|--|--|--|--|--|--|

| Describer | Meaning                                                                    |
|-----------|----------------------------------------------------------------------------|
| YID       | Unique yield model number referenced from MATDEUL. (Integer > 0; Required) |
| A         | Initial yield parameters. (Real > 0; Required)                             |
| B         | Hardening parameter. (Real; Default = 0.0)                                 |
| N         | Hardening exponent. (Real; Default = 1.0)                                  |
| M         | Strain rate exponent. (Real; Default = 1.0)                                |
| C         | Minimum yield stress. (Real; Default = 1.E20)                              |

Remarks:

1. The yield stress is computed from

$$\sigma_y = \text{MAX}(C, A + B \varepsilon_p^n \dot{\varepsilon}^m)$$

where

|                     |   |                          |
|---------------------|---|--------------------------|
| $\varepsilon_p$     | = | effective plastic strain |
| $\dot{\varepsilon}$ | = | effective strain rate    |

and  $A$ ,  $B$ ,  $n$ ,  $m$  and  $C$  are constants.

2. YID must unique among all YLDxx entries in one model.

## YLD SG

## Steinberg-Guinan Yield Model

Defines the Steinberg-Guinan yield model where the yield stress is a function of effective plastic strain, pressure and temperature. Used in SOL 700 only.

Format:

| 1      | 2     | 3     | 4  | 5  | 6  | 7 | 8 | 9  | 10 |
|--------|-------|-------|----|----|----|---|---|----|----|
| YLD SG | YID   | A1    | A2 | A3 | A4 | H | B | CP |    |
|        | TMELT | TROOM |    |    |    |   |   |    |    |

Example:

|        |      |      |        |     |     |  |  |  |  |
|--------|------|------|--------|-----|-----|--|--|--|--|
| YLD SG | 7    | 8E+6 | 100E+6 | 110 | 0.5 |  |  |  |  |
|        | 1500 | 273  |        |     |     |  |  |  |  |

| Descriptor | Meaning                                                                            |
|------------|------------------------------------------------------------------------------------|
| YID        | Unique yield model number referenced from a MATDEUL entry. (Integer > 0; Required) |
| A1-A4      | Yield parameters. (Real > 0; Required)                                             |
| H, B       | Yield parameters. See Remark 4. (Real; Default = 0.0)                              |
| CP         | Specific heat. (Real > 0; Default = 1.E20)                                         |
| TMELT      | Melt temperature. (Real; Default = 1.E20)                                          |
| TROOM      | Room temperature. (Real; Default = 293.0)                                          |

Remarks:

1. This material model can be used to model metals for a wide range of strain rates.
2. The yield stress is computed from

$$A_T = A_1(1 + A_3 \varepsilon_p)^A$$

$$\sigma_y = \min(A_2, A_T) \left[ 1 - H(T - T_r) + Bp \left( \frac{p}{p_{ref}} \right)^{\frac{1}{3}} \right] \quad T < T_m$$

$$\sigma_y = 0, T \geq T_m$$

And  $A_1, \dots, A_4, H$  and  $B$  are constants.

3. The reference and quasi-static strain rate are per unit time.
4. YID must unique among all YLDxx entries in one model.

## YLDTM

## Tanimura-Mimura Yield Model

Defines the Tanimura-Mimura yield model where the yield stress is a function of effective plastic strain, strain rate and temperature. Used in SOL 700 only.

Format:

| 1     | 2     | 3     | 4   | 5 | 6 | 7    | 8    | 9  | 10 |
|-------|-------|-------|-----|---|---|------|------|----|----|
| YLDTM | YID   | A     | B   | C | D | M    | EPSM | CP |    |
|       | TMELT | TROOM | SCR | E | K | EPS0 |      |    |    |

Example:

|       |   |        |         |       |     |     |       |  |  |
|-------|---|--------|---------|-------|-----|-----|-------|--|--|
| YLDTM | 7 | 45.6E6 | 19.5E6  |       |     | 1.0 | 0.001 |  |  |
|       |   |        | 4000.e6 | 2100. | 0.5 | 1.0 |       |  |  |

| Describer | Meaning                                                                    |
|-----------|----------------------------------------------------------------------------|
| YID       | Unique yield model number referenced from MATDEUL. (Integer > 0; Required) |
| A         | Static yield parameter. (Real > 0; Required)                               |
| B         | Hardening parameter. (Real; Default = 0.0)                                 |
| C         | Strain rate parameter C. (Real; Default = 0.0)                             |
| D         | Strain rate parameter D. (Real; Default = 0.0)                             |
| M         | Temperature exponent. (Real; Default = 0.0)                                |
| EPSM      | Quasi-static strain rate. (Real > 0; Default = 1.0)                        |
| CP        | Specific heat. (Real > 0; Default = 1.E20)                                 |
| TMELT     | Melt temperature. (Real; Default = 1.E20)                                  |
| TROOM     | Room temperature. (Real; Default = 293.0)                                  |
| SCR       | Critical yield stress. (Real > 0; Default = 1.0)                           |
| E         | Strain rate parameter E. (Real; Default = 0.0)                             |
| K         | Strain rate exponent. (Real; Default = 1.0)                                |
| EPS0      | Reference strain rate. (Real > 0; Default = 1.0)                           |

Remarks:

1. This material model can be used to model metals for a wide range of strain rates.
2. The yield stress is computed from

$$\sigma_Y = \left[ A + B\varepsilon_P + (C + D\varepsilon_P) \left( 1 - \frac{A + B\varepsilon_P}{\sigma_{cr}} \right) \ln \left( \frac{\dot{\varepsilon}}{\dot{\varepsilon}_s} \right) \right] (1 - T^{*m}) + E \left( \frac{\dot{\varepsilon}}{\dot{\varepsilon}_0} \right)^k$$

where

|                       |   |                           |
|-----------------------|---|---------------------------|
| $\varepsilon_P$       | = | effective plastic strain  |
| $\sigma_{cr}$         | = | critical yield stress     |
| $\dot{\varepsilon}$   | = | effective strain rate     |
| $\dot{\varepsilon}_s$ | = | quasi-static strain rate  |
| $\dot{\varepsilon}_0$ | = | reference strain rate     |
| $T^*$                 | = | $(T - T_r) / (T_m - T_r)$ |
| $T$                   | = | temperature               |
| $T_r$                 | = | room temperature          |
| $T_m$                 | = | melt temperature          |

and  $A, B, C, D, m, E$  and  $k$  are constants.

3. The reference and quasi-static strain rate are per unit time.
4. YID must unique among all YLDxx entries in one model.

## YLDUDS

## User-defined Yield Model for Elements.

Specifies that a user subroutine is being used to define a simple yield model. Use in SOL700 only.

Format:

| 1      | 2   | 3     | 4     | 5 | 6 | 7 | 8 | 9 | 10 |
|--------|-----|-------|-------|---|---|---|---|---|----|
| YLDUDS | YLD | GROUP | UNAME |   |   |   |   |   |    |

Example:

*In FMS Section of the MSC Nastran input stream:*

```
CONNECT SERVICE myyld 'SCA.MDSolver.Obj.Uds.Dytran.Materials'
```

*In Bulk Data:*

| 1      | 2  | 3     | 4     | 5 | 6 | 7 | 8 | 9 | 10 |
|--------|----|-------|-------|---|---|---|---|---|----|
| YLDUDS | 12 | myyld | EXYLD |   |   |   |   |   |    |

| Describer | Meaning                                                                                    |
|-----------|--------------------------------------------------------------------------------------------|
| YLD       | Unique yield model ID. (Integer > 0; Required)                                             |
| GROUP     | The group name used for the FMS section CONNECT SERVICE statement. (Character; no Default) |
| UNAME     | User subroutine name associated with the entry. (Character; default=EXYLD)                 |

Remarks:

1. Only can be used for SOL 700.
2. The YLD must be referenced by a MATDEUL or MAT1 entry.
3. This yield model is applicable only for Euler elements with shear strength
4. UNAME can be:

| Subroutine Name | Function                          |
|-----------------|-----------------------------------|
| EXYLD           | Standard user defined yield model |

5. The yield strength can depend on the amount of failure or damage of the Euler element and on the VOLPLS and SOFTE element variables. This amount of damage can be either specified by the damage variable of the FAILJC entry or by a more general failure estimate by using the FAILUDS entry with UNAME=EXFAIL2. The VOLPLS and SOFTE variables can also be filled by the YLDUDS entry and FAILUDS entry with UNAME=EXFAIL2.

6. The damage variable is determined by either FAILJC or FAILUDS entry with UNAME=EXFAIL2. In UNAME=EXYLD, the yield stress can be reduced depending on the magnitude of the damage variable. In that case the NOFAIL option should be set on the FAILJC or FAILUDS entry with UNAME=EXFAIL2.

## YLDVM

## von Mises Yield Model

Defines a bilinear or piecewise-linear yield model with isotropic hardening, using the von Mises yield criterion. Used in SOL 700 only.

Format:

| 1     | 2     | 3     | 4    | 5 | 6 | 7 | 8 | 9 | 10 |
|-------|-------|-------|------|---|---|---|---|---|----|
| YLDVM | YID   | YIELD | EH   |   |   |   |   |   |    |
|       | TABLE | TYPE  | TABY | D | P |   |   |   |    |

Example:

|       |    |        |         |  |  |  |  |  |  |
|-------|----|--------|---------|--|--|--|--|--|--|
| YLDVM | 32 | 250.E6 | 2000.E6 |  |  |  |  |  |  |
|       |    |        |         |  |  |  |  |  |  |

| Descriptor | Meaning                                                                                                                                                                                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| YID        | Unique yield-model number referenced from MATDEUL. (Integer > 0; Required)                                                                                                                                                                                                 |
| YIELD      | Yield stress. (Real; Required)                                                                                                                                                                                                                                             |
| EH         | Hardening modulus. (Real; Default = 0.0)                                                                                                                                                                                                                                   |
| TABLE      | Number of a TABLED1 entry giving the variation of effective stress (y-value) with effective strain (x-value). See Remark 4. (Integer > 0)                                                                                                                                  |
| TYPE       | The type of stress and strain defined in TABLED1. (Character; Default = TRUE)<br>ENG            Engineering stress and strain.<br>TRUE           True stress and strain.<br>PLAST         True stress and plastic strain.<br>PMOD         Plastic modulus and true stress. |
| TABY       | Number of TABLED1 entry giving the variation of the scale factor for the yield stress (y-value) with the strain rate (x-value). Strain-rate effects are also specified using the Cowper-Symonds relation (see input parameters D and P). See Remark 6. (Integer > 0)       |
| D          | Factor D in the Cowper-Symonds rate enhancement equation. See Remark 6. (Real ≥ 0)                                                                                                                                                                                         |
| P          | Factor P in the Cowper-Symonds rate enhancement equation. See Remark 6. (Real ≥ 0)                                                                                                                                                                                         |

Remarks:

1. A bilinear stress-strain characteristic is used by specifying YIELD and EH:

where the yield stress  $\sigma_y$  is given by

$$\sigma_y = \sigma_0 + \frac{EE_h}{E - E_h} \varepsilon_p$$

where

|                 |                                               |
|-----------------|-----------------------------------------------|
| $\sigma_0$      | = yield stress specified in the YIELD field   |
| $E$             | = Young's modulus                             |
| $E_h$           | = hardening modulus specified in the EH field |
| $\varepsilon_p$ | = equivalent plastic strain                   |
| $\sigma_y$      | = yield stress                                |

2. A piecewise linear, stress-strain characteristic is used by specifying TABLE and TYPE (beams and shells only)

$$\sigma_{ij} = [(\sigma_i - \sigma_{i-1})(\varepsilon - \varepsilon_{i-1}) / (\varepsilon_i - \varepsilon_{i-1})] + \sigma_{i+1}$$

The stress-strain characteristic used internally in the solver is in terms of true stress and equivalent plastic strain. However, for convenience, the stress-strain characteristic can be input in any of the following ways:

True stress/true strain (TYPE = TRUE)

Engineering stress/engineering strain (TYPE = ENG)

True stress/plastic strain (TYPE = PLAST)

Plastic modulus/true stress (TYPE = PMOD)

3. With Lagrangian and Eulerian solid elements, only an elastic perfectly plastic yield model is currently used. Only the YIELD field is used.
4. If TABLE is blank or zero, a bilinear stress-strain curve is assumed. If TABLE has a value, it refers to a TABLED1 entry giving the stress-strain curve for the material.
5. If TABLE is defined, the value of YIELD is left blank, since it is determined from the stress-strain curve.
6. If TABY is blank or zero and  $D$  and  $P$  are blank or zero, the yield stress does not vary with strain rate. If TABY has a value, then it references a TABLED1 entry, which gives the variation of the scale factor applied to the yield stress with strain rate. ( $D$  and  $P$  must be blank or zero.)  
 If TABY is blank or zero and  $D$  and  $P$  are defined, the enhancement of the yield stress with strain rate is calculated as

$$\frac{\sigma_d}{\sigma_y} = 1 + \left( \frac{\dot{\epsilon}_p}{D} \right)^{1/p}$$

Where  $\sigma_d$  is the dynamic stress,  $\sigma_y$  is the static yield stress (YIELD), and  $\dot{\epsilon}_p$  is the equivalent plastic strain rate.

7. If TYPE is PLAST or PMOD, Young's modulus must be defined. If TYPE is ENG or TRUE and Young's modulus is defined it will override the value calculated from the stress-strain curve.
8. Note that for values exceeding the maximum x-value of either of the TABLED1 entries (see TABLE and TABY fields), linear extrapolation is used based upon the last two points specified in the TABLED1.
9. YID must unique among all YLDxx entries in one model.

## YLDZA

## Zerilli-Armstrong Yield Model

Defines the Zerilli-Armstrong yield model where the yield stress is a function of effective plastic strain, strain rate and temperature. Used in SOL 700 only.

Format:

| 1     | 2   | 3 | 4 | 5 | 6 | 7 | 8    | 9 | 10 |
|-------|-----|---|---|---|---|---|------|---|----|
| YLDZA | YID | A | B | n | C | m | EPS0 |   |    |
|       | D   |   |   |   |   |   |      |   |    |

Example:

|       |     |        |       |     |  |  |  |  |  |
|-------|-----|--------|-------|-----|--|--|--|--|--|
| YLDZA | 7   | 200.E6 | 50.E6 | 0.1 |  |  |  |  |  |
|       | 0.0 |        |       |     |  |  |  |  |  |

| Describer | Meaning                                                                            |
|-----------|------------------------------------------------------------------------------------|
| YID       | Unique yield model number referenced from a MATDEUL entry. (Integer > 0; Required) |
| A         | Static yield parameters. (Real > 0; Required)                                      |
| B         | Hardening parameters. (Real ≥ 0; Default = 0.0)                                    |
| n         | Hardening exponent. (Real; Default = 0.0)                                          |
| C         | Strain rate parameter. (Real; Default = 1.0)                                       |
| m         | Temperature exponent. (Real; Default = 1.0)                                        |
| EPS0      | Reference strain rate. (Real > 0; Default = 1.0)                                   |
| CP        | Specific heat. (Real > 0; Default = 1.E20)                                         |
| D         | Bcc parameter. See Remark 4. (Real; Default = blank)                               |

Remarks:

1. This material model can be used to model to model Fcc (iron and steels) and Bcc (aluminum and alloys) metals.
2. The yield stress is computed from  
for Fcc metals:

$$\sigma_y = (A + B\varepsilon_p^n) \varepsilon \left[ -mT + CT \ln \left( \frac{\dot{\varepsilon}}{\varepsilon_0} \right) \right] \text{ for Fcc metals}$$

$$\sigma_y = (A + B\varepsilon_p^n) + De \left[ -mT + C \ln\left(\frac{\dot{\varepsilon}}{\dot{\varepsilon}_0}\right) \right] \text{ for Bcc metals}$$

where

|                                         |   |                          |
|-----------------------------------------|---|--------------------------|
| $\varepsilon_p$                         | = | effective plastic strain |
| $\dot{\varepsilon}$                     | = | effective strain rate    |
| $\dot{\varepsilon}_0$                   | = | reference strain rate    |
| $T$                                     | = | temperature              |
| $A, B, n, C, m,$ and $D$ are constants. |   |                          |

3. The reference strain rate are per unit time.
4. In case the Bcc parameter  $D$  is not supplied, it is assumed that a Fcc metal is defined.

# A

## Configuring the Runtime Environment

- [Specifying Parameters](#)
- [User-Defined Keywords](#)
- [Resolving Duplicate Parameter Specifications](#)
- [Customizing Command Initialization and Runtime Configuration Files](#)
- [Symbolic Substitution](#)

## Specifying Parameters

MSC Nastran execution is controlled by a variety of parameters, either keywords or special Nastran statements, both required and optional. The purpose of this section is to describe how and where these parameters may be specified, not to describe these parameters in detail. This is done in subsequent sections. The MSC Nastran parameters may be specified on the command line, in a command initialization (INI) file, in runtime configuration (RC) files and, for some parameters, from environment variables. The information from these sources is consolidated at execution time into a single set of values. Much of this information is passed to analysis processing in a **control file**, built using the templates ([Customizing the Templates, 53](#)). (The records in this control file are echoed to the .log file.) Examples of INI and RC files are given in the [User-Defined Keywords, 3355](#) and [Customizing Command Initialization and Runtime Configuration Files, 3363](#).

## Command Initialization and Runtime Configuration Files

Although the purposes of the INI and RC files are somewhat different, the format of each file is the same. All INI and RC files are processed twice, once (the "first" pass) to extract parameters (keywords and other information) that are to be used for all MSC Nastran jobs, and once (the "second" pass) to extract parameters specific to a particular job. This is accomplished by separating the INI and RC files into a series of "sections" identified by a "section header" and "subsections" within sections, identified by a subsection "header." There are two types of sections: "unconditional" and "conditional." Subsections are always "conditional."

- An unconditional section is one that starts with the name of the section enclosed in square brackets ("[" , "]" ). Section names may not contain any embedded blanks but may be separated from the square brackets by any number of blanks. As currently implemented, there are three valid unconditional names: "General", "Solver" and "Nastran". (These section names are case-insensitive.) In addition, there is an implicit "unnamed" section that consists of all parameters in the INI or RC file that appear before the first named section or subsection. There is no special meaning assigned to any of the unconditional sections. Their use is optional; the section names are intended to be used for descriptive purposes.
- A conditional section or subsection is one that starts with an expression in the form:

`<keyword><operator><value>`

enclosed in section header identification characters. For a conditional section, the section header identification characters are square brackets ("[" , "]" ), just as for unconditional sections. For a subsection, the section header identification characters are "less than" and "greater than" ("<" , ">") characters. Keywords and values may not contain any embedded blanks but may be separated from each other and from the enclosing section header identification characters (the square brackets or "less than"->greater than" characters) by any number of blanks. In the expression:

|                               |                                                                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;keyword&gt;</code>  | represents any valid internal keyword (see <a href="#">Keywords, 184</a> ) or user-defined keyword (see <a href="#">User-Defined Keywords, 3355</a> ). |
| <code>&lt;operator&gt;</code> | specifies the comparison to be performed between <code>&lt;keyword&gt;</code> and <code>&lt;value&gt;</code> as follows:                               |
| <code>=</code>                | equal (either string or numeric)                                                                                                                       |

|         |                                                                       |
|---------|-----------------------------------------------------------------------|
| !       | not equal (either string or numeric)                                  |
| !=      | not equal (either string or numeric)                                  |
| <       | numerically less than                                                 |
| <=      | numerically less than or equal                                        |
| >       | numerically greater than                                              |
| >=      | numerically greater than or equal                                     |
| <value> | specifies the appropriate keyword value to be used in the comparison. |

Keywords and values may be specified in any case.

Parameters in unconditional sections, but not in subsections (which are always conditional) within unconditional sections, are processed on the first pass through an INI or RC file. On the second pass, these parameters are ignored (they are not reprocessed). Parameters in conditional sections and subsections are ignored on the first pass. Parameters in conditional sections and subsections whose expressions evaluate to "true" are processed on the second pass through an INI or RC file, thus allowing conditional expressions to reference all of the valid keywords. Note that for subsections within conditional sections, both the conditional expression for the section *and* the conditional expression for the subsection must evaluate to "true" before parameters in the subsection are processed.

Parameter specifications in, either unconditional or conditional sections, may be continued, if necessary, by specifying a backslash (“\”) character as the last non-blank character of the line. Note for Windows users, if the parameter value itself ends with a backslash, the statement must have additional characters, such as a comment, after the value specification. For example, a specification such as:

```
sdir=e:\
```

will not work properly. Instead, write the statement as:

```
sdir=e:\ $ Specify the scratch directory
```

In addition to parameters, INI and RC files may contain “comment” records. There are two types of comment records: ignored and printed.

- Ignored comments are records that start with a semi-colon (“;”) or pound sign (“#”). These records are completely ignored. When running in Windows, there is a special form of ignored comments that may be specified in an INI file (but not in RC files). These are records that start with "REM", short for "REMARK". The test for "REM" is case-insensitive.
- Printed comments are records that start with the currency symbol (“\$”). These records are passed on as part of the analysis information but are otherwise ignored.

**Note:** Although sectioning within INI and RC files was first introduced in MSC Nastran 2004, valid INI and RC files from prior versions of MSC Nastran are fully compatible with this new format. Since sections were not supported in previous versions (except for INI files on Windows, which allowed unconditional sections), all parameters will be in the "unnamed" implicit section (or, on Windows, in named unconditional sections) and will be processed on the first pass through the file. No information will be extracted from these files on the second pass.

- Command Initialization (INI) File

This file is used to define keywords that are to be set whenever the nastran command is executed. Typical keywords in the unconditional sections include the installation base directory and the version of MSC Nastran. Conditional sections and subsections might include keywords such as "rcmd" and "rsdirectory" in sections that are conditional upon the value of the "node" keyword.

Default installation directories are:

LINUX: *install\_dir/prod\_ver/arch/nastran.ini*

Windows: *install\_dir\prod\_ver\arch\nastran.ini*

Starting with MSC Nastran 2011, there are two possible RC files that may be defined in each of the locations that are searched for RC files. The first name is a version independent name and the second name is a version dependent name, where the version number is indicated by *<vernum>* in the file name and the version number for MSC Nastran is 2022.1. The list below specifies the INI and RC files that MSC Nastran uses. Any or all of these files may be omitted. [Table 1-1](#) lists the keywords that are generally set in the unconditional sections of the command initialization file. [Table 1-2](#) lists the keywords that are generally set in RC files.

*prod\_ver* is the msc version (msc20221 for MSC Nastran 2022.1).

In addition, the default *install\_dir* of MSC Nastran 2022.1 is as follows:

Linux: /msc/MS\_C\_Nastran/2022.1

Windows: C:\Program Files\MSC.Software\MS\_C\_Nastran\2022.1.

- System RC Files

These files are used to define parameters that are applied to all MSC Nastran jobs using this installation structure. Many of the parameters that might be specified in the INI file could, alternatively, be specified in this file.

LINUX: *install\_dir/conf/nastranrc* and  
*install\_dir/conf/nast<vernum>rc*

Windows: *install\_dir\conf\nastran.rcf* and  
*install\_dir\conf\nast<vernum>.rcf*

- Architecture RC Files

This files are used to define parameters that are applied to MSC Nastran jobs using this architecture.

LINUX: *install\_dir/conf/arch/nastranrc* and  
*install\_dir/conf/arch/nast<vernum>rc*

Windows: *install\_dir\conf\arch\nastran.rcf* and  
*install\_dir\conf\arch\nast<vernum>.rcf*

- Node RC Files

These files are used to define parameters that are applied to MSC Nastran jobs running on this node. Alternatively, the parameters in this file could be specified in a conditional section in one of the previous files, using *nodename* as the value of the "s.hostname" keyword in the conditional expression.

LINUX: *install\_dir/conf/net/nodename/nastranrc* and  
*install\_dir/conf/net/nodename/nast<vernum>rc*

Windows: *install\_dir\conf\net\nodename\nastran.rcf* and  
*install\_dir\conf\net\nodename\nast<vernum>.rcf*

- User RC Files

These files are used to define parameters that are applied to MSC Nastran jobs run by an individual user.

LINUX: `$HOME/.nastranrc` and  
`$HOME/.nast<vernum>rc`

Windows: `%HOMEDRIVE%%HOMEPATH%\nastran.rcf` and  
`%HOMEDRIVE%%HOMEPATH%\nast<vernum>.rcf`

- Local RC Files

These files should be used to define parameters that are applied to MSC Nastran jobs that reside in the input data file's directory. This RC file is in the same directory as the input data file. If the "rcf" keyword ([page 215](#)) is used, this local file is ignored.

LINUX: `.nastranrc` and  
`.nast<vernum>rc`

Windows: `nastran.rcf` and  
`nast<vernum>.rcf`

Please note that the LINUX shorthand "~", to refer to your or another user's home directory, cannot be used in an RC file. In addition, environment variables are only recognized within the context of a logical symbol definition.

Also, note that, on LINUX systems, the leading period (“.”) on the User RC Files and Local RC Files file names cannot be deleted even if alternate names are specified using the “a.urc” and “a.urcb” keywords as described below.

The file names listed above may be changed by the user using the “a.rc”, “a.rcb”, “a.urc” and “a.urcb” keywords, noting that the directories in which the files are located may not be changed.

- The “a.rc” keyword can be used to change the names of the version dependent RC file names for the System RC Files, the Architecture RC Files and the Note RC File. The default for this keyword is “nast<vernum>rc” for LINUX and “nast<vernum>.rcf” for Windows.
- The “a.rcb” keyword can be used to change the names of the version-independent RC file names for the System RC Files, the Architecture RC Files and the Node RC Files. The default for this keyword is “nastranrc” for LINUX and “nastran.rcf” for Windows.
- The “a.urc” keyword can be used to change the names of the version dependent RC file names for the User RC Files and the Local RC Files. For LINUX, the default for this keyword is the value of the “a.rc” keyword with a leading period (“.”) added. For Windows, the default for this keyword is the value of the “a.rc” keyword.
- The “a.urcb” keyword can be used to change the names of the version-independent RC file names for the User RC Files and the Local RC Files. For LINUX, the default for this keyword is the value of the “a.rcb” keyword with the leading period (“.”) added. For Windows, the default for this keyword is the value of the “a.rcb” keyword.

In addition to keyword specifications, the following MSC Nastran statements (from the NASTRAN and FMS Sections) may appear in RC files and conditional sections in an INI file: NASTRAN, ACQUIRE, ASSIGN, CONNECT, DBCLEAN, DBDICT, DBFIX, DBLOAD, DBLOCATE, DBSETDEL, DBUNLOAD, DBUPDATE, DEFINE, ECHOOFF, ECHOON, ENDJOB, EXPAND, INCLUDE, INIT, PROJ, RESTART and RFINCLUDE. Except for minimal checking of the NASTRAN and PARAM statements, the syntax of these statements is not validated. These records are simply passed on for use in MSC Nastran analysis processing.

INI files and RC files also may contain PARAM statements that specify values that affect MSC Nastran analysis processing. The values associated with PARAM names may be specified using PARAM statements in INI files and RC files or by using PARAM keywords, defined using the PARAM keywords feature as described in [User-Defined Keywords, 3355](#). PARAM statements must be specified in "free-field format", i.e., in the Case Control PARAM format (PARAM,name,value), not in Bulk Data fixed-field format. Please see [Parameters](#) (Ch. 6) in the *MSC Nastran Quick Reference Guide* for more information on PARAM names and statements and their usage.

## Environment Variables

Several keywords may have their values set from associated environment variables. When this is the case, the environment variable takes precedence over any INI or RC file keyword specification. A command-line specification will over-ride the environment variable specified value. This same precedence rule applies to user-defined keywords that may have their initial values taken from environment variables, as described in the next section. A list of the keywords and their associated environment variables, along with a description of each keyword, may be obtained by using the following command:

`nast_ver help env`

## User-Defined Keywords

In addition to the internally defined keywords (see [Keywords, 184](#)), MSC Nastran allows users to define their own keywords. There are two classes of user-defined keywords:

- General keywords. These are intended for use in INI file or RC file conditional section clauses, in user modifications to the run template files (nastran.dmp, nastran.lcl, nastran.rmt or nastran.srv) and, for LINUX, in customized queue commands (“submit” keyword).
- PARAM keywords. These are keywords associated with a PARAM name. Using descriptive keywords to set a PARAM value may be more convenient than specifying the PARAM statement in an RC file. Also, keywords are not limited to a maximum of eight characters, as PARAM names are, and may be more descriptive of the action being affected or requested.

User-defined keywords are supported by the “help” and “whence” functions.

## General Keywords

These keywords are defined in the file specified by the "0.kwds" keyword. While the file is not delivered, an administrator could create the file. The default file names are:

```
LINUX:          install_dir/prod_ver/arch/nastran.kwds
Windows:       install_dir\prod_ver\arch\nastran.kwds or
               install_dir\bin\nast20221.kwds
               The file used is the first one found.
```

The records in this file consist of:

- Comment records. These are records that start with a comment character (hash, '#', semi-colon, ';', or currency symbol, '\$') and are completely ignored.
- Blank or null records. These records are ignored.
- Keyword records. These records consist of the keyword name along with an optional value descriptor and comment in the form:

```
keyword_name[,attributes] : value_descriptor comment
```

where:

|                               |                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>keyword_name</code>     | is the name to be assigned to the user keyword. This name may not contain any embedded blanks and may not be the same as any internal keyword or previously specified user-defined keyword. It is also case-insensitive except in the case when its initial value may be set from an environment variable with the same name.                                                       |
| <code>attributes</code>       | specifies optional attributes to be assigned to the keyword defined by <code>keyword_name</code> . Currently, the only defined attribute is:<br><code>argv keyword</code> and its value is to be added to the "r.argv" keyword value<br>Any number of blanks may separate <code>keyword_name</code> , the separating command and the attributes specification.                      |
| <code>value_descriptor</code> | is optional. If specified, it should be as described in <a href="#">Value Descriptors, 3357</a> and may not contain any embedded blanks. If this field is not present, the separating colon may be omitted.. The default value descriptor is "string". This field may also specify that the initial value of this keyword be taken from an environment variable with the same name. |
| <code>comment</code>          | is an optional comment field. If present, it must be separated from <code>value_descriptor</code> or <code>keyword_name</code> by blanks or must begin with a comment character.                                                                                                                                                                                                    |

There may be any number of leading blanks in the record and before and after the separating colon.

General keywords and the values assigned to them only affect MSC Nastran processing if:

- there are customized INI and RC files that have conditional sections, using these keywords in expressions, that specify other keywords and statements (e.g., NASTRAN and PARAM statements) that modify MSC Nastran processing to meet the requirements of a user's site and installation.
- they are used in customized templates ([Customizing the Templates, 53](#)).
- for LINUX systems, they are used in customized queue commands defined using the "submit" keyword ([Customizing Queue Commands \(LINUX\), 51](#)).

## PARAM Keywords

These keywords are defined in the file specified by the "0.params" keyword. The default file names are:

LINUX:            *install\_dir***|***prod\_ver**|arch*/nastran.params

Windows:        *install\_dir***\***prod\_ver**\arch*\nastran.params

The records in this file consist of:

- Comment records. These are records that start with a comment character (hash, '#', semi-colon, ';', or currency symbol, '\$') and are completely ignored.
- Blank or null records. These records are ignored.
- Keyword-name records. These records consist of the keyword name, the associated PARAM name, along with an optional value descriptor and comment in the form:

keyword\_name : param\_name : value\_descriptor comment

where:

|                               |                                                                                                                                                                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>keyword_name</code>     | is the name to be assigned to the PARAM keyword. This name is case-insensitive, may not contain any embedded blanks and may not be the same as any internal keyword, general user-defined keyword or previously specified PARAM keyword.                                                       |
| <code>param_name</code>       | is the PARAM name to be associated with <code>keyword_name</code> . This name is case-insensitive, may be a maximum of eight characters, must begin with an alphabetic character and may not contain any embedded blanks. Also, it may not be the same as any previously specified PARAM name. |
| <code>value_descriptor</code> | is optional. If specified, it should be as described in <a href="#">Value Descriptors</a> and may not contain any embedded blanks. If this field is not present, the separating colon may be omitted. The default value descriptor is "string".                                                |
| <code>comment</code>          | is an optional comment field. If present, it must be separated from <code>value_descriptor</code> or <code>param_name</code> by blanks or must begin with a comment character.                                                                                                                 |

There may be any number of leading blanks in the record and before and after the separating colons.

Keyword names that are the same as PARAM names are allowed, as long as the keyword name is not an internal or general user-defined keyword name.

Values associated with PARAM names, whether set using PARAM keywords or set using PARAM statements (statements having the form `PARAM,name,value`), directly affect MSC Nastran analysis processing.

## Value Descriptors

Value descriptors enable limited syntax checking for values assigned to general and PARAM user-defined keywords. For general keywords, they may also specify that the initial value of the keyword be set from the value associated with the environment variable having the same name as the keyword. There are two types of syntax checking available: value must be one of a list of entries or value must be numeric. Also, the two forms can be combined. These are specified as follows:

List: { "val1", "val2", ..., "valn" }

That is, the acceptable values are enclosed in double quotes (") and separated from each other by commas. The specification, including the various acceptable values, may not contain any embedded blanks. Values are case-insensitive and any partial specification is acceptable and will be replaced by the full value. For example, if a keyword may only have the values "preliminary", "check" and "final", the value descriptor would be:

```
{"Preliminary", "Check", "final"}
```

and a value specification of "Ch" would be accepted and replaced by "check".

Numeric: `number`

Values will be checked to see if they are valid numbers, either integer or floating point. For example, valid keyword value specifications could be: "1", "-3.247", "4.e-5", "3.75-4", "4.24x" and "-4-5" are invalid specifications.

**Note:** This checking does *not* support the NASTRAN "nnnsee" numeric format, where the 'e' between the number and the signed exponent ("see") is missing.

Complex value: `number, number`

This format is only supported for PARAM keyword value descriptors. Values will be checked to see if they consist of two valid numeric values, separated by a comma.

Combined: `{"val1", "val2", ..., "valn", number}`

**Note:** This "combined" format does not support complex numbers.

In addition, for general keywords, if the value descriptor starts or ends with the string "env", specified in any case and separated from the rest of the value descriptor with a comma (unless the value descriptor is only "env"), the keyword value will be set using the value associated with the environment variable having the same name as the keyword. The environment value will be subjected to the same syntax-checking rules that an INI file, RC file or command line specification would be, with a warning message generated if syntax checking fails. This occurs even if the keyword is specified on the command line. Note that, for LINUX systems, since environment variable names are case-sensitive, the keyword name must be specified exactly the same as the environment variable name. This is the only time that the keyword name is case-sensitive. For Windows systems, since environment variable names are not case-sensitive, this restriction does not apply. Keyword values set from environment variables over-ride keyword values set in INI or RC files but do not over-ride keyword values set on the command line.

If a value descriptor is omitted or is not one of these formats, no syntax checking will be performed.

## Examples:

1. The following value descriptor would accept a value of "test", "final" or a number:

```
{"Test", "Final", Number}
```

Acceptable values would be: `te` (replaced by `test`), `FIN` (replaced by `final`), `7`, `14.5`, `3.e-4`, `-5`

2. The following value descriptor would accept only the strings "abc", "def", "ghi" and "glm":

```
{"abc", "def", "ghi", "glm"}
```

Acceptable values would be: `g` (replaced by `ghi`), `aB` (replaced by `abc`), `g1` (replaced by `glm`), `D` (replaced by `def`)

3. The following value descriptor, only valid for a PARAM keyword, would only accept a complex number specification:

```
number, number
```

Acceptable values would be: `1`, `2`, `7.54`, `3.14`

4. The following value descriptors, only valid for a general keyword, would accept only the strings "qrs", "test", and "xyz". In addition, the value descriptor requests that the keyword value be set from the environment.

```
enV, {"qrs", "test", "xyz"}
```

or

```
{"qrs", "test", "xyz"}, Env
```

Acceptable values would be: `q` (replaced by `qrs`), `xY` (replaced by `xyz`), `T` (replaced by `test`)

## Resolving Duplicate Parameter Specifications

MSC Nastran processing information is obtained by scanning the various INI and RC files, the system environment, and the Nastran command line in the following order:

1. Nastran command line, first pass. Only "program options", i.e., "-x" options, are processed during this command line scan. For example, this is when the "-i *ini\_file\_name*" program option is processed.
2. Environment variables, first pass. During this pass, the only keywords whose values are set are those that may only be specified as environment variables. This includes keywords such as HOME (for LINUX), HOMEDRIVE and HOMEPATH (for WINDOWS) and PWD.
3. INI file, first pass, if this file exists. During this pass, only unconditional sections are processed. Generally, the only keywords processed in this pass are: 0.kwds, 0.params, accmd, acvalid, rcmd, rsdirectory, sysmsg and version (although rcmd and rsdirectory probably should be in conditional sections scanned during the second pass).
4. Environment variables, second pass. During this pass, only those keywords that may only be set in global sections of the INI file or as environment variables are processed. This includes keywords such as MSC\_ARCH, MSC\_BASE and MSC\_VERSD.
5. Nastran command line, second pass. The only general use keywords processed during this command line scan are: dmparallel, jid, jidpath, jidtype, node, pause, rcf, username, version and whence. The processing of other command line keywords is deferred until later command line scans.

This is the time that the user-defined keyword definition files (for both general use and PARAM keywords), if any, are processed and the keyword specifications defined by these files are added to the keywords tables. The keywords defined in these files may be used just as internal keywords are used. (See [User-Defined Keywords, 3355](#).)

6. System RC files, first pass, if these files exist. During this pass, only unconditional sections are processed.
7. Architecture RC files, first pass, if these files exist. During this pass, only unconditional sections are processed.
8. Node RC files, first pass, if these files exist. During this pass, only unconditional sections are processed.
9. User RC files, first pass, if these files exist. During this pass, only unconditional sections are processed.
10. Local RC files, first pass, if these files exist. During this pass, only unconditional sections are processed.
11. Environment variables, third pass. During this pass, only "general" user-defined keywords that have been flagged to be set from environment variables are processed. (This pass will be skipped if there are no "general" user-defined keywords.)
12. Nastran command line, third pass. Only "general" user-defined keywords are processed during this command line scan. (This pass will be skipped if there are no "general" user-defined keywords.)

At this point, all keyword values that can be used in conditional section expressions are known.

13. INI file, second pass, if this file exists and has conditional sections. During this pass, only the conditional sections are processed.
14. System RC files, second pass, if these files exist and have conditional sections. During this pass, only the conditional sections are processed.
15. Architecture RC files, second pass, if these files exist and have conditional sections. During this pass, only the conditional sections are processed.
16. Node RC files, second pass, if these files exist and have conditional sections. During this pass, only the conditional sections are processed.
17. User RC files, second pass, if these files exist and have conditional sections. During this pass, only the conditional sections are processed.
18. Local RC files, second pass, if these files exist and have conditional sections and if they are not ignored. During this pass, only the conditional sections are processed.
19. Environment variables, fourth pass. During this pass, all keywords that may be set from environment variables and that have not been processed previously are now processed.
20. Nastran command line, fourth pass. All keywords not processed during the previous passes are now processed. For example, this is when user-defined PARAM keyword specifications are processed.  
At this point, all information necessary to generate the "control file" has been collected. This file is generated when the "script templates" (see [Customizing the Templates, 53](#)) are processed.
21. NASTRAN, FMS and PARAM statements in the input file.

If duplicate keywords are encountered, the *last* specification found is the one used. That is, the above list specifies the precedence order, from lowest precedence (number 1) to highest (number 21). The only case in which the last keyword specification is not used is when keywords are "locked", i.e., when a specification of the form

```
lock=keyword
```

is processed. After this "lock" request is processed, any requests to set *keyword*, whether from INI files, RC files, environment variables or command line arguments, are quietly ignored. That is, processing proceeds as if any *keyword* specifications specified after the "lock=*keyword*" request do not exist. Once a keyword has been "locked," there is no way to "unlock" it. (Note that it is valid to "lock" the `lock` keyword itself.)

If duplicate NASTRAN and FMS statements are encountered, they are simply passed on for use in MSC Nastran analysis processing in the order in which they were encountered.

Thus, the general rule for resolution is:

- Information specified in NASTRAN input data files always takes precedence over any other values.
- Command line parameters have the next highest precedence.
- Environment variables associated with keywords and that have non-null values are next.
- RC file parameter specifications are next.
- INI file parameter specifications are last.

Generally, the only exceptions to this precedence ordering are "general" user-defined keyword specifications. The command line values take precedence over values specified in unconditional INI file and RC file sections but have lower precedence than values specified in conditional INI file and RC file sections. Because the primary purpose for general user-defined keywords is for conditional section selection, changing a general user-defined keyword in a conditional section *may* lead to unexpected results. Such specifications should be used with care. Also, because user-defined PARAM keywords on the command line are not processed until the last command line scan, PARAM keywords should not be used in INI file and RC file conditional section expressions since command line specified values will not be in effect when these expressions are evaluated.

Because PARAM values may be specified either using PARAM statements or using PARAM keywords, they require further explanation. PARAM statements and PARAM keywords referring to the same PARAM name are considered equivalent definitions for the PARAM name. As such, the last specification, regardless of whether it was a PARAM statement or a PARAM keyword, is the one that is used to establish the value associated with the PARAM name.

## Customizing Command Initialization and Runtime Configuration Files

Table 1-1 lists the keywords that are generally set in the unconditional sections of the command initialization file.

Table 1-1      Command Initialization File Keywords

| Keyword         | Purpose                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------|
| <b>0.kwds</b>   | Alternate name for user-defined keywords definition file.                                 |
| <b>0.params</b> | Alternate name for PARAM keywords definition file                                         |
| <b>acct</b>     | Enables job accounting, see <a href="#">Enabling Account ID and Accounting Data, 40</a> . |
| <b>acvalid</b>  | Activates account ID validation, see <a href="#">Enabling Account ID Validation, 40</a> . |
| <b>MSC_BASE</b> | Defines the installation base directory.                                                  |
| <b>version</b>  | Specifies the default version of MSC Nastran to be run.                                   |

Most of the command line keywords can be set in any of the RC files. Table 1-2 lists keywords that are generally set in the system, architecture, or node RC files:

Table 1-2      RC File Keywords

| Keyword              | Preferred RC File | Purpose                                                                                                                   |
|----------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>accmd</b>         | System            | Command line to invoke accounting logger program.                                                                         |
| <b>acct</b>          | System            | Enables job accounting.                                                                                                   |
| <b>acvalid</b>       | System            | Enables account ID (acid) validation.                                                                                     |
| <b>authorize</b>     | System            | Specifies the licensing method.                                                                                           |
| <b>buffsize</b>      | System            | Set the default buffsize. Suggested values are in <a href="#">Table 4-5</a> .                                             |
| <b>lock</b>          | Any               | Prevent further changes to a keyword's value.                                                                             |
| <b>memory</b>        | Node              | Specifies a default memory allocation                                                                                     |
| <b>memorymaximum</b> | Node              | Specifies a maximum "memory" request. May be specified as a percentage of RAM e.g.<br><code>memorymax=0.5xPhysical</code> |
| <b>ncmd</b>          | Architecture      | Specifies the notify command when "notify=yes" is set.                                                                    |
| <b>news</b>          | System            | Controls the display of the news file at the beginning of the .f06 file.                                                  |

Table 1-2 RC File Keywords (continued)

| Keyword            | Preferred RC File | Purpose                                                                                                                                                  |
|--------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>post</b>        | Architecture      | LINUX: Specifies commands to be run after each job is completed.                                                                                         |
| <b>ppcdelta</b>    | Architecture      | LINUX: Specifies the value that is subtracted from the "CPU" keyword value to determine the NQS per-process CPU time limit.                              |
| <b>ppmdelta</b>    | Architecture      | LINUX: Specifies the value that is added to the "memory" keyword value to determine the NQS per-process memory limit.                                    |
| <b>pre</b>         | Architecture      | LINUX: Specifies commands to be run before each job begins.                                                                                              |
| <b>prmdelta</b>    | Architecture      | LINUX: Specifies the value that is added to the "ppm" value to determine the NQS per-request (per-job) memory limit.                                     |
| <b>qoption</b>     | Architecture      | LINUX: Specifies a string of additional queuing options to be set in the queue submittal command.                                                        |
| <b>rcmd</b>        | Any               | Specifies the remote Nastran command to be used when "node" is specified. Should be in a conditional section using "node" in the conditional expression. |
| <b>real</b>        | Node              | Specifies the "REAL" parameter to limit virtual memory usage.                                                                                            |
| <b>rsdirectory</b> | Any               | Specifies the scratch directory to be used when "node" is specified. Should be in a conditional section using "node" in the conditional expression.      |
| <b>scratch</b>     | Any               | Specifies the default job status as scratch or permanent.                                                                                                |
| <b>sdirectory</b>  | Node              | Specifies a default scratch directory.                                                                                                                   |
| <b>submit</b>      | Architecture      | LINUX: Defines queues and their associated submittal commands.                                                                                           |
| <b>sys<i>n</i></b> | Any               | Specifies system cells. Can also be specified using the synonym keywords, e.g., buffsize is equivalent to sys1.                                          |

## Examples

The following (relatively simplistic) examples illustrate how unconditional and conditional sections could be used.

### Example 1:

Assumptions: There are three computer nodes, sysnode1, sysnode2 and sysnode3, that may be accessed.

On sysnode1:

- MSC Nastran 2014 and MSC Nastran 2022.1 are installed:
  - MSC Nastran 2014 is accessed using "/local/msc/bin/nast2014"
  - MSC Nastran 2022.1 is accessed using "/local/msc/bin/nast20221"
  - The scratch directory is /local/temp

On sysnode2:

- Only MSC Nastran 2014 is installed and is accessed using "/local1/msc/bin/nast2014"
- The scratch directory is /local1/temp

On sysnode3:

- MSC Nastran 2014 and MSC Nastran 2022.1 are installed:
  - MSC Nastran 2014 is accessed using "/local2/msc/bin/nast2014"
  - MSC Nastran 2022.1 is accessed using "/local2/msc/bin/nast20221"
- The scratch directory is /local2/temp

All of this information could be specified in an INI file, identical on all three nodes, as follows:

```
;
; This is the MSC Nastran Command Initialization File
; The default version is to be set to 2022.1
;
version=2022.1
; Define conditional sections giving the appropriate sdir
; values when MSC Nastran is run locally.

[ s.hostname = sysnode1 ]
sdir=/local/temp
[ s.hostname = sysnode2 ]
sdir=/local1/temp
[ s.hostname = sysnode3 ]
sdir=/local2/temp

; Define conditional sections giving the appropriate
; remote access keywords when a "node" value,
; requesting remote execution, is specified.
;
[ node = sysnode1 ]
rsdir=/local/temp
< version = 2014.0 >
rcmd=/local/msc/bin/nast2014
```

```

< version = 2022.1 >
rcmd=/local/msc/bin/nast20221

[ node = sysnode2 ]
rsdir=/local1/temp
< version = 2014.0 >
rcmd=/local1/msc/bin/nast20140

[ node = sysnode3 ]
rsdir=/local2/temp
< version = 2014.0 >
rcmd = /local2/msc/bin/nast2014
< version = 2022.1 >
rcmd=/local2/msc/bin/nast20221

;
; This is the end of the Command Initialization file
;

```

Alternatively, the information could be split between an INI file and a system RC file, identical on all three nodes, as follows:

In the INI file:

```

;
; This is the MSC Nastran Command Initialization File
; The default version is to be set to 2022.1
;
version=2022.1

; Define conditional sections giving the appropriate
; remote access keywords when a "node" value,
; requesting remote execution, is specified.
;
[ node = sysnode1 ]
rsdir=/local/temp
< version = 2014.0 >
rcmd=/local/msc/bin/nast2014
< version = 2022.1 >
rcmd=/local/msc/bin/nast20221

[ node = sysnode2 ]
rsdir=/local1/temp
< version = 2014.0 >
rcmd=/local1/msc/bin/nast20140

[ node = sysnode3 ]
rsdir=/local2/temp
< version = 2014.0 >
rcmd = /local2/msc/bin/nast2014
< version = 2022.1 >
rcmd=/local2/msc/bin/nast20221

;
; This is the end of the Command Initialization file;

```

In the system RC file, identical on all three nodes:

```

;
; This is the MSC Nastran system RC file.
;

```

```

; Define conditional sections giving the appropriate sdir
; values when MSC Nastran is run locally.

[ s.hostname = sysnode1 ]
sdir=/local/temp
[ s.hostname = sysnode2 ]
sdir=/local1/temp
[ s.hostname = sysnode3 ]
sdir=/local2/temp

;
; This is the end of the system RC file
;

```

### Example 2:

Assumptions: User keywords defining "run type" and "data complexity" are needed and AUTOSPC, AUTOSPCR, BAILOUT and ERROR PARAM values are to be set based on these keywords.

The nastran.kwds file could be:

```

; User Keywords
Runtype:{"prelim","development","final"};Analysis stage
      Level :      number      # Data complexity level
;

```

The nastran.params file could be:

```

; PARAM keywords

Set_AutoSPC : AutoSPC      : {"Yes","No"}
Set_AutoSP_CR : AUTOSPCR : {"yes","no"}
Bai_lout_Val_ue : bailout : number
Set_Err_ör : Error : number
;

```

Then, the system RC file could contain:

```

; RC file
[ runtype = prelim ]
set_autospc = yes
bailout_value = -1
set_error = 0
set_autosp_cr = yes

[ runtype = development ]
set_autospc=yes
bailout_value=0
set_error=-1

[runtype=final]
set_autospc=no
param,bailout,0
param,error,-1
param,autospcr,no

[level < 3]
; basic data complexity parameters
[level >= 3]
<level>8>

```

```
; advanced data complexity parameters  
<level<=8>  
; intermediate data complexity parameters  
; End of RC file
```

# Symbolic Substitution

## Introduction

Symbolic Substitution is a capability added to MSC Nastran that allows a user to effectively modify a Nastran data file using command line and RC file keyword specifications without actually editing the file. This capability is very similar to “environment variable” expansion that happens in various command prompt shells such as the Linux Bourne, Korn and C shells and the Windows Command Prompt shell when scripts are processed. It is also analogous in some ways to the capabilities provided by programming language preprocessors, for example, the CPP preprocessor used by the various C/C++ compilers. The key feature of symbolic substitution is that these modifications do *not* affect the actual data file but present the data read from the data file to the processing program as if it was the modified data that was being processed.

Generally, symbolic substitution means that a data record is scanned to see if it contains special data strings (that identify the “symbolic” variables) that specify “symbolic substitution” requests. If such strings are found, the record is modified to replace the special data strings with user-defined substitution (replacement) strings (the values currently associated with the “symbolic” variables, i.e., the variable “values”) and it is this modified record that is actually processed. This symbolic substitution happens before any other processing of the record occurs, thus making it transparent to the rest of the program processing the data record. In the case of MSC Nastran, this symbolic substitution processing will happen immediately after a record is read from the Nastran data file and before any other processing (with the possible exception of special processing required to satisfy licensing requirements) is performed.

## Simple Examples

Two very simple examples illustrate how this capability could be used in Nastran data files. Note that the details of the syntax are completely described in the following sections and may be ignored for now. Also note that the examples do not deal with things such as managing the output from multiple Nastran runs. These issues, involving, among other techniques, using command line or RC file keywords such as "out=", "append=" and "old=yes", are beyond the scope of this document.

### Example 1:

Suppose you want to make several tests where the thickness of a PSHELL element is to be varied. You could do this by defining the thickness of the PSHELL element as a "symbolic variable" (identified using the string "%thickness%"), setting a default value (using the "%defrepsym" statement) and specifying the desired thickness on the command line (using the "REPSYM=" keyword). A very simple data file (sym.dat) could be (where most of the BULK entries are in an include file named "model.bdf", not shown here):

```
%defrepsym thickness=5.0
SOL 103
CEND
TITLE = 1st perturbation, t = %thickness%
ECHO = NONE
SUBCASE 1
    METHOD = 100
    SPC = 1
```

```

        DISP = ALL
    BEGIN BULK
    EIGRL,100,,,6
    PARAM,POST,0
    PARAM,GRDPNT,0
    $PBEAML Properties
    PBEAML 2      1      I
           70.0    60.0    60.0    3.3    5.    5.
    $
    $PSHELL Properties
    $
    pshell,1,1,%thickness%,1,,1
    $
    include 'model.bdf'
    enddata

```

If the test is run using the following command line:

```
nast20221 sym repsym=thickness=1.0 ...
```

the test will run as if the "TITLE" and "pshell" records are:

```
TITLE = 1st perturbation, t = 1.0
```

and

```
pshell,1,1,1.0,1,,1
```

If the test is run using the following command line:

```
nast20221 sym repsym=thickness=3.5 ...
```

the test will run as if the "TITLE" and "pshell" records are:

```
TITLE = 1st perturbation, t = 3.5
```

and

```
pshell,1,1,3.5,1,,1
```

If the test is run without specifying any REPSYM setting for "thickness", e.g., using the following command line:

```
nast20221 sym ...
```

the test will run as if the "TITLE" and "pshell" records are:

```
TITLE = 1st perturbation, t = 5.0
```

and

```
pshell,1,1,5.0,1,,1
```

## Example 2:

Suppose you have a test that contains two superelements, where the only difference between the data for each superelement is the area of a PBAR element. Instead of having two different definitions, you could have a single definition of the data in an include file, where the area of the PBAR is specified as a symbolic variable. The include file (called "bar.bdf") could be:

```

%defrepsym area=1.
grid,2,,1.0,0.0,0.0
grid,3,,2.0,0.0,0.0

```

```

grid,4,,3.0,0.0,0.0,,123456
cbar,2,2,2,3,0.,1.,0.
cbar,3,2,3,4,0.,1.,0.
pbar,2,2,%area%,1.,1.,1.
mat1,2,1.e7,,.3

```

and the actual input file could be:

```

sol 101
cend
title=simple part se
echo=both
subcase 1
load=1
disp=all
elforce=all
begin bulk
grid,1,,0.0,0.0,0.0
grid,2,,1.0,0.0,0.0
cbar,1,1,1,2,0.,1.,0.
pbar,1,1,1.,1.,1.,1.
mat1,1,1.e7,,.3
force,1,1,,1.,1.,1.,1.
$
begin super=1
%setrepsym area=1.
include 'bar.bdf'
$
begin super=2
%setrepsym area=2.
include 'bar.bdf'
enddata

```

The first "include 'bar.bdf'" statement will be processed as if the pbar record is

```
pbar,2,2,1.,1.,1.,1.
```

and the second "include 'bar.bdf'" statement will be processed as if the pbar record is

```
pbar,2,2,2.,1.,1.,1.
```

## Detailed Specifications

The use of the Symbolic Substitution capability is defined by a number of “rules”. These “rules” are given in the following sections and provide the complete specification. Following the rules, there is information about requesting report information and about error handling. Finally, there are some (again simple) examples showing usage.

### Symbolic Substitution Rules

The following rules define the symbolic substitution user interface. The descriptions start with the rules for variable naming, followed by the rules for defining the replacement width information, followed by the various keywords and statements used to control symbolic substitution.

### Variable Naming

The rules for naming symbolic substitution variables are:

- Symbolic variable names are not case-sensitive, are a maximum of 32 characters long and may not contain leading, trailing or embedded blanks or special characters including (“\_”). Variable names must start with an alphabetic character followed by zero or more alphabetic or numeric characters. For example:
  - The variable name "VaRiaBLe1" is the same as "VARIABLE1" and "variable1"
  - The following variable names are valid:
    - abcdef
    - abc123
    - Name1
  - The following variable names are not valid:
    - 123abc      Does not start with an alphabetic character
    - a bcd        Contains an embedded blank
    - abc&        Contains an invalid character ('&')
    - /def         Does not start with an alphabetic character
    - \_abc123     Uses an underscore in the name.
- Unless symbolic variable values are quoted, they are not case-sensitive and may not contain leading, trailing or embedded blanks or percent ("%") characters. The quoting rules are given below.

### Substitution Field Width Specification

The ability to control the appearance of any symbolic substitution is an important requirement when generating data for a program such as MSC Nastran. The result of a symbolic substitution request is identified as a *field*. Substitution field width information can be taken by default, specified in the data file or specified using command line and/or RC file keywords. These methods are explained below.

The rules for defining substitution field width information are:

- Symbolic variable substitution is, by default, *exact*. That is, the number of characters occupied by the symbolic symbol replacement is exactly the same as the replacement value. However, this default replacement processing can be controlled by specifying the substituted field *width*, the field *precision* and the *justification* within the field. This information is specified using the syntax

`-w.p`

where the ‘-’, ‘w’ and ‘p’ are all optional and have the following meanings.

- The field width specification (w) defines the *minimum* number of characters the field is to have as a decimal integer value. If the replacement value has fewer characters than the field width, it will be padded with spaces on the left (by default) or on the right (if the left justification flag is specified). If the replacement value has more characters than the field width and if no precision

value was specified, the entire replacement string will be used. A field width value of 0 (zero) is equivalent to omitting the width specification. Note that a negative width value will be processed as if the “left-justification” flag was specified (see below) since a negative field width is meaningless.

- The field precision specification (*p*) defines the *maximum* number of characters the field is to have. The format is a period (.) followed by a decimal integer value. If the replacement value length exceeds the precision value, only the last *p* (by default) or the first *p* (if the left justification flag is set) characters of the replacement value will be used. A field precision value of 0 (zero) (or a negative value) is equivalent to omitting the precision specification.
  - If both field width and field precision are specified and are positive, the precision value cannot be less than the width value. If it is, it will be reset to the field width.
  - The ‘-’ character is the “left-justification” flag and specifies that the replacement value is to be left-justified within the field. If this character is omitted, the replacement value will be right-justified within the field.
- For example, the width, precision and justification of a typical field in the Bulk Data portion of a Nastran data file is:
 

```
-8.8
```

 meaning that the field is exactly eight characters wide and that data is to be left-justified within the field. For a wide-format Bulk Data record, this specification would be:
 

```
-16.16
```

 The specification for an exact replacement, i.e., where the replaced field is exactly the size of the replacement value, is:
 

```
0.0
```
  - To simplify width specification for Nastran widths, the following (case-insensitive) synonyms for common widths are available and may be used wherever a width specification can be used:

|                    |                                      |
|--------------------|--------------------------------------|
| <code>exact</code> | is equivalent to <code>0.0</code>    |
| <code>bulk</code>  | is equivalent to <code>-8.8</code>   |
| <code>wide</code>  | is equivalent to <code>-16.16</code> |

It is very important to note that there are two distinct portions to a Nastran data file, that part that is before the first BEGIN statement and that has “free format”, and that part that is after the first BEGIN statement (the Bulk Data Section) and often has fixed format fields. Because of this, two different sets of field width information are maintained for use when field width information is not explicitly specified as part of a symbolic substitution request, one for use before the first BEGIN statement and one for use after the first BEGIN statement.

### Defining Variable Values and Width Information

Symbol names and associated values and symbol width specifications may be set using keywords on the command line or in RC files and may be set using special statements in the Nastran data file itself. Each keyword and statement is explained in detail.

### *Using Command Line or RC File Keywords*

#### **Setting Variable Value Using REPSYM**

Symbolic variables and associated values may be set on the Nastran command line or in RC files using the keyword

```
repsym=<varname>=<varvalue>
```

where <varname> specifies the name of the symbolic variable and <varvalue> specifies the value to be associated with the variable name. For example,

```
repsym=abc=1.23e-5
```

#### **Setting Variable Width Information Using REPWIDTH**

Symbolic variable substitution default width information may be set on the Nastran command line or in RC files using the keyword

```
repwidth=<widthinfo1>,<widthinfo2>
```

where <widthinfo1> specifies the default width information for the portion of the Nastran data file before the BEGIN statement and <widthinfo2> specifies the default width information for the portion of the Nastran data file after the BEGIN statement. Each is specified using a `-w.p` specification or as one of the synonyms, as described previously. If either width specification is omitted, the current default for that section is not changed. Note that the separating comma is required if the Bulk Data Section width value is to be set, i.e., if <widthinfo2> is specified. For example,

```
repwidth=12,bulk
```

specifies that symbolic substitution default width is to be 12.0 before the BEGIN statement is encountered and -8.8 after the BEGIN statement is encountered and

```
repwidth=,bulk
```

specifies that symbolic substitution default width is to be EXACT (or 0.0, the default) before the BEGIN statement is encountered and -8.8 after the BEGIN statement is encountered.

Just as with other Nastran command line or RC file keywords, the REPSYM and REPWIDTH keywords are not case-sensitive.

### *Using Special Statements in a Nastran Data File*

#### **Setting Values Using setrepsym**

Symbolic variables and associated values may be set in a Nastran data file using the following statement:

```
%setrepsym <varname>=<varvalue>
```

where the '%' character *must* be in column 1 and nothing else may appear in the record except for optional comments following <varvalue>, where the start of the comment is indicated by a '\$' (blank, currency symbol). The setrepsym string is not case-sensitive and at least one blank must separate this string from the <varname> specification. For example,

```
%setrepsym abc=1.23e-5
```

#### **Clearing ("Unsetting") Values Using unsetrepsym**

A symbolic variable value set using the `%setrepsym` statement may be cleared ("unset") in a Nastran data file using the following statement:

```
%unsetrepsym <varname>
```

where the '%' character *must* be in column 1 and nothing else may appear in the record except for optional comments following `<varname>`, where the start of the comment is indicated by a '\$'. The `unsetrepsym` string is not case-sensitive and at least one blank must separate this string from the `<varname>` specification. For example, to clear the variable `abc`, use

```
%unsetrepsym abc
```

### Setting Default Values Using `defrepsym`

Default variable values can be set in a Nastran data file using the following statement:

```
%defrepsym <varname>=<varvalue>
```

where the '%' character *must* be in column 1 and nothing else may appear in the record except for optional comments following `<varvalue>`, where the start of the comment is indicated by a '\$'. The `defrepsym` string is not case-sensitive and at least one blank must separate this string from the `<varname>` specification. The specified value will be used *only* if a value for `<varname>` was not previously set, i.e., by a `repsym` keyword on the command line or in an RC file or by a `%setrepsym` statement previously specified in the data file that has not been unset by a `%unsetrepsym` statement. For example,

```
%defrepsym abc=2.46e+2
```

### Clearing ("Unsetting") Default Values Using `undefrepsym`

The default value for a symbolic variable may be cleared ("unset") in a Nastran data file using the following statement:

```
%undefrepsym <varname>
```

where the '%' character *must* be in column 1 and nothing else may appear in the record except for optional comments following `<varname>`, where the start of the comment is indicated by a '\$'. The `undefrepsym` string is not case-sensitive and at least one blank must separate this string from the `<varname>` specification. For example, to clear the default value associated with variable `abc`, use

```
%undefrepsym abc
```

### Setting Width Information Using `setrepwidth`

Symbolic variable substitution default width information may be set in a Nastran data file using the following statement:

```
%setrepwidth <widthinfo1>,<widthinfo2>
```

where the '%' character *must* be in column 1 and nothing else may appear in the record except for optional comments following `<widthinfo2>`, where the start of the comment is indicated by a '\$'. The `setrepwidth` string is not case-sensitive and at least one blank must separate this string from the width specifications. There may not be any blanks within the width specifications. `<widthinfo1>` specifies the width information for the portion of the Nastran data file before the `BEGIN` statement and `<widthinfo2>` specifies the width information for the portion of the Nastran data file after the `BEGIN` statement. Each is specified using a `-w.p` specification or as one of the synonyms, as described above. If either width specification is omitted, the current width information for that section is not changed. Note that the

separating comma is required if the Bulk Data Section width value is to be set, i.e., if `<widthinfo2>` is specified. For example,

```
%setrepwidth 0.0,wide
```

specifies that the symbolic substitution width specification is to be 0.0 before the BEGIN statement and is to be -16.16 after the BEGIN statement.

### Clearing ("Unsetting") Width Information Using `unsetrepwidth`

Symbolic variable substitution width information set using the `%setrepwidth` statement may be cleared in a Nastran data file using the following statement:

```
%unsetrepwidth
```

where the '%' character *must* be in column 1 and nothing else may appear in the record except for optional comments following the `unsetrepwidth` string, where the start of the comment is indicated by a '\$'. The `unsetrepwidth` string is not case-sensitive and must be followed by at least one blank. This statement does not have any arguments and clears both width specifications.

### Setting Default Width Information Using `defrepwidth`

Default symbolic variable substitution width information may be set in a Nastran data file using the following statement:

```
%defrepwidth <widthinfo1>,<widthinfo2>
```

where the '%' character *must* be in column 1 and nothing else may appear in the record (except for optional comments following `<widthinfo2>`), where the start of the comment is indicated by a '\$'. The `defrepwidth` string is not case-sensitive and at least one blank must separate this string from the width specifications. There may not be any blanks within the width specifications. `<widthinfo1>` specifies the default width information for the portion of the Nastran data file before the BEGIN statement and `<widthinfo2>` specifies the default width information for the portion of the Nastran data file after the BEGIN statement. Each is specified using a `-w.p` specification or as one of the synonyms, as described above. If either width specification is omitted, the current width information for that section is not changed. Note that the separating comma is required if the Bulk Data Section width value is to be set, i.e., if `<widthinfo2>` is specified. For example,

```
%defrepwidth 0.0,wide
```

specifies that default symbolic substitution is to be 0.0 before the BEGIN statement and is to be -16.16 after the BEGIN statement.

### Clearing ("Unsetting") Default Width Information Using `undefrepwidth`

Default symbolic variable substitution width information may be cleared in a Nastran data file using the following statement:

```
%undefrepwidth
```

where the '%' character *must* be in column 1 and nothing else may appear in the record except for optional comments following the `undefrepwidth` string, where the start of the comment is indicated by a '\$'. The `undefrepwidth` string is not case-sensitive and must be followed by at least one blank. This statement does not have any arguments and clears both default width specifications.

### *General Information For Special Statements*

The %setrepsym, %unsetrepsym, %defrepsym, %undefrepsym, %setrepwidth, %unsetrepwidth, %defrepwidth and %undefrepwidth statements are deleted, logically, from the data file and will never be processed by the rest of Nastran unless an error is encountered while they are being processed. This is discussed in the [Error Handling, 3380](#).

### Requesting Symbolic Substitution

Symbolic variable substitution will occur when a string having the form

```
%<varname>,<widthinfo>:<varvalue>%
```

is found anywhere within a Nastran data file, except that this string may *not* span records, i.e., the substitution request must be on a single record (line). The leading and trailing '%' characters are required as is the <varname> field. The <widthinfo> field is optional. If it is omitted, the comma (,) separating it from the <varname> field may be omitted and the rules for determining what width specification will be used are discussed below. The <varvalue> field is optional and provides a way of specifying a default value, i.e., the “local default value”, as described below. If it is omitted, the colon (:) separating it from the <varname> (or <widthinfo>) field may be omitted. The rules for determining what symbolic value will be used as the substitution value are discussed below. For example, if the symbolic variable abc is to be replaced by its current value with no special processing (or if default width processing is to be used), the substitution request would be:

```
%abc%
```

If the symbolic variable is to be replaced by its current value, with the minimum field width to be 12 characters and with the value always to be left-justified, the substitution request would be:

```
%abc,-12%
```

### Quoting Rules For Symbolic Variable Values

- If a symbolic variable value is case-sensitive, if it contains leading, trailing or embedded blanks or if it contains percent characters, tab characters or other special characters, it must be quoted. (Note that "escape" sequences such as '\t' or '\n' are not given any special treatment; that is, they are left as is.)
  - If the value is part of a repsym keyword command-line specification, the quoting rules of the command shell being used apply.
  - If the value is part of a repsym keyword specified in an RC file, it must be enclosed in single quotes (').
  - If the value is part of a %setrepsym or %defrepsym record or if it specified as the “local default value” in a symbolic substitution request, quoting a symbolic variable value means enclosing the value in one of the following pairs of characters:

| Starting Quote Character | Ending Quote Character |
|--------------------------|------------------------|
| "                        | "                      |
| '                        | '                      |
| /                        | /                      |
| \                        | \                      |

| Starting Quote Character | Ending Quote Character |
|--------------------------|------------------------|
| [                        | ]                      |
| {                        | }                      |
| (                        | )                      |

If the first non-blank character encountered in a variable value specification is one of the starting quote characters, the variable value *must* be ended by the associated ending quote character. The actual variable value will be the (possibly null) string between (but not including) the starting and ending quote characters. If the variable value starts with one of the starting quote characters, it must be quoted using an alternate quote character.

### General Rules For Symbolic Variable Substitution

- Nested symbolic substitution is not supported. Even if the value associated with a symbolic variable name is, itself, in the format of a symbolic variable substitution request, that request will be ignored. That is, after symbolic variable substitution has occurred, the substituted string is *not* re-scanned.
- Determining what symbolic variable value will be used when a variable substitution request is encountered depends on where the variable value associated with the specified variable name was set. The *first* value encountered in the following hierarchy is the value that will be used:
  - A value specified in the Nastran data file using the `%setrepsym` statement, if there is one active, i.e., if it has not been deactivated by a `%unsetrepsym` statement.
  - A value specified on the Nastran command line or in RC files using the `repsym` keyword.
  - As part of the variable symbol substitution request, using the local default value, if there is one.
  - A value specified in the Nastran data file using the `%defrepsym` statement, if there is one active, i.e., if it has not been deactivated by a `%undefrepsym` statement.

This precedence follows normal MSC Nastran ordering, i.e., "the data file wins," while still providing great flexibility. Also, the ordering of the last two items in this hierarchy allows a user to set all defaults except for special cases and follows the idea that the specification "closest" to the use is the one used. If no replacement value is found, the substitution request will be ignored and the record will be unchanged.

- Determining what symbolic width specification will be used when a variable substitution request is encountered depends on where the width information has been specified and on the part of the Nastran data file that is being processed, i.e., is the variable substitution request before or after the first `BEGIN` statement. The *first* width specification value encountered in the following hierarchy is the specification that will be used:
  - A value specified in the symbolic substitution request itself, i.e., if a `<widthinfo>` entry was specified as part of the symbolic substitution request.
  - A value specified on a `%setrepwidth` statement corresponding to the current section in the Nastran data file, if there is one active, i.e., if it has not been deactivated by an `%unsetrepwidth` statement.

- A value specified on the Nastran command line or in RC files using the `repwidth` keyword corresponding to the current section in the Nastran data file.
- A value specified in the Nastran data file using the `%defrepwidth` statement corresponding to the current section in the Nastran data file, if there is one active, i.e., if it has not been deactivated by a `%undefrepwidth` statement.
- The program default value of exact (0 . 0).

This precedence also follows normal Nastran ordering, i.e., "the record wins followed by the data file wins," while still providing great flexibility.

- When running in licensing "Interlock" mode, i.e., in CRC validation mode, the following restrictions will be in effect. If a restriction is violated, Nastran processing will be terminated.
  - The `%setrepsym`, `%unsetrepsym`, `%defrepsym` and `%undefrepsym` statements are not allowed. Also, specifying a default value within the symbolic substitution request is not allowed. That is, symbolic variable values may only be set using the `repsym` keyword on the command line or in an RC file. Note that the `%setrepwidth`, `%unsetrepwidth`, `%defrepwidth` and `%undefrepwidth` statements *are* allowed.
  - A maximum of two symbolic substitution specifications are allowed per record and a maximum of ten symbolic substitution requests are allowed in the entire input data file.
  - Interlock CRC calculations will be made on the input record *before* symbolic substitution occurs. Note that any alterations to the record made as part of the CRC calculation processing will not affect symbolic substitution processing.

### Requesting Symbolic Substitution Replacement Information Using REPINFO

- A report of what symbolic substitutions were made is generated at the end of Nastran processing, with the level of detail in the report controlled by an "information level" flag set using the `repinfo=n` keyword, where `n` is an integer number that specifies the level of detail desired. The meanings the various values for `n` are as follows:

- 0 suppress the report altogether
- 1 report the various values assigned using the `repsym` keyword
- 2 same as 1 except add the various values assigned using the `setrepsym` statement
- 3 same as 2 except add the various values assigned using the `defrepsym` statement
- 4 same as 3 except add the various values assigned as local default values
- 5 same as 1 except add all locations where the specified `repsym` value was used
- 6 same as 2 and 5 except add all locations where the specified `setrepsym` value was used
- 7 same as 3 and 6 except add all locations where the specified `defrepsym` value was used
- 8 same as 4 and 7 except add all locations where local default values were used.

The report is written to the .f06 file. If there is not enough dynamic memory available to save the report information, the `repinfo` level may be reduced. When running in MSC Nastran, the default is `repinfo=1`. Otherwise, `repinfo=0` will be forced.

- Just as with other Nastran command line or RC file keywords, the `REPINFO` keyword is not case-sensitive.

## Error Handling

If an error is encountered processing a `setrepsym`, `unsetrepsym`, `defrepsym`, `undefrepsym`, `setrepwidth`, `unsetrepwidth`, `defrepwidth` or `undefrepwidth` statement, a comment string will be added to the record giving the error information and the record will be passed to Nastran (or the application reading the data file) as if the record was a normal Nastran data record. If an error is encountered in a record containing a symbolic substitution request, the symbolic substitution request will not be processed and, if `repinfo=1` or greater is in effect, a message giving information about the error will be written to the .log file. It is expected that the statements in error will not be valid Nastran statements and so will be flagged as an error.

## Examples

1. The value on an “OPTION” statement is to be settable using the command line, taking a default value of “OPT1val” (case-sensitive) if no command line value is set. The OPTION statement could be

```
OPTION=%Option:'OPT1val' %
```

and the command line parameter that would be used to set OPTION to a different value, OP2VAL (not case-sensitive), would be

```
RepSym=Option=op2val
```

2. An INCLUDE file contains records that are to be used four times in the Bulk Data Section of a Nastran data file, with the only difference being the value in Field 3 of one record. The first time the file is used, this field must contain the value 1.234, the second time this field must contain the value 4.567 and the last two times this field must contain the value -12.578. In all cases, the replacement field must be eight characters wide and the data must be left-justified in the field. Assuming that the symbolic variable is DATFL3 and that the include file name is incl.data, this could be done as follows:

In the include file, specify the following statements before the record to be modified:

```
%DefRepSym datfl3=-12.578
```

then the record to be modified could be specified as follows:

```
FL1      FL2      %datfl3%FL4      FL5      FL6
```

and, for completeness, specify the following record after the record to be modified:

```
%Undefrepsym datfl3
```

Then the data file would contain:

```
. . .
%setrepsym DATFL3=1.234
%DefRepWidth ,bulk
include 'incl.data'
```

```
. . .  
%setrepsym DATFL3=4.567  
include `incl.data'  
%Unsetrepsym datfl3  
. . .  
include `incl.data'  
. . .  
include `incl.data'
```
